IL-12 expression on allergen-containing VNP prevents Th2 induction in a humanized mouse model of mugwort allergy

Bernhard Kratzer[1], Sandra Hofer[1], Peter Tauber[1], Doris Trapin[1], Mirjam Schaar[1], Gerhard Hofer[2], Walter Keller[2], Gabriele Gadermaier[3], Winfried Pickl[1;4]
[1]Medical University of Vienna, Center for Pathophysiology, Infectiology and Immunology, Institute of Immunology, Vienna, Austria; *[2]University of Graz, Institute of Molecular Biosciences, BioTechMed, Division of Structural Biology, Graz, Austria*; *[3]University of Salzburg, Department of Biosciences, Division of Allergy and Immunology, Salzburg, Austria*; *[4]Karl Landsteiner University of Health Sciences, Krems, Austria*

Purpose: Virus-like nanoparticles (VNP) can be loaded with allergens that are safely shielded inside them to achieve allergen-specific T-cell activation in the absence of sensitization. In addition, VNP can be decorated with functional cytokines on their surface. We have analyzed whether a combination of both approaches, i.e., surface decoration of allergen-laden VNP with IL-12, would improve their immunomodulatory properties.
Methods: The major mugwort pollen allergen Art v 1 was N-terminally fused to the viral matrix protein MAp15 of MoMLV for shielded expression, while the single-chain (p35::p40) mIL-12 was C-terminally fused to the minimal CD16b GPI-anchor acceptor sequence for surface expression. The immunomodulatory capacity of such VNP was analyzed with the help of a mugwort allergen-specific humanized mouse model *in vitro* and *in vivo*.
Results: Stimulation of splenocyte cultures of humanized allergy mice with allergen-expressing IL-12$^+$VNP induced the secretion of high levels of IFN-g, moderate levels of IL-10, and very low levels of IL-4, IL-5, IL-13 and IL-17A compared to recombinant allergen. This was accompanied by moderately inhibited T-cell proliferation but a significantly increased proportion of IFN-g$^+$CD4$^+$T-cells, which additionally co-expressed IL-10, indicative of the induction of a Th1/Tr1 T-cell response. To mimic a prophylactic approach *in vitro*, sorted naïve allergen-specific T-cells from humanized mice were incubated with allergen-expressing IL-12$^+$VNP in the presence of bone marrow-derived dendritic cells, resulting in a high proportion of IFN-g$^+$CD4$^+$Th1-cells, similarly obtained upon classical Th1 polarization. The IL-12-VNP-induced Th1-cells remained stable after secondary stimulation with recombinant allergen, demonstrating their strong and sustained polarization. The addition of IL-12$^+$VNP to pre-polarized Th2-cells (IL-4 and anti-IL-12/anti-IFN-g mAb) strongly inhibited the further expansion of allergen-specific IL-13$^+$Th2-cells *in vitro*. *In vivo*, prophylactic intranasal treatment with IL-12-decorated allergen-laden VNP before exposure to allergen aerosol as acute challenge reduced the expansion of IL-4$^+$ and IL-13$^+$CD4$^+$T-cells compared to control VNP decorated with an inactive form of IL-12.
Conclusion: Decoration of allergen-laden VNP with IL-12 improves their Th1-priming capabilities and therefore could be a useful new tool for the treatment of allergies in the future.

Funding: Federal State of Lower Austria, Danube Allergy Research Cluster (Danube ARC, project no. 10) and the Medical University of Vienna.

Development of an in vivo model of IgE-mediated allergy

Caterina Vizzardelli[1], Alessio Gentile[1], Eva Untersmayr[1], Alex Farr[2], Barbara Bohle[1]
[1]Department of Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria., Vienna, Austria; *[2]Clinical Department of Obstetrics and Feto-Maternal Medicine, Medical University of Vienna, Vienna, Austria, Vienna, Austria*

Mast cells are central in IgE-mediated allergies. These hematopoietic cells reside in barrier tissues and bind allergen-specific IgE antibodies *via* the high-affinity Fc epsilon receptor (FcεRI) on their surface. Cross-linking of the receptor by IgE-binding to allergen induces their degranulation and the release of various factors, e.g. histamine, that cause allergic reactions. We sought to establish an *in vivo* model of IgE-mediated allergy by engrafting non-obese diabetic severely immunodeficient $\gamma c^{-/-}$ mice transgenic for human membrane-bound stem cell factor [NSG-Tg(hu-mSCF)] with human stem cells (HSC) in order to develop human mast cells.
$CD34^+$ HSC were isolated from cord blood mononuclear cells (CBMC) by positive selection with magnetic beads. Their purity and viability were assessed by flow cytometry. HSC were intravenously (i.v.) injected in NSG-Tg(hu-mSCF) mice. The percentage of human (hu) $CD45^+$ cells in blood was assessed by flow cytometry every 4-weeks. After 16-weeks, $huCD45^+$ cells and $Fc\varepsilon RI^+CD117^+$ mast cells were stained in bone marrow, peritoneal lavage, lung, and spleen. A serum pool from birch pollen allergic donors (50µl/mouse) containing >100 kU_A/ml Bet v 1-specific IgE was subcutaneously injected. After two-days, mice received intracutaneous injections of 30µl PBS containing recombinant (r) Bet v 1 in the belly skin and ears. Allergic reactions were detected by i.v. injection of Evans blue (0.5%) and local visualization, anaphylactic reactions by core body temperature measurements.
CBMC contained 0.52% HSC on average, which were enriched to >95% $CD34^+$ cells and injected ($0.5\text{-}1x10^5$) per NSG-Tg(hu-mSCF) mouse. The percentage of $huCD45^+$ cells in blood constantly increased. After 16-weeks, 55±4% (SEM) of alive $huCD45^+$ cells were found in bone marrow. At the same time, 19±4% of $Fc\varepsilon RI^+CD117^+huCD45^+$ cells were detected in bone marrow and peritoneal lavage, followed by 18±6% and 5±1% in lungs and spleen, respectively. NSG-Tg(hu-mSCF) mice passively sensitized with birch pollen-specific IgE reacted anaphylactic to 0.5µg rBet v 1 but not to PBS.
NSG-Tg(hu-mSCF) mice injected with HSC developed mast cells and anaphylactic reactions to allergen after sensitization with human allergen-specific IgE. This *in vivo* model of IgE-mediated allergy will now be used to study agents that block anaphylactic reactions.

Supported by Austrian Science Fund (FWF) project P35791.

Impact of micro- and nanoplastic particles on allergic responses in BALB/c mice

Ece Danisman[1], Sahar Kazemi[1], My Nguyen[2], Lukas Wimmer[2], Lea Ann Dailey[2], Michelle M. Epstein[1]
[1]*Experimental Allergy Laboratory, Department of Dermatology, Medical University of Vienna, Vienna, Austria*;
[2]*Department of Pharmaceutical Sciences, University of Vienna, Vienna, Austria*

Abundant micro- and nano-plastic particles (MNPs) in the environment raise concerns about potential impacts on human health. Our study aimed to investigate the influence of MNPs on allergic responses, which might relate to the rising incidence and prevalence of allergic diseases over recent decades. We conducted experiments utilizing BALB/c mice co-administered intranasal ragweed pollen along with either manufactured polyethylene terephthalate (PET) or polypropylene (PP) MNP spheres (1-25 µm) to test our hypothesis. Assessments included evaluating allergen-specific responses such as airway inflammation, mucus secretion in the respiratory tract, and levels of allergen-specific immunoglobulin in sera. Our results revealed distinct effects of different MNPs on allergic responses. Specifically, PP MNPs exacerbated ragweed pollen-induced airway inflammation, indicating an adjuvant-like activity. In contrast, PET MNPs demonstrated an unexpected immunosuppressive effect, as evidenced by reductions in airway inflammation, mucus production, and allergen-specific immunoglobulin levels. These findings shed light on the potential divergent roles of PP and PET MNPs in modulating allergic responses, suggesting a need for further mechanistic investigations. Understanding the underlying mechanisms will be critical for elucidating the complex interplay between MNPs and allergic diseases, informing strategies for mitigating their adverse effects on human health.

Eosinophil responses in adaptive pulmonary type 2 immunity is locally regulated by interferon type 1 and -2

Sjoerd Schetters[1;2], Stijn Verwaerde[1;2], Julien Catherine[3], Sina Karimi[3], Sam Dupont[1], Karel Van Damme[1;2], Elisabeth De Leeuw[1;2], Louis Boon[4], Florence Roufosse[3], Bart Lambrecht[1;2]
[1]VIB Center for Inflammation Research, Ghent, Belgium; *[2]Ghent University, Ghent, Belgium*; *[3]Universite Libre de Bruxelles, Brussels, Belgium*; *[4]JJP Biologics, Warsaw, Poland*

Purpose: Eosinophils are considered terminally differentiated innate effector cells associated with both homeostatic and pathogenic immune responses. It is currently unclear how eosinophil function is shaped within the tissue, especially in eosinophilic afflictions like allergic asthma. Indeed, eosinophil-intrinsic decision-making during allergic inflammation is completely understudied and might explain their role in common acute allergic exacerbations to allergens and viruses.
Results: Surprisingly, we find that interferons intrinsically shape the function of eosinophils in type 2 immunity in the airways. Specifically, eosinophils infiltrating the lung during HDM exacerbations directly respond to interferon (IFN)α, resulting in robust ISG-transcriptomes and membrane expression of the type 1 interferon-sensitive markers. In fact, using interferon-reporter mice we show the local transcriptional reactivity of eosinophils in response to IFNα. This response is required for eosinophils to simultaneously respond to IFNγ, locally produced by activated NK cells under the control of the IL18-IL18BP-IL18R axis. Eosinophil-specific transgenic mice and BM chimera showed the intrinsic requirement of IFNAR1, IFNGR1 and STAT1 for this response. Importantly, the time-dependent dual interferon requirement of eosinophils is conserved in mice and humans, *in vitro* and *in vivo*. MultiNicheNet analysis on CITEseq data from the lungs of eosinophil-specific IFNAR1- or IFNGR1-KO mice showed the role of IFN in modulating eosinophil-mediated airway inflammation.
Conclusion: We find the surprising role of interferons in shaping the phenotype and function of eosinophils during acute allergic exacerbations. Indeed, type 2 inflammation in response to HDM allergen is preceded by an interferon-dominant type 1 immune response in the airways, which modulates local eosinophil responses. This novel interferon circuitry will advance our understanding of eosinophil functioning during asthma exacerbations, both allergic (HDM) and virally induced.

Heterogeneous ILC responses in severe asthma patients undergoing anti-IL5/5Rα therapy

Kyle Mincham[1], Lola Loewenthal[1], Garance Meyer[1], Martina Marfia[1], Minerva Garcia Martin[1], Pujan Patel[1;2], Clare Lloyd[1], Robert Snelgrove[1]
[1]Imperial College London, London, United Kingdom; *[2]Royal Brompton Hospital, Guys and St Thomas' NHS Foundation Trust, London, United Kingdom*

Purpose: Historically, asthma has been defined as a type 2-driven disease. However, severe asthma (SA) is heterogeneous with additional non-type 2 features. Innate lymphoid cells (ILCs) are early effector cells with crucial roles in tissue homeostasis, yet ILC2s are also implicated in asthma pathology. There is limited understanding of the role of additional ILC subsets in SA. While type 2 biologics are effective at ameliorating disease in subsets of asthma patients, little is known regarding their impact upon ILC populations. This study sought to exhaustively characterise ILCs in SA relative to healthy controls (HC), and infer the impact of anti-IL5/5Rα therapy on these populations.
Methods: Patient demographics, spirometry and FeNO were prospectively collected with blood and induced sputum from HCs (n=20) and SA subjects pre and post-establishment on benralizumab/mepolizumab (n=26) for ≥3 months. 21-colour full-spectrum flow cytometry was used for ILC evaluation and proteomic profiling performed via the Olink Inflammation assay.
Results: SA was associated with increased ILC progenitors (ILCPs) in the blood and sputum, as well as elevated T-bet$^+$ ILC1s, GATA-3$^+$ ILC2s (including those with an IL-13$^+$ and c-Kit$^+$ pathological phenotype) and RORγt$^+$ ILC3s within the airways only of SA subjects. Moreover, increased sputum ILC1 and ILC2 populations correlated with clinical outcomes of disease (Asthma control questionnaire-7 score and FEV_1 % predicted). Anti-IL5/5Rα therapy did not alter ILC subset numbers in the blood or sputum, however there was a reduction in ILCs displaying type 2 features within the airways. Proteomic profiling highlighted a significant positive correlation between total ILCs within the airways of SA subjects and expression of type 2-associated cytokines, with all correlations absent following anti-IL5/5Rα therapy.
Conclusion: SA subjects exhibit a multifaceted ILC subset response in their airways that correlates with type 2 cytokines and clinical prognosis. Importantly, pathogenic airways ILC2 responses are selectively dampened following anti-IL5/5Rα therapy, perhaps contributing to the capacity of these biologics to ameliorate eosinophilic inflammation and instigate disease control.

Selective elimination of allergen-specific B cells in house dust mites allergy model

Nikola Ralchev[1], Nikola Kerekov[1], Nikolina Mihaylova[1], Diana Hristova[2], Andrey Tchorbanov[1]
[1]Department of Immunology, Institute of Microbiology, Bulgarian Academy of Sciences, Sofia, Bulgaria; *[2]Allergology Clinic, Alexander's University Hospital, Sofia, Bulgaria*

Purpose: House dust mites (HDM) allergy is widely spread and over 50% of asthmatic individuals are sensitized to its allergens. Der p1 is one of the major allergens from the house dust mite *Dermatophagoides pteronyssinus* (Dpt). Thus Der p1-specific B cells play an important role in pathology as a producer of allergen-specific IgE antibodies and the specific elimination of these cells is a legitimate goal for ameliorating the allergic symptoms.
The targeted suppression of allergen-specific B cells could be accomplished by co-crosslinking of the human inhibitory Complement receptor 1 (CR1) and B cell receptor (BCR). This mechanism could be achieved by generation of protein-engineered chimeric molecules consisting of 3D9 monoclonal antibody against CR1 conjugated with proven epitope-carrying peptides from Der p1 molecule.
Methods: protein engineering, FACS, animal models, histology, ELISA
Results: The effectiveness of the chimeric molecule was assessed in a humanized mouse HDM allergy model by transferring human peripheral blood mononuclear cells (PBMCs) isolated from patients diagnosed with HDM allergy in immunodeficient Rag2- γc- mice. Intravenous injection of the chimeric molecule led to a reduction of Dpt-specific IgE antibodies in the serum and bronchoalveolar lavage fluid (BALF) compared to the control chimeric molecule consisting of the same antibody coupled with irrelevant peptide. The total protein level in BALF, as a marker of vascular permeability and the mast cell degranulation in the lungs evaluated by measuring β-hexosaminidase activity in BALF, were significantly reduced. Phenotyping of the lung cells revealed a tendency for reduction of the percentage of human CD45+ and CD4+ cells and increasing of CD8+ cells in the animals treated with chimera. Histology of mouse lungs showed decreased perivascular infiltration.
Conclusion: The present study proposed a new approach for the therapy of HDM allergy which aims specific elimination of allergen-specific B cells. Treatment with the protein-engineered chimeric molecules resulted in a reduction of Dpt-specific IgE antibodies and overall allergic inflammation. This effective approach could be further developed into a therapeutic agent for the treatment of patients and can help for a better understanding of the role of B cells in HDM allergy.

Neutrophil-specific targeting of STAT3 impairs tumor progression via the expansion of cytotoxic CD8+ T cells

Irem Ozel[1], Ekaterina Pylaeva[1], Gennadiy Zelinskyy[1], Cornelius Kürten[1], Zvika Granot[2], Jadwiga Jablonska[1]
[1]*University Hospital Essen, Essen, Germany*; [2]*Faculty of Medicine, Hebrew University, Jerusalem, Israel*

Purpose: Neutrophils have been shown to play heterogeneous roles during cancer progression. However, in the clinical situation these cells are mainly associated with tumor progression and worse patient survival. Therefore, multiple pre-clinical and clinical trials targeting neutrophil migration or activity are ongoing, but without visible success to date. Previously, we and others could show that elevated STAT3 is associated with pro-tumoral activity of neutrophils. Here, we addressed the possibility to target STAT3 in neutrophils to provide therapeutic opportunity in cancer.
Methods: We have created neutrophil-specific Stat3 knockout mice (NStat3$^{-/-}$) and injected them with murine head and neck cancer (HNC) and melanoma cell lines, MOPC and B16, respectively. Tumor growth, progression and metastasis, anti-tumor T cell response, as well as basic and tumor-related neutrophil functions, were evaluated.
Results: We demonstrated that deletion of STAT3 in neutrophil-specific manner results in significantly impaired tumor growth and metastasis in both HNC and melanoma cancer models. Neutrophils from NStat3$^{-/-}$mice showed a robust bias towards anti-tumoral phenotype, with upregulation of immune co-stimulatory molecules. Multi-parameter analyses of tumors and TDLNs revealed significant expansion of strongly cytotoxic CD8^{+} T cell populations, but hardly affected CD4^{+} cells. Inhibiting STAT3 phosphorylation in neutrophils using a small molecule inhibitor induced the expansion and activation of tumor cytotoxic CD8^{+} T cells in patient-derived tumor explants (HNC) when treated with such neutrophils, but not in those treated with STAT3 sufficient cells. Moreover, targeting neutrophil-STAT3 *in vivo* with intratumoral injection of STAT3 antisense oligonucleotide (STAT3ASO) impaired the tumor growth and elevated cytotoxic T cell activity in mice bearing HNC.
Conclusion: These findings provide new insights in therapeutic avenues and suggest targeted neutrophil-STAT3 inhibition as a potential immunotherapy in cancer patients.

Pharmacological activation of free fatty acid receptor 2 in intestinal type 3 innate lymphoid cells ameliorates experimental autoimmune encephalomyelitis

Milica Lazarević[1], Goran Stegnjaić[1], Suzana Stanisavljević[1], Neda Nikolovski[1], Miljana Momčilović[1], Mirjana Dimitrijević[1], Graeme L Fraser[2], Dorde Miljkovic[1], Bojan Jevtic[1]
[1]Institute for Biological Research "Siniša Stanković"- National Institute of Republic of Serbia, Belgrade, Serbia; *[2]Epics Therapeutics S.A, Gosselies, Belgium*

Innate lymphoid cells type 3 (ILC3) play a central role in maintaining intestinal homeostasis and regulating the balance between effector T cell populations and regulatory T cells (Treg) in the gut milieu. Dysregulation of this balance, which is strongly influenced by the gut microbiota and dietary components, is associated with autoimmune diseases such as multiple sclerosis (MS). Intestinal ILC3 are activated by dietary compounds like short-chain fatty acids (SCFA), which are produced by gut bacteria. SCFA, acting via the free fatty acid receptor 2 (FFAR2), stimulate ILC3 proliferation, IL-22 and IL-2 production in the small intestine. The secretion of IL-22 by ILC3 supports the integrity of the intestinal barrier and the balance of the immune system, while IL-2 enhances the activity of Treg and thus improves immune regulation in the intestine.
In this study, the efficacy of a FFAR2 agonist - Cpd1 as evaluated in a mouse model of chronic experimental autoimmune encephalomyelitis (EAE). Treatment with Cpd1 efficiently ameliorated EAE and showed significant attenuation of CNS inflammation and lessened infiltration of immune cells into the spinal cord. Flow cytometric analysis of immune cells in the spinal cord showed that the number of $CD4^+$ T cells, Th1, and Th17 cells decreased with Cpd1 treatment. In addition, Cpd1 treatment in EAE mice led to changes in the composition of immune cells in the lamina propria of the small intestine, which was characterized by an increased proportion of Treg and IL-22-producing ILC3 and a decrease in IL-17-expressing ILC3, while there was no difference in the proportion of IL-2-producing ILC3 cells between Cpd1-treated and control mice. Consistent with this, Cpd1 treatment also altered the composition of the microbiota in the EAE model.
In summary, these data indicate that activation of immune-regulatory, gut-resident ILC3 cells by FFAR2 agonists modulates the autoimmune response local to the small intestine as well as in distal tissues such as the spinal cord. These findings highlight the potential therapeutic use of FFAR2 agonists in the treatment of autoimmune diseases.

Early measles immunization in children before 12 month of age affects specific memory B cell responses

Maaike van der Staak[1;2], Hinke ten Hulscher[1], Jelle de Wit[1], Rik de Swart[2], Nynke Rots[1], Rob van Binnendijk[1]
[1]National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands; *[2]Erasmus Medical Center (ErasmusMC), Rotterdam, Netherlands*

Purpose: Children vaccinated against measles under 12 months of age show a reduced antibody response and waning of antibodies in the long-term. Whether this implies the loss of immune memory remains to be determined. We aim to investigate the presence and function of measles-specific memory B cells in such early vaccinated children.
Methods: Our study involves children that received an additional early dose of measles vaccine between 6 and 12 months alongside the routine vaccination at 14 months of age, and compared this to children who only received the routine vaccination at 14 months. Measles-specific neutralizing antibody concentrations were assessed up to 7 years post vaccination, to understand the influence of age at first vaccination on antibody persistence. To investigate effects on immune memory, we isolated B lymphocytes from blood and expanded them in vitro to generate antibody-producing plasma cells from single memory precursors. In addition to frequencies of measles-specific memory B cells, the functionality, avidity, and epitope specificity of these measles-specific antibodies at the long-term, up to 3 years after vaccination, are currently investigated.
Results: Measles-specific neutralizing antibody data indicated a negative correlation between the age at first vaccination and antibody concentrations later in life. Around 6-7 years of age, a considerable proportion of early-vaccinated children exhibited antibody concentrations which are considered below the level of protection. Preliminary analysis of memory B cells indicate lower frequencies of measles-specific B cells in the circulation. Further characterization of the specificity and function of the antibodies produced from these memory B cells is ongoing. This will provide better insight into the effect of early immunization with live attenuated measles vaccine on the development and maintenance of immune memory.

IFN-γ induced trained immunity metabolically reprograms macrophage metabolism and promotes immunity to Mycobacterium tuberculosis.

Dearbhla Murphy[1], Isabella Batten[1], Sarah Connolly[1], Grainne Jameson[1], Donal Cox[1], Joseph Keane[1], Sharee Basdeo[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Background: Tuberculosis (TB) is a leading cause of death worldwide and a major global health concern due to increased incidence of multi-drug resistant infections. Host-directed therapies (HDT) are therapies which harness a patient's own immune system to fight infection, to support the efficacy of antibiotics. Trained immunity is a functional reprogramming of innate immune system whereby myeloid cells are metabolically and epigenetically reprogrammed, resulting in heightened responses to infection. This work aimed to determine if IFN-γ could induce trained immunity in human monocytes and airway macrophages and assess its potential as a HDT for TB.
Methods: We aimed to assess if a single exposure to IFN-γ could metabolically reprogram human monocytes or airway macrophages to induce trained immunity resulting in enhanced response to challenge with *Mycobacterium tuberculosis* (*M.tb)*. Monocytes were enriched from PBMC, or airway macrophages were isolated from bronchioalveolar lavage fluid (BALF), trained with IFN-γ for 24 hours, washed and allowed return to homeostasis and rest. On day 6, metabolic reprogramming was analysed using Seahorse extracellular flux analysis and by examining changes in the gene expression of key glycolytic enzymes following challenge with *M.tb*. Trained macrophages were stimulated for 24 hours with *M.tb* and cytokine and chemokine production, and the expression of cell surface markers associated with trained immunity were assessed.
Results: Macrophages trained with IFN-γ had an increased glycolysis and produced more IL-1β upon stimulation with *M.tb*, compared with untrained controls. Trained macrophages also showed increased expression of glycolytic enzymes, supporting the evidence that metabolic rewiring had occurred. Functionally, IFN-γ trained macrophages produced higher concentrations of TNF, IL-6, CXCL1, MIP-1α and IL-10 when stimulated with *M.tb*.
Conclusion: IFN-γ can induce trained immunity in human macrophages resulting in enhanced glycolytic metabolism and cytokine production which are associated with better *M.tb* clearance. Inhalable IFN-γ may therefore be beneficial as HDT for people in high-risk settings or in individuals at risk of recurrent TB disease.

Trained immunity drives neutrophil reprogramming providing protection against pneumococcal sepsis

Charly Gilbert[1], Tiia Snäkä[1], Maelick Brochut[1], Charlotte Theroude[1], Marta Reverte[1], Didier Le Roy[1], Thierry Roger[1]
[1]*Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland*

Purpose: Trained immunity reflects the capacity of the innate immune system to adapt to an initial challenge and mount an improved response to a secondary challenge. Trained immunity is associated with metabolic, epigenetic and functional reprogramming of stromal cells and myeloid cells. We reported that trained immunity protects mice from a wide range of bacterial infections. Surprisingly, while neutrophils play a key role in host defences, their role during training is poorly understood. We aimed to determine whether neutrophils are reprogrammed during training and to assess their role during streptococcal pneumoniae.
Methods: Mice were challenged with PBS (control) or β-glucan (training) given intraperitoneally. After one week, mice were sacrificed to collect organs and cells, or were challenged intranasally with *Streptococcus pneumoniae* with or without control or trained neutrophils. Control and trained neutrophils were labelled and co-injected intravenously in mice challenged intranasally with lipopolysaccharide (LPS). Samples were analysed by flow cytometry, scRNAseq and multiplex bead assay. Mouse morbidity and mortality were registered daily.
Results: Training increased bone marrow myeloid stem and progenitor cells, and immature and mature neutrophils in bone marrow, blood, spleen and lungs ($P<0.001$). scRNAseq pseudobulk analyses revealed an alteration of neutrophil developmental subsets in the bone marrow and spleen. The transcriptome of trained neutrophils was enriched in gene pathways related to cellular effector functions. In agreement, trained neutrophils showed increased *S. pneumoniae*-induced phagocytosis and cytokine production, and chemotaxis towards CXCL2 ($P<0.05$). Trained neutrophils migrated to a greater extent than control neutrophils in the lungs of LPS-challenged mice ($P<0.01$). Training decreased bacteremia and increased survival of mice with lethal pneumococcal pneumonia ($P<0.0001$). The protection was lost upon neutrophil depletion (0.0% *vs* 87.5% survival in neutrophil-depleted *vs* neutrophil-non-depleted trained mice, $P<0.001$). The adoptive transfer of trained neutrophils to naive mice increased their resistance to *S. pneumoniae* infection.
Conclusion: Training triggered central and extramedullary hematopoiesis and elicited a marked rewiring of the neutrophil compartment. Trained neutrophils had enhanced chemotactic and antibacterial functions and played a key role in protecting against lethal pneumococcal pneumonia. The molecular mechanisms underlying neutrophil reprogramming are under investigation.

Purpose: Sepsis induces immune alterations, which last for months after the cure. The impact of this immunological reprogramming on the risk of developing cancer remains unclear.
Methods: We use scRNA-seq dataset from a publicly available database of immune cells from bronchoalveolar lavages of moderate or severe COVID-19 patients, RNA-seq datasets from publicly available databases of human tissue-resident T cells sorted from lung tumors or the dermis, national claims database, well-defined mouse model of lung metastasis and skin metastasis, adoptive transfer of immune cells into the lungs and high-throughput scRNAseq, TCRseq and ChIPseq analysis of the immune cells from murine lungs.
Results: Using a national claims database, we observed that sepsis survivors had a lower cumulative incidence of cancers than matched controls. We identified a chemokine network released from sepsis-trained resident macrophages that triggers tissue residency of T cells via CCR2 and CXCR6 stimulations as the immune mechanism responsible for this decreased risk of *de novo* tumor development after sepsis-cure. While non-septic inflammation did not provoke this network, laminarin injection could therapeutically reproduce this protective sepsis consequence. This chemokine network and CXCR6 tissue-resident T-cell accumulation were observed in humans with sepsis and were associated with prolonged survival in humans with cancer.
Conclusion: Here, we identified a novel and therapeutically relevant anti-tumor consequence of sepsis-induced trained immunity.

Sustained immune and metabolic effects of a traditional African diet and fermented beverage versus a Western diet: insights from a short dietary transition study in Kilimanjaro, Tanzania

Godfrey Temba[1], Tal Pecht[2], Vesla Kullaya[3], Nadira Vadaq[4], Mary Mosha[1], Paolo Lionetti[5], Andre van der Ven[4], Duccio Cavalieri[5], Leo Joosten[4], Blandina Mmbaga[3], Joachim L. Schultze[2;6], Mihai Netea[2;4], Quirijn de Mast[4]

Purpose: Traditional diets of many African communities are being rapidly replaced by Western-style diets. African populations are underrepresented in nutrition immunology research, resulting in a scarcity of data on the immune and metabolic effects of traditional, largely plant-based African diets and fermented food products. This study aimed to investigate these effects through a short controlled dietary intervention in the Kilimanjaro region in Tanzania.
Methods:
We conducted a short-term dietary intervention study involving young men residing in urban and rural areas in Moshi district. Participants (n=22 per group) underwent two-week periods of transitioning between a traditional diet (TD) and a Western diet (WD), as well as consumption of a traditional fermented banana beverage (‘Mbege’) for one week by urban participants (n=22). Additionally, ten controls who maintained their habitual diet were also enrolled. Functional immune assays (cytokine production capacity) and omics analyses (targeted plasma proteomics, whole blood transcriptomics, untargeted plasma metabolomics) were employed to assess changes in immune and metabolic parameters before, immediately after, and four weeks post-intervention (follow-up).
Results:
Our findings demonstrate that transitioning from a TD to a WD induces a pro-inflammatory state at the level of circulating leukocytes, proteins, and gene expression, whereas transitioning from a WD to a TD and consuming the fermented beverage exerts an overall anti-inflammatory effect. In addition to traditional markers of inflammation and immune function, these effects encompassed alterations in circulating concentrations of proteins involved in cardiometabolic processes and the plasma metabolome, including lipid and amino acid metabolism. Importantly, these effects persisted at follow-up, suggesting sustained impacts on immune and metabolic profiles following the intervention.
Conclusion:
This study provides new insights into the potential health risks associated with abandoning traditional African diets and the potential health effects of consuming traditional fermented beverages. Our findings underscore the importance of preserving indigenous dietary practices amidst dietary transitions in Africa and highlight the role of nutrition transition in the rising burden of non-communicable diseases in urbanized areas across Sub-Saharan Africa.

Regulatory T cells require IL-6 receptor alpha signaling to control skeletal muscle function and regeneration

Maike Becker[1;2], Sini Susan Joseph[1;2], Francisco Garcia-Carrizo[2;3], Robby Z. Tom[1;2], Daria Opaleva[1;2], Isabelle Serr[1;2], Matthias H. Tschöp[1;2;4], Tim J. Schulz[2;3;5], Susanna M. Hofmann[1;2;6], Carolin Daniel[1;2;6]
[1]Helmholtz Center Munich, Munich, Germany; *[2]German Center for Diabetes Research, Munich, Germany*; *[3]German Institute of Human Nutrition, Potsdam, Germany*; *[4]Technical University Munich, Munich, Germany*; *[5]University of Potsdam, Potsdam, Germany*; *[6]Ludwig-Maximilians-University Munich, Munich, Germany*

Tissue-residing Foxp3$^+$ regulatory T cells (Tregs) control local tissue integrity and function by exerting non-canonical functions which go beyond classic immune-modulation. These tissue Tregs interact with the local microenvironment they reside in and implement environmental and metabolic cues. Recently, a special subset of tissue Tregs was described in the muscle. However, the molecular interface that connects Treg-based regulation with muscle function and regeneration remained largely unexplored.
Here, we show that exercise (i.e. voluntary wheel running) fosters a stable induction of highly functional muscle-residing Tregs with increased expression of amphiregulin (sedentary vs. pre-exercised p=0.0064; exercised vs. pre-exercised p=0.0009), EGFR (sedentary vs. exercised p=0.0192, sedentary vs. pre-exercised p<0.0001, exercised vs. pre-exercised p<0.0001), ST2 (sedentary vs. pre-exercised p=0.0031, exercised vs. pre-exercised p=0.0002) and IL6Rα (sedentary vs. pre-exercised p=0.0064,exercised vs. pre-exercised p=0.0001).
Mechanistically, we find that mice lacking IL6Rα on T cells (TKO) show significant reductions in muscle Treg phenotypic maturation, deficits in numbers of satellite cells (IL6Rα floxed vs TKO p=0.046) and fibro-adipogenic progenitor cells (IL6Rα floxed vs TKO p=0.0021), which are required for proper muscle regeneration. Using exercise and additionally sarcopenia models, IL6Rα TKO mice demonstrate deficits in muscle Tregs, their functional maturation and a more pronounced decline in muscle function as assessed by grip strength tests (IL6Rα floxed vs TKO p=0.0146). Furthermore, a chemical muscle injury model shows that IL6Rα TKO mice have significant impairments in muscle regeneration 14 days post injury as indicated by reduced fiber cross sectional areas (IL6Rα floxed vs TKO p=0.0017). Importantly, Treg gain-of-function by Treg expansion restores the impaired muscle repair in IL6Rα TKO mice, highlighting the importance of Tregs for proper muscle function. Of note, pharmacological IL6R blockade in WT mice (as used to treat autoinflammatory disorders in the clinics) phenocopies impairments in muscle function (control InVivo mAb vs anti-IL6R InVivo mAb p=0.0014) identified in IL6Rα TKO mice, thereby underscoring the clinical implications of these findings.
Overall, the results of this study highlight the relevance of dissecting the molecular basis of muscle-specific immune regulation which will be of importance for the design of tailored precision medicines targeting niche-specific Tregs in the future.

Local thyroid hormone action in T cells and its role for protective immunity

Christina Wenzek[1], Devon Siemes[2], Eva Pastille[3], Torben Knuschke[3], Sebastian Hönes[1], Anita Boelen[4], Astrid Westendorf[3], Daniel Robert Engel[2], Lars Möller[1], Dagmar Führer[1]
[1]University Hospital Essen, Department of Endocrinology, Diabetes and Metabolism, Essen, Germany; *[2]University Hospital Essen, Institute for Experimental Immunology and Imaging, Essen, Germany*; *[3]University Hospital Essen, Institute of Medical Microbiology, Essen, Germany*; *[4]Amsterdam UMC, Amsterdam Gastroenterology Endocrinology and Metabolism, Amsterdam, Netherlands*

Purpose: Thyroid hormones (TH) are critical regulators of development, growth and physiological function of many tissues and cells among which the immune system has emerged as an important target. However, the effect of TH in T cells, which play a central role in protective immunity, is poorly understood. Therefore, we aimed to address local TH action in T cells and its role for protective immunity.
Methods: Using mice, which either lack the TH receptor α (TRα) or exclusively the canonical TRα action, we analyzed the impact of TH-TRα signaling on T cell immunity in health and disease.
Results: Our findings suggest a significant role of TRα-mediated TH signaling in T cell immunity. In naïve, female mice, lack of classical, canonical TRα action increased the frequency of regulatory T cells (Treg) and induced an activated and migratory Treg phenotype. Moreover, canonical TRα action reduced activation of the NFκB pathway previously shown to play a pivotal role in Treg differentiation and function. Similarly, during influenza A virus (A/PR8/34) infection body weight loss was attenuated in absence of canonical TRα action, whereas entire loss of TRα signaling aggravated disease as shown by increased viral loads in lung.
Conclusion: Taken together, our findings demonstrate for the first time that TRα impacts T cell differentiation and phenotype and thus may have an important role regulating protective immune responses during disease.

Oleic acid improves clinical features in psoriasis mouse model: effects on immune cells

Beatriz Burger[1], Roberta Sagiorato[1], Isabela Baccarin[1], Hernandez Moura Silva[2], Hosana Rodrigues[1]
[1]*Universidade Estadual de Campinas, Limeira, Brazil*; [2]*Rangon Institute, Cambridge, United States*

Purpose: Psoriasis is an auto-immune disease that affects thousands of millions of people in the world. There is no cure for psoriasis and the treatments available focus on block the cytokines involved in the disease. Considering that diet is a trigger for the disease, we aimed to investigate the effects of oral supplementation with oleic acid (OA), the main fatty acid found in the Mediterranean diet, on psoriasis.
Methods: Male C57BL/6 mice were induced with psoriasis by applying a 5% imiquimod-based cream (IMQ) for 5 consecutive days while simultaneously receiving OA by gavage. We assessed skin thickness, body weight, water and food intake, and spleen area and weight, and gene expression of cytokines and markers of keratinocytes proliferation in the skin. We also performed flow cytometry and WB analyses. Statistical analyses were performed using one-way or two-way ANOVA followed by Bonferroni's post-test ($p < 0.05$).
Results: IMQ increased skin thickness, redness, and peeling on the dorsal skin compared to the control group. Treatment with OA reduced these clinical symptons. The gene expression of IL-17, IL-22, IL12p40, IL-23 were increased in IMQ and reduced in IMQ+OA. IMQ elevated the percentage of monocytes on dermis, and OA reduced it. The same pattern was observed for macrophages; IMQ increased the proliferation rate of skin macrophages while OA returned it to control rate. Performing dextran tracking experiments, we observed that IMQ reduced the migration of macrophages from blood to skin and OA reversed this effect. Considering the results obtained so far we investigated the effects on NLRP3/Caspase 1 pathway. By WB, we observed the increase in activated Caspase 1 in IMQ samples and a reduction in IMQ+OA.
Conclusion: OA has beneficial effects on psoriatic inflammation acting on immune cells, mainly monocytes and macrophages. OA seems to reduce the exacerbation of the skin inflammation inhibiting the proliferative response and reducing cell death. Altogether, these effects explain the improvemnet in the clinical aspects of psoriasis.

Hyperandrogenism cause tissue specific alterations of NK cells in a mouse model of polycystic ovary syndrome

Sara Torstensson[1], Haojiang Lu[1], Allan Zhao[1], Sanjiv Risal[1], Eva Lindgren[1], Gustaw Eriksson[1], Benedict Chambers[1], Maria Johansson[1], Anna Benrick[2], Elisabet Stener-Victorin[1]
[1]*Karolinska Institutet, Stockholm, Sweden*; [2]*University of Gothenburg, Göteborg, Sweden*

Immune dysfunction is linked to several features of polycystic ovary syndrome (PCOS), including reproductive failure and metabolic comorbidities. Uterine NK (uNK) cells are pivotal for a successful implantation, while immune cells residing in visceral adipose tissue (VAT) are central for glucose homeostasis. We have previously shown that hyperandrogenism, a hallmark of PCOS, render female mice insulin resistant and alters immune populations, with an increased number of uNK cells and a higher frequency of $CD69^+$ NK cells in VAT. However, it remains unknown if this corresponds to a disturbed NK cell function.
To better understand how hyperandrogenism affect NK cells, phenotypic markers were analyzed by flow cytometry in dihydrotestosterone-exposed mice (PCOS-mice). Co-treatment with flutamide, an androgen receptor (AR) antagonist, was used to study AR activation. Preliminary data show a clear reduction of mature $CD27^-CD11b^+$ NK cells in uteri of PCOS-mice, with a higher proportion of $CD27^+CD11b^-$ and $CD27^+CD11b^+$ NK cells. A similar but less pronounced effect was seen in VAT, spleen, and blood. Decreased frequencies of NK cells expressing the maturation marker KLRG1 was also found in all analyzed compartments. Moreover, PCOS mice displayed reduced frequencies of $NKG2A^+$ uNK cells. NKG2A has been shown to educate uNK cells and correlate with the expression of the activating molecule DNAM1. Indeed, a lower frequency of $DNAM1^+$ uNK cells was seen in PCOS mice, which may suggest alterations in uNK education. Surprisingly, a population of $PD1^+$ NK cells was found in uteri, which was reduced in PCOS-mice and absent in spleen and blood. In contrast, a higher frequency of NK cells co-expressing CD69 and CXCR6 was found in in VAT of PCOS-mice, indicating that tissue-resident NK cells in VAT are specifically affected by androgen exposure. Most effects were prevented by co-treatment with flutamide, indicating AR driven alterations.
Our results propose an inhibitory effect of androgens on NK cell maturation, while other alterations are tissue specific. Hyperandrogenism may distort uNK education, which could be detrimental for embryo implantation. In turn, tissue-resident NK cells in VAT seem specifically affected with an unknown effect on metabolic regulation.

Intestinal microbiota controls multiple aspects of the body homeostasis including the development of many diseases. Microbiota composition is regulated by the host's immune system as well as by extrinsic factors, such as diet. Patients with type II diabetes (T2D) are characterized by impaired glucose tolerance, microbiota dysbiosis and enhanced amount of immunoglobulin A (IgA) antibodies in blood. However, the molecular mechanisms of how increased glucose levels affect humoral immune responses remain elusive. IgA is one of the major regulators of microbiota composition on the mucosal surfaces. Using a panel of monoclonal IgA antibodies cloned from the intestinal plasma cells, we found that some of them cross-reacted between microbial species and host tissues such as pancreas in steady state. Interestingly, high-glucose diet (HGD) in mice amplified the amount of cross-reactive IgA antibodies towards microbiota and pancreatic antigens. First of all, HGD increased *Akkermansia muciniphila* abundance in gut that was accompanied by the expansion of *Akkermansia*-specific IgA. Strikingly, *Akkermansia*-specific IgA cross-reacted with several pancreatic surface proteins on acinar cells as revealed by the competitive inhibition of binding to the tissue by bacterial antigens. Notably, treatment of mice with monoclonal IgA antibody cross-reactive to pancreas resulted in improved glucose tolerance. Mechanistically, such cross-reactive IgA response was controlled by TNF expression induced via TLR4 signaling during HGD. Altogether, our data reveal that glucose rich diet induced cross-reactive IgA production that ameliorated diabetes development.

Single-cell proteomics and transcriptomics resolve the development of eosinophils and the role of IL-5 in their lineage transit amplification.

Joseph Jorssen[1], Glenn Van hulst[1], Kirena Mollers[1], Julien Pujol[1], Georgios Petrellis[2], Antonio P. Baptista[3], Sjoerd Schetters[3], Frédéric Baron[1], Jo Caers[1], Bart Lambrecht[3], Benjamin Dewals[2], Fabrice Bureau[1], Christophe J.Desmet[1]
[1]GIGA Institute, Liege, Belgium; *[2]FARAH Institute, Liege, Belgium*; *[3]VIB-UGent, Gent, Belgium*

Eosinophils, specialized granulocytes initially recognized to accumulate in response to helminth infection, have also been attributed roles in immune homeostasis, microbial defense, metabolism, or anticancer protection. Despite their proposed beneficial functions, eosinophils are predominantly considered for their diagnostic value and implication in various type 2 immune disorders. "Anti-eosinophil" biologics targeting IL-5 or its receptor IL-5Rα, which drastically reduce circulating eosinophils, are now commonly used for the treatment of asthma and chronic rhinosinusitis. Yet, our understanding of the eosinophil lineage, and therefore of the mechanisms of action of targeted therapies, remains limited. We integrated single-cell proteomics and transcriptomics with a novel transgenic IL-5Rα reporter (IL5RAporter) mouse model to comprehensively resolve eosinophil development in human and mice. This approach reconciles human and murine eosinophilopoiesis and facilitates further exploration of eosinophilopoiesis at both cellular and molecular levels. We notably reveal that eosinophil lineage expansion is driven by IL-5-promoted transit amplification, which is characterized by increased cycling activity, prolonged proliferative capacity, and delayed maturation. Conversely, IL-5 deletion or neutralization attenuates eosinophil progenitor transit amplification without compromising maturation, challenging previous assumptions. Additionally, we demonstrate that Interferon Response Factor-8 is not inherently essential for eosinophilopoiesis, contrary to earlier hypotheses. The IL5RAporter strain also allows the identification of cells expressing IL-5Rα in mice, which include eosinophils, subpopulations of B cells, but not neutrophils or their progenitors. In addition, IL5RAporter mice indicate that IL5-Rα becomes expressed after the divergence of the murine basophil/mast cell and eosinophil lineages. This is unlike in humans, where IL-5Rα is expressed in common basophil/eosinophil progenitors and their progeny, which explains the impact of "anti-eosinophil" biologicals on both lineages. Overall, our study provides valuable resources, accessible methodologies, and novel insights into eosinophil ontogeny, the impacts of precision therapeutics, and the broader regulation of eosinophil development in health and disease.

Neutrophils: not as ready-to-go as we thought?

Cora Schwendele[1], Andreas Müller[1]
[1]*Institute of Molecular and Clinical Immunology, Magdeburg, Germany*

Neutrophil granulocytes (neutrophils) are first responders in inflammation, patrolling the bloodstream and ready to invade infected tissue. In recent years, the historical view of neutrophils as uniform and finally differentiated cell type has been challenged by increasing reports of heterogeneity in neutrophils. In the bone marrow, we find different stages of maturation, after which circulating neutrophils age over time, altering their appearance and functionality in the blood. This phenotypic diversity is also observed in different tissues upon recruitment.
We made use of a reporter mouse expressing an irreversibly photoconvertible protein (mKikumeGR) to track arrival time of neutrophils at the site of *Staphylococcus aureus (S. aureus)* infection. "Tissue-matured" neutrophils that had remained at the site of infection for several hours differed greatly from those "recently-recruited" from the blood. The phenotypic changes that accompany extravasation of circulating neutrophils into infected tissue further increased when the recently-recruited cells transformed into tissue-mature neutrophils over time. In particular, as CXCR2 and CD62L expression decreased, CD11b as well as CXCR4 increased.
Furthermore, behavioural differences were observed between the two subtypes in terms of phagocytic activity, which was much higher in tissue-matured neutrophils compared to recently-recruited cells. This was true towards bacteria at the site of infection, as well as beads inoculated into the infection site. Using a biosensor to measure bacterial proliferation *in vivo*, we were able to show that recently-recruited neutrophils harbour not only fewer bacteria, but that these bacteria also show higher proliferation. Finally, using intravital 2-photon microscopy, we were able to map the behaviour of neutrophils at the site of infection. We found that while recently-recruited neutrophils behave in a fairly uniform manner, tissue-matured neutrophils exhibit distinct morphodynamic changes depending on their proximity to *S. aureus.*
Taken together, we provide a dynamic map of how neutrophils unleash their full microbicidal potential following arrival at the site of infection.

Deciphering phenotype, dynamics, and function of early-life neutrophils using single-cell RNA sequencing and lineage tracing

Julian Hofmann[1;2;3], Laura Lintukorpi[1;2;3], Emmi Lokka[1;2;3], Venla Ojasalo[1;2;3], Sheyla Cisneros Montalvo[1;2;3], Marko Salmi[1;3;4], Pia Rantakari[1;2;3]
[1]Institute of Biomedicine, University of Turku, Turku, Finland; *[2]Turku Bioscience Centre, University of Turku, Turku, Finland*; *[3]InFLAMES Research Flagship Center, University of Turku, Turku, Finland*; *[4]MediCity Research Laboratory, Turku, Finland*

In the adult immune system neutrophils are considered the first responders to all types of acute tissue damage and infections. In line with the known ontogeny of other innate immune cells, neutrophils are first detected in circulation prior to birth at day 12.5 of embryonic development. Nevertheless, these cells have thus far not been subjected to the same rigorous scrutineering as other myeloid cells like macrophages. This project has hence aimed to consolidate this gap in knowledge of the prenatal and early-life innate immune system.
For the first time, we here provide a detailed look at the phenotype, kinetic dynamics, and functionality of neutrophils during late embryogenesis and postpartum. Using single-cell RNA sequencing of $CD45^+$ immune cells in the early immune compartments, we deciphered their transcriptomic landscape. Through *in silico* integration of published adult neutrophil transcriptome data, we were able to re-construct their journey from progenitor to mature immune cells.
We next analysed the kinetics and surface marker phenotype of neutrophil populations across haematopoietic tissues from embryogenesis until adulthood using multiplexed flow cytometry. Furthermore, we dissected their behaviour in relation to the circadian rhythm and used *in vitro* assays to validate characteristic neutrophil functions *ex vivo*. By utilizing state-of-the-art lineage tracing in combination with tissue clearing-aided 3D wholemount imaging, we were also able to study cellular location and distribution of the cells in their undisturbed environment.
Taken together, we provide a thorough, multimodal description of the phenotypic, kinetic, and functional landscape neutrophils during the crucial timeframe of embryogenesis and early life.

Neutrophils acquire a peculiar phenotype in psoriatic arthritis patients

Luca Modestino[1], Manuela Tumminelli[1], Marialuisa Trocchia[2], Annagioia Ventrici[2], Leonardo Cristinziano[3], Francesco Palestra[2], Anne Lise Ferrara[2], Stefania Loffredo[2;3], Francesca Wanda Rossi[1;2;3], Amato de Paulis[1;2;3], Maria Rosaria Galdiero[1;2;3]
[1]*Department of Internal Medicine and Clinical Immunology, University Hospital of Naples "Federico II, Naples, Italy*; [2]*Department of Translational Medical Sciences (DiSMeT), University of Naples "Federico II, Naples, Italy*; [3]*Center for Basic and Clinical Immunology Research (CISI), University of Naples "Federico II, Naples, Italy*

Backgroud: Neutrophils (polymorphonuclear leukocytes: PMNs) are the most abundant subtype of white blood cells and the main actors in the inflammatory response. Psoriatic arthritis (PsA) is a chronic inflammatory disease that affects the axial and peripheral joints. Typically associated to psoriasis, can also affect multiple systems and organs, including nails and enthesis. PMNs are also involved in the pathogenesis of PsA but their role has not been fully understood, yet. This study aimed to investigate the role of neutrophils and neutrophil-related mediators in PsA patients.
Matherials and Methods: 30 PsA patients and 22 healthy controls (HCs) were prospectively recruited. PMNs were freshly purified from peripheral blood and *in vitro* stimulated with lipopolysaccharide (LPS), N-Formylmethionyl-leucyl-phenylalanine (fMLP), tumor necrosis factor alpha (TNF-α), phorbol 12-myristate 13-acetate (PMA) or control medium. Highly purified peripheral blood neutrophils (>99%) were evaluated for activation status, reactive oxygen species (ROS) production, phagocytic activity, granular enzymes, and Neutrophil Extracellular Trap (NETs) release. Serum levels of matrix metalloproteinase-9 (MMP-9), myeloperoxidase (MPO), TNF-α, interleukin 23 (IL-23) and interleukin 17 (IL-17) were measured by ELISA. Serum concentrations of Citrullinated histone H3 (CitH3) was measured as NET biomarker.
Results: activated PMNs from PsA patients displayed reduced activation profile, ROS production and reduced phagocytic activity upon stimulation with TNF-α, compared with HCs. Upon stimulation with TNF-α, PMNs from PsA patients displayed also reduced granular enzyme release (MPO) and NET release. PsA patients presented higher circulating levels of MMP-9, MPO, TNF-α, IL-23, IL-17 and CitH3 compared with HCs. CitH3 serum levels were positively correlated to MPO and TNF-α concentrations in PsA patients. Moreover, IL-17 concentrations showed a positive correlation with IL-23 levels in PsA patients. These findings show a reduced *in vitro* activation of neutrophils purified from peripheral blood of PsA patients upon activation with TNF-α, but increased levels of neutrophil-derived mediators (MMP-9, MPO, TNF-α, IL-23, IL-17 and CitH3) in serum of PsA patients.
Conclusions: Taken together, our findings suggest the acquisition of an "exhausted" phenotype of neutrophils in PsA and highlight their plasticity and multiple roles in PsA pathophysiology.

DEVELOPMENT OF A MAST CELL DEPLETING ANTIBODY FOR THE TREATMENT OF MASTOCYTOSIS

William Worrall[1], Léna Andrieux[1], Nadine Serhan[1], Jasper Kamphuis[1], Alexia Loste[1], Edouard Leveque[1], Heleen Dewitte[2], Emmanuel Mbida[2], Emilie Maure[1], Cyprien Pecalvel[1], Roland Liblau[1], Nicolas Gaudenzio[1], Laurent Reber[1]
[1]Toulouse Institute for Infectious and Inflammatory Diseases, Toulouse, France; *[2]Argenx, Ghent, Belgium*

Purpose: Mast cells (MCs) are key effector cells in allergic reactions, and express KIT receptor which is essential for MC maturation, growth and survival. Somatic mutations in *c-kit* cause hyper- or constitutively- active receptor signalling, leading to mastocytosis. An anti-KIT monoclonal antibody (mAb), CDX-0159, depletes normal MCs. This mAb blocks KIT signalling without engaging effector functions, due to its Fc Silent format. This, however, renders CDX-0159 likely unsuitable for mastocytosis treatment, as mutations in the KIT receptor are known to signal regardless of ligand binding or receptor homodimerization.
Here, the objective is to develop an Fc-Engineered anti-KIT mAb able to deplete normal and KIT mutant MCs through its effector function.
Methods: An anti-mKIT mAb, clone ACK2, blocks KIT signalling and is therefore a surrogate for CDX-0159. This mAb was produced in three different formats called Fc Silent, WT, and Fc-Engineered. C57BL/6 mice or KIT^{K512I} mice, containing a constitutively active KIT receptor, were treated with 30μg of anti-mKIT mAbs with differently engineered Fc portions on day 0 and 7. Subsequently, MC burden was assessed in several tissues using flow cytometry or histochemistry.
Post-depletion functional tests of MC-dependent anaphylaxis were carried out, specifically IgE mediated- or mrgprb2 mediated- passive systemic anaphylaxis. Core body temperature was measured as hypothermia is the gold standard read out of anaphylaxis in mice.
Results: An Fc-Engineered anti-mouse KIT mAb is most efficient at depleting normal MCs compared to other Ab formats in numerous tissues. Subsequently, this treatment significantly reduces the severity of MC-mediated anaphylaxis. The Fc-Engineered anti-KIT but not the Fc Silent mAb also depletes MCs in KIT^{K512I} mice.
Conclusion: The murine surrogate of CDX-0159 can reduce MC burden. Fc-Engineering of this mAb can increase the efficacy of MC depletion. Furthermore, the Fc-Engineered anti-KIT can deplete KIT mutant MCs, whereas the Fc Silent cannot. These results provide a proof of concept that an Fc-Engineered mAb against the KIT receptor would be effective in mastocytosis.

This work was carried out in collaboration with Argenx SE, biotechnology company. W.P.M.W was supported by fellowships from INSERM-Region Occitanie and the Fondation ARC.

Innovative approaches for neutrophil elastase imaging in vivo using low-molecular-weight NIR fluorescent probes in inflammatory disorders

Galyna Bila[1;2;3], Sai Kiran Mavileti[4], Valentyn Utka[2;3], Evgenia Bila[2;5], Manuela Calin[1], Elena Butoi[1], Tamaki Kato[4], Shyam Pandey[4], Rostyslav Bilyy[1;2;3]
[1]Institute of Cellular Biology and Pathology "Nicolae Simionescu", Bucharest, Romania; *[2]Lectinotest R&D, Lviv, Ukraine*; *[3]Danylo Halytsky Lviv National Medical University, Lviv, Ukraine*; *[4]Graduate School of Life Science and System Engineering, Kyushu Institute of Technology, Kitakyushu, Japan*; *[5]Department of Organic Chemistry, Ivan Franko National University of Lviv, Lviv, Ukraine*

Purpose: Neutrophil Elastase (NE) plays a crucial role in inflammation by degrading bacterial components and extracellular matrix proteins, thus facilitating phagocytosis and tissue remodeling. Dysregulated NE activity is implicated in various inflammatory disorders such as chronic obstructive pulmonary disease, pancreatitis, inflammatory bowel disease, and acute lung injury. Furthermore, NE also cleaves extracellular matrix proteins such as elastin and collagen, promoting neutrophil migration and tissue remodeling during inflammation, e.g. lung damage at COVID or heart damage in a range of cardiovascular disorders. Uncontrolled and unregulated activity of NE can inflict adverse effects, degrading host tissues and exacerbating inflammatory responses. In this study, we aimed to develop innovative approaches for in vivo imaging of NE using low-molecular-weight near-infrared (NIR) fluorescent probes, with the goal of improving our understanding of NE dynamics in inflammatory processes and potentially aiding in the diagnosis and management of these disorders.
Methods: We synthesized squaraine-based fluorescent probes connected with peptides designed to specifically bind to or be cleaved by NE. These probes were used to develop both fluorescence resonance energy transfer (FRET)-based and non-FRET fluorescent NIR probes for NE detection. We evaluated the specificity, kinetics, and photostability of the probes in vitro and then applied them in models of chronic inflammatory conditions in vivo.
Results: Our findings revealed increased NE activity in a neutrophil-driven heart fibrosis model under both acute (isoproterenol) and chronic (angiotensin) inducers of fibrosis. The developed probes allowed us to visualize NE activity in various inflammatory settings, including MSU crystal-induced footpad inflammation and nanoparticle-induced air pouch inflammation. Furthermore, a non-FRET NIR probe enabled NE quantification at the cellular level using modified immunohistochemistry techniques.
Conclusion: Our study demonstrates the feasibility and utility of using low-molecular-weight NIR fluorescent probes for in vivo imaging of NE in inflammatory disorders. These probes offer a promising tool for studying NE dynamics, understanding the pathogenesis of inflammatory diseases, and potentially facilitating the development of targeted therapies.

Purpose: Systemic sclerosis (SSc) is characterized by an unknown etiopathogenesis**,** where platelet-derived growth factor receptors (PDGFRs) show an overexpression in patients with SSc. Since PDGFRα is the entry receptor for the adeno-associated virus type 5 (AAV5), here we analysed the prevalence of AAV5 in the lung of SSc patients with interstitial lung disease (ILD) and correlated the results to anti-PDGFRα immune responses.
Methods: The binding of the AAV5 capsid to the monomeric human PDGFRα was assessed by *in silic*o molecular docking, surface plasmon resonance (SPR), and using cells lacking PDGFRα through CRISPR/Cas9 technology. AAV5 was detected in SSc lung by *in situ* hybridization, immunohistochemistry, confocal microscopy, and molecular analyses of bronchoalveolar lavage (BAL). Immune responses to AAV5 and PDGFRα were evaluated by immunoprecipitation, SPR, liquid chromatography-tandem mass spectrometry (LC-MS/MS) with multiple reaction monitoring (MRM) of the composite peptides within the HLA class I immunopeptidomes in SSc peripheral blood mononuclear cells (PBMCs), and *in vitro* stimulation of PBMCs with peptides detected by MRM/MS.
Results: AAV5 was detected in the BAL of 41 out of 66 (62.1%) SSc patients and in 17 out of 66 controls with lung disorders (25.7%) ($p<0.001$). In SSc, AAV5 localized in type II pneumocytes and in lung interstitial cells. A molecular complex between AAV5 and PDGFRα was characterized. Composite peptides spanning specific fragments of huPDGFRα and AAV5 capsid were identified in HLA class I immunopeptidome of SSc PBMCs by MRM/MS. These peptides elicited *in vitro* a significant immune reactivity in PBMCs from SSc patients compared to controls.
Conclusions: The identification of the presence of AAV5 in lungs of SSc patients with ILD and the immune responses to AAV5 and PDGFRα composite peptides suggest a newly unrecognized role of AAV5 in the etiopathogenesis of SSc and of viruses in autoimmune disorders.

Exploring the germline diversity of various macaque B-cell receptor regions

Susan Ott[1], Giang Le[1], Nanine de Groot[1], Marit van der Wiel[1], Jesse Mittertreiner[1;2], Natasja de Groot[1], Jesse Bruijnesteijn[1], Ronald Bontrop[1;3]
[1]BPRC, Rijswijk, Netherlands; *[2]Hogeschool Leiden, Leiden, Netherlands*; *[3]Utrecht University, Utrecht, Netherlands*

Macaque species are widely applied as a model for the study of infectious diseases and vaccine efficacy. Despite their importance, genomic characterization of some macaque immune regions remains limited, such as regions encoding the highly variable B-cell receptor (BCR). Specificity of each BCR is dictated by the rearrangement of variable (V), diversity (D), and joining (J) gene segments, the pairing of heavy and light chains, combinatorial and junctional diversity, and somatic hypermutations. The well-characterized human V(D)J segments are located on three chromosomes, forming distinct regions encoding the heavy chain (IGH) and two light chains (IGK, IGL). At an individual level, these BCR regions are highly diverse, featuring insertions, deletions, and allelic variations. The macaque BCR regions, also distributed across three chromosomes, seem to display more diversity, especially in IGK and IGL V segments.
To refine translatability of immunological research from macaques to humans, a deeper understanding of the macaque BCR layout is essential. In this study, long-read sequencing was performed using ONT and PacBio platforms to characterize complete BCR regions. Using a custom bioinformatic pipeline, macaque BCR clusters were assembled and annotated. Despite abundant repetitive sequences and highly similar segments, phased haplotypes were resolved for IGH, IGK and IGL regions. This allowed identification and mapping of previously reported and novel gene segments, including potentially functional and pseudo entities.
Our sequencing approach enabled a comprehensive characterization of the heavy and light chain BCR regions in macaques, revealing extensive allelic and structural variations. Further implementation of this strategy would generate accurate germline references of V, D, and J segments, which allows assessment of mutational rates and BCR affinity maturation in response to infection or vaccination, thereby refining the macaque model in biomedical research.

Dynamics of T cell and B cell receptor repertoires in response to obesity in a murine model of atherosclerosis

Ivana Mikocziova[1;2], Lea Mikkola[1;2], Senthil Palani[3], Anne Roivainen[2;3], Ana Hernández de Sande[4], Merja Heinäniemi[4], Tiit Örd[5], Minna U Kaikkonen[5], Tapio Lönnberg[1;2]
[1]Turku Bioscience Centre, University of Turku, Turku, Finland; *[2]InFLAMES Research Flagship Centre, University of Turku, Turku, Finland*; *[3]Turku PET Centre, University of Turku, Turku, Finland*; *[4]School of Medicine, University of Eastern Finland, Kuopio, Finland*; [5]*Faculty of Health Sciences, A.I. Virtanen Institute for Molecular Sciences, University of Eastern Finland, Kuopio, Finland*

Purpose: Atherosclerosis is caused by a buildup of lipid-rich plaques within arterial walls. While T cells and B cells are both implicated in the immune response associated with atherosclerosis, the specific alterations in their respective receptor repertoires in response to obesity remain poorly understood. Here, we investigate obesity-induced changes in the T cell receptor (TCR) and B cell receptor (BCR) repertoires in a mouse model of atherosclerosis.
Methods: For this study, we used ten Ldlr-/- Apob100/100 mice, of which half received high-fat diet, while the remaining five were fed standard chow diet. From each mouse, we collected four different tissue types: perivascular adipose tissue, aorta, spleen, and epididymal white adipose tissue. The same tissue type from all mice in the same diet group was combined into one pool, resulting in eight sample pools. Afterwards, the tissues were dissociated and aorta samples were enriched for CD45+ cells. Finally, we performed single-cell RNA-sequencing using a 5' gene expression and VDJ immune profiling protocol. By analyzing VDJ repertoires, we aimed to identify clones with shared motifs and inspect them in the context of their gene expression profiles.
Results: The TCR repertoires were markedly distinct between obese and non-obese mice, with a more pronounced overlap between tissues from obese mice, suggesting a potential difference in predominant epitopes between the two diet groups. TCR clones that were more abundant in adipose tissues and/or the aorta were also present in the spleen, albeit in smaller numbers. In contrast, in the BCR repertoires, there was more overlap between the different diet groups, and the largest overlap was again seen between tissues from obese mice. We also observed tissue-specific BCR clones, which, although present in both diet groups, were much more abundant in obese mice.
Conclusion: This study contributes to the broader effort of unravelling the immunological mechanisms underlying cardiovascular diseases. Understanding the effect of diet on the dynamics of TCR and BCR repertoires in various tissues may inform the development of therapeutic strategies aiming to mitigate the progression of atherosclerosis in genetically predisposed individuals.

Broadly neutralizing HIV-1 antibodies have unusually high capacity to bind heme

Robin Lacombe[1], Valérie Lorin[2], Maxime Lecerf[3], Hugo Mouquet[2], Jordan Dimitrov[3]
[1]Sorbonne Université, Paris, France; *[2]Institut Pasteur, Paris, France*; *[3]Inserm, Paris, France*

Purpose: An antibody able to recognize many structurally unrelated antigens is referred to as polyreactive. Polyreactive antibodies play an important role for neutralization of human immunodeficiency virus (HIV-1) and represent >60% of broadly neutralizing HIV-1 antibodies (bNAbs). Besides the naturally polyreactive antibodies, healthy humans contain a fraction of antibodies that can acquire polyreactivity upon contact with the cofactor molecule - heme. Although in normal condition it is intracellularly constrained, heme can be released *in vivo* in case of hemolytic disease and / or tissue damage. Previous data have demonstrated that HIV-1 is unusually sensitive to heme. However, it remains unclear whether heme can impact specificity and functions of HIV-1 bNAbs.
Methods: The presence of cryptic antigen-binding specificities in a panel of 37 HIV-1 bNAbs was assessed by various binding assays (ELISA, Western Blots, immunofluorescence) and was compared to a panel of 43 neutralizing Abs specific for influenza virus. The molecular mechanism of interaction of heme-induced polyreactive antibodies with HIV-1 gp120 and gp41 proteins was studied by site-directed mutagenesis and biophysical methods (SPR, absorbance and fluorescence spectroscopy). The functional activity of heme-bound bNAbs was studied using virus neutralization assay.
Results: Here, we show that a considerable number (>60%) of HIV-1 bNAbs are able to bind heme, which is not the case for the other panel of human antibodies. HIV-1 bNAbs bind to heme especially to regions of the protein molecule that are rich in aromatic and positively charged amino acid residues. In addition, we demonstrated that the binding of heme results in a dramatic extension of the spectrum of antigens recognized by these antibodies. Nevertheless, heme does not impact the recognition of envelope protein (gp120) and neutralization of a panel of HIV-1 strains.
Conclusion: These findings might have relevance for understanding the unique molecular properties and the binding mechanism of HIV-1-neutralizing Abs. While some of these HIV-1 bNAbs have been already evaluated in clinical trials with encouraging results, further work is needed to characterize the importance of their capacity to interact with heme in viral recognition and immune processes during HIV-1 infection. This may contribute to harnessing their full therapeutic potential.

Surrogate light chain-deficient B cells expressing short and hydrophobic H-CDR3 loops escape from the bone marrow and expand in the periphery

Alaitz Aranburu[1], Erik Engström[1], Erik Demitz-Helin[2], Weicheng Ren[3], Alessandro Camponeschi[1], Timothy Sundell[1], Lill Mårtensson[1]
[1]Dept. Rheumatology and Inflammation Research, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; *[2]Dept. of Chemistry and Molecular Biology, Faculty of Science, University of Gothenburg, Gothenburg, Sweden*; *[3]Dept. of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden*

Purpose: In mice lacking the surrogate light chain proteins (SLC$^{-/-}$), antibody heavy chain selection at the pre-BCR checkpoint is defective, resulting in reduced numbers of precursor (pre) B, immature, mature and follicular B cells. In addition, B cell tolerance at the BCR checkpoint is also severely compromised, both in the bone marrow and in the periphery, resulting in overly autoreactive follicular B cells. Here we investigated whether the features of expressed heavy chains present in early bone marrow B cell precursors are also found in spleen and bone marrow plasma cells. We chose to analyse the molecular features associated with the H-CDR3 of the heavy chain repertoire because of its strong influence on antigen binding.
Methods: To better understand how the selection process occurs during (self-) antigenic activation, we have analysed high-throughput *IGH-VDJ* sequences from bone marrow progenitor (pro) B, preB and mature B cells as well as plasma cells from the spleen and bone marrow of mice with and without SLC deficiency.
Results: Our results show that certain plasma cell populations are highly expanded in *SLC*$^{-/-}$ mice and that they predominantly express heavy chains with short H-CDR3 loops, a feature that is already present at the preB cell stage. In addition, the use of *D* gene segment reading frames (RFs) is abnormal in the expanded plasma cell populations of *SLC*$^{-/-}$ compared to wild-type animals, with the otherwise "counter-selected" RFs II and III being favoured. Early bone marrow B cells and plasma cells from *SLC*$^{-/-}$ mice have an increased hydropathy index in the H-CDR3 loops compared to wild-type animals. PCA analysis based on H-CDR3 features shows that selection occurs in *SLC*$^{-/-}$ mice, but not to the same extent as in wild type.
Conclusion: The absence of SLC proteins severely compromises the *bona fide* selection process and thus the pre-B cell heavy chain repertoire, with changes being propagated to the next developmental stages, ultimately affecting the repertoire of plasma cells residing in the spleen or bone marrow.

Recognition of SARS-CoV-2 spike sequence by HLA-E-restricted CD8+ T cells

Valentina Ferrari[1], Alice Galante[1], Donatella Galgano[2], Philipp Nawrath[1], Daniela Vaqueirinho[1], Blanca Fernandez[1], Sandra Jovic[1], Federico Mele[1], Antonio Lanzavecchia[2], Federica Sallusto[1]
[1]Institute for Research in Biomedicine, Bellinzona; *[2]National Institute of Molecular Genetics, Milan, Italy*

Some viruses can evade the immune system by downregulating the expression of HLA class Ia on infected cells. However, virus-mediated downregulation of HLA class Ia can result in upregulation of HLA-E, a class Ib molecule, on the surface of infected cells. In homeostatic conditions, HLA-E presents self-peptides derived from the leader sequence of HLA class Ia molecules, termed VL9 peptides, that act as a negative regulator of NK cell lysis by interacting with CD94/NKG2A molecules on NK cells. Therefore, maintenance of HLA-E surface expression with simultaneous downregulation of HLA class Ia allows for viral escape from both HLA class Ia-restricted cytotoxic CD8+ T cells and HLA-E-recognizing NK cells. However, it has been reported that, in addition to VL9 peptides, HLA-E can also present virus-derived peptides which could instead be a target for protective HLA-E-restricted CD8+ T cells.
Here we utilized SARS-CoV-2 spike (S) protein transduced cell lines for a target agnostic approach to sort HLA-E-restricted CD8+ T cells from the peripheral blood of healthy donors. Isolated cells were cloned and specificity for SARS-CoV-2 S confirmed by proliferation, cytokine secretion, degranulation, and cytotoxicity. To refine target recognition, epitope mapping using overlapping peptides spanning the SARS-CoV-2 S sequence was performed. In addition, we sequenced the TCR of positive clones to ensure distinct clonotypes were isolated.
Our data show that HLA-E-restricted SARS-CoV-2 S-specific CD8+ T cells are present in the peripheral blood of healthy donors. These clones are multifunctional, secreting activating cytokines such as IFNγ, GM-CSF, and IL-13. In addition, these SARS-CoV-2 S-specific clones effectively lyse target cells transduced with the S protein. Overall, these results highlight a potential use for HLA-E-restricted CD8+ T cells in immunotherapy applications, such as adoptive cell transfer, or to synergize with vaccine-induced antibody responses by modifying vaccine design. However, these HLA-E-restricted CD8+ T cells are rare and a deeper understanding of how to better elicit HLA-E-restricted virus-specific CD8+ T cells is needed.

Compromised T cell development in Down syndrome is driven by intrinsic defects in early thymocytes

Annika Boxnick[1], Sarah-Jolan Bremer[1;2], Laura Glau[1], Daniel Biermann[3;4], Friederike Thiele[1], Jonathan May[1], Kati Tillack[1], Julian Dresse[1], Manuela Kolster[1], Romy Hackbusch[1], Ida Hüners[3], Martin Munz[3], Rainer Kozlik-Feldmann[5], Michael Hübler[3;4], Jörg Siegmar Sachweh[3;4], Eva Tolosa[1], Anna Gieras[1]
[1]Department of Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; *[2]University Children's Research, UCR@Kinder-UKE, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*; *[3]Congenital and Pediatric Heart Surgery, Children´s Heart Clinic, University Heart & Vascular Center Hamburg, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*; *[4]German Centre for Cardiovascular Research (DZHK), Partner Site Hamburg/Kiel/Lübeck, Hamburg, Germany*; *[5]Department of Pediatric Cardiology, University Heart & Vascular Center Hamburg, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Purpose: Down Syndrome (DS), caused by trisomy 21, is clinically associated with immunological dysfunction. Infants with DS have a small thymus with structural and functional stromal abnormalities, suggestive of a compromised thymocyte development. However, a detailed analysis of T cell development in DS is still missing and the underlying mechanisms of immunological alterations are not yet understood.
Methods: We performed multiparameter flow cytometry analysis on paired thymic and peripheral blood immune cells from 32 DS and 40 children with non-syndromical congenital heart disease, all under one year of age. We used CITE-seq for the analysis of thymocytes in carefully selected age- and heart condition-matched donors. Finally, we generated artificial thymic organoids (ATOs) using thymic CD34+ progenitor cells to study the particularities of T cell development in DS *in vitro*.
Results: Analysis of DS thymocyte subpopulations revealed lower frequencies of immature single-positive CD4 cells and an overrepresented CD8 compartment. *In vitro* modelling showed accelerated differentiation of DS cells into CD8+ T cells, indicating that these changes are intrinsic to the hematopoietic cells. CITE-seq analysis of DS thymocytes revealed differential expression of genes relevant for T cell development and lineage commitment. Finally, multiparameter flow cytometry analysis of peripheral blood at the time of heart surgery revealed higher frequencies of γδ T cells in infants with DS.
Conclusions: Our data demonstrate significant changes in T cell development in infants with DS, which are likely predetermined in thymic progenitor cells. The identification of a disproportionate CD4/CD8 composition in the thymus of DS children, together with the characteristic transcriptomic signature, advances our understanding of the impaired immune fitness observed in individuals with DS.

Purpose: Recent advances in -omics technologies enable detailed evaluation of the human immune system in the context of important clinical phenotypes. Here, we apply such technologies to investigate predictors of vaccine immune responsiveness in individuals with a range of immunosuppressive conditions who are vulnerable to COVID-19 vaccine failure.
Methods: Using bulk and cellular indexing of transcriptomes and epitopes (CITE)-sequencing, Olink proteomics and spectral flow cytometry we assessed the pre- and 21 days post-third dose COVID-19 mRNA vaccine immunophenotype of 133 individuals with various immunosuppressive diseases (inflammatory bowel disease, rheumatic conditions, solid organ and haematological stem cell transplant, cirrhosis, haematological malignancies and primary immunodeficiencies) and 22 healthy individuals. By integrating this data with vaccine-induced antibody (binding and neutralisation) and functional T-cell responses, we use machine learning enabled analyses to find associations between the baseline immunophenotype and vaccine immune responsiveness.
Results: We identified distinct pre-vaccination transcriptional signatures which predicted post-vaccine antibody responsiveness across immunosuppressive conditions. The signatures included increased B and plasma cell related gene modules and decreased inflammatory, monocyte and neutrophil-related gene modules. Spectral flow cytometry of peripheral blood samples confirmed that the changes in B-cell and monocyte-related gene signatures were partially explained by changes in the frequency of these cell-types. Cytometric analysis of B-cell subsets found that transitional and memory B-cell frequencies were significantly associated with vaccine-induced antibody responses.
The differences identified in pre-vaccine inflammatory gene signatures were validated at the protein level through analysis of 364 inflammatory proteins in pre-vaccine plasma samples. Further analysis identified a network of 16 inflammatory proteins which when measured together could predict post-vaccine immune responsiveness with an area under the receiver operating characteristic curve value of 0.82.
Persistence of the altered pre-vaccine immunophenotype was observed post-vaccine using CITE-sequencing. This gave insights into the cellular identity of transcriptomic and proteomic signatures related to vaccine immunogenicity and identified key regulators of vaccine immune responsiveness which were perturbed across immunosuppressive conditions.
Conclusion: Through comprehensive immune profiling of pre- and post-vaccine blood samples from immunocompromised individuals we identified novel cellular and molecular signatures that predict vaccine responsiveness and give insight into mechanisms of vaccine failure.

Purpose: Although serology has been a powerful tool in infectious disease epidemiology supporting epidemiologists and mathematical modellers to parameterize their simulation models thereby allowing epidemic forecasting and public health decision-making (e.g. SARS-CoV-2 vaccination), serological analysis of infected individuals is complicated by the variability of pathogen-induced antibody responses and is limited due to its use of antibodies as the sole marker of immunity against pathogens. On the other hand, pathogen-induced cell-mediated immunity is considered more sustained but remains poorly characterized at an epidemiological level.
Methods: In this ERC-funded study, we would like to introduce the celluloepidemiology method which analyses systematically T-cell responses against pathogens from an epidemiological perspective. We have applied the proposed celluloepidemiology method to characterise SARS-CoV-2 specific T-cell responses in convalescent patients recovered from COVID-19 for over 3 months and compared them to controls, household members of the recovered COVID-19 patients, general practitioners, hospital healthcare workers, and pre-COVID era donors.
Results: Applying flow cytometry and machine learning approaches to data from more than 500 individuals, we showed that the number of activated and exhausted $CD4^+$ and $CD8^+$ T-cells (having positive expression of CD154, OX40, CD137, CD69, TIGIT, and LAG-3) could be used to distinguish COVID-19 patients from controls and pre-pandemic participants, identify asymptomatic patients from those with mild, moderate, and severe COVID-19, as well as differentiate healthcare worker groups with different SARS-CoV-2 exposure/infection status. In addition, in our T-cell receptor (TCR) repertoire analysis, we found that recovered COVID-19 patients do not only harbour TCRs specific to SARS-CoV-2 but also those reactive against other coronaviruses (inc. MERS-CoV). This highlights that the celluloepidemiology approach is useful for discerning between different infections and backward tracing of pathogen-infected patients thanks to the added layer of TCR specificity.
Conclusion: We believe that the proposed celluloepidemiology method is complementary to conventional seroepidemiology in offering high dimensionality, sensitivity, and deep insight into the heterogeneity of human immune response against pathogens. Although the celluloepidemiology method was introduced and evaluated using the SARS-CoV-2 model in this study, the same concept is highly transferable to different pathogens and infectious diseases in the future.

The multi-omics landscape of systemic inflammation in people living with HIV

Javier Botey-Bataller[1;2;3], Nienke van Unen[1;3], dos Santos Jéssica[2], Maartje C.P. Jacobs-Cleophas[2], Marc JT Blaauw[2], Wilhelm A.J.W. Vos[2], Louise van Eekeren[2], Albert Groenendijk[2;4], Xun Jiang[1;3], Manoj Gupta[1;3], Nhan Nguyen[1;3], Cheng-Jian Xu[1;3], Leo Joosten[2], Mihai Netea[2], Andre van der Ven[2], Yang Li[1;2;3]

Background: People living with HIV (PLHIV) with viral suppression because of HIV-treatment have a higher susceptibility to non-AIDS co-morbidities, such as cardiovascular diseases (CVD), due to systemic inflammation. Systemic inflammation is potentially caused by immune activation by viral glycoproteins, but its underlying mechanisms are largely unknown.
Methods: We analyzed 1342 virally suppressed PLHIV participating in the 2000HIV project. By integrating five different omics layers together with immune function profiling, we deciphered mechanisms underlying persistent inflammation.
Results: Integrating epigenomics, transcriptomics, proteomics, metabolomics, and cytokine responses resulted in a set of co-morbidity related factors capturing inter-individual variation across layers. Specifically, we identified latent factors associated with CVD and accelerated aging. Furthermore, we used genomics to understand the sources of inter-individual variation in the different omics layers and identified 4,766 expression-QTLs, 1,155 protein-QTLs, 22 metabolite-QTLs and 2 cytokine-QTLs at study-wide significance level. The identified QTLs were largely concordant with existing QTL studies performed in healthy cohorts. Mendelian randomization analysis revealed baseline determinants of immune responses, such as gene *TNFRSF8* and protein IL17D as regulators of immune responses to HIV. Lastly, by linking genetic variation to the latent factors we identified, we discovered that the NLRP12 locus regulates the inflammasome complex at different layers. This suggests a causal factor in determining systemic inflammation in PLHIV.
Conclusion: All in all, we discovered intricate molecular mechanisms underlying inter-individual variation in systemic inflammation in 1342 virally suppressed PLHIV, identified molecular QTLs in PLHIV, and pinpointed baseline regulators orchestrating the immune response to HIV stimulation.

Modeling gene-enviroment interactions in Parkinson's disease: Helicobacter pylori infection of PINK1 -/- mice induces autoreactive cd8 T/ regulatory T cell disbalance associated with motor and cognitive dysfunction

Alexandra Kazanova[1], Jacqueline Sung[1], Christina Gavino[1], Hicham Bessaiah[1], Nathalia Luisa Oliveira[1], Lindsay Burns[1], Jessica Pei[1], Morgane Brouillard-Galipeau[1], Willemien Miller[1], Sherilyn Junelle Recinto[1], Moustafa Nouh Elemeery[2], Lei Zhu[1], Adam MacDonald[1], Lucia Guerra[1], Joel Lanoix[2], Pierre Thibault[2], Heidi McBride[1], Michel Desjardins[2], Jo Anne Stratton[1], Nathalie Labrecque[1;2], Samantha Gruenheid[1]
[1]McGill University, Montreal, Canada; *[2]Universite de Montreal, Montreal, Canada*

Purpose: Parkinson's disease (PD) is a neurodegenerative disorder characterized by the progressive loss of dopaminergic neurons in the brain that manifests in motor dysfunction upon the loss of the larger portion of neurons in substantia nigra. Genetic risk factors, environmental triggers, and dysregulated immune response have been implicated in PD. Understanding PD pathophysiology in its pre-motor prodromal phase is needed for earlier diagnosis and intervention. Here, we aim to study the impact of the PD-associated gene - *PINK1* and pathogen-*Helicobacter* (*H.*) *pylori* on PD development and immune autoreactivity.
Methods: We established *H. pylori* infection in *Pink1* $^{-/-}$ mice and wild-type littermate controls, with unaltered or depleted CD8 T cells. At two months post-infection mice underwent Y-maze, beam crossing and Pole behavioural tests. The stomachs, brains and spleens were harvested for immunophenotyping, multiplex cytokine assay, *H.pylori* qPCR; and detection of mitochondrial antigen reactive (MitAg+) CD8 T cells. We developed additional *in vitro* assays to assess *Pink1*and *H.pylori* effects on MitAg+ CD8 T cell priming and suppression by regulatory T cells (Treg).
Results*: H.pylori* infected *Pink1-/-* mice developed a PD-like motor-behavioural dysfunction that was abrogated by CD8 cell depletion prior to infection. Motor-behavioural phenotype in infected *Pink1-/-* but not wild type mice strongly correlated with the yield of autoreactive MitAg+ CD8 cells and CD8 T cell brain infiltration. *H.pylori* infection *in vivo* and *in vitro* altered Treg FoxP3 expression, with a more robust FoxP3 loss in *Pink1 -/-* Tregs. The absence of PINK1 in dendritic cells exposed to *H.pylori* triggered robust priming of primary MitAg+ 2C T cells resulting in activation and proliferation. Addition of Pink +/+ Tregs to the co-culture effectively supressed 2C CD8 T cell proliferation, while PINK1-deficient Tregs lost their suppressor function.
Conclusion: Using a model that integrates genetic PD susceptibility and a PD-relevant pathogen we recapitulated the major features of complex PD pathophysiology including immune dysregulation that consisted of simultaneous Treg dysfunction associated with increased yield of autoreactive CD8 T cells

Recent developments of immuno-modulating therapies and their application to a broad range of pathologies ranging from cancer to infectious diseases is a major advance in medical research. Nevertheless, responses to these treatments vary from one patient to another which highlights the need to better understand immune response variability. This is particularly striking regarding low and middle resources countries, as most in-depth immunological studies have so far focused on western populations.
To address this limitation we compared two cohorts, the Milieu Interieur cohort, which consists of 1000 healthy French donors and the HGGP Senegal cohort, which consists of 48 healthy Senegalese donors. These two populations are subjected to different environmental and pathogen exposures with different genetic backgrounds, as well as different lifestyles and diets. We characterized their baseline immune cells using multi-analyte flow cytometry to quantify circulating granulocytes, myeloid cells, NK cells and T and B cell subsets. To assess their functional immune responses, we stimulated their whole blood in TruCulture systems with LPS, Poly:IC, and SEB which covers bacterial, viral, and T cell immunity. 13 cytokines were measured in the stimulated supernatants by Luminex, and the stabilized cell pellet was assessed by Nanostring hybridization arrays. We also assessed microbiome populations by 16S sequencing in fecal samples and nasal swabs.
Our preliminary results show remarkably comparable cellular population and cytokine levels in both baseline phenotypes and after stimulation between these two very different healthy human populations. Notable exceptions were observed for certain phenotypes for example Senegalese donors had significantly lower naïve CD4 T cells, higher IL-8 in Null and LPS conditions, and lower IL-17 after LPS stimulation. In contrast to systemic immune responses the microbiome composition in both fecal and nasal samples were significantly different between the two cohorts, with much greater diversity observed in the Senegalese donors.
Ongoing analysis will focus on how such diverse microbiomes may impact immune homeostasis and responses.

Ruxolitinib restores disease tolerance in malaria-infected glucocorticoid receptor knockout mice by preventing lethal hypoglycemia

Fran Prenen[1], Leen Vandermosten[1], Sofie Knoops[1], Emilie Pollenus[1], Hendrik Possemiers[1], Pauline Dagneau de Richecour[1], Giorgio Caratti[2], Christopher Cawthorne[3], Sabine Vettorazzi[2], Christophe Deroose[3], Uwe Himmelreich[4], Jan Tuckerman[2], Philippe Van den Steen[1]

Malaria is a global disease with yearly around 600 000 deaths. Lethality is caused by various complications, including dysmetabolism. Previously, we have shown that adrenal hormones prevent excessive inflammation and severe hypoglycemia in malaria, and we recently detected decreased glucocorticoid (GC) sensitivity in both patients and mice with severe malaria. To further investigate the specific effects of endogenous GCs in malaria, we infected wildtype (WT) and tamoxifen-inducible global glucocorticoid receptor (GR) knockout (GRiKO) mice with *Plasmodium chabaudi* AS parasites. A 50% lethality rate was observed in infected GRiKO mice while all WT mice survived the infection, indicating that GR is critical for disease tolerance. Lethality in the GRiKO mice was coinciding with severe hypoglycemia and hyperlactatemia. With [18]F-fluorodeoxyglucose-PET/MRI imaging, drastic increases in glucose uptake and/or retention in liver and spleen of infected global GRiKO mice were observed. The hypoglycemic phenotype observed in the infected global GRiKO mice did not develop upon infection of hepatocyte, T cell or myeloid-specific GR knockout mice, suggesting that a combined dysregulation in both hepatic and immune cells might be required for the development of lethal hypoglycemia in GRiKO mice. Furthermore, RNAseq analysis of the liver revealed glycolytic reprogramming and an aggravated impairment of gluconeogenic gene expression in infected GRiKO mice compared to WT. A similar glycolytic trend was observed in the spleen, and highly significant correlations were found between hypoglycemia and the glycolytic transcriptome. Transcription factor enrichment analysis of the transcriptome suggested STAT3 involvement. Correspondingly, increased STAT3 activation, and elevated *il6* mRNA levels were found in liver and spleen of infected GRiKO. Importantly, Ruxolitinib, a JAK/STAT inhibitor, prevented the development of severe hypoglycemia, and improved the survival of GRiKO mice upon infection. Overall, this study provides proof of a protective role for GCs during severe malaria. Impairment of GC signaling during malaria infection leads to an exaggerated activity of the JAK/STAT pathway, which ultimately drives development of lethal hypoglycemia. Inhibition of the JAK/STAT pathway by administration of Ruxolitinib restored normoglycemia and prevented lethality upon infection of GRiKO mice. Therefore, this study uncovers a potential new therapeutic strategy for the treatment of dysmetabolism in severe malaria.

Microbial infections trigger tissue mechano-responses to initiate innate immunity.

Giulia Stucchi[1], Laura Marongiu[1], Giuseppe Rocca[1], Marco Galli[1], Anna Celant[1], Stefano Cozzi[1], Francesca Mingozzi[1], Alessandra Martorana[2], Alessandra Polissi[2], Ivan Orlandi[1], Marina Vai[1], Metello Enzo Innocenti[1], Francesca Granucci[1]

Neutrophil recruitment from the bloodstream to tissues is a key early step in inflammation but how this happens remains unclear. This process occurs in response to both sterile and microbial injuries, suggesting the existence of a general strategy to minimize tissue damage while preparing for the containment of potential infections. This raises questions about the involvement of Pattern Recognition Receptors (PRRs) in early neutrophil recruitment during microbial infections and their role in microbial inflammation.
To investigate the mechanisms regulating neutrophil recruitment and function upon infection, we utilized a skin infection model wherein microbes are injected intradermally to minimize tissue damage while introducing PAMPs in large amounts. We employed different types of microorganisms, a fungus, *C. (Candida) albicans*, and Gram-positive or negative bacteria, *S. (Staphylococcus) aureus* and *P. (Pseudomonas) aeruginosa,* respectively.
To study the molecular mechanism leading to neutrophil recruitment during infection, we first characterized the immune infiltration through multi-parametric flow cytometry both in WT and mice KO for PRRs or interleukin receptors. We then characterized in depth the molecular cascade leading to neutrophil recruitment *in vivo* through qPCR and ELISA. Finally, we corroborated the results obtained in KO mice with pharmacological and genetic approaches.
We discovered that neutrophil recruitment is temporally defined by different upstream mediators, all converging to MyD88. Specifically, we identified two "waves" of neutrophil recruitment and were able to mechanistically define the first one. This initial wave occurs during the first 6 hours and is mediated by an LTB_4 (Leukotriene B4)- IL-1α axis, regardless of the type of infection. Neutrophils are recruited to the infected site via IL-1-CXCL1 axis, and conditional deletion of $CD11c^+$ immune cells abrogate neutrophil recruitment only at early stages. Surprisingly, this event is largely PRR-independent and instead relies on mechanoreceptor PIEZO1 and TRPV4, which directly regulate LTB_4 synthesis *in vivo*.
Thus, we propose a model of early neutrophil recruitment acting through a lipid-cytokine-chemokine axis that is pathogen-independent and relies on mechanosensing without major contribution from PRRs. This is a general mechanism deployed during various infection contexts.

Spatial multi-omics identifies acyltransferase activity associated with granulomas

Shoumit Dey[1], Jian-Hua Cao[2], Benjamin Balluff[2], Nidhi Sharma DEy[1], Peter O'Toole[3], Grant Calder[3], Sally James[3], Lesley Gilbert[3], Ron Heeren[2], Paul Kaye[1]
[1]York Biomedical Research Institute, Hull York Medical School, University of York, York, United Kingdom; *[2]Maastricht MultiModal Molecular Imaging (M4I) Institute, Division of Imaging Mass Spectrometry, Maastricht University, Maastricht, Netherlands*; *[3]Department of Biology, University of York, YORK, United Kingdom*

Purpose: We sought to elucidate the metabolic state of immune cells within granulomas that form in response to intracellular pathogens such as mycobacteria and Leishmania. Despite progress in understanding the phenotypic characteristics of these cells, their metabolic profiles, particularly lipid metabolism, remain largely unexplored. We studied granuloma immuno-metabolism in the context of experimental *Leishmania donovani* infection, to understand lipid metabolism regulation within these complex structures and its implications for disease outcomes.
Methods: We integrated spatial lipidomic and transcriptomic data. Liver sections from both *L. donovani* infected and control mice were subjected to non-targeted lipidomic (MALDI MSI) and transcriptomic profiling (10x Visium). The data obtained were then co-registered and analyzed using graph-based clustering to discern the distinct lipid and transcriptomic signatures between the hepatic granulomas and the surrounding parenchyma. Matched single-cell RNA sequencing data (10x) was used to spatially resolve cell-type deconvolutions and enrichment. Additionally, immunohistochemistry was used to validate the upregulation of certain enzymes, Lysophosphatidylcholine acyltransferase 2 (LPCAT2), ApoE and parasite specific protein OpB within the granulomatous regions.
Results: Our analysis revealed significant compositional differences in lipid signatures between granulomas and the adjacent liver parenchyma. We found that certain lipid classes were preferentially localized to granulomatous tissue, indicating a unique lipidomic profile. Several lipid classes were upregulated in these granulomas, highlighting the potential for lipid-led heterogeneity within these structures. Specifically, Lands cycle acyltransferases were associated with granulomas, with their enzyme products and substrates detected as lipid components in the MALDI data and the corresponding gene expression in the transcriptomic data. Single-cell expression of LPCAT2 suggested a myeloid-specific signature. Finally at the protein level, LPCAT2 expression was found to be upregulated in granulomas.
Conclusion: This study provides novel insights into the lipid metabolic changes that occur within granulomas during L. donovani infection. The distinct lipidomic and transcriptomic profiles identified suggest a specialized regulation of lipid metabolism in granulomatous regions, which may be crucial for the pathophysiology of granulomatous diseases. Our data serves as a platform for further investigation into the role of lipid metabolism in disease progression and treatment.

Differential antigen patterns during cyst degeneration in porcine neurocysticercosis

Luz Toribio[1;2], Lizziee Tello[2], Javier A. Bustos[2], Gianfranco Arroyo[2], Manuela Verastegui[2], Hector H. Garcia[2;3]
[1]Infection and Immunity Institute. St George's University of London, London, United Kingdom; [2]Universidad Peruana Cayetano Heredia, Lima, Peru; [3]Bloomberg School of Public Health. Johns Hopkins University, Baltimore, MD, United States

Purpose: Neurocysticercosis (NCC), caused by *Taenia solium* larvae invasion in central nervous system of humans and pigs, remains as a public health concern as the leading cause of acquired epilepsy worldwide. Cyst degeneration process, linked to focal epilepsy, is accompanied by active release of parasite antigens causing neuroinflammation. However, antigen distribution across cyst stages (viable, degenerating, calcified) and their impact on neuronal structures remain poorly explored. We utilized anti-*T.solium* monoclonal antibodies (moabs), targeting antigens from total cysts, vesicular fluid, and excretory/secretory (E/S) products, aiming to identify antigen patterns within cerebral cysts and surrounding parenchyma from NCC-infected pigs during cyst degeneration.
Methods: To identify antigens targeted by our moabs, we performed western blots against recombinant *T.solium* antigens related to anchoring, scaffold formation, and secretion (rGP50, rT24H and sTsRS2-sTs14/18, respectively). Subsequently, we optimized moab-based immunohistochemistry (IHC) to evaluate antigen distribution in brain tissue samples containing viable, granulomas and calcified cysts from 17 pigs post-antiparasitic treatment (2-, 4-, 8-, and 12-month). Image J software analysed images assessing immunoreactivity percentages.
Results: Moabs against total cysts targeted rGP50, rT24H and sTsRS2, while moabs against vesicular fluid and E/S products principally recognized sTs14/18 and sTsRS2. Two moabs targeting anchoring antigens (TsW5/TsW8) and two targeting E/S products (TsV3/TsE1) were selected for IHC evaluation. Visual examination identified two different antigen patterns. TsW5/TsW8 recognized antigens in cyst wall, vesicular fluid, and in the spiral canal in viable cysts, whereas TsV3/TsE1 recognized antigens only in cyst wall and vesicular fluid. In degenerating cysts, all moabs recognized antigens in cyst wall, vesicular fluid and surrounding tissue. Surprisingly, in calcified cysts residual antigens were detected and distributed inside the cyst for TsW5/TsW8 and only in surrounding parenchyma (500µM) for TsV3/TsE1, with a significant and gradual decrease in immunoreactivity (4 months:30.8%, 8 months:7.5%, 12 months:1.8%, $p<0.0005$).
Conclusion: Our findings reveal the dynamic nature of cyst degeneration and antigen distribution, suggesting antigen diffusion from the parasite into surrounding tissue, potentially inducing structural alterations in brain cells. This study contributes to understanding NCC pathogenesis and lays the groundwork for future investigations into the relationship between brain cell antigens, neuronal structure changes, and clinical NCC features.

A vaccination strategy utilizing exosomes induces protective immune responses in an experimental model of Leishmania infantum infection in BALB/c mice

Antonia Efstathiou[1], Maria Agallou[1], Dimitra K. Toubanaki[1], Evdokia Karagouni[1]
[1]*Hellenic Pasteur Institute, Athens, Greece*

Purpose: Leishmania, a protozoan parasite of the trypanosomatid family, is the causative agent of leishmaniasis which has wide range of clinical manifestations including cutaneous, mucocutaneous and visceral leishmaniasis. Annually, 0.9–1.6 million new infections are reported and 20–50 thousand deaths occur due to Leishmania infection. Current chemotherapy for treating leishmaniasis exhibits numerous drawbacks while there are no effective human vaccines with protective immune responses which could help on elimination of the disease. To this end, exosomes, extracellular vesicles that contain protein, RNA and DNA constituents of the cells that secrete them, play a new role in the vaccination approach of a variety of diseases such as cancer, Toxoplasma gondii etc.
Methods: In the current study, exosomes derived from Leishmania infantum promastigotes were isolated by density gradient ultracentrifugation and were characterized. Subsequently, BALB/c mice were immunized with the isolated exosomes with two intramuscular immunizations with 15-day interval in the presence and absence of Addavax adjuvant. The mice were then infected with L. infantum parasites and the effect of the regimen was evaluated on the acute and chronic phase of the disease (1 and 3 months upon infection, respectively).
Results: Vaccination with exosomes in the presence of adjuvant resulted in a dramatic reduction of the parasitic burden in both the acute and the chronic phase of the experimental model of Leishmania infantum infection in BALB/c mice, accompanied by an immunomodulatory effect on the host. More specifically, the parasitic burden was reduced by 93% in both liver and spleen during the acute phase and 80% in spleen and 90% in liver during the chronic phase of the disease. The reduction in parasite load was accompanied by an increase in antigen-specific $CD4^{+}IFN\gamma^{+}$ T-lymphocytes in the host.
Conclusion: According to the above data, an exosome-based vaccine regimen emerges as a new potent vaccination approach and promising tool in the fight against the parasitic disease leishmaniasis.

Leishmania mexicana-infected Lutzomyia longipalpis sand flies induce inflammasome derived IL-1β in C57/BL6 mice

Somaditya Dey[1;2], Eva Iniguez[1], Cláudio Meneses[1], Jesus Valenzuela[1], Shaden Kamhawi[1]
[1]*Laboratory of Malaria and Vector Research, NIAID, National Institutes of Health, USA, Rockville, MD, United States*; [2]*Barasat Government College, Barasat, North 24 Pgns, West Bengal, India*

Leishmaniasis is the second cause of mortality for a parasitic disease after malaria. Cutaneous leishmaniasis manifests in different forms, ranging from uncomplicated self-healing skin lesions (*Leishmania major*) to chronic diffuse lesions (*L. mexicana*). Here, we compare the early immune response to bites of *L. mexicana*-infected ($LmxSF_i$) and *L. major*-infected *Lutzomyia longipalpis* ($LmjSF_i$) sand fly bites in mice. We demonstrate that at 6 hours, $LmxSF_i$ and $LmjSF_i$ produced an acute inflammatory response with a 1.94-fold and a 1.77-fold higher recruitment of $Cd11b^+$ cells, respectively, compared to steady state earskin. Sand flies infected with either $LmxSF_i$ or $LmjSF_i$ produced a comparable influx of both neutrophils (median [M] of 33400, and 34750), and inflammatory monocytes (iMOs; M of 11750 and 10000), respectively, compared to steady state for neutrophils (M= 925) and iMOs (M=1250). A significant production of IL-1β was observed after infected sand fly bites, albeit at a lower magnitude in iMOs for both $LmxSF_i$ and $LmjSF_i$ (M= 2600, 3450) compared to neutrophils (M = 24280, 28400), respectively. Western blots of ear cell lysates from both *Leishmania spp*. 6 hours after sand fly bites show production of NLRP3 and cleavage of pro-IL-1β into its active form, indicative of pore formation and canonical inflammasome activation. Collectively, we show that a robust recruitment of innate immune cells after $LmxSF_i$, accompanied by a significant upregulation of inflammasome-derived IL-1β, reinforces the signature early host immune response to infected sand fly bites that regulates skin inflammation and modulates disease outcome.

Profiling maternal immune activation-induced alterations and training effects in offspring's immune cell compartments

Walaa Jradi[1], Fabien Prodjinotho[2], Clarissa Prazeres da Costa[2]
[1]Institute for Medical Microbiology, Immunology and Hygiene, Technical University of Munich (TUM), Munich, Germany; *[2]1Institute for Medical Microbiology, Immunology and Hygiene, Technical University of Munich (TUM), 2Center for Global Health, Technical University of Munich (TUM), Munich, Germany*

Background and objectives: The developmental origins of health and disease (DOHaD) concept has revealed the profound impact of the prenatal environment on postnatal health outcomes. We have previously shown that maternal chronic infection shapes the fetal immune system and response to antigenic challenges later in life. In the present study, we explore whether timely exposure to maternal immune activation (MIA) in utero alters stem cell development and modifies innate and adaptive immune cell compartments and their respective functionality.
Methods: We utilize a mouse model of MIA induced by the administration of Poly: IC during mid-gestation (E12.5) and analyze changes in 3-, 7- and 10-week-old offspring in regards to hematopoietic stem cell development and tissue-specific alterations of immune cell populations (DCs, B). Especially, we assess the MIA-induced alteration of FACS-sorted DC functionality.
Results: So far, we have observed a decrease of cDCs, especially cDC2, in lungs of MIA-offspring, including a decreased expression of CD80. This effect is more pronounced in females than in males, suggesting a sex-dependent maternal impact. Furthermore, we have observed alterations in the hematopoietic stem cells (HSCs) and other precursor cells, specifically the long-term (LT-HSC) and short-term (ST-HSC) HSCs, within the bone marrow. These changes indicate a shift towards activated hematopoiesis, where the cells are primed for differentiation rather than being maintained as stem cells. Moreover, we have also shown tissue-specific patterns in the immune alterations induced by MIA.
Conclusions: This research contributes to a better understanding of the developmental origins of health and disease theory and provides insights into the underlying mechanisms associated with immune alterations in offspring. Further work is ongoing to explore the extent of these changes and their influence on the development of allergic airway inflammation.

The Influenza Virus Hemagglutinin (HA): A Novel functional Ligand for the Immunosuppressive Receptor LAG-3

Dina Khateeb[1], Ardeshir Ariana[2], Marceline Cote[2], Yotam Bar-On[1]
[1]Technion-Israel Institute of Technology, Haifa, Israel; *[2]University of Ottawa, Ottawa, Canada*

In the realm of clinical research, there is growing interest in Lymphocyte Activation Gene 3 (LAG-3, CD223) as a promising inhibitory receptor, expressed on the surface of activated and exhausted CD4+ and CD8+ T cells, as well as regulatory T-cells. Its potential for enhancing immune responses against cancer and viral infections has sparked considerable attention. However, the identification of LAG-3 ligands remains elusive, impeding the development of LAG-3-targeted therapeutics. Concurrently, influenza viruses continue to pose significant global health challenges, with an observed inverse correlation between clinical symptoms and the frequency of influenza-specific T cells following infection. As such, there is a critical need for comprehensive research to unravel the role of LAG-3 during influenza virus infection and its potential implications.
The interaction between LAG-3 and the Influenza-virus infected cells, as well as the interaction with the influenza virus different proteins, was evaluated using Flow cytometry and ELISA and other immunological and virological assays. C57BL/6 mice model were used for the in vivo studies to understand the effect of LAG-3-Ig on the Influenza virus immune response.
We found that the Influenza virus hemagglutinin (HA) glycoprotein is a novel functional ligand for the immunosuppressive receptor LAG-3. Furthermore, blocking the interaction between LAG-3 and HA resulted in an improved antiviral $CD8^{+}$T cells response in vivo. Moreover, we showed that this binding is mediated by the glycans residues present on LAG-3. We suggest that blocking the LAG-3-HA interaction should serve as a new immune checkpoint target in Influenza virus infection.
We identified the Influenza virus HA protein as a new functional ligand for the inhibitory immune receptor LAG-3 and demonstrated that this interaction is glycan mediated. Thus, we uncovered a new immune checkpoint pathway that modulate the T-cell response during viral infection.

Role of NK cell circadian clock in Influenza pathogenesis

Shaon Sengupta[1;2], Oindrila Paul[1], Mahendra Padmini[1], Kaitlyn Forrest[1], James Garifallou[1]
[1]The Children's Hospital of Philadelphia, Philadelphia, United States; *[2]Perelman School of Medicine, Philadelphia, United States*

Purpose: Circadian rhythms provide an anticipatory system for the host to adapt to changes in its environment, including the threat of pathogens. Influenza infection causes extensive immunopathology; few consistently effective therapies exist. A hallmark of circadian control is that the response of the host varies by the time of day at which the insults are sustained. We have previously shown that mice infected at dawn had 3-fold better survival than those infected at dusk. Depletion of NK cells abrogated this time-of-day specific protection from IAV. This was mediated by exaggerated immunopathology but not by controlling early and peak viral titers. While the depletion experiment strongly supports the role of the NK cells in mediating the circadian regulation of lung injury, whether the NK cell-intrinsic clock is relevant to this process is not known.
Methods: To distinguish NK cell-intrinsic clock mechanisms from extrinsic circadian influences over this population, we generated a model wherein the clock is disrupted in the NK cells, *Ncr1cre*$^{+}$ *Bmal1*$^{fl/fl}$ (*Bmal1Δ*^{NK})**.** *Bmal1Δ*^{NK} and their WT littermates were infected with IAV (PR8) and lungs harvested for flowcytometry, viral titration, ELISA for cytokines and histological analyses, including Immunofluorescence staining. Further, we also sorted NK cells from the lungs of naive and flu-infected (day 4 post-infection) mice, and performed sc-RNA sequencing and analyses.
Results: *Bmal1Δ*^{NK} lungs had more leukocytes, but fewer NK cells in the uninfected state, and after infection, had 3-fold higher mortality, worse immunopathology, but fewer NK cells than WT littermates. Following IAV infection, the lungs of *Bmal1Δ*^{NK} mice had more Krt5^{+} areas and lesser SPC^{+} alveolar type 2 epithelial cells than WT controls, suggesting dysplastic repair in the mutant mice. Single-cell RNA sequencing of sorted pulmonary NK cells from both *Bmal1Δ*^{NK} and WT littermates revealed that the NK cell clock may be relevant to not only the regulation of host immune response but also lung repair processes during recovery from IAV.
Conclusion: In summary, NK cell- intrinsic circadian clock mediates regulation of host response to IAV through the regulation of acute inflammation and thereby affecting chronic repair.

Deletion of Dipeptidyl peptidase 3 in mice unleashes protective antibacterial immunity against Klebsiella pneumoniae

Amanda Facoetti[1], Luca Lambroia[1], Elena Fontana[1], Dario Strina[1;2], Maria Lucia Schiavone[1], Federico Nicchiotti[3], Ciro Menale[4], Cecilia Garlanda[1], Cristina Sobacchi[1;2], Veronica Marrella[1;2], Barbara Cassani[1;3]

Klebsiella pneumoniae is a common cause of pneumonia, particularly in elderly and immunocompromised patients, often leading to sepsis. Over the past decades, the emergence of multi-drug resistant strains made the treatment of *K. pneumoniae* a big challenge. Recent studies have demonstrated that host defense plays a critical role in eradicating *K. pneumoniae*.
The dipeptidyl peptidase 3 (DPP3) is a ubiquitous cytosolic metallopeptidase acting in the degradation of various bioactive peptides. In addition, it has been involved in the Nrf2 antioxidant pathway. Its high blood concentrations, related to massive cell death and inflammation, predict high risk organ dysfunction and mortality in patients with septic shock. To address the relevance of DPP3 in *K. pneumoniae* infections, we applied a model of lung infection in the DPP3 knock-out mice. We evaluated the mortality and the pulmonary and systemic bacterial load at different time points post infection. The levels of pro- and anti-inflammatory cytokines were measured, histopathological damage and inflammation were assessed in the lung. Results showed that DPP3 deficiency was associated with markedly decreased lung colonization and systemic bacterial burden, resulting in a significant survival advantage. Upon bacterial infection, DPP3-/- mice exhibited reduced tissue damage and weakened pulmonary and systemic inflammation compared with WT mice. Adoptive transfer experiment indicated that deficiency of DPP3 in immune cells was sufficient to enhance the lung bacterial clearance. Thus, we further used transcriptomics and cellular assays to define the specific role of DPP3 in lung immune cell biology. We found that lack of DPP3 induced transcriptional and metabolic programs characteristic of effector cells, associated with enhanced inflammatory signaling pathways. Accordingly, both innate and adaptive DPP3-deficient immune cells exerted more potent antimicrobial responses, particularly ROS and Th1/Th17 cytokines production. These findings point to DPP3 as novel immune checkpoint that shapes immunity by controlling the threshold for activation and resistance pathways. These results provide a framework for new therapeutic strategy against K. pneumoniae through improving host immunity.

Mast cell granules serve as endogenous C-type lectin receptor ligands skewing dendritic cell function towards type II immunity

Johanna Kotrba[1], Sascha Kahlfuß[1], Bernd Lepenies[2], Anne Dudeck[1]
[1]*Otto-von-Guericke University Magdeburg, Magdeburg, Germany*; [2]*University of Veterinary Medicine Hannover, Hannover, Germany*

Purpose: Mast cells (MCs) are best known as key effector cells of type I allergic reactions. Despite increasing evidence for an additional, critical impact of MCs on adaptive immunity, the underlying mechanisms are poorly understood. We recently reported that, upon skin inflammation, dermal dendritic cells (dDCs) engulf MC secretory granules (MCG), which boosts DC functionality and thereby adaptive immunity remotely (Dudeck et al. 2019). Based on this study, we intended to decipher underlying molecular mechanisms and consequences on DC functions.
Methods: Different transgenic mouse lines were used to clarify mechanistic details of the MCG uptake process. Mouse models of inflammatory disorders, basically hapten-induced skin inflammation and allergic airway inflammation, were used to determine the relevance of involved mechanisms for the respective immune response.
Results: We could show, that immature DCs sense and engulf MCG in a Card9-dependent manner. Consistently, Card9 deficiency resulted in a reduced T cell priming/differentiation upon hapten sensitization and diminished T cell driven adaptive ear swelling response upon elicitation. Questioning the MCG sensing DC surface receptors, we could identify that the c-type lectin receptors (CLRs) MCL and SIGNR3 bind to MCG and mediate their uptake. Most importantly, MCG uptake by DCs modulated their antigen-presenting capacity towards a type II immune response. Hence, mice that lack both, *Mcl* and *Signr3* expression, showed reduced allergic airway inflammation, in line with reduced cDC2 numbers and Th2 cytokine production.
Conclusions: Herein, we show that MCG are endogenous CLR ligands that translate (MC degranulation inducing) danger signals into adjuvant effects promoting lymph node-borne adaptive immunity. Understanding the uptake mechanism and DC modulating properties of MCG may give rise to therapeutic strategies to either intentionally boost adaptive immunity or dampen elevated immune responses.

Molecular regulation of innate lymphoid cell type 2 in inflammatory lung disease

Wen Jie Yeoh[1], Kristyna Hlavacková[1], Philippe Krebs[1]
[1]*University of Bern, Institute of Tissue Medicine and Pathology, Bern, Switzerland*

Airway inflammatory diseases like asthma and chronic obstructive pulmonary disease (COPD) are common disorders of increasing prevalence, for which no curative therapies currently exist. The phosphoinositide-3 kinase (PI3K) is often hyperactivated in these chronic lung inflammatory disorders, thereby promoting disease. The inositol phosphatase SHIP1 is a negative regulator of the PI3K pathway in hematopoietic cells, and SHIP1-deficient mice (styx) spontaneously develop a chronic airway inflammatory disorder that exhibits characteristics of both asthma and COPD. Here, we found that genetic ablation of IL-33 signaling prevented lethal inflammatory lung disease in styx mice. Innate lymphoid cells type 2 (ILC2s) were the main cells expressing of IL-33 receptor in lung infiltrates of styx mice, suggesting these cells as disease initiators. Indeed, lymphocyte deletion entirely rescued airway disease in lymphocyte-deficient Rag2-/-/Il2rg-/-/styx mice. Furthermore, depletion of ILC2s prevented, while adoptive transfer of ILC2s or associated cytokines restored lung disease in our model. Compared to other immune subtypes in the mouse lung, SHIP1 expression is particularly high in ILC2. In vitro experiments and single-cell RNA sequencing analyses indicate an intrinsic role of SHIP1 in restraining both murine and human ILC2 function. Lastly, SHIP1 expression is altered in lung ILCs from COPD versus control patients, suggesting a contribution of SHIP1 to ILC regulation in humans with chronic lung inflammatory disorders.
These findings collectively emphasize the critical role of SHIP1 in restraining ILC2 activity during airway inflammation and provide compelling support for the exploration of small-molecule SHIP1 agonists as a therapeutic approach for individuals suffering from asthma or COPD.

IgA production decrease is associated with B cell differentiation and proliferation defects in multiple sclerosis

louise Le Gal[1], Boussamet Léo[1], Morille Jeremy[1], Shah Sita[1], Mathé Camille[1], Rodriguez Stephane[2], Chesneau Mélanie[1], Mandon Marion[2], Garcia Alexandra[1], Amé-thomas Patricia[2], Tarte Karin[2], Dugast Emilie[1], Nicot Arnaud[1], Sophie Brouard[1], Laplaud David-Axel[1], Michel Laure[2], Berthelot Laureline[2]
[1]*Centre de Recherche Translationnelle en Transplantation et Immunologie CR2TI UMR1064, Nantes, France*;
[2]*MicrOenvironment and B-cell: Immunopathology cell DIfferentiation and Cancer MOBIDIC UMR 1263, Rennes, France*

Objectives: Multiple sclerosis (MS) is an inflammatory disease of the central nervous system leading to major disabilities in young adult. Growing evidences show the important role of B cells through their antibody/proinflammatory cytokine production and antigen presentation in MS pathology. Opposite to IgG+ B cells exercising inflammatory functions, IgA secreting plasmablasts / plasma cells are able to downregulate neuroinflammation in experimental autoimmune encephalomyelitis. The failure of TACI-Ig as an MS therapy, a treatment that targets all B cells including plasma cells, confirmed the protective and regulatory role of plasma cells in MS. We aim here to studying plasma cells in MS.
Methods: As plasmablast/plasma cells are rare in blood, they were differentiated *in vitro* from sorted blood B cells of MS patients and healthy controls (HC). Cytokines and immunoglobulins from B cell culture supernatants were measured by Luminex. In blood and cerebrospinal fluid (CSF), immunoglobulins were measured by ELISA. A single cell RNA sequencing was performed on PBMC from MS patients and HC using 10X genomics technology.
Results: We reported a lower differentiation and a lower proliferation of B cell from MS patients associated to a decrease of IgA production. MS patients also exhibited a lower concentration of serum IgA and IgA represented a lower proportion of immunoglobulins in the CSF compared to HC. Moreover, we observed a lower frequency of IgA^+ memory B cells and their activated subset in the blood of RRMS patients during relapse compared to HC. Finally, memory IgA+ B cells exhibit a specific transcriptomic signature in MS patients compared to controls.
Conclusions: IgA^+ B cells, that have been described as a potential reservoir of regulatory B cells, exhibited defects of proliferation and survival in MS. With a specific transcriptome not observed in other Ig-secreting B cells, IgA^+ B cells appear as an important component of B cell response in MS, which could be a target of future therapeutic strategies.

6-Formylindolo(3,2-b)carbazole ameliorates Graft-versus-Host Disease of the central nervous system via arylhydrocarbon receptor/NF-κB pathway in microglia

Alexander Johannes Zähringer[1], Sangya Chatterjee[1;2], Janaki Manoja Vinnakota[1], Daniel Erny[3], Rachael Claire Adams[1;4;5], Jana Gawron[1;2], Marlene Langenbach[1;2], Lennard Schwöbel[1], Valentin Wenger[1], Dominik Schmidt[1;2], Bodo Grimbacher[6], Marco Prinz[3;7;8], Robert Zeiser[1;7]
[1]Department of Medicine I, Medical Center, University of Freiburg, Faculty of Medicine, Albert-Ludwigs-University Freiburg, Freiburg, Germany; *[2]Faculty of Biology, Albert-Ludwigs-University Freiburg, Freiburg, Germany*; *[3]Institute of Neuropathology, Faculty of Medicine, Albert-Ludwigs-University Freiburg, Freiburg, Germany*; *[4]Faculty of Medicine, The University of Queensland, Brisbane, Australia*; *[5]QIMR Berghofer Medical Research Institute, Brisbane, Australia*; *[6]Center for Chronic Immunodeficiency CCI, Medical Center, University of Freiburg, Faculty of Medicine, Albert-Ludwigs-University Freiburg, Freiburg, Germany*; *[7]Signaling Research Centers BIOSS and CIBSS, Center for Integrative Biological Signaling Studies, Albert-Ludwigs-University Freiburg, Freiburg, Germany*; *[8]Center for NeuroModulation, Faculty of Medicine, Albert-Ludwigs-University Freiburg, Freiburg, Germany*

Purpose: 30-50% of patients receiving allogeneic hematopoietic cell transplantation (allo-HCT) develop acute Graft-versus-Host Disease (aGvHD), also affecting the central nervous system (CNS). The majority of allo-HCT patients need to undergo antibiotic therapy due to infectious complications which alter the microbiome, thereby promoting GvHD. Therefore, we investigated the mechanism through which microbiota modulates GvHD of the central nervous system to offer a potential new therapeutic target.
Methods: In a murine MHC II-mismatch transplantation model (C57BL/6 to Balb/c), we administered antibiotic treatment orally every day. We analyzed the brain using histological techniques including confocal imaging and investigated underlying cellular mechanisms *in vitro* using primary murine microglia and the arylhydrocarbon receptor (AhR) ligand 6-formylindolo(3,2-b)carbazole (FICZ) as *in vivo* experiments revealed reduced AhR signaling. We further confirmed our results *in vivo* by treating GvHD mice with FICZ.
Results: Antibiotic treatment of GvHD mice led to a significant increase in microglia and T-cell numbers in the brain, indicating increased inflammation. Immunofluorescence analysis showed a proinflammatory phenotype for microglia with increased NF-κB and Src activity. In addition, their morphology shifted to a highly branched phenotype compared to vehicle treated GvHD mice. Staining for the arylhydrocarbon receptor, a receptor for microbial metabolites, revealed a significant decrease in nuclear localization following antibiotic treatment. Alongside, treatment of primary murine microglia with the AhR ligand FICZ resulted in reduced expression of Syk and p38 MAPK as well as disrupted NF-κB signaling. FICZ treatment reduced the expression of NF-κB and significantly blocked its nuclear translocation upon lipopolysaccharide stimulation in primary microglia. Our observations on diminished NF-κB signaling were confirmed by the reduced secretion of the cytokines IL-6, MCP-1 and TNF-α. Microglia's functional analysis showed a decrease in phagocytosis and migration *in vitro*. When translating these findings to the *in vivo* model, we could demonstrate that FICZ treatment reduced T-cell infiltration into the brain, the number of microglia and the morphological changes of microglia in GvHD mice, indicating reduced inflammation.
Conclusion: Antibiotic treatment increases brain inflammation in GvHD. The AhR ligand FICZ rescues CNS inflammation by inhibiting NF-κB, thereby providing a potential target to treat Graft-versus-Host Disease of the CNS.

Long-term use of rituximab increases T cell count in MS patients

Gunnar Sigfus Bjornsson[1], Hildur Sigurgrimsdottir[1;2], Solrun Melkorka Maggadottir[1;2], Berglind Osk Einarsdottir[1], Olafur Arni Sveinsson[1;3], Haukur Hjaltason[1;3], Sigurveig Thora Sigurdardottir[2], Bjorn Runar Ludviksson[1;2], Siggeir Fannar Brynjolfsson[1;2]
[1]Faculty of Medicine, University of Iceland, Reykjavik, Iceland; *[2]Department of Immunology, Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland*; *[3]Department of Neurology, Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland*

Purpose: Rituximab has been used to treat MS patients in Iceland for over a decade. However, long-term effect of rituximab on the leukocyte population has not yet been elucidated. We investigated whether a long-term effect of rituximab on the leukocyte population in Icelandic MS patients was present and evaluated whether the effect is dose dependent (1000 mg vs 500 mg).
Methods: Retrospective analysis of flow cytometric data from 349 patients visiting the neurological ward at The National University Hospital of Iceland from 2012 to 2023 for rituximab treatment. Differential counts and classification of leukocytes were analysed.
Results: No difference in efficacy of B cell depletion was detected in patients treated with 500mg compared to 1000 mg of rituximab. Efficacy of the treatment was neither age nor sex dependent. The persistence of depletion was stable for both doses for 300 days. However, long-term use of rituximab led to an increase in T cell count (p=0.0015) in patients receiving 3-8 doses of rituximab (1.5-8 years of treatment). The increase occurred in both CD4+ (p=0.0028) and CD8+ T cells and led to a decrease in the CD4/CD8 ratio (p=0.004).
Conclusion: Since no difference in B cell depletion was detected between the two patient groups, 1000mg might be an excessive dose. However, the clinical implications of long-term treatment of rituximab and its effect on the T cell pool needs to be explored further. Based on this data a personalized dosing regimen might have therapeutic and financial advantages that should be explored further.

Targeting pyruvate kinase M2 to limit T cell pathogenicity in multiple sclerosis

Alyssa Schnabl[1], Elena Ellmeier[1], Anika Stracke[1], Katharina Seifried[1;2], Cansu Tafrali[2], Rina Demjaha[2], Sebastian Wurth[2], Michael Khalil[2], Stefano Angiari[1]

Multiple sclerosis (MS) is a chronic autoimmune inflammatory disease of the central nervous system (CNS) in which infiltration of leukocytes into the CNS leads to neuronal death, cognitive impairment, and disability. Among immune cells, T lymphocytes are key players in MS pathogenesis, controlling the development of CNS inflammation. Immunometabolism studies have shown that T cells regulate their activity by modulating their intracellular metabolic profile, and that targeting T cell metabolism represents a novel strategy for the treatment of autoimmunity. In particular, recent works suggested that the glycolytic enzyme pyruvate kinase M2 (PKM2) may be a potential therapeutic target in T cell-mediated autoimmune neuroinflammation. PKM2 can translocate into the nucleus in its monomeric/dimeric form, where it performs moonlighting functions different from its canonical enzymatic one, such as regulation of gene transcription. Several pre-clinical studies have demonstrated that PKM2 moonlighting activity controls T cell pathogenicity in the CNS and modulates neuroinflammatory responses in experimental autoimmune encephalomyelitis, a mouse model of MS. This project aimed to investigate the role of PKM2 in T cell inflammatory potential in human donors and MS patients. We first observed that PKM2 is differentially expressed in blood T cell subpopulations, with CD4+ T cells showing higher PKM2 levels compared to CD8+ T cells. Moreover, central memory, effector memory, and effector T cells display higher PKM2 expression, compared to naïve T cells. Interestingly, T cells from MS patients may display higher PKM2 levels than T cells from control individuals, depending on the disease form and activity. We then evaluated whether limiting PKM2 moonlighting activity with the PKM2 allosteric activator TEPP-46 may impact the inflammatory profile of T cells from healthy and MS individuals. We found that TEPP-46 inhibits T cell proliferation and decreases pro-inflammatory cytokine production by T cells in both control donors and MS patients, suggesting that PKM2 may control T cell pathogenicity. Overall, our data indicate that PKM2 may represent a novel biomarker for T cell activation and MS activity, and that targeting PKM2 moonlighting functions may be of relevance in MS. PKM2 allosteric activators thus represent promising pharmacological tools for MS treatment.

Natalizumab Treatment Induces Proinflammatory CD4 T Cells Preferentially in the Integrin β7+ Compartment

Iris Hasantari[1], Mélanie Nguyen Ky[1], Adrien Duran[1], Agnes Bru[1], Mathilde Deloire[2], Bruno Brochet[3], Aurélie Ruet[2;3], Nathalie Schmitt[1]
[1]CNRS UMR 5164 Immunoconcept- Université de Bordeaux, Bordeaux, France; *[2]Service de Neurologie, Centre Hospitalier de Bordeaux (CHU), Bordeaux, France*; *[3]Inserm U1215, Bordeaux, France*

Natalizumab, a monoclonal humanized antibody targeting integrin α4, inhibits the transmigration of lymphocytes into the CNS by preventing the interaction of integrin α4β1 with V-CAM expressed on brain vascular endothelial cells. Although natalizumab treatment reduces the clinical relapse rate in patients with relapsing-remitting MS, its discontinuation after reactivation of the JC virus is associated with a rebound of the disease in 20% of patients. The mechanisms of this rebound are not elucidated, but natalizumab increases the frequencies of circulating CD4 T cells expressing proinflammatory cytokines as well as the proportion of circulating Th17/Th1 cells (Th1-like Th17 cells). Gut-derived memory CD4 T cells are a population of growing interest in the pathogenesis of MS, but whether and how their properties are affected by natalizumab is not known. Here, we studied the phenotype and cytokine expression profile of circulating gut-derived memory CD4 T cells in patients with relapsing-remitting MS under natalizumab. We identified gut-derived memory CD4 T cells by their expression of integrin β7 and compared their properties and those of integrin β7- memory CD4 T cells across healthy donors and patients with relapsing-remitting MS treated or not with natalizumab. We also compared the capacity of integrin β7- and integrin β7+ CD4 T-cell subsets to transmigrate in vitro across a model of blood-brain barrier. The proportions of proinflammatory Th17/Th1 cells as well as of IL-17A+IFNγ+ and IL-17A+GM-CSF+ cells were higher in memory CD4 T cells expressing integrin β7 in patients receiving natalizumab compared with healthy donors and patients with relapsing-remitting MS not receiving natalizumab. By contrast, integrin β7 negative memory CD4 T cells only presented a modest increased in their proportion of Th17/Th1 cells under natalizumab. We further observed that integrin β7+ Th17/Th1 cells migrated as efficiently as integrin β7- Th17/Th1 across a monolayer of brain microvascular endothelial cells. Our study shows that circulating integrin β7+ memory CD4 T cells of patients with relapsing-remitting MS under natalizumab are enriched in proinflammatory cells supporting the hypothesis that integrin β7+ memory CD4 T cells could play a pathogenic role in the disease rebound observed at natalizumab discontinuation.

Primed monocytes in gamma-herpesvirus-induced EAE exacerbation

Annet van de Waterweg Berends[1;2], Xiang Du[2], Justine Javaux[2], Remy Sandor[2], Malyvanh Pathammavong[2], Bieke Broux[1], Bénédicte Machiels[2], Niels Hellings[1], Laurent Gillet[2]
[1]BIOMED Biomedical Research Institute, Diepenbeek; [2]Laboratory of Immunology-Vaccinology, Liège, Belgium

Purpose: Multiple sclerosis (MS) is a chronic inflammatory disease of the central nervous system (CNS). MS is a multifactorial disease caused by genetic, immunological and environmental factors. The most strongly associated environmental risk factor for MS is Epstein-Barr virus (EBV), for which it is still unclear how it contributes to disease development. While most studies on EBV and MS focus on lymphocytes, here the contribution of EBV-imprinted myeloid cells to MS development is investigated.
Methods: Experimental autoimmune encephalomyelitis (EAE) is induced in mice pre-infected with Murid Herpesvirus 4 (MuHV-4). Phenotypic changes of CNS infiltrating immune cells are determined by flow cytometry. To find human translation, the phenotype of monocytes of EBV seropositive and negative donors are compared.
Results: A significantly worse EAE outcome and an increase in CNS infiltrating immune cells were found in pre-infected mice. MuHV-4 infection led to a high activation status of monocytes in blood, shown by an upregulation of MHC-II, Sca-1, CD86, Saa3 and CXCL9 and this phenotype remained present after the lytic infection phase. After EAE induction, an increased infiltration of these monocytes is found in the CNS of MuHV-4 infected mice. Also, highly activated microglia are seen after MuHV-4 infection. EBV seropositivity in humans altered the phenotype of monocytes resulting in more CXCL9 and CCR2, while reducing the anti-inflammatory phagocytosis receptor CD93 and the myelin scavenger receptor CD36. MuHV-4 infected mice show a similar disease aggravation after adoptive transfer of MOG35-55 T cells, further indicating that the observed MuHV-4-mediated EAE aggravation is not directly mediated by T cells. Finally, monocyte depletion during EAE diminished clinical symptoms to the level observed in non-infected mice without affecting T cell phenotype, indicating a causative role of monocytes in MuHV-4-mediated EAE exacerbation.
Conclusion: EBV mediated priming of the myeloid cell compartment is seen in both humans and mice and leads to worse disease. Future research in this understudied field focuses on what myeloid changes worsen disease symptoms and thus provide support for EBV targeted interventions.

Background: Longitudinal monitoring of SARS-CoV-2-specific antibody responses in the population has enriched our knowledge about the virus. In the face of ever-changing SARS-CoV-2 variants, regular sample collection irrespective of the presence of symptoms provides representative data on infection and seroconversion/seroreversion rates.
Methods: Our 31-months longitudinal seroepidemiological study (n=1446) in the community of the first German SARS-CoV-2 superspreading event includes analyses of acute infection, seroconversion, virus neutralization, T cells and cross-protective immunity against SARS-CoV-2 omicron variants.
Results: Spike(S)-specific IgAs decreased shortly after initial infection, while IgGs remained stable. Expectedly, both increased significantly after vaccination. Our longitudinal analysis predicts an 18-months half-life of S IgGs upon natural infection. N-specific responses declined over a period of 12 months after the initial infection, but showed an increase ($p < 0.0001$) during omicron. Frequencies of SARS-CoV-2-specific $CD4^+$ T cells expressing TNF-α and IFN-γ declined for 12 months after infection ($p < 0.01$; $p < 0.01$, respectively). S antibody levels and neutralization titers were highest in triple-vaccinated participants infected late in the pandemic compared to those infected early. Cross neutralization against omicron strains BQ.1.18 and XBB.1.5 was extremely low in all groups.
Conclusion: N-specific antibodies strongly increased during new sub-variants´ infection waves, but did not correspond to better neutralization against new variants.

SUV39H1 controls the differentiation of CD8+ tissue resident memory T cell precursors

Guadalupe Suarez[1], Sandrine Heurtebise-Chrétien[1], Pierre-Emmanuele Bonte[1], Diego Sebastian Amigorena[1]
[1]*INSERM U932, PSL University, Institut Curie, Paris, France*

Introduction: Activation of CD8+ T cells leads to the differentiation of short-lived terminal effectors and long-lived memory precursors. Some of these memory precursors remain in lymphoid organs and become central memory cells (TCM), while others home to non-lymphoid peripheral tissues early after antigen recognition and give rise to tissue resident memory T cells (TRM). The early stages of memory precursor differentiation into TCM and TRM remain poorly understood.
Aim: Explore the role of the histone methyl-transferase SUV39H1 on the differentiation of CD8+ TRM cells
Methods: We characterized CD8+ T cells residing in different lymphoid and non-lymphoid tissues of SUV39H1-KO and conditional SUV39H1-flox-CD4-Cre mice and WT littermates at steady state and upon flu infection by flow cytometry. We also explored tissue homing and TRM differentiation of SUV39H1-KO or WT TCR transgenic OT-I CD8+ T cells upon adoptive transfer into lymphopenic mice and upon flu infection by flow cytometry and CITE-seq. Finally, we analysed the capacity of SUV39H-KO lung-homing cells to delay lung tumor metastases compared to WT OT-I cells.
Results: We show that at steady state, during homeostatic proliferation and upon flu infection, lack of SUV39H1 in CD8+ T cells leads to the accumulation of CD49d+ CD69+ CD103- TRM cells in lungs and other non-lymphoid tissues. CITEseq analysis showed that SUV39H1-defciency increased proportions of CD49d+ CD8+ T cells which can differentiate into CD69+ CD103- TRM cells, suggesting that SUV39H1 can restrain TRM precursor differentiation. Consistently, SUV39H1-deficient CD8+ T cells accumulating in lungs upon flu infection give rise to CD69+ CD103- TRM after adoptive transfer. Finally, SUV39H1-defective TCR transgenic OT-I TRM cells that accumulated in lungs delay tumor growth more effectively than SUV39H1-sufficient OT-I cells. These results show that SUV39H1 in CD8+ T cells restricts the differentiation of TRM precursors, reducing CD69+ TRM colonization and persistence in lungs and other peripheral non-lymphoid tissues. Together with previous studies showing that SUV39H1 restricts the differentiation of TCM precursors, the results presented here indicate that TCM and TRM share epigenetic mechanisms of precursor differentiation.

Authors' Disclosures: SA is Scientific co-founder and Chief Schientific Oficer of MNEMO therapeutics and owner of a patent on SUV39H1.

Latent Cytomegalovirus upon Intranasal Infection provides immune protection against COVID in experimentally infected mice

Upasana Kulkarni[1], Henning Jacobsen[1], Sarah Leist[2], Tatjana Lüddecke[1], Ralph Baric[2], Luka Cicin-Sain[1]
[1]*Helmholtz Centre for Infection Research, Braunschweig, Germany*; [2]*University of North Carolina, Chapel Hill, United States*

Introduction: Cytomegalovirus (CMV) is a ubiquitous herpesvirus that elicits a uniquely strong and lasting memory T cell response, which is a major driver for immune system variation. Limited clinical data have argued for a potential adverse effect of latent herpesvirus infections on the outcome of COVID-19 infections, but experimental and mechanistic validation have been lacking.
Methods: Using a mouse model of intranasal infection with mouse CMV (MCMV) and superinfection with a SARS-CoV-2 adapted variant (MA-10), we tested the effects of a latent CMV infection on COVID clinical outcomes and virological parameters. Mice were latently infected for at least 3 months, challenged with MA-10, followed by clinical, immunological and virological analysis and comparison to MCMV-naïve controls.
Results: We observed that both young and aged mice latently infected with MCMV display less weight loss and milder clinical symptoms than control mice upon MA-10 challenge. This was accompanied with lower SARS-CoV-2 RNA copy numbers and less plaque forming units in lungs, arguing for antiviral and protective effects of latent MCMV. In mice with latent MCMV infection, we also observed higher frequencies of CD8 T cells recognizing a SARS-CoV-2 antigenic peptide upon challenge. Interestingly, the same mice featured strong CD8+ tissue resident memory T cells (T_{RM}) in lungs and inflationary effector memory T cells in the blood (T_{EM}) before challenge. Latency upon intraperitoneal MCMV infection was not protective against COVID in a related model of challenge, and induced no T_{RM} responses in the lungs. To define the role of these cells on protection against COVID, we used mice that lack NFATc1 in T cells (N*FATc1*$^{fl/fl}$*Cd4cre*). These mice mount primary CD8+ T-cell responses to MCMV infection, but not the lasting CMV-specific T_{EM} or T_{RM} responses (Chaudhry et al. 2024). While naïve N*FATc1*$^{fl/fl}$*Cd4cre* mice were equally affected by SARS-CoV-2 infection as the parental C57BL/6 mice, we observed a difference in mice latently infected with MCMV: in NFATc1-deficient mice, the protective effect of MCMV against COVID was absent.
Conclusion: Our results strongly suggest that latent MCMV infection was protective against SARS-CoV-2 infection in mice due to an activation of T_{RM} CD8+ T cells, which facilitated antiviral defenses.

Bifidobacterium shapes antimicrobial T-cell responses during infancy and adulthood

Katrin Vogel[1], Aditya Arra[1], Holger Lingel[1], Dirk Bretschneider[2], Florian Prätsch[3], Denny Schanze[4], Martin Zenker[4], Dunja Bruder[5], Robert Geffers[6], Thomas Hachenberg[3], Christoph Arens[7], Monika Brunner-Weinzierl[1]
[1]Department of Experimental Paediatrics, University Hospital, Otto-von-Guericke University, Magderbug, Germany; *[2]Department of Paediatrics, Hospital St Marienstift, Magdeburg, Germany*; *[3]Department of Anaesthesiology and Intensive Care Medicine, University Hospital, Otto-von-Guericke-University, Magderbug, Germany*; *[4]Institute of Human Genetics, University Hospital, Otto-von-Guericke University, Magderbug, Germany*; *[5]Infection Immunology Group, Institute of Medical Microbiology and Hospital Hygiene, Health Campus Immunology, Infectiology and Inflammation, Otto-von-Guericke University, Magderbug, Germany*; *[6]Genome Analytics, Helmholtz Centre for Infection Research, Braunschweig, Germany*; *[7]University of Giessen, Department of Otorhinolaryngology, Head and Neck Surgery, Giessen, Germany*

Bifidobacterium is the first microbial coloniser of the gut and is therefore involved in the establishment of tolerance to innocuous environmental antigens. Although *Bifidobacterium* is thought to have a beneficial effect on health, its mechanism of action is not well understood. Our study examines age-related differences in T-cell responses to different strains of the bacteria *Staphylococcus sp.* and *Bifidobacterium*.
To achieve this, we enriched naive $CD4^+$ T cells from children of different ages, as well as umbilical cord and peripheral blood from healthy donors, using magnetic cell sorting. We characterised these cells using flow cytometry and functional tests. To stimulate the enriched T cells, non-classically matured monocytes were used. This was achieved by pulsing $CD14^+$ monocytes with heat-inactivated extracts of *S. aureus*, *S. epidermidis* and *B. infantis*.
Analyses of T-cells from the different age groups show that $CD4^+$ T-cell responses are initiated from birth with bacterial-specific properties. T-cells activated by *Staphylococcus sp.* display an enormous proliferative capacity, increased plasticity and diversity, whereas *B. infantis* induced T-cell responses were significantly attenuated. Interestingly, there is an inverse correlation between the percentage of proliferating T-cells induced by *S. aureus* and the age of the children. Additionally, we observed by RNA sequencing that *B. infantis*-stimulated T-cells exhibited a regulatory phenotype. In line with these results, we found that *B. infantis* increased the frequency of CTLA-4-dependent $FOXP3^+$ T-cells, suggesting an induction of Treg cells. High levels of galectin-1 was detected in cell culture supernatants of *B. infantis*-stimulated T-cells, which may act as an autocrine negative growth factor regulating cell proliferation and activation. Strikingly, pre-stimulation of T-cells with *B. infantis* not only suppressed activation of *S. aureus* and *S. epidermidis*-specific T-helper cells but also dampened the "cytokine storm" of critically ill COVID-19 patients. These observations suggest that *B. infantis* could be used at any age as a tool to mitigate and resolve immune system overreactions.
Our study demonstrates, for the first time, how *B. infantis* specifically modifies the responsiveness of $CD4^+$ T-cells and the underlying regulatory mechanisms that play an important role in shaping antigen-specific responses of human T-cells.

Cross reactive responses between filovirus species amongst a cohort of Ebolavirus Zaire survivors in Guinea, West Africa

Yasmin Jiwa[1], Joseph Akoi Bore[1], Tom Tipton[1], Francesca Donnellan[1], Grace Hood[1], Simon Draper[1], Kim Fornace[2], Miles Carroll[1]
[1]*University of Oxford, Oxford, United Kingdom*; [2]*National University of Singapore, Singapore, Singapore*

Purpose: New and emerging filoviruses such as Ebola and Marburgvirus pose a major risk to public health as demonstrated by recent outbreaks across West and Central Africa. Amongst a cohort of Ebolavirus disease survivors in Guinea, West Africa we examined the cross-reactive response to Ebolavirus Sudan and Marburgvirus glycoproteins.
Methods: We used an in-house anti-glycoprotein ELISA and pseudovirus neutralisation assays to investigate the cross-reactive serological response. Additionally, we used IFNγ ELISpot and memory B cell phenotyping to examine the cross-reactive cellular response augmented by T and B cells.
Results: We assayed 40 serum or peripheral blood mononuclear cell (PBMC) samples from Ebolavirus disease survivors, who contracted Ebolavirus Zaire in 2015. Samples were collected in 2024 and it was found that at the humoral level all survivors showed a response to Ebolavirus Zaire glycoprotein, whereas 75% (30/40) showed a cross-reactive response to Sudan Ebolavirus and 40% (16/40) showed a cross-reactive response to Marburgvirus, however the magnitude of these responses varied. At the cellular level we found that 70% (28/40) showed a T cell response to Ebolavirus Zaire glycoprotein peptides, whereas 10% (4/40) and 0% (0/40) showed a T cell response to Ebolavirus Sudan or Marburgvirus glycoprotein peptides respectively. Using Ebolavirus species specific fluorescently conjugated glycoprotein we were able to identify Marburgvirus or Ebolavirus Sudan cross-reactive memory B cells and show that these are primarily activated memory, memory or atypical memory B cells.
Conclusion: We conclude that the natural immune response to Ebolavirus Zaire leads to the generation of detectable immunity across the species. It is unknown what level of protection, if any, these cross-reactive responses will provide. However, these cross-reactive responses will provide the foundations for any future immune response across the filovirus family. The identification of cross-reactive memory B cells could have implications for the identification of broadly reactive B cell clones that could be used to design therapeutics.

Investigating the effects of variability of *Streptococcus agalactiae* isolates on macrophage immune response and pathogenesis

Larisa Janzic[1], Lucija Levstek[1], Andreja Natasa Kopitar[1], Alojz Ihan[1]
[1]*Institute of Microbiology and Immunology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia*

Purpose: *Streptococcus agalactiae* (Group B *Streptococcus*, GBS) remains one of the main causes of invasive neonatal infections, usually manifesting as sepsis, meningitis, or pneumonia. As intrapartum antibiotic prophylaxis is only effective in preventing early-onset disease, but not in preventing late-onset disease and infections in the elderly and immunocompromised individuals, further research into GBS-associated pathogenesis is needed. To date, 10 different serotypes (Ia, Ib, II – IX) have been described, which differ in their virulence and the immune response they elicit.
Methods: Since the severity of the disease depends on both the GBS isolate and the immune status of the individual, we investigated how genotypic and phenotypic differences between GBS isolates influence the innate immune response of macrophages. The immune response was studied at multiple levels, from phagocytic uptake to inflammatory mediator production, inflammatory cell death and metabolic changes, both at the functional assay level and at the gene expression/protein production level using flow cytometry, Seahorse extracellular flux analyzer, quantitative real-time PCR, fluorescence microscopy, and multi-modal microplate readers.
Results: Significant isolate-specific differences in phagocytic uptake and expression of polarization markers characteristic of M1 or M2 macrophages were observed. By measuring inflammatory and anti-inflammatory cytokines and chemokines as well as the expression of genes involved in antimicrobial activity and inflammation at different time points, the data also revealed that different isolates have a different potential to become invasive or remain colonizing. By measuring LDH secretion, IL-1β and IL-18 production, as well as caspase-1 and caspase-3 expression and activity, we further demonstrated that individual isolates strongly induce the formation of an inflammatory cell death, pyroptosis. Furthermore, by measuring extracellular acidification, oxygen consumption, and glycolytic gene expression, differences in the metabolism of infected macrophages were also observed.
Conclusion: Our data suggest that the severity of the disease depends not only on the immune status of the individual but also on the isolate itself, as infection with different isolates leads to significant differences in the immune response of macrophages and to varying degrees of induction of inflammation and cell death.

This work was founded by the ARIS under postgraduate program and grant number P3-0083.

CXCR4 minor pocket ligands inhibit immune response by selectively blocking TLR7/8 mediated phosphorylation of NFκB

Birgit Caspar[1], Séverine Grinberg[2], Ivana Stoilova[2], Nassima Bekaddour[2], Dominique Cathelin[2], Jean-Philippe Herbeuval[2]
[1]Université Paris Cité, UMR8601, Paris, France; *[2]Université Paris Cité, UMR8601, CNRS, Paris, France*

Purpose: Toll-like receptors (TLRs) are stimulated by pathogens. The activation by viral DNA/RNA in the endosome or by bacterial components on the cell surface can be mimicked by synthetic resiquimod (R848, TLR7/8) or lipopolysaccharides (LPS, TLR2/4). CXCR4, a chemokine receptor, has recently been published to regulate the production of type I interferons in virus treated monocytes. Treating cells with CXCR4 minor pocket ligands (MPL) leads to a reduced immune response, this effect can be abolished by addition of the CXCR4 antagonist AMD3100 or by treatment with siRNA targeting CXCR4. It is unclear how MPLs reverse the immune response of TLRs. Here, the MPLs IT1t, CB, and NP1411 were investigated in their impact on TLR activation and in their signalling at CXCR4.
Methods: HTRF kits based on an antibody sandwich technique were used to look at the phosphorylation of key signalling proteins (NFκB, and IKK-β) in THP-1 cells. The activation of NFκB and the IRF pathways were further monitored in a THP1-dual cell line stably transfected with reporters for both pathways in the presence and absence of various compounds including R848, IT1t and PKA blockers. G protein activation recruitment was measured at CXCR4 in HEK293T cells transfected with BRET sensors. (All:n≥3)
Results: IT1t reversed the R848-mediated but not the LPS-mediated phosphorylation of the transcription regulator NFκB. CXCR4 was previously suggested to increase PKA activity via an increase of cAMP. In agreement, IT1t showed an inhibition of basal G_i-protein activity at CXCR4, thereby increasing cAMP and PKA activity. When testing the initial hypothesis by adding cAMP or PKA blocker, they surprisingly reduced the response of R848 on their own opposite to the previously stated mechanism.
Conclusion: So far, CXCR4's role as a regulator in immune response has not been fully elucidated. While our studies show a clear and direct impact of the compounds on TLR and CXCR4 signalling, it is unclear from which step onwards the signalling of R848 is impacted. The selectively towards TLR7/8 over TLR2/4 opens new questions. Differences could be caused by the endosome vs cell surface environment but could also be based on target engagement interference.

Investigation into obesity related defects in MAIT cells - is glutamine the missing link?

Nidhi Kedia-Mehta[1], Linda Sinclair[2], Andrew Hogan[1]
[1]*Maynooth University, Maynooth, Ireland*; [2]*University of Dundee, Dundee, United Kingdom*

Mucosal Associated Invariant T cells or MAIT cells are important innate effectors that produce pro-inflammatory cytokines such as IFNg and IL17. MAIT cells are not only critical for fighting bacterial and viral infections. They are also emerging to be important in defense against cancer. TCR+cytokine induced activation of MAIT cells results in a change in MAIT cell metabolism whereby MAIT cells show a significant upregulation of glycolysis. This glycolytic reprogramming is essential for MAIT cell function and proliferation. We have also previously shown that mTORC1 and cMyc play an integral role in enabling this metabolic switch. However, little is known about amino acid uptake and requirement to support MAIT cell function and metabolism. Here we show by proteomic analysis that several amino acid transporters including the glutamine transporter SLc1A5 is upregulated in activated MAIT cells. Along with this, the enzymes involved in glutamine lysis such as GLUD1 and GLS are also upregulated. We explore the requirement of glutamine in further detail by utilizing the inhibitor of GLS -CB839 which led to MAIT cell dysfunction in vitro. Furthermore, we show that enzymes involved in glutamine metabolism are defective in obesity. These data identify an essential role for glutamine and its metabolism in optimal MAIT cell responses upon activation.

Eosinophil peroxidase induces a pro-resolving phenotype in macrophages

Mohammed Safhi[1;2], Gerhard Krönke[3], Georg Schett[1;2], Aline Bozec[1;2], Darja Andreev[1;2]
[1]Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander-University (FAU) Erlangen-Nürnberg and Universitätsklinikum Erlangen, Erlangen, Germany, Erlangen, Germany; *[2]Deutsches Zentrum für Immuntherapie (DZI), Erlangen, Germany, Erlangen, Germany*; *[3]Department of Rheumatology and Clinical Immunology, Charité University Medicine, Berlin, Germany., Berlin, Germany, Berlin, Germany*

Purpose: Macrophages play a pivotal role in the development of rheumatoid arthritis. While classical macrophages contribute to inflammation, alternatively activated macrophages (AAMs) counteract inflammation through the production of anti-inflammatory cytokines and the clearance of dying cells via efferocytosis. Eosinophils are recognized as crucial regulators of AAM polarization. Recent findings indicate that this regulatory mechanism extends to the synovial environment, where eosinophils govern the resolution of inflammatory arthritis by inducing AAMs. Given that eosinophils are significant producers of eosinophil peroxidase (EPX) and heme peroxidases have been associated with monocyte/macrophage polarization, our study aims to elucidate the role of EPX in macrophage polarization and the resolution of inflammatory arthritis.
Methods: Bone marrow derived macrophages (BMDMs) were stimulated *in vitro* with EPX without and with the following stimuli: IL-4 for the polarization of classical AAMs and Lipopolysaccharide (LPS) for the polarization of classical pro-inflammatory macrophages. To dissect the phenotypic characteristics of macrophages in response to EPX, we examined their gene expression signature by bulk RNA sequencing, their polarization status by flow cytometry and immunofluorescence microscopy, their secretion profile by ELISA and their metabolic switch by extracellular flux assays. Moreover, the effect of EPX on the morphology and efferocytosis capacity of macrophages was illustrated by Spinning Disc confocal microscopy using BMDMs from *Cx3cr1^{cre}Rosa26*(*R26*)*-tdTomato* mice.
Results: The stimulation of macrophages with EPX caused their polarization into AAMs. Our data revealed a distinct anti-inflammatory macrophage subtype characterized by the upregulation of the anti-inflammatory markers PD-L2, CD206, along with induction of the efferocytosis markers CD36, CD93, and Trem2. In contrast, pro-inflammatory genes such as NOS2, IL-1β, IL-6, and TNFα were downregulated. Strikingly, EPX-treated macrophages displayed enhanced mitochondrial respiration and glycolysis, suggesting that these cells generally have a higher energy consumption. Visually and mechanistically, EPX altered the morphology of macrophages and enhanced their efficiency to take up apoptotic neutrophils.
Conclusion: These findings indicate a hitherto undiscovered pro-resolving signature in macrophages upon EPX treatment that is independent of the classical IL-4-mediated pathway. EPX induces the expression of AAM-related surface proteins, influences the metabolic state, promotes the secretion of anti-inflammatory cytokines, and facilitates the efferocytosis of apoptotic neutrophils.

Endogenous Secretory leukocyte protease inhibitor contributes to regulation of inflammatory responses in peritoneal macrophages by modulating Matrix metalloproteinase-9 production

Mariia Tyshchenko[1;2], Natalia Pocałuń[1;2], Patrycja Kwiecińska[1], Joanna Cichy[1], Mieszko Wilk[1], Ewa Oleszycka[1]
[1]*Department of Immunology, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Kraków, Poland*; [2]*Doctoral School of Exact and Natural Sciences, Jagiellonian University, Kraków, Poland*

Purpose: Secretory leukocyte protease inhibitor (SLPI) is described as a potent regulator of inflammation and tissue homeostasis with pleiotropic functions. It has been shown to inhibit NF-κB and proinflammatory responses in macrophages. However, its expression patterns and specific functions in different macrophage populations remain poorly understood.
Methods: SLPI expression was analysed in various mouse macrophage populations using databases, RNA-Seq data, flow cytometry, and gene expression analysis. Additionally, the impact of endogenous SLPI on macrophage activation was investigated by proteome array and myeloid cells were compared during *in vivo* inflammatory responses.
Results: Among macrophage populations, peritoneal macrophages exhibited the highest endogenous SLPI expression. While SLPI deficiency did not affect proinflammatory cytokine production in activated macrophages, it regulated Matrix metalloproteinase-9 (MMP-9) expression. Similar results were observed in thioglycolate-elicited macrophages. Furthermore, *in vivo* administration of LPS induced changes in SLPI expression across myeloid populations.
Conclusion: SLPI expression by macrophages is modulated during both homeostasis and inflammation. Contrary to expectations, endogenous SLPI does not inhibit proinflammatory cytokine production but specifically upregulates MMP-9 expression in peritoneal macrophages. These findings highlight a specific role for SLPI in inflammation, rather than broad anti-inflammatory properties and suggests that SLPI might play a role in tissue remodelling orchestrated by macrophages.

The involvement of plasmacytoid dendritic cells and endoplasmic reticulum stress in systemic sclerosis-associated fibrosis

Beatriz Ferreira[1;2], Daniela Barros[3], Fátima Leite-Pinheiro[1], Andreia Mendes[1], Adrienne Paton[4], James Paton[4], Iola Duarte[2], Philippe Pierre[1;3], Catarina Almeida[1]
[1]iBiMED - Institute of Biomedicine, Department of Medical Sciences, University of Aveiro, Aveiro, Portugal; *[2]CICECO - Aveiro Institute of Materials, Department of Chemistry, University of Aveiro, Aveiro, Portugal*; *[3]Aix Marseille Univ, CNRS, INSERM, CIML, Centre d'Immunologie de Marseille-Luminy, Marseille, France*; *[4]Department of Molecular and Biomedical Science, Research Centre for Infectious Diseases, University of Adelaide, Adelaide, Australia*

Systemic sclerosis (SSc) is a rare autoimmune disease characterized by microvascular damage, chronic inflammation, and fibrosis of the skin and, in some cases, of internal organs. Recent studies suggest that plasmacytoid dendritic cells (pDC), immune cells specialized in type I interferon (IFN-I) production, are key in the fibrotic process, although the mechanism remains to be elucidated. Due to their high secretory capacity, these cells possess a large endoplasmic reticulum (ER) and basal activation of the unfolded protein response (UPR), which is triggered by ER stress. We have found that pDC activation is impacted by ER stress, and it has been recently suggested there is dysregulation of UPR-related genes in pDC of SSc patients. Therefore, we are exploring the contribution of pDC and ER stress for fibrosis development. We found that CAL-1, a pDC cell line, and IMR-90 lung fibroblasts physically interact when in direct co-culture. Crucially, exposure of the co-culture to the ER stress inducer subtilase cytotoxin (SubAB) resulted in a significant increased expression of both fibronectin, an extracellular matrix (ECM) protein, and α-smooth muscle actin (α-SMA), a marker for fibroblast activation. This effect was found to depend on the presence of the ER stress sensor protein kinase R-like ER kinase (PERK) on CAL-1 cells. Moreover, cell-to-cell contact between IMR-90 and CAL-1 was required, since the soluble factors produced by SubAB-exposed cells were insufficient to induce fibroblast activation. The mechanisms behind this ER stress and pDC-mediated fibrosis are being further dissected. With this work we expect to identify molecular targets for treatment of not only SSc-associated lung fibrosis, but also other fibrotic diseases.

This work is being developed within the scope of iBiMED – Institute of Biomedicine (UIDB/04501/2020 and UIDP/04501/2020) and CICECO – Aveiro Institute of Materials (UIDB/50011/2020, UIDP/50011/2020 & LA/P/0006/2020). Cytokine synergy and increased T cell polyfunctionality drives the aggressive synovial fibroblast phenotype in Down Syndrome associated Arthritis.

Adam Dignam[1], Serena Foo[1], Mary Canavan[2;3], Viviana Marzaioli[1;3], Achilleas Floudas[1], Ronan Mullan[4], Charlene Foley[5], Emma MacDermott[5], Douglas Veale[3], Orla Killeen[5], Ursula Fearon[1;3]
[1]Molecular Rheumatology, Trinity College Dublin, Dublin, Ireland; *[2]Translational Immunopathology, Trinity College Dublin, Dublin, Ireland*; *[3]Centre for Arthitic and Rheumatic Diseases (CARD), Department of Rheumatology, Dublin, Ireland*; *[4]Department of Rheumatology, Tallaght University Hospital, Dublin, Ireland*; *[5]Department of Paediatric Rheumatology, CHI at Crumlin, Dublin, Ireland*

Purpose: Down syndrome associated arthritis (DA) is an aggressive, erosive form of arthritis that occurs 20-times more frequently in children with Down syndrome (DS) than juvenile idiopathic arthritis (JIA), however little is known of the underlying pathogenic immunological mechanisms of disease. The aim of this study was to characterize T cell polyfunctionality and examine the effect of T-cell derived cytokines on primary DA synovial fibroblast (DA-FLS) and EC function.
Method: PBMC were isolated from children with DS, DA, JIA, and HCs and T-cell polyfunctionality and chemokine receptor expression was analysed by flow cytometry. DA-FLS and EC were stimulated with TNF-α, IL-17a and IFN-γ alone and in combination, or pre-primed for 24 hrs before cytokine combinations. Gene/protein expression of inflammatory mediators were quantified by RT-PCR, flow cytometry, ELISA/MSD-Multiplex assays, and cellular function assessed by adhesion and migration assays. Real-time metabolic activity was assessed by Seahorse XFe96 Analyser and RT-PCR.
Results: Higher CD8+ T-cell frequency and reduced CD4+ T-cell frequency was observed in DA compared to other groups. A significant enrichment of polyfunctional T-cells which simultaneously produced TNF-α, IFN-γ and IL17A was also demonstrated in DA compared to all other groups. Differential expression of chemokine receptors (CCR4, CCR5, CXCR3, CXCR6) in both CD4+ and CD8+ T-cells (effector, memory and T_{emra}) was also demonstrated. IL-17A and IFN-γ potentiated the effects of TNF-α on IL-6, MCP-1 and RANTES secretion in DA-FLS and EC compared to cytokine stimulation alone. Additionally, IFN-γ potentiated the effects of TNF-α on CXCR3,-CXCR4 and CCR6 in DAFLS and EC, and on leukocyte-adhesion, however differentially regulated adhesion molecule expression with ICAM-1 significantly induced in DA-FLS and VCAM-1 in EC. Cytokine synergy shifted the metabolic profile of DA-FLS to a highly energetic glycolytic phenotype, in addition to significantly inducing gene expression of key glycolytic mediators (HIF1a,-Glut-1,-HK2,-PKM2), however had minimal effect on EC metabolism. IFNγ-priming for 24hr further potentiated DA-FLS activation/invasive function in response to TNF-α. Finally, blockade with Tofacitinib inhibited cytokine-induced pro-inflammatory mediator expression.
Conclusion: These data have implications for combination therapy or manipulation of metabolic pathways for the treatment of this aggressive form of Inflammatory arthritis in children with DS.

Halting type 1 diabetes progression: use of regulatory T cell-derived extracellular vesicles

Clorinda Fusco[1], Kristyna Ruggiero[1], Ilaria Spatocco[1], Giorgia Mele[1], Claudio Russo[2], Giusy De Rosa[1], Alessandra Colamatteo[1], Francesca Di Candia[3], Enza Mozzillo[3], Claudio Procaccini[4;5], Giuseppe Matarese[1;4], Mario Galgani[1], Paola de Candia[1]
[1]Dipartimento di Medicina Molecolare e Biotecnologie Mediche, Università di Napoli Federico II, Naples, Italy; *[2]Azienda Ospedaliera Universitaria Federico II, Naples, Italy*; *[3]Dipartimento di Scienze Mediche Traslazionali, Naples, Italy*; *[4]Laboratorio di Immunologia, Istituto per l'Endocrinologia e l'Oncologia Sperimentale, Consiglio Nazionale delle Ricerche (IEOS-CNR), Naples, Italy*; *[5]IRCCS Fondazione Santa Lucia, Rome, Italy*

Purpose: Type 1 diabetes (T1D) is a childhood autoimmune disease in which immune cells invade the pancreatic islets causing β-cell destruction and insulin loss. Defective $CD4^+$ regulatory T (Treg) cells have been reported in T1D individuals and, while much effort is devoted to expand/activate them for slowing disease progression, these "living drugs" are prone to cell plasticity and loss of immune suppressive capacity *in vivo*. We here aim at analyzing whether the extracellular vesicles (EVs) released by Treg cells may stably mediate the immune protective effects of the originating cells.
Methods: Peripheral blood mononuclear cells were separated from whole blood of healthy donors (HD) or subjects with T1D using Ficoll-Paque, and isolated Treg cells were expanded for 14 days and characterized for their phenotype and suppressive function through flow cytometric analyses. EVs released by expanded Treg cells (expTreg-EVs) were analyzed for their microRNA and protein content by RT-qPCR and proteomics, respectively; in parallel, expTreg-EVs are tested for their suppressive function on both allogeneic $CD4^+$ and $CD8^+$ T cells *in vitro*, and, for the *in vivo* part, in non-obese diabetic (NOD) mice.
Results: Our results show that expTreg cells from both HD and T1D subjects maintain substantial expression of Foxp3 and significant suppressive function. In parallel, expTreg-EVs demonstrated the ability to dramatically hinder $CD4^+$ and $CD8^+$ T cell proliferation compared to mock controls, although the immune suppressive ability was found to be diminished in T1D compared to healthy conditions. This EV functional impairment has been functionally linked to specific differences in terms of microRNA and protein EV-cargo between HD and T1D expTreg-EVs. *In vivo* expTreg-EV testing is in progress in order to optimize time of treatment and EV dose in NOD mice for efficiently delaying pancreatic β-cell destruction and insulin loss and hamper diabetic progression.
Conclusion: Based on the above results, we believe expTreg-EVs have to potential to be developed as novel cell-free therapeutics in autoimmune diabetes. Moreover, the identification of specific expTreg-EV associated molecular determinants of immune suppression may lead to the design of artificial nanoparticles with potentially enhanced pharmacological activity.

Unveiling CD300e as a pivotal immune checkpoint in colorectal cancer

Annica Barizza[1], Stefania Vassallo[1], Marta Tromboni[1], Sofia Giacometti[1], Sara Coletta[1], Gaia Codolo[1]
[1]*Department of Biology, University of Padova, Padua, Italy*

In the landscape of colorectal cancer (CRC), tumor-associated macrophages (TAMs) represent the primary immune cell population, fostering the pro-tumor and immunosuppressive features of the tumor microenvironment. Our recent investigation uncovered a compelling link between the activation of the immune receptor CD300e and a compromised antigen presentation capacity in macrophages. Remarkably, the majority of TAMs in CRC patients exhibit a $CD300e^{high}/MHC\text{-}II^{low}$ expression profile, suggesting a potential role for CD300e in shaping the immunosuppressive traits of TAMs and prompting the investigation of its involvement in immune evasion mechanisms and CRC progression. Supporting our hypothesis, human macrophages exposed to patient-derived tumor colon organoids strongly upregulated the surface expression of CD300e, concomitant with the acquisition of immunosuppressive features, compared to macrophages exposed to patient-derived normal colon organoids. Taking our findings to a murine system, we revealed that CD300e knockout (KO) macrophages, when co-cultured with mouse-derived tumor colon organoids, exhibited a prominent proinflammatory/antitumor profile compared to their wild-type counterparts. Importantly, this shift in macrophage profile correlated with diminished expression of genes associated with epithelial-to-mesenchymal transition and a decreased epithelial permeability in the tumor epithelium interacting with CD300e-deficient macrophages. Our *in vitro* observations find validation in an *in vivo* murine colitis-associated CRC model, where CD300e KO mice displayed improved protection from colitis and lower mortality rates compared to wild type counterparts. Most promisingly, CD300e-deficient mice developed a reduced colon tumor burden and an enhanced anti-tumor immune response, the latter being notably characterized by an enrichment of interferon-γ-producing $CD8^+$ T cells in local lymph nodes and a favorable cytokine milieu. Intriguingly, preliminary insights suggest a potential influence of CD300e on gut microbiota composition, with CD300e KO mice harboring an enrichment in CRC protective bacterial taxa. In essence, our data unveil a multifaceted role for CD300e in CRC progression, positioning this understudied receptor as a potential novel immune checkpoint. These novel findings pave the way for a comprehensive exploration of CD300e mechanisms in tumor progression, leading to the perspective of targeting CD300e as a therapeutic strategy for CRC patients.

Elucidating the interaction of CD96 and its ligand CD155 in T cells

Diana Shinko[1], Meryl Attrill[1;2], Rosemarie Ford[1], Maja Kos[1], Heather Cross[1], Rafter Wu[1], Claudia Hinze[1], Anne M Pesenacker[1]
[1]UCL Institute of Immunity and Transplantation, London, United Kingdom; *[2]UCL Great Ormond Street Institute of Child Health, London, United Kingdom*

Co-receptors are vital in modulating immune responses, particularly in effector and regulatory T cells and thus are potential targets for immunotherapy for cancer and autoimmunity. CD96, CD226, and TIGIT are an immunoglobulin superfamily of co-receptors that bind to a shared ligand, CD155. TIGIT is thought to be co-inhibitory and CD226 co-stimulatory, while the role of CD96 remains unclear.
In humans, two natural CD96 isoforms (variant 1 and variant 2) differ in their domain 2 structure. To test CD96 variant interactions and ligand-dependency, we utilised the luciferase-based NanoBiT® system in stably transduced cell lines and demonstrated that CD96 isoforms form dimers irrespective of variant specificity or ligand availability. Using co-culture models of T cell lines stably transduced with CD96 variant 1 or 2 and APCs transduced with CD155, we showed ligand interaction with both variants and a ratio-dependent uptake of CD155, but with a higher uptake by CD96 variant 2 compared to variant 1 with a significant AUC difference ($p=0.0039$).
We assessed *in vitro* the binding kinetics of CD96 to a recombinant CD155Fc at various concentration and timepoints and found that CD96 internalises the ligand in stably transduced cell lines and primary T cells. Furthermore, we developed a CRISPR/cas9 knockout model of total CD4+ and Tregs and showed that CD155 uptake and internalisation was highly dependent on CD96 alone regardless of TIGIT/CD226 expression. Interactions were confirmed utilising confocal microscopy. In addition, we showed that the ligand is undergoing degradation within cell lines and primary T cells, which was inhibited by Bafilomycin A1.
Understanding the mechanism of CD96 interaction with the other co-receptors, as well as with their shared ligand, shape the activity of effector and regulatory T cells. This will be important in the development of more potent immunotherapy in cancer and/or autoimmunity targeting this co-receptor family.

Regulatory T-cells (Tregs) maintain immune homeostasis, but the antigens that activate adaptive Tregs in human pathologies are ill-defined. FOXP3$^-$EOMES$^+$type-1 regulatory T(EOMES+Tr1-like)-cells had a dysregulated homeostasis in multiple sclerosis (MS), which was related to their migration and activation in the CNS. Selectively EOMES$^+$Tr1-like cells were enriched and clonally expanded in patient's cerebrospinal fluid (CSF), and cells of the same clonotypes were present among circulating EOMES$^+$Tr1-like cells. EOMES$^+$Tr1-like cells were the major IL-10-producing T-cell population in the CSF in MS. Importantly, EOMES+Tr1-like cells and FOXP3$^+$Tregs in MS responded poorly to myelin-derived self-antigens, but were activated by Epstein-Barr Virus (EBV) to produce IL-10 and IFN-g. EOMES$^+$Tr1-like cells responded selectively to the latent EBV antigen EBNA1, whereas FOXP3$^+$Tregs responded also to lytic antigens. Notably, EBNA1-specific EOMES$^+$Tr1-like cells were associated with major MS risk factors, namely anti-EBNA1 IgG and HLA-DRB1*15. Finally, IL-10$^+$EOMES$^+$Tr1-like cells were identified in MS brain lesions, and some were close to EBV-infected B-cells. The aberrant anti-viral specificities of Tregs in MS may explain their inability to prevent CNS immunopathology.

Regulatory functions of redox processes during host-pathogen interactions in tuberculosis

Benthe Beu[1], Tobias Dallenga[1;2], Ilana Braunstein[3], Moran Benhar[3], Ulrich E. Schaible[1;2]
[1]*Research Center Borstel, Borstel, Germany*; [2]*German Center for Infection Reseaech (DZIF), Hamburg - Lübeck - Borstel, Germany*; [3]*Technion - Israel Institute of Technology, Haifa, Israel*

Infection with *Mycobacterium tuberculosis* results in increased necrosis among phagocytes, impairing the ability of macrophages and neutrophils to effectively combat the pathogen. Instead, macrophages become a proliferative niche for *M. tuberculosis*, leading to uncontrolled pathogen growth and increased tissue damage caused by neutrophil necrosis. The specific signaling pathways and the role of reactive oxygen species underlying these processes remain unclear.
By use of the mass spectrometric method OxRAC we explore the proteome of different cell types for oxidative changes. Preliminary investigations reveal a modified oxidation status in various proteins within macrophages and neutrophils following *M. tuberculosis* infection. As alterations in the oxidation status of enzymes can affect their function and signaling molecules or antigens may influence subsequent pathways, this study aims to identify essential thiol modifications in the proteome of *M. tuberculosis*-infected macrophages and neutrophils. These modifications can serve as targets for further analysis.
In addition to the OxRAC-based proteome investigation, we examine the influence of cellular antioxidant systems and reactive oxygen species production through inhibition of key molecules to uncover the underlying signaling pathways. The resulting insights could provide a better understanding of how *M. tuberculosis* modulates the host's immune system, offering potential targets for host-directed therapies.

Disentangling the heterogeneity and differentiation process of CD11c+ B cells

Alan Courey-Ghaouzi[1;2;3], Linn Kleberg[1;2;3], Maximilian Julius Lautenbach[1;2;3], Girish Malagi[4], Zaynab Mousavian[1;2;3], Ganesh Phad[5], Mattias Forsell[4], Anna Färnert[1;2;3], Christopher Sundling[1;2;3]
[1]Center for Molecular Medicine, Karolinska Institutet, Stockholm, Sweden; *[2]Division of Infectious Diseases, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden*; *[3]Department of Infectious Diseases, Karolinska University Hospital, Stockholm, Sweden*; *[4]Department of Clinical Microbiology, Umeå University, Umeå, Sweden*; *[5]Christine Kühne – Center for Allergy Research and Education (CK-CARE), Davos, Switzerland*

An alternative subset of B cells characterized by the expression of markers such as CD11c, T-bet, and FcRL5, is present at low levels in healthy individuals but expands upon inflammatory responses, such as certain infections or autoimmune disease. We have previously shown a substantial heterogeneity among CD11c$^+$ B cells, but it remains unclear if this is due to different stimulation cues, different origins, or different stages of differentiation.
Here, we investigate the origin and heterogeneity of CD11c$^+$ B cells in humans. Employing paired single-cell transcriptomic and VDJ sequencing of CD11c$^+$ B cells isolated from a patient two weeks after acute malaria, and CITE-seq with targeted single-cell RNA sequencing of four patients at three-time points (acute, two weeks, 12 months) after acute malaria, we observed the presence of early, intermediate, and late clusters of CD11c$^+$ B cells. These clusters differed in their expression of CD27, CD24, and CD1c, among other genes. Clonal analysis of V(D)J sequences further revealed a divergent origin for the intermediate clusters, while they were mixed in the fully polarized cluster. This suggests a convergent differentiation program of naïve and memory B cells to a shared fully polarized subset. To further explore if this was a general mechanism, we analyzed publicly available datasets from blood and tissues of SARS-CoV-2 infected patients. We also performed our own flow cytometric confirmation of both the malaria and SARS-CoV-2 gene expression data using peripheral blood mononuclear cells and tissue samples. Finally, we employed an *in vitro* stimulation protocol to delineate how different B cell activation cues lead to the progressive development of an atypical phenotype. Altogether, this work has allowed us to have a better understanding of the origin, heterogeneity, and differentiation route of CD11c$^+$ B cells.

HIV-1 exploits LBPA-dependent intraepithelial vesicular trafficking pathway for persistent infection of human intestinal mucosa

Anusca Rader[1;2;3], Alexandra Cloherty[1;2], Kharishma Patel[1;2], Renee Schreurs[1;2;3], Carla Ribeiro[1;2;3]

Despite the advent of highly suppressive antiretroviral therapies, HIV-1 infection remains a major public health concern. The intestinal mucosa, which houses HIV-1 target cells including dendritic cells (DCs) and CD4+ T-cells, is a major anatomical site of HIV-1 persistence and replication during acute and chronic HIV-1 disease. Retention of replication-competent viruses and residual viral production in secluded tissue compartments, such as the intestinal tract, represent major obstacles to HIV-1 curative strategies. However, the key underpinning mechanisms involved in HIV-1 penetration and latency within intestinal mucosal barrier remain elusive. Here, we present human 2D intestinal immuno-organoid systems to model intestinal HIV-1 pathogenesis. These systems recapitulate tissue compartmentalization and epithelial-immune cellular interactions. Primary cell-derived intestinal epithelial monolayers on cell-culture inserts were co-cultured with either subepithelial DCs or tissue-derived CD4+ T-cells on the basolateral side of the insert membrane. These co-culture models permitted the concomitant assessment of intestinal barrier integrity, luminal sampling and immune phenotyping alongside virus trafficking and infection pathways. Our data demonstrate that apical exposure of intestinal epithelium to HIV-1 results in viral internalization, with subsequent basolateral shedding of replication-competent viruses, in a manner that is impervious to antiretroviral treatment. Markedly, intraepithelial viral capture ensued an altered distribution of specialized endocytic vesicular pathways alongside durable sequestration of infectious HIV-1 within lysobisphosphatidic acid (LPBA)-rich endocytic vesicles. The retention of replication-competent HIV-1 and subsequent viral transmission by intestinal epithelium did not compromise tight junction function or barrier permeability. Furthermore, HIV-1 targeting to basolateral CD4+ T-cells allowed us to monitor cellular reservoir formation and HIV-1 induced T-cell activation/exhaustion signatures within epithelial-T cell co-cultures systems. Incorporation of subepithelial dendritic cells resulted in HIV-1 luminal sampling and amplification of the *de novo* mucosal HIV-1 replication. Notably, therapeutic neutralization of LBPA-dependent endosomal trafficking suppressed HIV-1 replication across immuno-organoid systems, and thereby demonstrated the pivotal role of intraepithelial multivesicular endosomes as niches for virulent HIV-1 within the intestinal mucosa *in vitro*. Our study showcases the application of primary human 2D immune-competent organoid cultures in uncovering mechanisms of intestinal HIV-1 invasion and disease pathogenesis, as well as a platform for preclinical antiviral drug discovery.

Investigating the impact of Parkinson's Disease-associated genes on intestinal homeostasis.

Jessica Pei[1], Sherilyn Junelle Recinto[1], Alexandra Kazanova[1], Lindsay Burns[1], Adam MacDonald[1], Christina Gavino[1], Michel Desjardins[2], Jo Anne Stratton[1], Samantha Gruenheid[2]

Purpose: Intestinal epithelial cells (IECs) provide an essential physical barrier between luminal contents and host tissue. Dysregulation of IECs results in the loss of barrier function, causing pathologies in both intestinal and extra-intestinal diseases. While Parkinson's Disease (PD) is primarily a neurodegenerative disorder, there is increasing evidence linking PD progression and gastrointestinal dysfunction. Our group recently developed a model to investigate the role of the gut in PD, demonstrating that mice with genetic ablation of the PD-associated gene *Pink1* exhibited motor phenotypes only when previously infected with Gram-negative *Citrobacter rodentium* intestinal bacteria. As *Pink1* is expressed in IECs, we hypothesize that PD-associated gene mutations directly affect the epithelium, impacting early PD pathophysiology.
Methods: Single-cell RNA sequencing (scRNAseq) of IECs from *Pink1* WT and KO mice was conducted at steady state and following *in vivo C. rodentium* infection. Colons were collected seven days post infection to elucidate transcriptional differences between epithelial lineages of each genotype. *Ex vivo* colonic organoids (colonoids) were derived from primary *Pink1* WT and KO epithelium. Colonoids were either grown in Matrigel (basal-out) or inverted in suspension (apical-out), then stimulated with inflammatory cytokines or infected with gram-negative pathogens to determine how PINK1 loss-of-function affects the inflammatory response of the epithelium.
Results: ScRNAseq analysis revealed significant upregulation of interferon (IFN)-signaling genes in *Pink1* KO enterocytes (ECs) compared to WT at steady state; whereby 70% of upregulated differentially expressed genes (DEGs) were linked to type I or II IFN signaling pathways. Current validation through *in vivo* enterocyte isolation, RNAscope staining, and *ex vivo* colonoids is ongoing. Under infection, *Pink1* KO stem cells demonstrated downregulation in Wnt signaling pathway genes, whereas *Pink1* KO ECs showed increased expression of MHC I pathway genes.
Conclusion: Using *in vivo* and *ex vivo* models that encompass PD-genetic susceptibility and environmental stimuli, we identified dysregulation in *Pink1* KO epithelium, suggesting altered inflammatory responses at baseline and infection. Investigating PD genes in the gastrointestinal tract offers insights into early PD initiation and intestinal epithelium dynamics.

Exploring macrophage heterogeneity in Crohn's disease

Monika Mykhaylyshyn[1], Thomas Laurent[1], Aurélie Joussaume[1], Gaëlle Bériou[1], Nicolas Chapelle[1], Lucas Brusselle[1], Camille Lécuroux[1], Laurence Delbos[1], Jérémie Poschmann[1], Cynthia Fourgeux[1], Arnaud Bourreille[2], Catherine Le Berre[2], Caroline Trang[2], Théo Soudé[2], Juliette Podevin[2], Jean-François Mosnier[2], Cécile Girard[2], Miriam Merad[3], Samarth Hedge[3], Clotilde Hennequin[3], Jessica Le Berichel[3], Saurabh Mehandru[3], Pablo Canales-Herrerias[3], Ephraim Kenigsberg[3], Jérôme Martin[1]

Crohn's Disease (CD), one of the two main forms of inflammatory bowel disease (IBD) is a disabling condition with a growing incidence worldwide. CD is associated with severe complications, frequently leading to surgical resection. Anti-TNF therapy has transformed CD outcome but efficacy is limited to a subset of patients. We previously described a cellular response enriched in inflamed ileums of future non-responders to TNF blockers (Martin et al., 2019), which suggested major roles for dysregulated actions of mononuclear phagocytes (MNP). In this study, we cell-sorted MNP from surgical resections of CD patients and characterized them by single-cell RNA sequencing (scRNA-seq).
Using Metacells (Baran et al. 2019; Ben-Kiki et al. 2022) and a gene module-based analysis, we captured 17 molecular programs of coregulated genes present in the monocytes/macrophages compartment, the combinatorial expression of which allowed to resolve 10 molecular states of monocytes and macrophages. While monocyte-like cells were constantly enriched in inflamed ileums, our approach enabled the identification of an inflammatory subset characterized by coexpression of *CD274* and *IL3RA* that was uniquely enriched in inflamed tissues from patients with severe forms of the disease, including anti-TNF resistance and surgical recurrence.
Using spectral flow cytometry, we validated the enrichment of PD-L1$^+$ CD123$^+$ monocyte-like cells in inflamed ileums. Transcription factor binding motif enrichment analyses of the 17 molecular programs suggested the generation of PD-L1$^+$ CD123$^+$ monocyte-like cells depended on a complex inflammatory milieu, which was validated in *in vitro* reductionist approaches. Ligand:receptor analyses suggested central roles for PD-L1$^+$ CD123$^+$ monocyte-like cells through their specific interactions with pathogenic states from other lineages, including T and stromal cells. Importantly, PD-L1$^+$CD123$^+$ monocyte-like cells exhibited a high JAK/STAT activity *in vivo* and *in vitro*. Accordingly, the JAK inhibitor upadacitinib, which was recently approved by the FDA to treat patients resistant to anti-TNF therapy, interfered with the generation and activity of PD-L1$^+$CD123$^+$ monocyte-like cells in both in vitro and ex vivo experiments.
In summary, our study identifies a druggable molecular state of inflammatory monocytes uniquely enriched severe in CD, as compared to anti-TNF primary responders, and provides a molecular rational to help guide immunotherapy prioritization in ileum CD.

IL4 prevents the gluten-induced inflammation in the gut mucosa of children with potential celiac disease

Ilaria Mottola[1], Serena Vitale[1], Roberta Esposito[1], Mariantonia Maglio[2], Renata Auricchio[2], Riccardo Troncone[2], Carmen Gianfrani[1]
[1]Institute of Biochemistry and Cell Biology - Department of Biomedicine - CNR, Naples, Italy; [2]Department of Translational Medical Science & European Laboratory for the Investigation of Food-Induced Diseases, University Federico II, Naples, Italy

Purpose: Celiac disease (CeD) is a chronic intestinal inflammation caused by gluten proteins in genetically predisposed individuals. Childhood CeD is characterized by two main forms: acute disease (positive anti-tissue transglutaminase-tTG antibodies and intestinal villous atrophy) and potential disease (positive anti-tTG and normal mucosa architecture). The mechanisms preventing the intestinal villous atrophy in subjects with potential-CeD, and on regular diet, have not been completely elucidated. Recently, we have demonstrated a marked infiltration of IL4-secreting T cells in the intestinal mucosa of potential-CeD children that correlated with clinical outcomes, such as anti-tTG antibody titers and histological scores of mucosal damage (1-2), By contrast, these cells are almost undetectable in gut mucosa of acute patients. In this study, we investigated the protective role of IL4 in preventing the inflammatory response to gluten that leads to villous atrophy in celiac gut mucosa.
Methods: Gluten-reactive T-cell lines (TCLs) were established from gut biopsies of either potential- and acute-CeD children (N=10 patients for each group), in absence or presence of exogenous IL4. The effect of IL4 treatment on cytokine production, cell infiltrates (CD4+, CD8+, TCR γ/δ+, Tregs) and gluten peptides recognition pattern of TCLs was evaluated collected at different time-frames by ELISA/Luminex and multiparametric flow-cytometric analyses.
Results: IL4 treatment induced a statistically significant reduction of IFN-γ production associated with a mild increase of IL10 production in culture supernatants of TCLs in potential-CeD patients, collected over time up to 6 weeks. Furthermore, a significant decrease of densities of CD8+ and TCR γ/δ+ T cells was detected in IL4-TCLs compared to control cultures. In addition, IFN-γ production in response to whole gliadin/immunodominant peptides was significantly reduced in IL4-TCLs. In contrast, no significant changes were observed in TCLs grown with IL4 generated from acute-CeD patients, for any of the experimental read-outs.
Conclusions: Our study demonstrated a hitherto unexplored immunoregulatory function of IL4 on gluten-induced inflammation in gut mucosa of patients with potential disease, suggesting an important role of this cytokine in counteracting the transition mechanisms to villous atrophy.

BAMBI, a regulator of intestinal epithelial cell permeability and apoptosis, controls colitis and colon cancer development.

Paula Perez Adrián[1;2], Marta Muñoz[2], Vincenzo Cappitelli[1], Thais M. Gil[2], Mª Luisa Cagigal[3], Jose Andrés Vazquez[4], Juan Ignacio Raba-Díez[4], Maria Luisa del Rio[5], Jose-Ignacio Rodriguez-Barbosa[5], Jesus Merino[2], Victoria Casado Medrano[1], Ramón Merino[2;6]
[1]Inhibitec Anticuerpos S.L., Santander, Spain; *[2]University of Cantabria, Santander, Spain*; *[3]Servicio de Anatomía Patológica, Hospital Universitario Marqués de Valdecilla, Santander, Spain*; *[4]Servicio de Oncología Radioterápica, Hospital Universitario Marqués de Valdecilla, Santander, Spain*; *[5]University of León, León, Spain*; *[6]Instituto de Biomedicina y Biotecnología de Cantabria, CSIC-Universidad de Cantabria-SODERCAN, Santander, Spain*

The BMP and Activin Membrane-Bound Inhibitor (BAMBI) is an inhibitor of TGFβ signaling involved in the differentiation of $CD4^+$ T cells into Tregs and Th17 cells. Due to the importance of TGFβ and of Treg and Th17 cells in the maintenance of intestinal homeostasis, we have evaluated here the effects of BAMBI deficiency in the composition of gut-associated lymphoid tissue (GALT) and in the development of colitis and inflammation-associated colon cancer. We show that in the gut epithelium of wild type (WT) mice, BAMBI expression is mostly restricted to colon epithelial cells and its absence promotes changes in GALT composition, characterized by an increase of Tregs, total B cells and germinal center B cells in different GALT locations. In contrast, lack of BAMBI causes a marked and general reduction of Th17 cells. Furthermore, BAMBI deficiency protects mice against Dextran Sodium Sulfate (DSS)-induced colitis by TGFβ-dependent, but immune suppression-independent, mechanisms, tightly associated to increased resistance of intestinal epithelial cells to DSS-induced apoptosis and a decreased intestinal permeability. Finally, the absence of BAMBI inhibits the development of colon cancer associated to chronic inflammation. In conclusion, our present findings point to BAMBI as an essential regulator of intestinal homeostasis and as a new promising therapeutic target in colorectal pathologies such as colitis and colon cancer associated to chronic inflammation.

T cell responses to dietary antigens

Anna Rudnitsky[1], Ranit Kedmi[1]
[1]*The Weizmann Institute, Rehovot, Israel*

Proper nutrient absorption requires the host to develop an immune response that tolerates food antigens. For this purpose, naive T cells, in response to dietary antigens, acquire a regulatory program (iTregs) known to suppress peripheral inflammatory responses to these antigens, even when introduced in an inflammatory setting—a process known as 'oral tolerance.' Type 1 conventional dendritic cells (cDC1s) are traditionally viewed as the primary inducers of the iTreg response to food antigens. Although they have been shown to present food peptides on MHC class II, support Treg differentiation in vitro, and interact with antigen-specific T cells, mice lacking cDC1s still maintain a Treg response to food antigens as well as oral tolerance. Recently, we identified RORγt+ antigen-presenting cells (APCs) as a dedicated subset required for the induction of iTreg cells in response to Helicobacter hepaticus (Hh) (Kedmi R. et al., Nature 2022). These findings prompt us to revisit the cellular requirements for the induction of an immune response to dietary antigens. Using genetic mouse models, we now show that antigen presentation by RORγt+ APCs is also required for the induction of the iTreg response to food antigens. While our data suggest that antigen presentation by cDC1 is incapable of eliciting the iTreg program, we found that it still plays a unique role in mediating immune responses to food antigens. Our studies offer significant insights into the basic mechanisms of immune responses to dietary antigens and propose novel mechanisms for the pathogenesis of celiac disease.

CXCR4 blockade reduces the severity of murine heart allograft rejection by plasmacytoid dendritic cell-mediated immune regulation

Jian Fu[1;2;3], Christian H. K. Lehmann[1;4], Xinning Wang[2;5], Ida Allabauer[1], Benjamin Wilde[2], Lukas Amon[4], Andreas Kribben[2], Joachim Wölfle[1], Diana Dudziak[6], Oliver Witzke[7], Andre Hörning[1]
[1]Department of Pediatric and Adolescent Medicine, Erlangen, Germany; *[2]Department of Nephrology, University Hospital Essen, Essen, Germany*; *[3]The Emergency and Trauma Center, The First Affiliated Hospital of Hai Nan Medical University, Haikou, China*; *[4]Department of Dermatology, Erlangen, Germany*; *[5]The Children's Hospital of Zhejiang University School of Medicine, Hangzhou, China*; *[6]Institute of Immunology, Jena, Germany*; *[7]Department of Infectious Diseases, West German Centre of Infectious Diseases, Universitätsmedizin Essen, Essen, Germany*

Purpose: Allograft-specific regulatory T cells (Treg cells) are crucial for long-term graft acceptance after transplantation. Although adoptive Treg cell transfer has been proposed, major challenges include graft-specificity and stability. Thus, there is an unmet need for the direct induction of graft-specific Treg cells. We hypothesized a synergism of the immunotolerogenic effects of rapamycin (mTOR inhibition) and plerixafor (CXCR4 antagonist) for Treg cell induction.
Methods: BALB/c (allogeneic) or C57BL/6J (syngeneic) mice served as heart donors and C57BL/6J as transplant recipients. Animal experiments adhered to EU directive 2010/63/EU and were approved (#G1071/09). Heterotopic intra-abdominal heart transplantation (HTX) was performed as previously described (1). Allograft function was evaluated daily by palpation. C57BL/6J recipients received injections with plerixafor (1 or 5 mg/kg s.c.) and/or rapamycin (0.4 mg/kg i.p.) two days before, immediately after HTX and every other day for 14 days. The subclinical dosage of rapamycin allowed to early distinguish differences in allograft survival.
Results: The combined treatment consisting of Plerixafor and Rapamycin lead to a longer prolongation of allograft survival compared to rapamycin-only ($p < 0.001$). Median allograft survival time in recipients from the non-treatment, plerixafor (P1 and P5 mg/kg), rapamycin and combined treatment group P1R or P5R were 8, 10, 10, 44, 49 and 78 days, respectively. Hearts of the respective syngeneic controls survived the whole observation period of 100 days.
Moreover, fibrosis and myocyte lesions were significantly reduced in the combined treatment group when compared to sole Rapamycin-treatment. Although less CD3+ T cell infiltrated, higher Treg cell numbers were observed. These findings were accompanied by a plerixafor-dependent plasmacytoid dendritic cell-mobilization as in vivo pDC-depletion abrogated the plerixafor-mediated increase in Treg cell numbers and led to a reduced allograft survival.
Conclusion: Our pharmacological approach allowed to increase Treg cell numbers due to pDC-mediated immune regulation. Therefore, pDCs can be an attractive immunotherapeutic target in addition to plerixafor treatment.

Translation of tacrolimus resistant antiviral T cell products: In depth-efficacy evaluation and human based safety assessment

Lisa Burkhardt[1], Lukas Ehlen[2], Anna Löwa[3], Niklas Wiese[1], Claudia Beltran Mestres[1], Ugarit Daher[1;4;5], Melanie Rothe[1], Anna-Catharina Krebs[2], Janine Arndt[2], Mathis Hertel[1], Andy Römhild[1], Stephan Schlickeiser[6], Mir-Farzin Mashreghi[7], Andreas Hocke[3], Hans-Dieter Volk[8], Petra Reinke[1], Michael Schmueck-Henneresse[2], Leila Amini[1;2]
[1]Berlin Center for Advanced Therapies, Berlin, Germany; *[2]Berlin Institute of Health (BIH) Center for Regenerative Therapies, Berlin Institute of Health at Charité – Universitätsmedizin Berlin, Berlin, Germany*; *[3]Department of Infectious Diseases and Respiratory Medicine, Charité-Universitätsmedizin Berlin, Berlin, Germany*; *[4]Einstein Center for Regenerative Therapies at Charité – Universitätsmedizin Berlin, Berlin, Germany*; *[5]Berlin Institute of Health (BIH) Center for Regenerative Therapies, Berlin Institute of Health at Charité-Universitätsmedizin Berlin, Core Unit for Stem Cells and Organoids (CUSCO), Berlin, Germany*; *[6]CheckImmune GmbH, Berlin, Germany*; *[7]Therapeutic Gene Regulation, Deutsches Rheuma-Forschungszentrum (DRFZ), Institute of the Leibniz Association, Berlin, Germany*; *[8]Institute of Medical Immunology, Charité-Universitätsmedizin Berlin, Berlin, Germany*

Immunocompromised patients e.g. in the case of solid organ transplantation (SOT) are commonly treated with immunosuppressive drugs to circumvent organ rejection. This entails patients being equipped with a strongly diminished endogenous T cell response against pathogens e.g. viruses. Seasonal and omnipresent pandemic viruses are major health concerns for these patients. In fact, long-term immunosuppression leads to insensitivity to vaccines and compromised viral defense results in organ rejection and mortality. In this case, common antiviral drugs cannot combat viral complications.
To fully regenerate a protective T cell response, we have focused on manufacturing tacrolimus resistant CMV, EBV, and IAV specific T cell products from limited amounts of peripheral blood to be co-administered with immunosuppressive treatment. Our next-generation manufacturing protocol represents a GMP compliant process allowing the production of up to 300 million antiviral T cells within 2 weeks using bioreactors. Knock-out of FKBP12, the functional adaptor protein for the immunosuppressant tacrolimus is achieved by a GMP compliant CRISPR-Cas9 ribonucleoprotein based approach. The efficacy and safety of these gene modified T cells is studied by characterizing effector cytokine production and artificial target specific killing assays as well as in depth by CITEseq, proteomics and epigenetic analyses. We recently gained proof-of-concept results with CITE seq showing functionality of gene edited T cell products in presence of immunosuppressive drugs in comparison to unedited controls. This included also verification of a safety switch using an alternative immunosuppressant, cyclosporine A. Since pre-clinical safety assessment is of high importance for the transition into early phase clinical trials, we focused on T cell product characterization in co-cultures with primary human cells, highlighting such models as efficient and reproducable. With this, we want to take a further step towards relevant human model based T cell product evaluation, which offers particular advantages in the complex environment of cell and gene therapies and immunological questions. All in all, we gathered preclinical data to pave the way for clinical translation of tacrolimus resistant antiviral T cell products.

Donor HLA-DQ landscape predicts the likelihood of controlling BK polyoma virus replication after kidney transplantation

Mathieu Chevalier[1], Vincent Allain[2;3], Julien Gras[2], Juliette Villemonteix[2], Gillian Divard[2], Linda Feghoul[2], Constance Delaugerre[2], Jean-Michel Molina[2], Jean-Luc Taupin[2], Marie-Noelle Peraldi[2], Cyrille Feray[4], Sophie Caillat-Zucman[1;2]
[1]INSERM U976 - Institut de Recherche Saint-Louis, Paris, France; *[2]Hôpital Saint-Louis, AP-HP, Paris, France*; *[3]University of California, San Francisco, San Fransisco, United States*; *[4]Hôpital Paul-Brousse, AP-HP, Paris, France*

Aim: BK polyomavirus (BKV) infection is a major concern after kidney transplantation (KT) increasing the risk of graft loss. Because of the lack of specific antiviral treatment, obtaining an optimal balance between maintaining antiviral immunity (i.e. reducing immunosuppression) while preventing alloreactive responses is a major clinical challenge. Therefore, early identification of patients at high risk of BKV replication is crucial to best tailor immunosuppression. The HLA evolutionary divergence (HED) metric, which quantifies the sequence divergence between the peptide binding domains of two alleles of a given locus, has shown relevance as a predictor of outcome in other pathophysiological contexts. Here, we aimed to investigate whether HLA diversity might impact the risk of BKV replication after KT.
Methods: We studied a large retrospective KT cohort (n=532 patients) with systematic screening of plasma BKV replication (DNAemia) during 2 years post-transplant. HLA class-I and -II typing (two-field resolution) was available for all donors and recipients. For each patient, the HED was measured (Grantham distance) for each HLA locus. Prediction of BKV peptides binding was performed in silico using NetMHCIIpan-4.2. Only stable HLA-DQαβ heterodimers were considered for peptide binding prediction to avoid counting peptides that cannot be presented in vivo.
Results: During the 2-year follow-up, 18% of patients experienced BKV DNAemia. HLA alleles and diversity from the recipients were not associated to BKV infection. However, high donor HLA-DQ HED was a significant and independent predictor of BKV-free outcome (adjusted HR 0.55, 95%CI 0.35-0.85; p=0.008), confirmed in G-computation analysis (time-varying causal inference). More generally, we highlighted a bimodal distribution of the HED-DQA, with higher values corresponding to HLA-DQA1*01/non-DQA1*01 allele combinations. Furthermore, HLA-DQ divergence was positively correlated to the size of the BKV-derived immunopeptidome bound by donor HLA-DQ supertypes (R=0.51; p<0.0001), with predominant contribution of the BKV-VP2 protein.
Conclusion: We provided evidence for a direct link between HLA-DQ divergence, the size of the BKV-derived DQ-bound immunopeptidome, and the control of BKV infection, which likely reflects a stronger anti-viral immune response. This easily accessible predictor could provide a unique opportunity for personalized monitoring of BKV DNAemia and initiation of prophylactic or prompt therapeutic intervention when warranted.

Immunosuppressive therapy modifies anti-Spike IgG subclasses distribution after 4 doses of mRNA vaccination in a cohort of kidney transplant recipients

Ignacio Juarez[1], Isabel Perez-Flores[2], Arianne Aiffil-Meneses[2], Ana López Gómez[1], Natividad Calvo-Romero[2], Raquel Gonzalez-Garcia[1], Belen Peix-Jimenez[2], Manuel Gomez del Moral[3], Ana Isabel Sanchez-Fructuoso[2], Eduardo Martinez-Naves[1]

Institute San Carlos for Medical Research (IdISSC), Madrid, Spain*; *[3]Department of Cell Biology. Complutense University School of Medicine, Madrid, Spain*

Background and hypothesis: Immunization with mRNA vaccines against SARS-CoV-2 prompts an increase in IgG4 against the Spike protein in healthy populations. However, the response of immunosuppressed individuals remains unclear. This study assesses the immune response, including IgG subclasses, to four mRNA vaccine doses in kidney transplant recipients (KTR).
Methods: A prospective cohort study involving 146 KTR and 23 dialysis patients (DP) who received three mRNA-1273 vaccine doses and a BNT162b2 booster. We evaluated anti-Spike IgG titers and subclasses, T-CD4+ and T-CD8+ cellular responses, and serum neutralizing activity (SNA).
Results: At the fourth dose, 75.8% of COVID-19 naïve KTR developed humoral and cellular responses (vs 95.7% in DP). A correlation existed between anti-Spike IgG titers/subclasses and SNA ($p<0.001$). IgG subclass kinetics after the third/fourth doses varied between COVID-19 naïve KTR and DP. Immunosuppressive therapy strongly influenced IgG subclasses: mTOR inhibitors (mTORi) positively impacted IgG1 and IgG3 ($p<0.05$), while mycophenolic acid negatively affected IgG1, IgG3, and IgG4 ($p<0.05$). A correlation emerged between SNA after four vaccine doses and breakthrough infections over the next six months in KTR; lower SNA (20.3% vs 45.8%, $p=0.012$). Multivariate analysis revealed mTORi as the only factor associated with SNA>65% in naïve KTR [4.29 (1.21-15.17), $p=0.024$].
Conclusions: KTR exhibit weaker cellular and humoral immune responses to mRNA vaccines. Immunosuppressive regimens strongly influence IgG subclasses. Elevated SNA after four vaccine doses is protective against infection. mTORi treatment positively impacts the humoral response and could benefit non-responding KTR.

Effects of corticosteroids therapy on immune reconstitution and function upon hematopoietic stem cell transplantation in cancer patients

Silvia Santopolo[1], Cecilia Ciancaglini[1], Han-Yu Sihi[2], Paola Vacca[1], Lorenzo Moretta[1], Linda Quatrini[1]
[1]IRCCS Bambino Gesù Children's Hospital, Rome, Italy; [2]National Institutes of Health (NIH), Bethesda, United States

Hematopoietic stem cell transplantation (HSCT) represents the only curative option for many hematological malignancies and an efficient immune reconstitution is necessary for a positive outcome in cancer patients. However, HSCT remains a high-risk procedure associated with many complications including graft-versus-host disease, therefore a percentage of HSCT recipients need to be treated with the anti-inflammatory glucocorticoids (GCs). Since GC therapy has been found to regulate innate lymphoid cells function and to inhibit their HSC-derived differentiation, a detailed characterization of the effect of GC on immune reconstitution would be beneficial to avoid HSCT low efficiency. It is known that GCs directly regulate gene expression through their nuclear receptor and that they can induce stable chromatin modifications. Our hypothesis is that GC therapy may generate transcriptional and long-term epigenetic modifications on HSCs, influencing their development towards the different immune cell subsets and hampering the correct immune reconstitution following HSCT. Here we characterized the effects of GC treatment on HSCs differentiation upon HSCT, both *in vitro*, on cultured HSCs and *in vivo*, on immunodeficient mice receiving human HSCs. Furthermore, we evaluated the impact of GC treatment on immune function against leukemia relapse following HSCT in an *in vivo* model of immunodeficient mice receiving human HSCs and infused with leukemic NALM cells. Finally, through RNA- and Assay for Transposase-Accessible Chromatin (ATAC)-sequencing experiments, we were able to identify the transcriptional signature and the chromatin landscape induced by GC treatment on *in vitro* cultured HSCs. These data shed light on the molecular mechanism by which GC therapy affects immune reconstitution and represent an important step towards the development of novel strategies to improve HSCT outcome in oncologic patients.

Tissue-resident lymphocyte subsets are associated with poor glucocorticoid response in acute gastrointestinal graft-versus-host disease

Johanna Strobl[1;2], Lukas Gaksch[3], Sandra Haingartner[3], Ariane Aigelsreiter[4], Peter Neumeister[3], Alexander Deutsch[3], Georg Stary[1;2], Hildegard Greinix[3]
[1]Department of Dermatology, Medical University of Vienna, Vienna, Austria; *[2]CeMM Research Center for Molecular Medicine, Vienna, Austria*; *[3]Division of Haematology, Department of Internal Medicine, Medical University of Graz, Graz, Austria*; *[4]Diagnostic and Research Institute of Pathology, Medical University of Graz, Graz, Austria*

Acute graft-versus-host disease (GVHD) of the gastrointestinal tract (GI) is a serious life-threatening complication of allogeneic hematopoietic stem cell transplantation. Only half of all patients respond to first-line intravenous methylprednisolone therapy and steroid-refractory (SR) GVHD is associated with a poor long-term prognosis and survival. Cellular specificities of SR-GVHD remain incompletely understood and there is still an unmet clinical need for biomarkers predicting response to glucocorticoid therapy.
In this study, we monitored 253 patients treated with HCT at the Medical University of Graz for development of GI GVHD, which occurred in 55 patients. We obtained GI-biopsies at the first onset of acute GI GVHD prior to start of steroid treatment. Formalin-fixed paraffin-embedded (FFPE) tissue from 50 patients, 24 steroid-sensitive patients (SS group), 26 steroid-refractory patients (SR group) and 13 healthy-appearing mucosa samples from bowel adenoma resections (control group) was labelled with T cell surface markers and intracellular staining of transcription factors, with subsequent software-based computational analysis.
Patients with SR GVHD experienced significantly higher GVHD scores and dramatically increased mortality from GVHD. Compared to the control group, patients with acute GI GVHD showed but a decrease in CD103+ tissue-resident memory T cells (TRM) and increased type-3 (RORgt+) innate lymphoid cells (ILC3) in tissue biopsies. No differences in total T cell numbers or RORgt+ T cells were observed between groups. Compared to SS-GVHD, we detected increased percentages of TRM in samples from SR-GVHD, as well as an increased proportion of CD4+ cells within the TRM subset. Regarding ILC3s, the SS group exhibited a trend towards higher ILC3 percentages compared to the SR group and significantly higher proportions of ILC3 compared to the reference group.
Our study shows that cellular infiltrates in intestinal biopsies differ regarding TRM and also ILC composition at onset of GI GVHD in patients who subsequently respond to glucocorticoid therapy compared to those developing steroid-refractory disease. This implicates pre-existing resident lymphocytes as potential pathomechanistic factor for steroid sensitivity. Intestinal tissue infiltration patterns of TRMs and ILC3s at GI GVHD onset may serve as useful clinical prognostic markers for response to glucocorticoid therapy.

Purpose: Autoreactive pro-inflammatory CD4+ T helper (Th) cells orchestrate the self-destructive immune response in chronic autoimmune diseases but remain difficult to track. The molecular characteristics of human autoreactive Th cells persisting in face of chronic autoantigen-stimulation and immunotherapy remain therefore poorly understood. The *ex vivo* characterization of autoreactive T cells is essential to understand their lifestyle, how they adapt to and maintain chronic autoimmunity and thereby enable their targeted elimination with novel immunotherapies. Neuromyelitis optica spectrum disorder (NMOSD) is a prototypic chronic autoimmune disease of the central nervous system targeting aquaporin-4 (AQP4). AQP4-specific CD4+ Th cells are centrally involved in disease development including the Th cell-dependent generation of AQP4-specific antibodies. However, their functional and molecular properties as well as peptide/HLA specificities are poorly characterized due to technical limitations for their *ex vivo* detection.
Methods: Combined HLA-tetramer- and activation-based antigen-reactive T cell enrichment (ARTE) characterized *ex vivo* AQP4-specific CD4 Th cells isolated from blood of patients and healthy controls. We performed multiparameter cytometric and functional characterization, single cell RNA-sequencing and re-expression of autoreactive T cell receptors (TCRs) to confirm specificity and identify peptide/HLA class II recognition.
Results: In aquaporin4-antibody-positive neuromyelitis optica spectrum disorder patients, autoreactive Th cells expressed CD154, but proliferative capacity and pro-inflammatory cytokines were strongly reduced. Instead, exhaustion-associated co-inhibitory receptors were co-expressed together with FOXP3, the canonical regulatory T cell (Treg) transcription factor. The proliferative blockade of autoreactive Th cells was reversed *in vitro* by checkpoint inhibition and patient clones expanded in this way provided potent B cell help. The same exhaustion-like phenotype was demonstrated in autoimmune hepatitis and bullous pemphigoid, antigen-specific autoimmune diseases of liver and skin, respectively.
Conclusion: We identified a new exhaustion-like Th cell phenotype and a potential role of FOXP3 for the regulation of chronic autoreactivity in human autoimmune disease. A better understanding of the lifestyle of autoreactive Th cells in patients defines novel strategies for their therapeutic targeting. Our data suggest CD4+ Th cell exhaustion as a common mechanism of adaptation to chronic (self-)stimulation across disease types.

The tissue-resident memory Th17 (TRM17) cells, the predominant source of interleukin (IL)-17 in inflammatory arthritis, is largely IL-23 independent in their effector function and epigenetically regulated by Bromodomain Containing 1 (BRD1)

Feng Liu[1], Rachel Anscombe[1], Hui Shi[1], paul Bowness[1], liye Chen[1]
[1]*Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford OX3 7LD, UK, Oxford, United Kingdom*

Purpose: The IL-17 pathway plays a key role in the immunopathogenesis of inflammatory arthritis including Ankylosing Spondylitis (AS). Produced by a variety of immune cells, whether a specific cell type dominates IL-17 production in AS is debated. Recent studies have implicated γδ T cells, iNKT cells, and MAIT cells as the main sources of IL-17 in AS joints. Increasing evidence, however, is highlighting a role for CD4+ tissue resident memory Th17 (TRM17) cells as key IL-17 producers in tissues such as the lung and brain. It is therefore possible that a role for TRM17 in AS may have been missed in previous studies focused on synovial fluid samples.
Methods: Digested synovial tissue from patients with AS (n=5) was profiled using single-cell RNA sequencing. To model TRM17 in vitro, isolated memory CD4+ T cells from the blood of AS patients were first cultured in Th17 expansion condition for 6 days (to model initial Th17 activation in tissue), followed by the exposure to TGF-β and IL-7 for 7 days (to model the resolution phase). A library of epigenetic inhibitors and CRISPR were used to identify epigenetic regulators for TRM17.
Results: IL-17A/F expression was restricted to CD4+CXCR6+ TRM17 cells. The in vitro generated TRM17 phenocopied the TRM17 found in joint tissue and produced IL-17A/F in response to TCR stimulation. IL-1β and IL-23 enhanced the IL-17A/F production in the presence of TCR stimulation but were incapable of inducing IL-17A/F production on their own. CRISPR KO of BRD1 inhibited the generation of TRM17 from memory CD4+ T cells from AS patients. Cell interaction analysis predicted dendritic cells to be the antigen presenting cells for TRM17.
Conclusions: TRM17 cells are the predominant source of IL-17 in AS and require TCR stimulation for their effector function. IL-1β and IL-23 enhance IL-17 production by TCR-stimulated Trm17 but do not induce IL-17 on their own, explaining the lack of clinical efficacy in their blocking antibodies in AS. Epigenetic regulator BRD1 contributes to the generation of TRM17. Targeting TRM17, the “factory” of IL-17, provides a new therapeutic strategy potentially superior to IL-17 blockage in inducing long-term remission.

T cell mediated immune responses in primary intestinal tissue slices from IBD patients ex vivo

Klaudia Maria Grieger[1], Valerie Beneke[1], Vanessa Neuhaus[1], Susann Dehmel[1], Ulf Kulik[2], Heiko Aselmann[3], Benjamin Gundert[3], Armin Braun[1], Christina Hesse[1], Katherina Sewald[1]
[1]Fraunhofer Institute for Toxicology and Experimental Medicine, Hannover, Germany; *[2]Hannover Medical School (MHH), Hannover, Germany*; *[3]KRK clinicum Siloah, Hannover, Germany*

Purpose: Inflammatory bowel diseases (IBD) are characterized by the dysregulation of innate and adaptive immune responses, in particular massive T cell infiltration, leading to aberrant inflammatory processes within the intestinal tissue. Our aim is to gain deeper insights into immunological signatures associated with IBD and to modulate tissue-resident T cell responses using ex vivo primary intestinal tissue slices (Precision Cut Intestinal Slices; PCIS). PCIS represent an immunocompetent human-based ex vivo tissue model that reflects the complex intestinal architecture with all relevant intestinal cells in their native microenvironment.
Methods: PCIS were prepared from ileum resections of IBD and non-IBD patients and stimulated ex vivo with mitogens or pro-inflammatory cytokines (e.g. bacterial lipopolysaccharide (LPS), IL-1β, Concanavalin A) and/or anti-inflammatory treatments, e.g. pimecrolimus for 24 h. We analysed tissue viability (ATP/LDH-assay), cytokine release (multiplex assay) and PCIS morphology (H&E, Immunofluorescence).
Results: Primary intestinal tissue slices of IBD and non-IBD patients remained viable for 24 h. The investigated substances showed no significant effect on LDH release. PCIS from IBD patients exhibited disease-specific morphological changes such as immune cell infiltrates and higher abundance of CD4+ and CD8+ T cells in the subepithelial layer of the inflamed mucosa. Further, PCIS from IBD patients showed increased secretion of clinically relevant biomarkers and disease-dependent cytokine signatures compared to PCIS from non-IBD patients. Overall, we characterized the secretion patterns of 30 different mediators in intestinal tissue ex vivo. Concanavalin A led to a significant increase of several T cell cytokines including IL-2 (~2-fold), IFN-γ (~3-fold), TNF-α (10-fold) and IL-17A (~7-fold) in PCIS from IBD patients compared to PCIS from non-IBD patients. Further, Concanavalin A-induced T cell cytokines were specifically reduced by treatment of PCIS with the calcineurin inhibitor pimecrolimus, while the release of proinflammatory mediators such as IL-8 was less affected.
Conclusion: In conclusion, primary tissue slices showed distinct and disease-specific immune responses ex vivo. PCIS from IBD patients exhibited increased and modulable Th1 and Th17 cell-associated responses. This study highlights the potential of PCIS for investigating immunological mechanisms and disease-specific biomarkers, providing a test platform for new drugs based on a complex human tissue system.

A novel humanized mouse model to study rheumatoid arthritis associated anti-citrulline T cell reactivity

Marlene Schülein[1], Diego Velasques Pulgarin[1], Aaron Winkler[2], Lars Klareskog[1], Alexander Espinosa[1], Vivianne Malmström[1], Bruno Raposo[1]
[1]Department of Medicine, Division of Rheumatology, Center for Molecular Medicine, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden; [2]Department of Inflammation and Immunology, Pfizer Inc., Cambridge, United States

Purpose: Two thirds of RA patients display anti-citrulline autoimmunity, however no existing animal model mimics such specificity, as they rely on immune reactivities unrelated to the human disease or that poorly represent reactivities observed in patients. Moreover, the majority does not consider the strongest genetic association with risk of RA – HLA-DRB1*04:01 (DR4). Hence, we generated humanized mice that better resemble patients autoreactivity, allowing a more straightforward translation of data to (pre)clinical settings.
Methods: Citrulline-reactive T cells were identified by peptide-HLA tetramers in peripheral blood and synovial fluid samples of DR4+ RA patients. Tetramer-positive CD4+ T cells were single-cell sorted and sequenced for their T cell receptors (TCRs). Identified paired alpha-beta TCRs were re-expressed in vitro to confirm their antigen and HLA specificity. Positively identified sequences were engineered into suitable DNA vectors for injection into murine zygotes. Germline alpha-beta TCR+ offspring were phenotypically assessed by flow cytometry and cell culture assays for antigen-reactivity.
Results: To date, we have generated TCR transgenic mice specific to citrullinated tenascin C (citTNC) and citrullinated fibrinogen (citFib). Here, we present data from the citTNC TCR transgenic line. citTNC mice develop both CD4+ and CD8+ T cells in the context of murine MHC. Analysis of double negative thymocytes indicate a skewed developmental stage towards a completely re-arranged TCR, and expression of the transgenic TCR was confirmed in single positive thymocytes by RT-PCR. When cultured in vitro with bone marrow derived dendritic cells (BMDCs), peripheral citTNC CD4+ T cells showed specific reactivity to their cognate antigen only in the presence of DR4+ BMDCs, but not murine H2-A^b expressing BMDCs. Similarly, when citTNC CD4+ T cells were transferred to citTNC-immunized DR4+ or H2-A^b+ recipient mice, antigen recall responses where only observed in DR4+ recipients.
Conclusion: We successfully generated transgenic mouse lines expressing patient-derived autoreactive TCRs of relevance to RA. citTNC mice develop CD4+ T cells that are activated in a HLA- and antigen-specific manner, showing both in vitro and in vivo functionality. These constitute the initial steps to developing a complex humanized mouse model for studying anti-citrulline immunoreactivity and better understand such immune responses in human RA.

CCL5/RANTES in the Pathogenesis of Systemic Lupus Erythematosus (SLE)

Xiaolin Cao[1], Niels van Heusden[1], Ellen Kaan[1], Maarten Limper[1], Marianne Boes[1]
[1]*University Medical Center Utrecht, Utrecht, Netherlands*

Purpose: SLE is a highly heterogeneous systemic autoimmune disease, the cause of its initiation and severity needs to be revealed. Increased levels of CCL5 (or RANTES), a C-C chemokine, in sera/plasma and urine from SLE patients have been observed. Hyper-released neutrophil extracellular traps (NETs) promote plasmacytoid dendritic cells (pDCs) to secrete type 1 interferon (IFN), which is considered a cardinal feature of SLE. Earlier, we demonstrated that CCL5 could be upregulated by NET and IFNα presence. We subsequently studied CCL5 as a biomarker for SLE by investigating the proliferative or anti-proliferative effects of NETs, IFNα and CCL5 on T lymphocytes, to clarify how hyper-secreted chemokines in SLE contribute to the pathogenesis of the disease, to possibly pursue a universal therapeutic strategy from what we discovered.
Methods: We isolated peripheral blood mononuclear cells (PBMCs) and plasma from SLE patients and age-and-sex-matched healthy donors; IFNα and in vitro generated NETs are used as stimuli in healthy monocytes and PBMC cultures. CCL5 secretion was measured by ELISA; CCL5 stimulation-induced activation makers of monocytes and T cells, as well as T-cell proliferation were gauged by flow cytometry; Transcriptional levels of CCL5, CCR5 and other signaling molecules on monocytes were quantified by real-time PCR.
Results: We confirm that SLE patients exhibit elevated plasma levels of CCL5 compared to healthy subjects. We show that monocytes from patients express more CCR5 than monocytes from healthy donors, most notably in the intermediate monocyte subclass. Exposure to IFNα and NETs did trigger increased CCR5 expression and CCL5 secretion of monocytes. When PBMCs were cultured in presence of CCL5 and NETs, we observed an expansion of T-cell proliferation.
Conclusion: Dysregulated NETs and IFNα in SLE could induce CCL5 secretion and CCR5 activation on monocytes, the released CCL5 could further serve as signal 3, together with NETs to contribute to T cells activation and proliferation, whereas IFNα exhibits an anti-proliferative effects on T lymphocytes when they are exposed to NETs at the same time. Besides the well-known role in chemotaxis, we provide new mechanistic roles of CCL5 in SLE pathophysiology.

Unravelling pathological mechanisms of Addison's disease using a novel animal model

Ales Neuwirth[1], Arina Andreyeva[1;2], Juraj Michálik[1], Ondrej Stepanek[1]
[1]*Institute of Molecular Genetics of the Czech Academy of Sciences, Prague, Czech Republic*; [2]*Faculty of Science, Charles University, Prague, Czech Republic*

Adrenal glands play a crucial role in regulating metabolic, immune, behavioral, and cardiovascular processes through steroid production. Autoimmune Addison's disease is an autoimmune disorder that occurs when adrenocortical cells are attacked by the immune cells, leading to functional failure. However, due to the lack of human samples and suitable mouse models, the immune mechanism behind adrenal destruction remains unknown. To address this, we developed the first defined mouse model of experimental autoimmune adrenalitis (EAA) by immunizing C57BL/6 mice with immunogenic peptides derived from CYP11A1, a rate-limiting enzyme in steroidogenesis. Our model resulted in $CD4^+$ and $CD8^+$ T cell infiltration into the adrenals, as well as the recruitment of inflammatory monocytes, and B cells. These immune cells were predominantly located in the adrenal cortex, the site of robust steroidogenesis and CYP11A1 production. The initial adrenal inflammation led to pathological changes followed by adrenal functional failure manifested by corticosterone deficiency. Adoptive transfers demonstrated the significance of $CD4^+$ T cells in disease pathogenesis. Using single-cell RNA sequencing of adrenal-recruited $CD4^+$ T cells during EAA, we identified a broad heterogeneity of T cell responses, including a novel pro-inflammatory subset. Simultaneous analysis of T-cell receptor recombination of individual cells showed intense clonal expansion of adrenal-infiltrated $CD4^+$ T cells. To study expanded T cell clones representing individual $CD4^+$ T cells subset in detail, we have generated two different monoclonal populations using retrogenic mice. Our data revealed that both $CD4^+$ T clones are specific to the same adrenal antigen but have different affinities. In conclusion, our models not only allow us to study the pathogenesis of Addison's disease but also provide a unique opportunity to investigate the fate decisions of self-reactive $CD4^+$ T cells and their clonal lineages in a well-defined autoimmune setting.

Systems level analysis of B-cell development across aging identifies BDNF as a driver for B-cell generation in the bone marrow

Neta Nevo[1], Ayelet Alpert[1], Tim J. Cooper[1], Neta Milman[1], Doron Melamed[1], Shai S. Shen - Orr[1]
[1]*Technion, Haifa, Israel*

Purpose: B lymphopenia is associated with increased morbidity and mortality in various clinical settings: following chemo/immunotherapy, aging and infections. Here, by leveraging a systems immunology approach, we identified drivers for B lymphopoiesis in the Bone Marrow (BM).
Methods: To prioritize B lymphopoiesis drivers, we analyzed scRNAseq data of BM samples from patients aged 24-67 and compared B lymphopoiesis trajectories using our CellAlign algorithm. Additionally, we measured 378 plasma proteins in healthy individuals and elderly B-cell depleted patients to find B-cell regeneration related drivers. Furthermore, we validated the drivers in biological experiments.
Results: To identify B-cell developmental genes, we initially created a B- cell trajectory that orders BM cells based on their developmental state, allowing high resolution identification of genes and regulatory programs that vary along B-cell development. As B lymphopoiesis is regulated by Mesenchymal Stromal Cells (MSC), we mapped 54 MSC expressed ligands interactions with B-cell developmental receptors, possible candidates for drivers of B-cell development. Leveraging age-associated differences in B lymphopoiesis, we aligned B-cell developmental trajectories of individuals in different ages to a common trajectory, and revealed 18 genes with significant differences in their expression profile dynamics upon aging. Additionally, we leveraged the B-cell rejuvenation process induced by depletion of B-cells in old patients to prioritize drivers. The upregulation of 17 proteins in elderly B-cell depleted patients restored to youthfulness, pointing to their role in B lymphopoiesis. Next, the putative drivers were filtered after analyzing their short stimulation impact on CD34+ Hematopoietic Stem and Progenitor cells (HSPC) assessed by scRNAseq. Following scoring the candidates by their results in the different analyses, we focused on one high scored putative driver, Brain Derived Neurotrophic Factor (BDNF). To validate BDNF we established an in-vitro biological system that mimics BM B lymphopoiesis process. Adding BDNF to isolated CD34+ HSPC led to their earlier and increased differentiation into progenitor B-cells.
Conclusion: High resolution systems-level analysis of B lymphopoiesis highlights BDNF as a candidate driver for B lymphopoiesis. Its expression may be used to predict B lymphopoiesis potential and to enhance their recovery toward restoring B lymphocyte function.

The RNA binding protein HuR is required for self-replenishment and preservation of the restricted BCR repertoire of innate B1 cells

Dunja Capitan Sobrino[1], Maïlys Mouysset[1], Manuel Diaz-Munoz[1]
[1]*Infinity Inserm U1291, Toulouse, France*

Purpose: Innate B1 cells are developed from restricted progenitors found in foetal and neonatal tissues and, in the adulthood, these progenitors drastically wane. Instead, B1 cells are self-maintained by signaling through their restricted BCR repertoire and clonal expansion. Our previous findings uncovered the RNA binding protein (RBP) HuR as an essential modulator of B-cell adaptive immunity. Thus, we hypothesized that HuR could also control innate B cell immunity.
Methods: To address this hypothesis, we used HuR conditional KO mice and tamoxifen inducible – Cre mice to assess the intrinsic role of HuR in innate B1 cell development, self-renewal and survival. Phenotypical characterization of the B1 cell subsets, protein:RNA interactomics and transcriptomics analyses revealed an important role for HuR in B1 B cell homeostatic maintenance examined further in-vivo and in-vitro.
Results: Deletion of HuR in B1 cells resulted in a three-fold decrease in B1 cell numbers associated to impaired self-renewal capacity and increased apoptosis. Molecular characterization of HuR targets and function using iCLIP and RNAseq revealed that this RBP controls a specific genetic program for tonic BCR signalling and homeostatic maintenance. Indeed, mechanistic validation revealed decreased BCR signalling, impaired clonal expansion and lack of preservation of the BCR repertoire in the absence of HuR in B1 cells. Additionally, we found HuR to be required for the expression of TACI and BAFFR and B1 cell survival.
Conclusion: In summary, our data show that HuR-dependent post-transcriptional regulation is required for the homeostatic maintenance and expansion of innate B1 cells.

Intracellular trafficking receptor SorLA is required for BCR uptake and trafficking, regulating B cell-mediated immune responses in vivo

Adam McShane[1], Melibea Berzosa[1], Pratiti Nanda[1], Fiona Hills[1], Dessi Malinova[1]
[1]*Wellcome-Wolfson Institute for Experimental Medicine, Queen's University Belfast, Belfast, United Kingdom*

Antigen presentation by B cells is crucial for efficient humoral immune responses. B cells internalise specific antigens through the B cell receptor (BCR). Internalised antigens are trafficked to and processed within degradative lysosomal compartments where antigenic peptides are loaded onto major histocompatibility complex-II (MHC-II) for presentation to cognate T follicular helper cells. Subsequent B cell activation leads to the generation of a high-affinity antibody repertoire for efficient antigen clearance. Improved understanding of antigen uptake and trafficking mechanisms will offer insights into B cell immune responses to infection, malignancy, and autoimmune disorders associated with dysregulated B cell antigen presentation.

A genome-wide CRISPR-Cas9 screen has highlighted a novel role for intracellular trafficking receptor, SorLA (encoded by the *SORL1* gene), in B cell antigen uptake. We aim to elucidate the mechanisms behind this novel trafficking during B cell activation.

Our findings reveal SorLA interacts with the BCR in murine splenic and Ramos B cells, immunoprecipitating with the BCR and localising to internalised antigen clusters. Using CRISPR-Cas9-mediated knockout of *SORL1* in Ramos B cells, we illustrate that SorLA is required for efficient uptake of both soluble and membrane-bound antigens. Moreover, *SORL1* gene disruption alters downstream antigen-BCR trafficking and processing, leading to dysregulated MHC-II antigen presentation and humoral immune responses *in vivo.*

In conclusion, we report a novel role for SorLA in BCR trafficking and B cell-mediated immune responses, providing evidence of a novel mechanism of antigen-BCR trafficking during B cell activation.

Active Inhibition of Chemokine-Mediated Migration Impacts Tumour-Lymph Node Crosstalk in TNBC

Victoire Boulat[1;2], Ellie Alberts[2], Carin Brundin[1], Dinis Pedro Calado[2], Anita Grigoriadis[1]
[1]*King's College London, London, United Kingdom*; [2]*The Francis Crick Institute, London, United Kingdom*

In triple negative breast cancer (TNBC), draining lymph nodes (LNs) serve as both the first site of metastasis and the orchestrator of antitumour immune responses. We have demonstrated that TNBC patients with high tumour-infiltrating lymphocytes (TILs) and the presence of tertiary lymphoid structures (TLS) have more LN germinal centers (GC). These features associate with longer distant metastasis-free survival and imply crosstalk between the tumour and the LN. Despite these findings, only up to 50% of TNBC patients exhibit TLS, suggesting impairment in the tumour-draining LN axis in the rest. Understanding the factors governing this impairment is crucial for establishing novel therapies including for the induction of TLS.

We immunophenotyped the primary tumours and draining LNs in two orthotopic mouse models of TNBC at various time points post-implantation. Remarkably, we consistently observed minimal B cell tumour infiltration despite robust induction of tumour-draining LN GC responses. These observations underscore the utility of these models for elucidating the impairment of the primary tumour-draining LN axis.

We validated the LN as the primary source of the limited tumour-infiltrating B cells (TIL-B) by employing FTY720, a LN egress inhibitor. To investigate the chemotactic ability of the tumour secretome, we established a tumour slice culture method. Using a high-throughput approach, we assessed the murine tumour secretome for the presence of TLS-associated chemokines identified using microarray data from 124 TNBC patients. Tumour slice supernatants lacked TLS-inducing factors and did not induce the migration of B and T cells in transwell assays. Next, we tested the ability of key chemokines to induce chemokine-mediated immune cell migration. Intriguingly, we observed that chemokine-supplemented tumour slice supernatants prompted significantly less B cell migration than chemokine-supplemented culture medium, suggesting that the tumour secretome contains chemokine-mediated migration inhibitor/s.

Our findings suggest that the absence of TIL-B and TLS in TNBC may result from a combination of mechanisms: namely the failure by the tumour microenvironment to produce necessary chemokines to induce immune infiltration from the LN; and the active secretion of factors which hinder chemokine function. Insights into the active inhibition of chemokine-mediated immune cell migration may provide new treatment strategies in TNBC.

Human B-cell development at the single-cell level

Timothy Sundell[1], Alessandro Camponeschi[1;2], Alaitz Aranburu[1], Inger Gjertsson[1;3], Lill Mårtensson[1]
[1]Department of Rheumatology and Inflammation Research, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; *[2]Clinical Immunology and Transfusion Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden*; *[3]Department of Rheumatology, Sahlgrenska University Hospital, Gothenburg, Sweden*

Purpose: B cells constitute an integral part of the immune system, actively participating in immune responses and forming immunological memory. Their development occurs in the bone marrow through a highly regulated process involving the generation of a diverse repertoire of B-cell antigen receptors. Although most studies of B-cell development have been carried out in mice, the advent of high-throughput single-cell sequencing methods enables us to unravel the complexity of human B-cell development in great detail. Understanding differences in B-cell development between mice and humans is essential, as it can uncover the mechanisms behind B cells in disease and lead to novel therapeutic strategies.
Methods: Here, we have analysed human bone marrow 'early' ($CD10^{+}CD24^{hi}CD38^{hi}$) B-lineage cells by 5´ single-cell RNA- and V(D)J-sequencing and flow cytometry.
Results: Based on distinct gene expression profiles, trajectory inference, and gene set enrichment analyses, we delineated a developmental pathway from progenitor (pro) B via large precursor B1 (L-preB1) and L-preB2 to small preB and subsequently to immature B1 (iB1) and iB2. The latter expressed higher levels of, for example, *MS4A1*, the gene encoding CD20. Flow cytometric analyses corroborated that the 'early' B-lineage cells contained two subsets of iB cells, $IgM^{+}IgD^{-}$ and $IgM^{+}IgD^{+}$, of which the latter expressed higher levels of CD20, indicating that they were more mature. Further confirmation that iB2 cells were indeed iB cells and not circulating transitional B cells came from integrative analyses of peripheral blood transitional B cells, which showed that the transcriptomes of iB2 and transitional B cells were distinctly different. Examination of differentially expressed genes between clusters revealed changes in the expression of transcription and survival factors, as well as signalling molecules. Gene set enrichment analyses highlighted differences in the involvement of different biological processes.
Conclusion: Our findings highlight the intricate journey of developing B cells in the human immune system, revealing a complex landscape. By using cutting-edge sequencing technologies, we provide a comprehensive perspective that not only enhances our understanding of lymphocyte development, but also opens new avenues for innovative strategies to study B-cell related diseases such as autoimmunity and B-cell driven leukaemia.

New mode of B-cell activation through extracellular release of native antigen by dendritic cells

Klara Cik[1;2], Louis Vasselin[1;2], Morgane Thepaut[1;2], Antoine Robert[1;2], Paul Courrieu[1;2], Florence Niedergang[1;2], Fatah Ouaaz[1;2]
[1]*Institut Cochin- INSERM U1016-CNRS UMR 8104, Paris, France*; [2]*Université Paris Cité, Paris, France*

Dendritic cells (DCs) are antigen-presenting cells (APCs), which sample antigen (Ag) in the periphery and migrate to the lymph node (LN) where they activate T cells. Previously, we showed that DCs are able to store and to release from late endosomes native Ag into the extracellular medium. Alternative modes of B-cell activation by APCs, beyond cell-to-cell contact, such as extracellular release of Ag by DCs remain however not investigated. Using a subcutaneous delivery of Ag-loaded DCs in vivo and an in vitro co-culture system, we aimed: 1)- to visualize Ag trafficking by DCs to the LN; 2)- to investigate the modalities of Ag transfer and B-cell activation by the distinct DC subsets; and 3)- to probe the role of exosomes (Exo) in Ag release and its regulation by glucocorticoids (GCs). Here, we show that peripheral DCs are transporters of native Ag to the LN-B cell zone and potent B-cell activators both in vivo and in vitro. We highlight a novel extracellular mode of B-cell activation by showing that Ag release by DCs is sufficient to efficiently induce early B-cell activation through the transcription factor NF-κB/cRel. Furthermore, LN-resident DC subsets including conventional DCs (cDCs) and plasmacytoid DCs (pDCs) are also able to release native Ag with an unexpected superiority for pDCs. Strikingly, this new mechanism consists of an Exo-free release of native Ag, contrasting with the Exo-dependent extracellular T-cell activation by DCs. Interestingly, glucocorticoids inhibit Ag release and the subsequent induced B-cell activation by DCs. Thus, our study provides new mechanistic insights into the modes of Ag delivery for B-cell activation by DCs and a promising approach of drug modulation of the DC-elicited Ag-dependent B-cell responses.

Meningeal γδ17 T cells and blood-brain barrier disruption: implications for neonatal Group B *Streptococcus* meningitis

Inês Lorga[1;2;3], Ana Magalhães[1;2;3], Ana Teixeira[2;3], Manuel Vilanova[1;2;3], Julie Ribot[4], Elva Bonifácio Andrade[1;2;3]
[1]ICBAS- Instituto de Ciências Biomédicas Abel Salazar, Universidade do Porto, Porto, Portugal; *[2]i3S- Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Porto, Portugal*; *[3]Instituto de Biologia Molecular e Celular, Universidade do Porto, Porto, Portugal*; *[4]Instituto de Medicina Molecular João Lobo Antunes, Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal*

Neonatal Group B *Streptococcus* (GBS) meningitis remains a devastating disease associated with significant morbidity. Urgent demand exists for novel therapeutic and neuroprotective interventions. Here, we hypothesise that meningeal inflammation contributes to the neurologic sequelae observed in humans surviving GBS meningitis. Using a clinically relevant mouse model that mimics GBS vertical transmission from pregnant females to their progeny, we found altered γδ T cells in the meninges of infected pups. Flow cytometry analysis showed an increased frequency of γδ T cells at postnatal day (P) 3, independently of the brain bacterial burden. We also observed a significant decrease of IL-17A (IL-17 herein onwards) transcription in this subset while detecting an increase of IL-17 in the supernatant of cultured meningeal cells isolated from infected P3 pups after 24h of PMA/ionomycin stimulation. Neonatal thymic analysis showed no differences in γδ T cells or their commitment to IL-17 or IFN-γ production. Notwithstanding, two- and six-week-old infected mice presented increased numbers of meningeal γδ17 T cells, suggesting an important role of this subset in this disease. To investigate the contribution of γδ T cells to GBS meningitis pathogenesis, we performed infectious studies in TCRδ$^{-/-}$ mice. Interestingly, the absence of γδ T cells resulted in decreased brain bacterial load at P1 and P3 while showing no differences in the lungs and meninges. TCRδ$^{-/-}$ mice surviving infection presented decreased long-term sequelae. To understand how γδ T cells contribute to bacterial parenchymal invasion, we next assessed the blood-brain barrier (BBB) permeability both *in vitro* and *in vivo*, in TCRδ$^{-/-}$ versus TCRδ$^{+/+}$ pups. Western Blot quantification of the BBB tight junction protein occludin showed a significant decrease in TCRδ$^{+/+}$ infected pups compared to the TCRδ$^{-/-}$ uninfected ones. No differences were observed between TCRδ$^{-/-}$ infected and uninfected pups. Moreover, *in vivo* administration of FITC-dextran proved that BBB permeability is increased in both infected groups, with the TCRδ$^{+/+}$ group being most affected. Mice lacking IL-17 have increased bacterial control. Our study demonstrates that during GBS meningitis, the meningeal γδ17 T cell population contributes to BBB disruption and GBS invasion, being associated with behavioural abnormalities later in life.

The interplay between inflammation and oxidative stress supports autistic-related behaviors in two mouse models of Autism Spectrum Disorders

Luca Pangrazzi[1], Enrica Cerilli[2], Luigi Balasco[2], Caterina Tobia[2], Enrico Domenici[3], Birgit Weinberger[1], Yuri Bozzi[2]
[1]Institute for Biomedical Aging Research, University of Innsbruck, Innsbruck, Austria; *[2]Center for Mind/Brain Sciences, University of Trento, Rovereto, Italy*; *[3]Department of Cellular, Computational, and Integrative Biology (CIBIO), University of Trento, Trento, Italy*

Autism Spectrum Disorders (ASD) are highly prevalent neurodevelopmental conditions characterized by social communication deficits and repetitive and restricted behaviors. Several studies showed that inflammation may contribute to ASD, as high levels of pro-inflammatory molecules were described in the peripheral blood (PB) of individuals with ASD. Here we used RT-qPCR, RNA sequencing, metabolomic analysis and flow cytometry to show that molecules related to inflammation were increased in the cerebellum, PB, bone marrow and spleen of mice lacking Cntnap2, robust model of ASD. In parallel, pro-inflammatory molecules were additionally increased in the brain and PB of Shank3b mutant mice, another mouse model of ASD. The frequency and branching of microglia cells were impaired in Cntnap2$^{-/-}$ mice. In parallel oxidative stress was increased in the cerebellum of mutant animals compared to controls. Systemic treatment with the antioxidant N-acetyl-cysteine (NAC) rescued ASD-related behaviours in Cntnap2 and Shank3b mutant mice. Oxidative stress and inflammation in the cerebellum, as well as pro-inflammatory conditions in the PB, bone marrow and spleen were counteracted by NAC treatment. In addition, the phenotype of microglia cells as well as the branching were improved in Cntnap2$^{-/-}$ mice injected with NAC. Taken together, our findings suggest that the interplay between oxidative stress and inflammation may support the pathogenesis of ASD-related behaviors in mice.

Fundings: This work was supported by the Strategic Project TRAIN-Trentino Autism Initiative (https://projects.unitn.it/train/index.html) from the University of Trento (grant 2018–2022) and Autism Research Institute (ARI) 2021 Research Award. LP was supported by a postdoctoral fellowship from the Umberto Veronesi Foundation (Milan, Italy) and a starting grant from the University of Trento.

Mapping midbrain immune response and potential gateway function of the choroid plexus in chronic gut inflammation

Rebecca Katharina Masanetz[1], Mark Dedden[2], Iris Stolzer[2], Claudia Günther[2;3], Mathias Linnerbauer[4], Veit Rothhammer[4], Wei Xiang[1], Pavel Kielkowski[5], Johannes Schlachetzki[6], Sebastian Zundler[2], Jürgen Winkler[1;3], Patrick Süß[1;3;4]

[1]Department of Molecular Neurology, Universitätsklinikum Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Erlangen, Germany; *[2]Department of Medicine 1, Universitätsklinikum Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Erlangen, Germany*; *[3]Deutsches Zentrum Immuntherapie, Universitätsklinikum Erlangen, Erlangen, Germany*; *[4]Department of Neurology, Universitätsklinikum Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Erlangen, Germany*; *[5]Department of Chemistry, Ludwig-Maximilians-Universität München, München, Germany*; *[6]Department of Cellular and Molecular Medicine, University of California, San Diego, United States*

Purpose: Chronic gut inflammation, as in inflammatory bowel disease (IBD), is associated with neuropsychiatric and neurodegenerative disorders, particularly Parkinson disease (PD). This link might be mediated by a gut-immune-brain axis suggested as a pivotal route of communication between the gut and the central nervous system. Specifically, gut-derived inflammatory factors are hypothesized to reach the systemic circulation and modulate brain function via distinct interaction sites, including the choroid plexus. Here, we used a mouse model of IBD to examine effects of chronic gut inflammation on the immune compartments of the choroid plexus and the midbrain. We thereby aim to better understand PD development in IBD.

Methods: Male and female adult C57BL6/J or *Hexb*$^{tdT/tdT}$ mice were fed with 2 % (w/v) dextran sulfate sodium (DSS) in drinking water for 5 days followed by normal drinking water for 10 days. The cycle was repeated thrice to induce chronic colitis that was confirmed by colonoscopy. Control mice received normal drinking water for the whole study period. Brain tissue was analyzed by multicolor flow cytometry and immunofluorescence. Bulk RNA-sequencing of three different brain regions was performed and complemented by proteomic analysis of the respective contralateral tissue. CD45^{+} immune cells were sorted from the midbrain and choroid plexus and subjected to single-cell RNA-sequencing.

Results: Mice treated with DSS developed colitis and showed signs of systemic, lung and liver inflammation. Transcriptomic and proteomic analyses revealed substantial reorganization of the immune cell compartment in the midbrain compared to other brain regions. By using a microglia-specific reporter gene mouse model, brain-resident macrophages (microglia) and microglia-derived molecules were identified as key elements in the inflammatory response. In addition, transcriptomic changes in the choroid plexus indicated endothelial dysfunction and increased blood-brain barrier permeability.

Conclusion: Our findings provide evidence for an innate and adaptive immune cell response in the midbrain to chronic gut inflammation, and point towards a key role of the choroid plexus in preventing immune cell entry into the brain parenchyma. These results significantly enhance our understanding of the gut-immune-brain axis that links peripheral inflammation to neurodegenerative processes, such as in PD.

Effects of microbial infection on the blood-brain barrier – high-dimensional tissue profiling using imaging mass cytometry

Marta Kaminska[1], Anne Klapper[2], Holger Cynis[2], Piotr Mydel[1]
[1]*University of Bergen, Bergen, Norway*; [2]*Fraunhofer Institute for Cell Therapy and Immunology, Halle, Germany*

Purpose: Blood-brain barrier (BBB) functions as an interface between the brain parenchyma and peripheral blood, regulating the exchange of metabolites and nutrients. Due to its critical role in maintaining health of the central nervous system (CNS), its breakdown may have long-term ramifications, including cognitive decline. In fact, it has been postulated that this vascular damage might be one of the early markers of Alzheimer's disease, the most frequent type of dementia. Therefore, in this study we postulate that one of the initiating factors of the BBB-breakdown might be the keystone periodontitis pathogen, *Porphyromonas gingivalis*, and that its translocation from the gingival tissue to the vicinity of BBB could cause pro-inflammatory response and vascular dysfunction, in the end resulting in the cognitive decline.
Methods: Tissues (brain, liver) of wild-type C57BL/6J and the 5xFAD murine strains orally infected with *P. gingivalis* for 22 weeks were collected. A novel panel of 40 metal-tagged antibodies suitable for imaging mass cytometry was designed, tested, and optimized using the harvested tissues to visualize tissue-specific protein expression and protein level changes resulting from *P. gingivalis* infection. Obtained data was analyzed *via* Steinbock pipeline.
Results: Of 40 markers, 9 were used to distinguish unique cell types (endothelium, pericytes, astrocytes, microglia, neurons, oligodendrocytes etc.). The rest allowed for characterization of the CNS' extracellular matrix, inflammatory responses, and BBB-specific markers (including GLUT1, AQP4, claudin 5). An antibody against *P. gingivalis*-derived virulence factor (rgpB) was included. Preliminary results indicate that rgpB can be reliably detected in tissues distant to the site of primary infection. Its presence induces local upregulation of pro-inflammatory markers (such as TLR4, IL17RA).
Conclusions: Oral infection with *P. gingivalis* caused pro-inflammatory response in distant tissues (liver and brain), which could contribute to the BBB breakdown and AD pathogenesis. Imaging mass cytometry can be successfully applied to characterize phenotypic changes of the BBB. Overall, the designed panel offers a unique opportunity to evaluate the blood-brain barrier breakdown and neuroinflammation in murine models.

This study was funded by the EU Joint Programme – Neurodegenerative Disease Research (project nr 311544) and Nasjonalforeningen for Folkehelsen (project nr 35318).

Innate immune signalling, and more specifically Type-I/II interferon (IFN) signalling, is a first line cellular defence mechanism against viral pathogens. With a specific focus on studying anti-viral neuro-immune responses in a human central nervous system (hCNS)-like environment, we first established and characterised a 5-month matured hiPSC-derived neurospheroid (NSPH) model containing TuJ1+ MAP2+ NeuN+ neurons and GFAP+ S100b+ AQP4+ Sox9+ CD49f+ astrocytes. Immune competence of these NSPHs was demonstrated by significant secretion of CXCL10 following stimulation with IL1b. Functional maturation of the NSPHs was confirmed by spontaneous and synchronized electrophysiological activity measured by calcium imaging.
Subsequently, NSPHs were infected with genetically engineered strains of either Varicella Zoster Virus (VZV-ORF23/GFP) or Sendai virus (SeV-eGFP). Live cell and immunocytochemical analysis here demonstrated that VZV spreads uninterrupted throughout the entire NSPH, while SeV spread was limited to the outer NSPH border. Next, using NanoString technology, broad transcript-level immune profiling was performed to explore the innate immune signatures of infected NSPHs. While SeV-infected NSPHs displayed a clear Type I/II IFN response, in VZV-infected NSPHs no Type I/II IFN response was activated. Even more, in the latter a strong suppression of genes related to the MHC Class I & II antigen presentation pathways was noted. Functionally validating these opposite innate immune signatures in VZV- and SeV-infected NSPHs, cytokine profiling of NSPH supernatant revealed increased secretion of IL6 and CXCL10 by SeV-infected NSPHs, but not by VZV-infected NSPHs. Similarly, immunocytochemical analysis demonstrated upregulation of Type I IFN activated anti-viral proteins Mx1, IFIT2 and ISG15 in SeV-infected NSPHs. Furthermore, CD74, a key part of the MHC class I antigen presentation pathway was found to be suppressed in VZV-infected NSPHs. We here demonstrate that our matured multicellular NSPH model is immune reactive, susceptible to viral infection, and most importantly, able to recapitulate VZV- and SeV-specific immune signatures. Therefore, this NSPH model will be suited to investigate viral neuro-immune responses and evasion strategies, as well as other neuro-inflammatory conditions following e.g., ischemic stroke and Parkinson's disease.

Neuroimmune responses to intranasal poly(I:C) are primed by time of day

Gregory Pearson[1], Brennan Falcy[1], Jiexin Wang[1], Nathan Santos[1], Stephanie Gottwals[1], Giancarlo Denaroso[1], Saïd Akli[1], Ilia Karatsoreos[1]
[1]*University of Massachusetts Amherst, Amherst, Massachusetts, United States*

Purpose: Neuroimmune responses are critical for survival. This is particularly evident with neurotropic (brain-targeting) virus infections, in which impaired immune signaling results in severe neuropathology and death. We previously found that the severity of neurotropic virus infection is impacted by time of day of infection. However, the mechanism by which time of day modulates this survival outcome remains unknown. To investigate potential mechanisms, our previous work shows that the olfactory bulb (OB), a site of neurotropic virus entry into the brain, rhythmically expresses neuroinflammation-related transcripts. These rhythmically expressed transcripts are enriched in genes associated with functional aspects of microglia. We also found that antiviral-related transcripts are upregulated in the OB at active phase onset, a time of enhanced survival following neurotropic virus infection. Here, we tested the hypothesis that time of day primes the OB to differentially respond to an intranasal virus-like challenge.
Methods: For Experiment 1, we intranasally challenged mice at resting phase onset (ZT0) or active phase onset (ZT12) with vehicle or poly(I:C) and collected tissues at 0-, 3-, 12-, and 24-hours post-inoculation. OB transcriptional responses were measured using NanoString technology. For Experiment 2, we intranasally challenged mice with vehicle or poly(I:C) at ZT0 or ZT12. We then isolated OB microglia at 24 hours post-inoculation and used imaging flow cytometry to analyze a population of cells characteristic of microglia.
Results: For Experiment 1, we found that intranasal poly(I:C) induced antiviral responses in the OB and that these responses unfolded more rapidly in mice challenged at ZT12 compared to ZT0. For Experiment 2, we found that time of day altered the number of OB microglia independent of treatment, with more OB microglia at ZT12 than ZT0. Surprisingly, we also observed a high proportion of microglia that contained intrinsically fluorescent puncta. The proportion of intrinsically fluorescent microglia was reduced following intranasal poly(I:C) at ZT12 but not affected following intranasal poly(I:C) at ZT0.
Conclusions: Time of day primes the OB to mount differential antiviral and microglial responses to intranasal virus-like stimuli, which may provide an antiviral gating mechanism underlying differential susceptibility to neurotropic virus exposure via the nasal route.

Purpose: Most autoinflammatory diseases are caused by mutations in innate immunity genes. Recently, four variants in the RHO GTPase CDC42 were discovered in patients affected by syndromes generally characterized by neonatal-onset of cytopenia and auto-inflammation, including hemophagocytic lymphohistiocytosis and rash (NOCARH syndrome). However, the mechanisms responsible for these phenotypes remain largely elusive.
Methods: Using microscopy and transcriptomics approaches, we analyzed protein trafficking, type I IFN response, STING activation and ER stress in both CDC42 patients' cells and THP-1 -transfected cells.
Results: We show that the recurrent p.R186C CDC42 variant, which is trapped in the Golgi apparatus, elicits a block in both anterograde and retrograde transports, and endoplasmic reticulum stress. Consequently, it favours STING accumulation in the Golgi in a COPI-dependent manner. This is also observed for the other Golgi-trapped p.*192C*24 CDC42 variant, but not for the p.Y64C and p.C188Y variants that do not accumulate in the Golgi. We demonstrate that the two Golgi-trapped CDC42 variants are the only ones that exhibit overactivation of the STING pathway. Consistent with these results, patients carrying Golgi-trapped CDC42 mutants present very high levels of circulating IFNalpha at the onset of their disease.
Conclusion: We report new mechanistic insights on the impact of the Golgi-trapped CDC42 variants. This increase in STING activation provides a rationale for combination treatments for these severe cases.

NLRC4 mosaicism as the cause of a severe, early-onset autoinflammatory disease

Daniel Lorca-Arce[1], Walaa Shoman[2], Anna Mensa[1;3], Susana Plaza[1], Virginia Fabregat[1], Juan Francisco Luchoro[1], Jordi Yague[1;3;4], Yasmine El Chazli[5], Juan Ignacio Arostegui[1;3;4]
[1]Immunology Department, Centre Diagnostic Biomèdic CDB, Hospital Clínic de Barcelona, Barcelona, Spain., Barcelona, Spain; *[2]Pediatric Immunology/Rheumatology Unit, Alexandria University Children's Hospital, Alexandria, Alexandria, Egypt*; *[3]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Universitat de Barcelona, Barcelona, Spain., Barcelona, Spain*; *[4]School of Medicine, Universitat de Barcelona, Barcelona, Spain*; *[5]Pediatric Hematology/Oncology Unit, Alexandria University Children's Hospital, Alexandria, Egypt*

Purpose: To investigate the cause of an early-onset uncharacterized autoinflammatory disease (AID).
Methods: Genetics studies were performed using two different next-generation sequencing (NGS)-based methods: a targeted gene panel (TGP) for detection of germline variants and the amplicon-based deep sequencing (ADS) for postzygotic variants.
Results: The patient is an 18-month-old girl, who was born from a non-consanguineous couple of Egyptian ancestry, with no relatives affected by immune-related diseases. At the age of 6 months, she experienced for the first time recurrent febrile episodes (7-10 days), which recurred less than one week later, accompanied by extreme irritability. During her first year of life, she was hospitalized 6 times for suspected meningitis. Cerebrospinal fluid analysis always revealed the absence of pathogens, supporting for the presence of recurrent aseptic meningitis. Physical examination showed failure to thrive, bilateral arthritis in knees and urticarial-like rash. Laboratory tests revealed increased acute phase reactants (CRP and ESR), leukocytosis, neutrophilia, thrombocytosis and anaemia. A poor response to oral colchicine was observed. In contrast, the disease was relatively well controlled with the anti-interleukin-1 drug Anakinra, which was started on the suspicion of cryopyrin-associated periodic syndrome (CAPS). TGP did not detect any pathogenic germline variant in any of the genes causing monogenic AID. However, a specific analysis for post-zygotic variants identified the unreported c.1329C>A/p.His443Gln variant at the *NLRC4* gene, with an allele fraction (9.3%) compatible with that expected for variants causing gene mosaicism. Subsequent analyses in the patient's healthy first-degree relatives confirmed its de novo nature. This variant was absent in different databases (gnomAD v4.0, Kaviar) and bioinformatics analyses predicted an impairment in the protein function. Furthermore, a recent article reported this amino acid substitution as pathogenic, albeit as a consequence of a different nucleotide exchange[1]. Altogether, these evidences strongly support the pathogenic classification for the detected *NLRC4* variant.
Conclusions: Our findings demonstrate the novel, postzygotic c.1329C>A/p.His443Gln *NLRC4* variant as the plausible cause of the disease observed in the patient. These novel findings should be considered in the diagnostic evaluation of patients with early-onset AID mimicking CAPS.

Functional analysis of inflammasome mutations in the inflammatory skin disease hidradenitis suppurativa

Ashish Neve[1], Daniel Johnston[2], Desmond Tobin[3], Lynn Petukhova[4]
[1]Conway Institute, Dublin, Ireland; *[2]Trinity Biomedical Sciences Institute, Dublin, Ireland*; *[3]UCD Charles Institute of Dermatology, Dublin, Ireland*; *[4]Ronald O. Perelman Department of Dermatology, New York, United States*

Purpose: Hidradenitis suppurativa (HS) is a common and debilitating inflammatory skin disease with a prevalence between 1 and 4%. The aetiology of HS is poorly understood, and treatment options are limited. Further research into the pathophysiology of HS is required to create better optimised, personalised treatment options and investigating the role of inflammasomes in HS is a promising avenue. Inflammasomes are multiprotein complexes that play a central role in innate immunity. Inflammasome activation is crucial for host defence to pathogens, but also contribute autoinflammatory diseases. Inflammasomes have also been implicated in HS disease pathogenesis as they control the potent inflammatory cytokines IL-1β, which is uniquely overexpressed in HS compared to other autoinflammatory skin disorders. Recent studies provide evidence that HS patients may bear mutations in inflammasome proteins which lead to excessive inflammation.
Methods: We have generated a plasmid library to perform time-of-flight inflammasome evaluation (TOFIE) with an Apoptosis-associated speck-like protein containing a CARD (ASC) reporter cell line system (HEK293T-hASC-GFP) to assess alterations in inflammasome formation.
Results: We identified 25 mutations in 5 inflammasome genes (*NLRP1*, *NLRP3*, *NLRC4*, *MEFV* [Pyrin], *PSTPIP1*) using exome sequencing from 219 HS patients that are predicted to be damaging and/or consequential in HS.
Of these, we have identified a number of mutations which appear to alter inflammasome activation status.
Conclusion: By combining the disciplines of human genetics, immunology and dermatology offers promise in the pursuit of this goal to understand HS pathophysiology. Our study takes genetic insights and probes them with sophisticated molecular biological methods with a view to discovering druggable targets and providing evidence for the need for genomics screening in inflammatory skin disease.

Constitutive phosphorylation of STAT3 hallmarks different subsets of atypical T-bet-expressing B cells in immune mediated disorders.

Francesca La Gualana[1], Giulia Garzi[1], Begi Petriti[1], Matteo D'Ambrosi[1], Francesca Maiorca[1], Alessandra Pinzon Grimaldos[1], Silvia Piconese[1], Massimo Fiorilli[1], Isabella Quinti[1], cinzia milito[1], Marcella Visentini[1]
[1]*Sapienza, University of Rome, Rome, Italy*

Purpose: Expansion of atypical CD21^{low}CD11c^{pos}CD19^{hi}T-bet^{pos} B-cells hallmarks several immunological conditions. Recent studies reported that JAK/STAT-signalling, activated by IL-21 plus IFN-γ, drives *in vitro* and *in vivo* the differentiation of naïve B-cells into CD21^{low}CD11c^{pos}T-bet^{pos} B-cells. *In vivo*, gain of function mutations of STAT3 cause uncontrolled accumulation of them in mice and humans. Our study explored the constitutive and inducible activation of STAT3 in T-bet^{pos} B-cells of normal subjects and of patients with immunological disorders. In vitro generation of T-bet^{pos}/phosphorylated STAT3-positive (pSTAT3^{pos}) B-cells was also investigated.
Methods: Freshly isolated peripheral blood mononuclear cells (PBMCs) of patients and healthy donors were fixed and permeabilized using BD-Phosphoflow Protocol III and intracellularly stained with fluorochrome-conjugated antibodies to T-bet and to STAT3 phosphorylated at Tyr705; this protocol permitted additional staining only of CD19 among relevant markers. CD11c and CD21 were investigated by staining viable cells followed by eBioscience-FoxP3 transcription factor kit treatment and T-bet staining. For *in vitro* experiments, PBMCs of healthy subjects were stimulated for five days with different combinations of CpG, anti-IgM, IL-21 and IFN-γ and stained with the two methods.
Results B-cells could be dissected into T-bet^{neg}, T-bet^{dim} and T-bet^{hi} populations with different levels of CD19, CD11c and CD21 expression. Constitutive STAT3 activation was significantly higher in CD19^{hi}T-bet^{hi} B cells than in T-bet^{neg} or T-bet^{dim} B-cells in patients with common variable immunodeficiency (n=9) or mixed cryoglobulinemia (n=6) and in healthy donors (n=12). Stimulation with IL-21 (15 min) further increased pSTAT3 in CD19^{hi}T-bet^{hi} B-cells whereas IFN-α and IL-6 did not. Five-day stimulation of normal PBMCs with CpG and anti-IgM induced the generation of CD19^{hi}T-bet^{pos} B-cells not expressing pSTAT3. The addition of IL-21 induced the generation of significant proportions of CD19^{hi}T-bet^{hi}pSTAT3^{hi} cells, which was not modified by co-stimulation with IFN-γ.
Conclusions Increasing levels of T-bet and pSTAT3 might identify distinct stages of differentiation of T-bet^{pos}-B-cells, and high constitutive activation of STAT3 hallmarks T-bet^{hi} B-cells in disease and health. IL-21, together with adaptative and innate B-cell stimuli, appears as a major player in the generation of T-bet^{hi}pSTAT3^{hi} B-cells. Further studies will need to address whether targeting JAK/STAT3-signalling could control the accumulation of these cells in autoimmunity.

Deep immune cell profiling of patients with defects in the leptin-melanocortin signaling pathway

Julia Hecker[1], Lisa Ruck[2], Désirée Kunkel[3], Britta Siegmund[1], Peter Kühnen[2], Carl Weidinger[1]
[1]Department of Gastroenterology, Infectiology and Rheumatology, Charité - Universitätsmedizin Berlin, Berlin, Germany; *[2]Department of Pediatric Endocrinology and Diabetology, Charité - Universitätsmedizin Berlin, Berlin, Germany*; *[3]Berlin Institute of Health at Charité - Universitätsmedizin Berlin, Flow & Mass Cytometry Core Facility, Berlin, Germany, Berlin*

The leptin-melanocortin signaling pathway plays an important role in body weight regulation and defects in this pathway can lead to rare monogenic forms of obesity. The most common defects include missense or nonsense mutations in the leptin receptor (*LEPR*), proopiomelanocortin (*POMC*), and the melanocortin-4 receptor (*MC4R*). While the effects of these mutations on the metabolism have been extensively studied, their role in immune regulation remains elusive.
To characterize the impact of the leptin-melanocortin signaling pathway on immune cell composition and function we collected a cohort of three patients with heterozygous mutations in *MC4R*, four patients with homozygous or compound-heterozygous mutations in *LEPR*, and six patients with homozygous mutations in *POMC*, as well as control groups of age- and sex-matched lean and obese individuals. Of note, most patients with *LEPR*, *POMC* and *MC4R* mutations included in this study were receiving the MC4R antagonist setmelanotide for treatment of monogenic obesity. Peripheral blood mononuclear cells (PBMCs) were isolated from all subjects, stimulated *ex vivo* for 4 h with ionomycin/PMA or lipopolysaccharide (LPS) and subsequently stained with a panel of 35 markers and analyzed by mass cytometry. By this, we performed an in-depth immune cell profiling of patients with monogenic obesity and compared the frequency and function of T cells, B cells, NK cells and myeloid cells to the control groups.
In patients with *LEPR* mutations, we detected a reduced frequency of pro-inflammatory IL-8$^+$ IL-6$^+$ TNFα$^+$ monocytes, whereas in patients with *MC4R* mutations we found an increased abundance of B cells. Patients with *POMC* mutations displayed increased frequencies of TNFα$^+$ IFNγ$^+$ CD4$^+$ and CD8$^+$ T cells as well as a significantly increased expression of TNFα and IFNγ in T cells.
Our study provides the first in-depth characterization of the immune cell composition of patients with monogenic obesity and indicate that LEPR, POMC and MC4R are not only important for appetite regulation but also have specific functions in the immune system. Functional assays are currently being performed to validate our findings and investigate underlying mechanisms leading to the observed differences.

Xpr1 deficiency dysregulates CD4+ T-cell responses by impaired calcium signalling and increased mTOR activation

Marion Mengel[1], Benita Kröger[1], Mandy Malle[1], Timur Alexander Yorgan[2], Björn-Philipp Diercks[3], Reiner Mailer[1]
[1]University Medical Centre Hamburg Eppendorf, Institute of Clinical Chemistry and Laboratory Medicine, Hamburg, Germany; *[2]University Medical Centre Hamburg Eppendorf, Institute of Osteology and Biomechanic, Hamburg, Germany*; *[3]University Medical Centre Hamburg Eppendorf, Institute of Biochemistry and Molecular Cell Biology, Hamburg, Germany*

Purpose: Transmembrane receptors control signal transduction during T-cell stimulation. Here, we investigated the function of xenotropic and polytropic retrovirus receptor 1 (Xpr1) for stimulation, proliferation and differentiation of CD4+ T cells.
Methods: We compared thymocyte development and activation marker expression profiles in splenocytes from mice with or without conditional knockout of Xpr1 in CD4+ T cells using flow cytometry, gene expression analysis and enzyme-linked immunosorbent assays. Differential T-cell stimulation pathways in the absence of Xpr1 expression were assessed by phospho-specific immunoblotting of signal molecules. The impact of Xpr1 on proliferation and differentiation of isolated CD4+ T cells under Treg-, Th1-, Th2- and Th17-skewing conditions was analysed by flow cytometry and validated by siRNA-mediated XPR1 knockdown experiments in Jurkat cells. Calcium signalling and nuclear NFAT translocation as well as TCR internalisation was measured by live cell imaging and ImageStream analysis, respectively.
Results: We found that Xpr1 deficiency leads to hyperstimulation of T cells which increases positive and negative selection of thymocytes and enhances the expression of activation markers in the periphery. Moreover, gene ontology analysis revealed that Xpr1 deficient naive T cells readily express a stimulated phenotype upon TCR stimulation and release increased amounts of IL-2. We showed that CD4+ T cells with Xpr1 deficiency are hyperproliferative and display increased mTOR signalling, while ERK phosphorylation is non-sustained in comparison to controls. Consistently, expression of TNF-α and IFN-γ in Th1 cell- and IL-22 in Th17 cell-differentiation conditions increased in Xpr1 deficient CD4+ T cells and XPR1 siRNA-treated Jurkat cells. Mechanistically, we found that Xpr1 deletion promotes TCR internalisation but reduces calcium signalling and nuclear NFAT translocation.
Conclusion: In summary, Xpr1 deficiency promotes T-cell stimulation, proliferation and cytokine expression by altered T-cell stimulation pathways and may represent a potential target to regulate T-cell responses.

AHR spying on bacterial communication and quorum during infection

Pedro Moura-Alves[1;2]
[1]*i3S, Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Porto, Portugal*; [2]*IBMC, Instituto de Biologia Molecular e Celular, Universidade do Porto, Porto, Portugal*

Purpose: The interaction between a bacterial pathogen and its host can be viewed as an "*arms race*" in which each participant continuously responds to the evolving strategies of the other partner. A mechanism allowing bacteria to rapidly adapt to such changing circumstances is provided by density-dependent cell-to-cell communication known as *Quorum Sensing* (QS). QS involves a hierarchy of signaling molecules, which in pathogenic bacteria is associated with biofilm formation and virulence regulation. We hypothesized that if a host sensor can detect and differentiate between bacterial QS molecules and their expression patterns, it will allow hosts to customize their immune responses according to the stage and state of infection.
Methods and Results: Taking advantage of different *in vitro* and *in vivo* (e.g., zebrafish and mouse) model systems, we demonstrate that infected hosts show differential modulation of the Aryl Hydrocarbon Receptor (AHR) signaling throughout a bacterial infection. AHR modulation depends on the relative abundances of different QS molecules, whereby their quantitative assessment enables the host to sense bacterial community densities that may have distinct gene expression programs and infection dynamics. The AHR is able to sense and bind to diverse microbial-derived ligands and regulate different host defence mechanisms, including ligand degradation, expression of pro-inflammatory mediators, immune cell recruitment and bacterial clearance. By sensing infection dynamics, the AHR regulates diverse host defense mechanisms and impacts bacterial clearance. Furthermore, AHR modulated by antibiotics and infection impacts therapeutic efficacy.
Conclusions: We propose that by spying on bacterial *quorum*, the AHR acts as a major sensor of infection dynamics, capable of orchestrating host defense according to the *status quo* of infection. Importantly, AHR modulation and activation status impact antibiotic therapeutic efficacy, potentially driving antimicrobial resistance and microbial adaptation strategies.

PYHIN proteins modulate dendritic cell responsiveness to immune-stimulatory DNA via negative regulation of type I interferon

Craig McEntee[1], Ross W. Ward[1], Sarah Hayes[1], Josephine Douglas[1], Ed Lavelle[1], Andrew Bowie[1]
[1]*Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland*

The mouse PYHIN proteins AIM2 and IFI204, as well as their human ortholog and functional homolog - AIM2 and IFI16 respectively, contribute to innate immunity by sensing pathogen-derived nucleic acids to drive inflammasome activation and type I interferon (IFN-I) production. In addition to their role as innate sensors, PYHIN proteins modulate several cellular processes including differentiation, proliferation, apoptosis and senescence, whilst some also serve as viral restriction factors and direct regulators of cytokine gene induction. To date, the majority of work on PYHINs has been performed in cell lines, monocytes and macrophages, while there has been little investigation of PYHIN function in dendritic cells (DCs). As the crucial bridge between innate and adaptive immunity via their ability to engage in antigen presentation to lymphocytes, a better understanding of the role of PYHIN proteins in DCs may uncover avenues to target these proteins therapeutically to modulate downstream adaptive immune responses.
Using *in vivo* and *ex vivo* systems, we identify PYHIN proteins as negative regulators of DNA-induced responses in DCs, a somewhat surprising finding given their known roles as nucleic acid sensors and regulators of IFN-I transcription. In response to transfected DNA, but not RNA or TLR ligands, DCs from mice lacking the entire PYHIN locus ($ALR^{-/-}$ mice) produce increased IFN-I and pro-inflammatory cytokines, exhibit an enhanced ability to process antigen and also display increased expression of DC maturation markers, including MHC and CD86, on their cell surface. These phenotypes are recapitulated in $Aim2^{-/-}$ cells and mechanistically are due to enhanced activation of the cGAS-STING-TBK1-IRF3 axis. Using co-culture assays we demonstrate that this dysregulated innate immune response influences T cell proliferative and effector immune responses in an IFN-I-dependent manner. Furthermore, in a therapeutic MC38 *in vivo* tumour challenge model, intra-tumoral administration of chitin-derived polymers known to induce cGAS-STING-dependent IFN-I production exhibit markedly enhanced protective efficacy in $ALR^{-/-}$ mice, including improved survival and increased tumour eradication compared to wildtype animals undergoing the same treatment.
Overall, this work identifies PYHIN proteins as negative regulators of DNA-induced responses, particularly IFN-I, and suggests that they may represent promising therapeutic targets to modulate anti-viral and/or anti-tumour immunity.

NLRP3 is a thermosensor that is negatively regulated by high temperature

Wei Wang[1], Chloe McKee[1], Junya Zhang[2], Damien Bertheloot[3], Marcia Munoz[4], Amelia Stennett[2], Shangze Xu[2], Melanie Cranston[1], Bernardo Franklin[3], Michael Rogers[4], Agnieszka Bronowska[2], Rebecca Coll[1]

Inflammation is an essential response to infection and injury, but unregulated inflammation is damaging and must be limited by negative feedback signalling. Inflammasome activation is highly inflammatory, driving both local inflammation and systemic responses like fever. However, our understanding of how inflammasome signalling is negatively regulated is limited. Mutations in the inflammasome sensor NLRP3 cause Cryopyrin Associated Periodic Syndromes (CAPS) that are characterised by recurrent fevers. A subgroup of NLRP3 mutations cause Familial Cold Autoinflammatory Syndrome (FCAS) where, remarkably, NLRP3 activation is triggered by cold temperature. In healthy individuals NLRP3 is activated by a vast number of stimuli and senses perturbations of cytoplasmic homeostasis. As temperature is a fundamental environmental stressor, we hypothesised that NLRP3 inflammasome signalling would be sensitive to increased temperatures.
We investigated the effects of high temperatures on NLRP3 in mouse and human macrophages. Short-term incubation at high fever range temperatures significantly inhibits NLRP3 activation, while secretion of the inflammasome-independent cytokines TNF and IL-6 are much less affected. High temperature blocks NLRP3 inflammasome formation in a transcription-independent manner, and NLRP3 is highly sensitive to temperature-mediated inhibition relative to the NLRC4, AIM2, and NLRP1 inflammasomes. Using cellular and *in silico* assays we show that the effect of high temperature on NLRP3 is protein intrinsic. The activation of NLRP3 is associated with a decrease in the thermal stability of the protein and molecular dynamics simulations identify a peptide in the C-terminal of the FISNA domain (COFI) that undergoes a significant conformational shift at high temperature. The COFI peptide is specific to NLRP3 and is not present in closely related proteins such as NLRP12 or NLRP6. Cellular assays demonstrate that the COFI regulates NLRP3 stability and is required for activation.
Finally, *in vivo* experiments demonstrate that elevation of mouse body temperature negatively regulates LPS-induced inflammatory cytokine production. Our studies reveal that high temperatures associated with fever limit NLRP3 activity in a classical negative feedback mechanism and identify a novel role for NLRP3 as a protein thermosensor.

Toll-like receptor 3 (TLR3) Leu412Phe (L412F): a candidate polymorphism in lung microbiome dysregulation and acute exacerbation in idiopathic pulmonary fibrosis patients

Aoife McElroy[1], Rachel Invernizzi[2], Andrew O'Neill[1], Andrew Bowie[1], Padraic Fallon[1], Toby M. Maher[3], Cory M. Hogaboam[4], Philip Molyneaux[2], Nik Hirani[5], Seamas Donnelly[1;6], Michelle E. Armstrong[1;6]
[1]Trinity College Dublin, Dublin, Ireland; *[2]Imperial College London, London, United Kingdom*; *[3]Keck School of Medicine USC, Los Angeles, United States*; *[4]Cedars-Sinai Medical Center, Los Angeles, United States*; *[5]MRC Centre for Inflammation Research, University of Edinburgh, Edinburgh, United Kingdom*; *[6]Tallaght University Hospital, Tallaght, Ireland*

Purpose: We previously established that the toll-like receptor 3 Leu412Phe (*TLR3* L412F; rs3775291) polymorphism attenuates anti-viral responses and is associated with accelerated disease progression and increased mortality risk in idiopathic pulmonary fibrosis (IPF) patients (*AJRCCM* 2013, 188: 1442). The role of *TLR3* L412F in bacterial infection, lung microbiome dysregulation and associated acute exacerbations (AE) in IPF patients is less well established.
Methods: Here, we investigated the effect of *TLR3* L412F on the IPF lung microbiome using 16S rRNA qPCR and pyrosequencing. The effect of *TLR3* L412F on anti-bacterial TLR-responses of primary IPF lung fibroblasts was quantitated. Hierarchical heatmap analysis was employed to establish bacterial and viral clustering in nasopharyngeal lavage samples from AE-IPF patients.
Results: We observed a significant increase in AE-related death in 412F-variant IPF patients. We demonstrated that 412F-heterozygous IPF lung fibroblasts have reduced anti-bacterial TLR responses to LPS (TLR4), Pam3CYSK4 (TLR1/2), flagellin (TLR5) and FSL-1 (TLR6/1) and have reduced responses to live *Pseudomonas aeruginosa* infection. Furthermore, 412F-heterozygous IPF patients had a dysregulated lung microbiome with increased frequencies of *Streptococcus* and *Staphylococcus spp*.
Conclusion: This study reveals that *TLR3* L412F dysregulates the IPF lung microbiome and reduces the responses of IPF lung fibroblasts to bacterial TLR-agonists and live bacterial infection. These findings identify a candidate role for *TLR3* L412F in viral- and bacterial-mediated AE-death.

SARM1 regulates pro-IL-1β expression in monocytes by an NADase-dependent mechanism

Ryoichi Sugisawa[1], Masahiko Honda[1], Suman Dash[1], Akiyoshi Komuro[1], Takeshi Ueda[1], Andrew Bowie[2], Hitoshi Okada[1]
[1]Department of Biochemistry, Kindai University Faculty of Medicine, Osaka, Japan; *[2]School of Biochemistry and Immunology, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland*

Sterile alpha and HEAT/Armadillo motif-containing protein 1 (SARM1) is a member of the Toll/IL-1R (TIR) domain protein family and is highly conserved in evolution with a role in innate immunity and neuronal cell death in diverse organisms. We recently showed that SARM1 is a regulator of inflammasome responses in murine macrophages, although the detailed role of SARM1 in innate immunity remains unclear. A major recent discovery was that the TIR domain of SARM1 actually has NADase enzymatic activity, and this activity is required for SARM1-dependent axon degeneration in neurons. Furthermore, a wide range of TIR domain protein orthologues in lower organisms, but not mammals, also have NADase activity and this activity has been reported to be essential for innate immune regulation. SARM1 is identified as a unique NADase enzyme among TIR proteins and intracellular proteins. Therefore, this study aimed to determine the role of SARM1 and its NADase enzymatic activity, in innate immune responses in monocytes. Here we show that SARM1 regulates proinflammatory cytokine expression in both an NADase-dependent and -independent manner in monocytes. Using both loss-of-function and gain-of-function cell models, whereby enzymatically active or inactive SARM1 is expressed, we find that SARM1 negatively regulates TLR4-dependent TNF mRNA induction independently of its NADase activity. In contrast, SARM1 negatively regulates IL-1b secretion through both NADase-dependent inhibition of pro-IL-1b protein expression and NADase-independent suppression of the NLRP3 inflammasome and hence of pro-IL-1b processing to the mature secreted form. Interestingly, proteomics analysis revealed that SARM1 NADase-dependent inhibition specifically regulates pro-IL-1b protein expression levels, and other detected pro-inflammatory cytokines and chemokines are not affected. Further, we identified numerous proteins that participate in regulating metabolic pathways, which are decreased by SARM1 NADase dependently, suggesting those proteins require NAD and/or are regulated by SARM1. Thus, our data, reveal multiple mechanisms whereby SARM1 regulates pro-inflammatory cytokines in myeloid cells and shows a distinct NADase-dependent role for SARM1 in innate immunity compared to other TIR proteins.

MicroRNAs released by UV-treated keratinocytes activate pDCs viaTLR7: a model mechanism of type I interferon triggering in psoriasis

Valentina Salvi[1], Carolina Gaudenzi[1], Barbara Mariotti[2], Paolo Bergese[1], Silvano Sozzani[3;4], Flavia Bazzoni[2], Daniela Bosisio[1]
[1]University of Brescia, Brescia; *[2]University of Verona, Verona, Italy*; *[3]Sapienza University of Rome, Rome, Italy*; *[4]IRCCS Neuromed, Pozzilli, Italy*

Purpose: Excessive production of type I interferons (IFNs) by plasmacytoid dendritic cells (pDCs) is the crucial event responsible for autoreactive T cell activation and tissue damage in a subgroup of autoimmune conditions known as "type I IFN-mediated diseases", including systemic lupus erythematosus (SLE) and psoriasis. We previously showed that circulating small extracellular vesicles (sEVs) from SLE patients activate pDCs via TLR7 triggering, suggesting a role for GU-rich microRNAs (miRNAs) as TLR7 endogenous ligands. Here, we used psoriasis as a model condition to investigate if deregulated miRNA secretion may represent a new pathogenic mechanism activating pDCs in type I IFN-mediated diseases.
Methods: Inflamed and UV-treated keratinocytes were used as in-vitro models of psoriatic skin to collect sEVs. Small RNAs contained in sEVs were sequenced and analyzed in terms of upregulated and TLR7-binding miRNAs. sEVs were used to stimulate primary human pDC activation, which was assessed in terms of type I IFN secretion and allogeneic $CD8^+$ T cell activation. The involvement of TLR7 was assessed by using specific inhibitors. An anti-BDCA-2 antibody and inhibitors of sEV production were also used. Psoriatic skin biopsies were collected and used to extract and quantify miRNAs by RT-PCR.
Results: TLR7-activating GU-miRNAs were selectively upregulated in sEVs derived from UV-treated keratinocytes as well as in psoriatic skin lesions. sEVs from UV-treated keratinocytes stimulated TLR7-dependent production of type I IFN and activation of cytotoxic $CD8^+$ T cells by pDCs. This activation was blocked upon triggering of the pDC-inhibitory receptor BDCA-2.
Conclusion: Our results identify miRNAs released by damaged keratinocytes as novel pathogenic mediators of pDC activation in the onset of psoriasis, setting the bases for the identification of new therapeutic targets and options in psoriasis and potentially in other type I IFN-mediated diseases.

Non-canonical proteome derived from transposable elements is a source of functional protein isoforms and cancer neoantigens

Yago Arribas[1], Maxime Rotival[2], Blandine Baudon[1], Pierre-Emmanuel Bonté[1], Guadalupe Suarez[1], Marianne Burbage[1], Benjamin Sadacca[1], Christel Goudot[1], Joshua J Waterfall[1], Montserrat Carrascal[3], Lluis Quintana-Murci[2], Antonela Merlotti[1], Diego Sebastian Amigorena[1]
[1]Institut Curie, Paris, France; *[2]Institut Pasteur, Paris, France*; *[3]Institut d'Investigacions Biomèdiques de Barcelona-CSIC, Barcelona, Spain*

Recent advances in ribosome profiling and mass spectrometry-based proteomics have expanded our understanding of the proteome by uncovering non-canonical proteins. Among these, transposable elements (TEs), which constitute 45% of the human genome and are repetitive sequences dispersed throughout it, play a significant role. TEs can serve as hosts for open reading frames in non-genic regions or, when transcribed, undergo non-canonical splicing events with protein-coding exons. In this study, we explore the role of splicing between exons and TEs as a source of unannotated functional isoforms and tumor-specific neoantigens.
Using transcriptome assembly, ribosome profiling, and mass spectrometry we showed that exonized TEs can be efficiently translated, resulting in a population of low-abundance isoforms that are generally shorter but stable. We characterize their subcellular localization and demonstrate that their functions can diverge from those of canonical isoforms. While many TE-derived isoforms are specific to individual samples, some are shared across different individuals. Moreover, a subgroup of these isoforms is recurrent in lung cancer patients but absent in healthy tissues.
Importantly, we provide evidence using immunopeptidomics that these unannotated isoforms encode HLA-I presented peptides, which are immunogenic and can be recognized by infiltrating CD8 T cells in lung tumors and tumor-invaded draining lymph nodes. Different TE families display varying capacities to encode stable protein isoforms or, on the contrary, short-lived polypeptides that enter the HLA-I processing pathway.
Our findings underscore the evolving nature of TE-derived proteins, which, while exploring new functions, may produce unstable and rapidly degraded products, giving rise to HLA-presented, recurrent, immunogenic, and tumor-specific antigens in cancer patients. Overall, our study emphasizes the clinical relevance of TE-derived antigens as promising targets for cancer immunotherapy and offers insights into the role of non-canonical splicing in TEs during protein evolution.

In human cells, recent advances in genomics and peptidomics challenged the definition of Open reading frames (ORFs) demonstrating that thousands of small ORFs (sORFs) encode polypeptides or microproteins. It has been estimated that 85% of the translation products originate from non-annotated regions of the human genome and mostly from out-of-frame sequences of ORF, so-called alternative ORF (ARF). The latest studies revealed that a significant fraction of peptides presented by MHC molecules is derived from sORFs encoded polypeptides that are specific or overrepresented in tumour cells.
In the context of HIV-1, T cells are also required to maintain the viral set-point and in some donors to naturally control viral replication to undetectable levels, without treatment. Others and our team have previously shown that HIV-specific T cells target peptides presented by MHC molecules derived from HIV ARFs. However, to date, the existence of ARFs in the HIV genome has been only highlighted using indirect approaches such as T cell-based assays and HLA footprint analyses.
In the present study, we defined the translatome of HIV-1 in infected CD4+ T cells. Using ribosome profiling, we provide an unbiased assessment of actively translated viral mRNA sequences in HIV-infected cells and highlight that HIV-1 genomes harbours 98 ARFs corresponding to sORFs and located in the 5' UTR region or overlapping ORF encoding canonical HIV-1 proteins. Using a database of HIV genomes, we show that most ARF amino-acid sequences are highly conserved among clade B and C of HIV-1, with 8 ARF-encoded amino-acid sequences being more conserved than the overlapping ORFs. In addition, using two complementary and independent approaches, detection of ARF-derived peptide-specific T cells in the PBMCs of people living with HIV (PLWH) and direct isolation of MHC-bound ARF-derived peptides using mass spectrometry-based immunopeptidomics, we readily demonstrated that the HIV-1 ARFs encode viral polypeptides capable of inducing broad and potent T cell responses. Remarkably, ARF-derived peptides are recognized by CD8+ and CD4+ T cells from PLWH.
Our findings broaden the spectrum of HIV-1 immunogenic antigens that will help designing efficacious vaccines. It might also reveal the existence of HIV-1 microproteins or pseudogenes.

Engagement of TNF superfamily regulates the formation of the dendritic cell immunological synapse.

Camille Clamagirand[1;2], Jérémie Rossy[1]
[1]Biotechnology Institute Thurgau (BITg), Kreuzlingen, Switzerland; *[2]Graduate School for Cellular and Biomedical Sciences, University of Bern, Bern, Switzerland*

Dendritic cells (DC) activate and prime T cells through the formation of a highly specialised interface called the immunological synapse. Expression of co-stimulatory or inhibitory molecules from the tumour necrosis factor (TNF) superfamily at the DC surface induces crucial signals for T cell differentiation, survival, proliferation, and cytokine production. Reciprocally, TNF superfamily members on T cells regulate DC maturation and survival. Interaction of CD40L, on CD4 T cells, with CD40, on DCs, leads to a new DC functional state, which increases their capacity to prime CD8 T cells. This phenomenon, known as "DC licensing", remains to be completely understood.
TNF superfamily receptors and ligands require a particular spatial organisation to induce signalling. Similarly, the spatial organisation of surface receptors and signalling proteins at the T cell side of the immunological synapse plays a crucial role in T cell activation. However, the spatial distribution of the TNF superfamily at the DC side of the immunological synapse has never been studied.
Here, we investigated the role of TNF superfamily members on the morphology and organisation of DC immunological synapses in the context of interactions with CD4 and CD8 T cells. We showed that interactions of CD40 on DCs with CD40L on CD4 T cells lead to larger DC synapses, where CD40 is concentrated at the centre. This process requires Myosin IIA activity and is necessary for proper DC licensing. We further showed that engagement of CD70 with its receptor CD27 in the context of interaction with CD8 T cells induces drastic changes in the DC synapse morphology and composition, which are even more pronounced in DCs that have been licensed through CD40. Altogether, our data indicate that engagement of TNF superfamily receptors and ligands regulate the DC immunological synapse and by doing so the very nature of their interactions with T cells.

Interferon-α promotes neo-antigen formation and preferential HLA-B-restricted antigen presentation in pancreatic β-cells

Fatoumata Samassa[1], Alexia Carré[1], Zhicheng Zhou[1], Javier Perez Hernandez[1], Christiana Lekka[2], Anthony Manganaro[3], Masaya Oshima[1], Hanqing Liao[4], Robert Parker[4], Barbara Brandao[1], Decio Eizirik[5], Orlando Burgos Morales[1], Amanda Anderson[6], Laurie Landry[6], Farah Kobaisi[1], Sylvaine You[1;7], Maki Nakayama[6], Sarah Richardson[2], Roberto Mallone[1;7]
[1]Université Paris Cité, Institut Cochin, CNRS, INSERM, Paris, France; *[2]Islet Biology Group, Exeter Centre of Excellence in Diabetes Research, University of Exeter Medical School, Exeter, United Kingdom*; *[3]Diabetes Center of Excellence, Department of Medicine, University of Massachusetts Chan Medical School, Worcester, MA, United States*; *[4]Centre for Immuno-Oncology, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom*; *[5]ULB Center for Diabetes Research, Université Libre de Bruxelles, Brussels, Belgium*; *[6]Barbara Davis Center for Diabetes, University of Colorado School of Medicine, Aurora, CO, United States*; *[7]Indiana Biosciences Research Institute, Indianapolis, United States*

Background: Interferon (IFN)-α is the earliest cytokine signature observed in individuals at risk for type 1 diabetes (T1D), but its effect on the repertoire of HLA Class I (HLA-I)-bound peptides presented by pancreatic β-cells is unknown.
Methods: Using immunopeptidomics, we characterized the peptide/HLA-I presentation in in-vitro resting and IFN-α-exposed β-cells.
Results: IFN-α increased HLA-I expression and peptide presentation, including neo-sequences derived from alternative mRNA splicing, post-translational modifications - notably glutathionylation - and protein cis-splicing. This antigenic landscape relied on processing by both the constitutive and immune proteasome. The resting β-cell immunopeptidome was dominated by HLA-A-restricted ligands. However, IFN-α only marginally upregulated HLA-A and largely favored HLA-B, translating into a major increase in HLA-B-restricted peptides and into an increased activation of HLA-B-restricted vs. HLA-A-restricted CD8+ T-cells. A preferential HLA-B hyper-expression was also observed in the islets of T1D vs. non-diabetic donors, and we identified islet-infiltrating CD8+ T-cells from T1D donors reactive to HLA-B-restricted granule peptides.
Conclusion: The inflammatory milieu of insulitis may skew the autoimmune response toward epitopes presented by HLA-B, hence recruiting a distinct T-cell repertoire that may be relevant to T1D pathogenesis.

scATAC-seq in epithelial cells of human and mouse thymic medulla reveals a conserved HIVEP3-dependent program sustaining their maturation and the control of self-antigen expression

Sümeyye Yayilkan[1], Lucas Brusselle[1], Erwan Kervagoret[1], Francine Padonou[1], Jérémie Poschmann[1], Matthieu Giraud[1]
[1]*Nantes Université, Inserm, CR2TI-Center for Research in Transplantation and Translational Immunology, UMR 1064, Nantes, France, Nantes, France*

Promiscuous expression of tissue-restricted self-antigen (TRA) genes in the thymus is crucial to the control of central T cell tolerance and autoimmunity. TRAs are expressed by mature medullary epithelial cells (mTECs) and presented to developing thymocytes, leading to depletion of those that recognize their cognate antigens and to Treg fate direction. Although the autoimmune regulator (AIRE) controls a wide array of TRAs, the induction of a large fraction of them is independent of AIRE and is specific to distinct sets of mTECs according to their level of maturation/differentiation. Here, to uncover the conserved missing transcription factors (TFs) that are implicated in TRA expression in regard to mTEC maturation, we carried out chromatin-accessibility analysis on individual human and mouse mTECs.
The diversity of mTEC chromatin landscapes led to the delineation of clusters that match the known maturation and differentiation states of these cells. TF motif and feature analyses revealed a striking enrichment of HIVEP recognition sites in pre-mature and mature AIRE-positive mTECs. HIVEP motif enrichment showed a similar pattern to the non-canonical nuclear factor NF-kB that was reported to control mTEC development, therefore highlighting a role for HIVEP TFs in mTEC maturation. Remarkably, we found a strong enrichment of HIVEP recognition sites in AIRE-dependent and independent TRA genes, and a conserved expression of the HIVEP3 gene in human and mouse mature mTECs. Thus, these findings point to a role of HIVEP3 in the control of mTEC maturation and TRA expression. In addition, motif enrichment comparison between AIRE-positive mTECs and terminal differentiated "mimetic" mTEC subtypes, revealed a dramatic reduction of HIVEP accessibility in favor of open chromatin for specialized TFs corresponding to extra-thymic cell types, such as HNF4G for microfold mTECs. Importantly, comparative analysis of lineage-specific master regulators revealed the involvement of conserved TFs in human and mouse mimetic mTECs while a few are species-specific.
Together, our data unveils a role for HIVEP3 on mTEC development and TRA expression in pre-mature and mature AIRE+ mTECs, in a mirror image with lineage-specific TFs that are implicated in mimetic mTEC subtypes and specific TRA expression programs.

Autoreactive CD4+ T-cells play a critical role in the pathogenesis of rheumatoid arthritis (RA), based on strong genetic associations at the *HLA-DRB1* locus. Identification of the autoantigens and responding CD4+ T-cells involved in the initiation and progression of RA is essential for a comprehensive understanding the disease process and for developing tolerising immunotherapies. Here, we determined the synovial immune-peptidome from synovial tissue (ST) of ACPA+ patients and assessed CD4+ T cell reactivity to these autoantigens.
Naturally presented HLA-DR-bound peptides were identified in seven ST samples from *HLA-DRB1* shared epitope-positive (SE+) ACPA+ patients using immunoaffinity capture and nUPLC-MS/MS. Expression of genes corresponding to parental source proteins was analysed across 18 synovial cell clusters using AMP1 phase 1 datasets[1]. Responses to ST-peptides in peripheral blood mononuclear cells from ST donor or genotyped-matched patients were analysed by IFN-γ fluorospot or 7-day CFSE proliferation assays. Peptide binding affinities to HLA-DRB1*01:01/*04:01/*10:01 allomorphs were determined by fluorescence polarisation.
274 HLA-DR bound peptides (79 source proteins) were identified in ST, with 39% of peptides identified in all biopsies across all patients, regardless of *HLA-DRB1* alleles. Genes corresponding to source proteins were expressed across distinct ST cell clusters, including fibroblasts, monocytes, and B cells. The number of antigen-specific responses observed in the periphery was variable across autologous/genotyped-matched patients with positive responses ranging from 6% to 56% out of 138 ST peptides tested. The highest frequency responses to a subset of ST-peptides (STAB1, GPNMB, DSG2, IGHG1) were observed in up to 80% of patients. Interestingly one of these GPNMB is enriched in monocytes and negatively correlates with risk of RA. Strong binding to HLA-DRB1*01:01 and HLA-DRB1*10:01 was confirmed for all lead peptides (IC50 range = 0.07-1.13mM). More variable binding was observed for DRB1*04:01 (0.31-13.43mM).
RA T-cells respond to a diverse repertoire of naturally processed peptides in the context of a range of *HLA-DRB1* alleles with parental proteins from a range of synovial resident cell types . The unique characteristics of peptide binding, TCR responses and the state of host immunity appear to dictate CD4+ T cell responses to these novel synovial-derived peptides (see accompanying abstract by Pook et al).

Prostate cancer (PCa) is one of the most common malignancies worldwide. Although available therapeutic options for early-stage PCa are generally efficient, treatment of advanced disease remains a clinical challenge. Epigenetic mechanisms, such as methylation or histone modifications play an important role, not only in in PCa development and progression, but also in tumor immune-evasion. Enhancer of zeste homolog 2 (EZH2) is the catalytic subunit of the polycomb repressive complex 2 (PRC2), involved in transcriptional repression by histone 3 trimethylation (H3K27me3). EZH2 is known to be involved in PCa progression. Moreover, EZH2 was shown to support tumor immune escape through MHC downregulation and PDL1 induction. Natural killer (NK) cells are main innate anti-tumor effectors, targeting tumor cells through an array of activating and inhibitory receptors that interact with cell surface ligands on target cells. A recent study showed that inhibition of EZH2 can result in upregulation of NK ligands on hepatocellular carcinoma. Here, we propose to use CPI-1205, a epi-drug targeting EZH2, to increase PCa sensitivity to NK-mediated killing.
PCa patient tissues immunohistochemistry showed an increase in EZH2 and H3K27me3 expression through disease progression. Inhibition of EZH2 with CPI-1205 in PCa cells resulted in the upregulation of NK cell activating ligands, particularly NKG2D ligands. CUT&RUN revealed H3K27me3 binding at the promoter region of those genes, which was reduced upon CPI-1205 treatment. Importantly, epi-drug treatment of PCa tumor cells co-cultured with NK cells led to an increased NK cell-mediated killing. Moreover, we established a PCa patient-derived explant (PDE) organotypic model accounting for tumor heterogeneity and architecture. Remarkably, CPI-1205 treatment of PCa-derived PDEs also induced NK ligand upregulation, supporting the results in a patient-derived model.
Our findings suggest that EZH2 inhibition with CPI-1205 can modulate PCa tumor cells rendering them more sensitive to NK cell-mediated killing, in both cell lines and a microtumor model, supporting the design of novel epigenetic-based therapeutic approaches for PCa patients.

This study was funded by CI-IPOP (CI-IPOP-27-2016 and EpImmunoPCa_PI143-CI-IPOP-131-2020) and the FCT grant - 022.04809.PTDC; MPC by FCT (CEECINST/00091/2018); FDdR by FCT (UI/BD/154816/2023).

Exploring the interplay between the RNA editing enzyme ADAR1 and innate immune responses in cervical cancer

Marta Kaciulis[1], Stefano Petrai[1], Valentina Tassinari[2], Emanuela Maria Greco[1], Angelina Pernazza[3], Martina Leopizzi[3], Francesca Belleudi[4], Danilo Ranieri[4], Silvia Ruggeri[1], Helena Stabile[1], Marco Cippitelli[1], Cristina Cerboni[1], Alessandra Soriani[1]
[1]Department of Molecular Medicine, Sapienza University of Rome, Rome, Italy; *[2]Department of Experimental Medicine, University of Rome Tor Vergata, Rome, Italy*; *[3]Department of Radiology, Oncology and Pathology, Sapienza University of Rome, Rome, Italy*; *[4]Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy*

Purpose: The main function of ADAR1 enzyme is editing double-stranded (ds) RNAs by deamination of adenosines into inosines. This prevents aberrant activation of innate immune pathways (e.g. IFN-I production) upon sensing of endogenous dsRNAs, which may resemble viral structures. Several tumors exploit ADAR1 to evade immune detection and, indeed, ADAR1 deletion causes a decrease in tumor viability and a global reshaping of infiltrating immune cells. This study aims to investigate the role of ADAR1 in immune evasion mechanisms of cervical cancer (CC), the fourth most common tumor causing death in women. To this end, we are defining the innate lymphoid cells (ILCs) within CC biopsies, and dissecting *in vitro* the impact that ADAR1 manipulation in tumor cells has on the activation of innate lymphocytes, mainly NK cells, via IFN-I signaling and pro-inflammatory cytokines.
Methods and Results: We characterized ADAR1 expression in CC biopsies via immunohistochemistry (IHC), observing higher ADAR1 expression in pre-malignant lesions and in CC tissues compared to controls. In fresh CC biopsies, FACS analysis showed a reduced percentage of $CD7^+$ innate cells in tumors compared to healthy samples. Among these, $CD56^+$ NK cells showed signs of a repressed activity, with a decrease in cytotoxicity markers and an increase in the inhibitory signature. Silencing of ADAR1 in CC cell lines (SiHa, CaSki) reduced cell proliferation and sensitized cells to exogenous IFN-β treatment, as shown by live cell imaging. Additionally, RNAseq analysis of ADAR1-silenced cells demonstrated increased expression of pro-inflammatory cytokines and chemokines (e.g., *CXCL9, CXCL10, CXCL11, IL-12α, IL-15, IL-18, IL-23*), and conditioned supernatants collected from these cells potentiated NK cell responses in terms of proliferation, migration and cytotoxicity. NK cell activation upon ADAR1 silencing in SiHa cells was confirmed in organotypic tissue models.
Conclusion: We provided evidences that ADAR1 expression increases with CC progression and it is accompanied by an inhibited NK cell phenotype in the tumor microenvironment. *In vitro,* ADAR1 silencing caused an enrichment of inflammatory factors able to potentiate anti-tumor NK cell activities. These findings suggest that inhibition of ADAR1 expression and/or editing might represent a therapeutic perspective for cervical and other cancers as well.

Clonal evolution analysis of paediatric lymphoma reveals a highly diversified and continuous cellular status and potential target for precision medicine

Tracer Yong[1], Roberta D'Aulerio[1], Christian Oertlin[1], Julien Record[1], Anna Kwiecinska[2], Fredrik Baecklund[1;3], Lisa S. Westerberg[1]
[1]Department of Microbiology, Tumor and Cell Biology, Karolinska Institutet, Solna, Sweden; *[2]Division of Hematopathology, Karolinska University Hospital, Solna, Sweden*; *[3]Pediatric Unit, Karolinska University Hospital, Solna, Sweden*

Lymphoma is the third most common paediatric cancer (10-15%) worldwide. Although with high survival rate, current treatment for paediatric lymphoma is associated with severe long-term side-effects, including infertility, neurological defects, heart failure and secondary malignancies. Moreover, relapsed lymphoma is associated with drug resistance and poor survival. These issues post an urgent need for precision medicine that specifically target lymphomagenesis and spare normal cells to the largest extend. To reveal mechanisms underlying lymphomagenesis, we combined single cell RNA sequencing (scRNAseq) and immune receptor sequencing (VDJ-seq) on paediatric samples covering non-cancerous reactive lymph nodes (n=7) and the 3 major types of paediatric lymphoma; Burkitt (BL, n=3), Hodgkin (HL, n=4), and T lymphoblastic lymphoma (TLL, n=3). VDJ clonal expansion was used for cancer cell annotation for BL and TLL. To investigate the tumour microenvironment in HL, we integrated patient-paired scRNAseq, spatial transcriptomics (Visium), together with immunohistochemistry (IHC) using fresh frozen tissues. We identified a cycling cluster that mainly consisted of dark-zone germinal centre B cells (DZGCBs) in reactive lymph nodes but harbours cancer cells from the BL and TLL samples, suggesting that the highly proliferative programme normally used by DZGCB cells is important for lymphomagenesis. Based on VDJ-seq, we identified single- hyperexpanded lymphoma clones in each BL and TLL. To our surprise, these lymphoma clones had a diverse transcriptomics profile, with BL sharing programme with germinal centre B cells, memory B cells and plasma cells. TLL underwent a unique transcriptomic shift bridging the T helper cell cluster and germinal center-like cycling cluster, suggesting lymphomagenesis is continuous and organised. Moreover, trajectory analysis showed increased expression of cell cycle genes and cytoskeletal remodelling towards the cycling cluster, indicating the mechanism of this transition. Using a predictive treatment score, we observed inter- and intra-tumoral heterogeneity that explained the efficacy and short-coming of current treatment against BL and TLL. Finally, cell type decomposition with spatial resolved transcriptomics revealed exhausted T cells proximal to Reed-Sternberg cells in HL. More investigation is underway. Taken together, our data reveals that paediatric lymphomagenesis is characterized by its diversified transcriptome which is valuable information to guide novel therapeutics development.

Light induced expression of gRNA allows for optogenetic gene editing of T lymphocytes in vivo

Diego Velasques Pulgarin[1], Nathalie Pelo[1], Lin Ferrandiz[2], Tilen Trselic[1], William Nyberg[3], Gary Bowlin[4], Alexander Espinosa[1]
[1]Karolinska Institutet, Stockholm, Sweden; *[2]Institut de Biologie Moléculaire et Cellulaire, Strasbourg, France*; *[3]University of California, San Francisco, San Francisco, United States*; *[4]University of Memphis, Memphis, United States*

Purpose: Spatial transcriptomics is revolutionizing our knowledge of cellular states in complex tissues. However, to understand the function of individual genes, we need more precise methods for spatiotemporal gene editing. Recently, optogenetic CRISPR has emerged as a promising method for this, but due to its current shortcomings it has not been broadly implemented. To solve this, we have developed a conceptually new optogenetic platform (BLU-VIPR) allowing for efficient optogenetic CRISPR in vivo based on blue-light induced expression of gRNA.
Methods: The BLU-VIPR optogenetic platform is based on combining a new potent light-responsive transcription factor (VPR-EL222) with ribozyme-flanked gRNAs. The transcription factor VPR-EL222 ensures robust transcription induced by blue light, while the ribozyme-flanked gRNA design ensures precise excision of multiple gRNAs from the resulting mRNA transcript. We demonstrate that this design allows for multiplexed and orthogonal optogenetic gene editing, and simultaneous light-induced expression of gRNAs and proteins (e.g. fluorescent reporters), making the system very versatile. Since the light-induced gRNAs can be combined with different Cas proteins off-the shelf, the BLU-VIPR platform allows for optogenetic control of different CRISPR functionalities.
Results: Using BLU-VIPR in cells *in vitro* we achieved optogenetic Cas9 mediated knockouts, optogenetic CRISPR activation and optogenetic base editing. Since BLU-VIPR is compact and genetically encoded, we could deliver it to primary T cells using viral vectors. Indeed, after transduction of $Cas9^{+}$ T cells with BLU-VIPR retrovirus, followed by adoptive transfer into $TCRb^{-/-}$ mice, we were able to achieve site-specific optogenetic knockouts in T cells *in vivo*.
Conclusion: We have for the first time achieved optogenetic gene editing of T cells in vivo, thus paving the way for spatiotemporal dissection of immune responses in vivo with high precision.

Hypomethylating agents (HMA) and histone deacetylase (HDAC) inhibitors, also referred to as epigenetic modifying therapies, have shown promising results in the treatment of acute myeloid leukemia (AML). Recent data point to an immunological mode of action suggesting that HMA-induced gene expression of endogenous retroviral element (ERV)-encoded promoters and various cancer/testis antigens (CTA) might result in the presentation of novel peptides on human leukocyte antigen (HLA) molecules. Thus, we investigated the impact of the DNA methyltransferase inhibitor decitabine (DAC) and the HDAC inhibitor vorinostat (VOR) on the immunopeptidome of AML cell lines and primary AML cells to evaluate novel treatment-induced antigens as targets for combinatorial T-cell based immunotherapies.
Implementing label-free quantitation mass spectrometry, we assessed HLA class I and II peptide presentation of (i) AML blasts of patients treated *in vivo* with DAC (n=3), or (ii) primary AML samples (n=7), and (iii) AML cell lines (n=3), after *in vitro* treatment with DAC, VOR, or a combination of both. In total, 612,763 HLA class I binders and 398,435 class II presented peptides were identified with 69,467 and 68,519 unique identifications, respectively. A comparative analysis of treated samples with respective untreated controls revealed 13,951 treatment-exclusive HLA class I binders and 17,330 treatment exclusive HLA class II peptides. Overlap analysis of these HLA class I binders with published benign samples (n=332) and untreated AML samples (n=47) revealed that 57% (7,950) of treatment-exclusive peptides were not priorly identified on benign or untreated samples, suggesting that these HLA ligands were induced upon treatment. Moreover, HLA ligands from several CTA (ATAD2, KI20B, PRAME) were found to be exclusively presented after epigenetic modifying therapy. Integrating mass spectrometry-based immunopeptidomics with genome-wide CpG methylation screening, and deep short- and long-read RNA sequencing technologies followed by reference-guided transcriptome assembly, further revealed treatment-induced HLA-ligands from canonical proteins as well as novel open reading frames (ORF).
Our results demonstrate that epigenetic therapies modify the immunopeptidome of primary AML cells by induction of treatment-exclusive novel HLA ligands, that will be further evaluated for their eligibility as targets for immunotherapeutic approaches.

Lurbinectedin-induced transcriptional reprogramming: a pathway to sensitise SCLC to immunotherapy

Joan Russo-Cabrera[1], Santiago Ponce-Aix[1], Patricia Cozar[1], Alicia Luengo[1], Alejandro Navarro[2], María de los Reyes Bernabé[3], María Eugenia Olmedo[4], José Manuel Trigo[5], Jon Zugazagoitia[1], Luis Paz-Ares[1;6], Itziar Otano[1;6]
[1]H12O-CNIO Lung Cancer Clinical Research Unit, Health Research Institute Hospital 12 de Octubre (i+12)/Spanish National Cancer Research Center (CNIO), Madrid, Spain; *[2]Hospital Universitario Vall d'Hebron, Medical Oncology Department, Barcelona, Spain*; *[3]Hospital Universitario Virgen del Rocío, Medical Oncology Department, Sevilla, Spain*; *[4]Hospital Universitario Ramón y Cajal, Medical Oncology Department, Madrid, Spain*; *[5]Hospital Universitario Virgen de la Victoria, Medical Oncology Department, Málaga, Spain*; *[6]Spanish Center for Biomedical Research Network in Oncology (CIBERONC), Madrid, Spain*

Background: For decades, platinum-based chemotherapy plus etoposide (ChT+E) has remained unchallenged at the first-line treatment for extensive-stage-SCLC (ES-SCLC), that is, until the introduction of immune-checkpoint blockade (ICB) anti-PD-L1. ChT+E susceptibility of SCLC relies on the high genomic instability observed in SCLC, further increased by ChT+E and surpassing DNA Damage Repair (DDR) capabilities. In the context of DNA damage and cell-intrinsic immunity, the addition of ICB improves the response of SCLC to ChT+E through tumour immunogenicity. Although initially responding to treatment, almost all patients relapse within the first 6 months, leading to limited options at second-line treatment, Lurbinectedin (LUR) among them. While LUR acts by degrading RNA polymerase II and, therefore, inhibiting transcription, it also causes DNA damage synergising with ICB. 2SMALL is a phase 1/2 study assessing the safety, tolerability and efficacy of LUR plus atezolizumab (ATZ) as second-line treatment for ES-SCLC.

Methods: 2SMALL Phase-I was a dose exploration trial combining increasing doses of LUR plus a fixed dose of ATZ every 3 weeks. The study endpoints included the safety profile and recommended dose for LUR, as well as, Objective Response Rate (ORR), Progression-Free Survival (PFS) and Overall Survival (OS). Pre-clinically, efficacy of LUR plus anti-PD-L1 mAb was evaluated in vivo in a syngeneic immunocompetent mice model for SCLC (Rb1-/-Trp53-/-), and several SCLC cell lines and PDX-derived-spheroids.

Results: LUR+ATZ was well tolerated, without unexpected toxicities. ORR were observed in 16/24 patients, including: 3/24 Complete Responses; 13/24 Partial Responses; 5/24 Stable Disease; and 3/24 Progressive Disease. Median PFS was 4.7 months (3.37-7.4) and median OS 14.5 months (9.5-23.4). In pre-clinical in vivo experiments, LUR+anti-PD-L1 achieved tumour rejection in 16/28 mice, from which 13/16 mice were protected against tumour-rechallenge. We observed that LUR increases expression of the Antigen Processing and Presentation (APP) machinery, activates IFN type-I signalling and promotes immune infiltration when combined with anti-PD-L1. Furthermore, anti-tumour effect of LUR+anti-PD-L1 was mainly mediated by CD8+ T lymphocytes.

Conclusions: LUR+ATZ anti-tumour activity is remarkable in both patients and pre-clinical in vivo experiments. Our results show effective tumour-activating IFN type-I, which increases immunity against tumours and provides the rationale to combine LUR with ICBs.

Bacterial nanoparticles as a novel platform for personalized cancer vaccines

Thomas van den Brekel[1], Sanne Duinkerken[1], Laura Kruijssen[1], Katarina Olesek[1], Eleonora Nardini[1], Magali Coccimiglio[1], Sjoerd Schetters[2], Wouter Jong[3], Joen Luirink[4], Yvette van Kooyk[1]
[1]Amsterdam University Medical Centers, Amsterdam, Netherlands; *[2]Lambrecht Unit – UIMI, University of Gent, Gent, Belgium*; *[3]Abera Bioscience AB, Uppsala, Sweden*; *[4]Vrije Universiteit, Amsterdam, Netherlands*

Contemporary vaccine formulations face challenges related to production time, costs, stability and storage, requiring stringent conditions. Bacterial derived nanoparticles called protein bodies (PBs) exhibit these properties and offer other, improvements such as high antigenic multiple epitope content, low toxicity and relative resistance to proteases. Therefore PBs are optimally suited as an antigenic vaccine formulation for T cell responses to linear epitopes, enhancing immune responses in cancer immunotherapy. We have demonstrated that *in vitro* PBs enhance DC maturation and drive strong CD8+ and CD4+ T cell responses *((Schetters et al. (2020))*. To eliminate bacterial derived endotoxin that would trigger TLR4, we generated the PBs in a *ClearColi BL21*, a LPS free bacterial strain of *E.Coli* to investigates it's *in vivo* efficacy. We generated PBs expressing the ovalbumin (OVA)-derived OT-I and OT-III epitopes and injected in a prophylactic and therapeutic vaccination setting using the B16OVA mouse melanoma model. Interestingly, the PB vaccinated mice showed no tumor outgrowth, compared to full tumor outgrowth observed in unvaccinated counterparts. Even in mice injected with PB vaccines after 7 days when tumor growth was present complete tumor eradication was observed, further emphasizing their efficacy. Although depletion of CD8 T cells restores tumor growth implicating an important role for the induction CD8+ T cells by PB vaccine, the percentage of antigen-specific CD4+ and CD8+ T cells remained relatively low compared to the soluble equivalent that did not eradicate the tumor as efficiently as PBs. These findings hint to additional immune players that orchestrate the efficacy of the anti-tumor response induced by PBs. Taken together, PBs show promising results for the use of effective therapeutic cancer vaccine formulation that triggers a full repertoire of immune players.

In-situ vaccination with Flt3L elicits immune responses against hepatocellular carcinoma and improves checkpoint blockade therapy

Isabella Lurje[1], Wiebke Werner[1], Ajay-Mohan Mohan[2;3], Nicola Beindorff[2], Natalie Nestel[1], Justus Pein[4], Anne Schlutt[1], Yaroslava Shevchenko[1], Paul Horn[1;5], Kirsten Reers[1], Alix Bruneau[1], Deniz Uluk[4], Georg Lurje[4], Henry Marsh[6], Michael Yellin[6], Frank Tacke[1], Linda Hammerich[1]
[1]Department of Gastroenterology and Hepatology, Campus Charité Mitte, Campus Virchow Klinikum, Charité-Universitätsmedizin Berlin, Berlin, Germany; *[2]Berlin Experimental Radionuclide Imaging Center, Charité - Universitätsmedizin Berlin, Berlin, Germany*; *[3]Department of Nuclear Medicine, Charité - Universitätsmedizin Berlin, Berlin, Germany*; *[4]Department of Surgery, Campus Charité Mitte, Campus Virchow Klinikum, Charité-Universitätsmedizin Berlin, Berlin, Germany*; *[5]Berlin Institute of Health at Charité – Universitätsmedizin Berlin, BIH Biomedical Innovation Academy, BIH Charité Digital Clinician Scientist Program, Berlin, Germany*; *[6]Celldex Therapeutics, Inc., Hampton, NJ, United States*

Purpose: Hepatocellular carcinoma (HCC) is a highly aggressive tumor developing in chronic inflammatory liver diseases. Current systemic therapies, including checkpoint blockade, insufficiently inhibit tumor progression. In a pre-clinical mouse model, we developed an *in-situ* vaccine (ISV) to recruit and activate classical dendritic cells type 1 (cDC1) and enhance cross-presentation of tumor-associated antigens to cytotoxic T lymphocytes.
Methods: Male C57BL/6J mice received a single injection of N-nitrosodiethylamine (DEN), followed by either repeated intraperitoneal carbon tetrachloride (CCl_4) injections or Western Diet feeding, inducing orthotopic HCC in liver fibrosis. The *ISV* combined systemic injections of the DC growth factor Fms-like tyrosine kinase 3 ligand (Flt3L), a Fas agonist, and two adjuvants (agonistic anti-CD40 or polyIC). ISV treatment was also combined with checkpoint blockade. Immune responses were evaluated using spectral flow cytometry, multiplex immunofluorescence and bulk RNA. Tumor growth was monitored with longitudinal magnetic resonance imaging. Signatures of cDC1 were explored in the human TCGA-HCC patient dataset.
Results: Injections of Flt3L significantly expanded intratumoral and systemic cDC1 numbers. Injection of both adjuvants induced upregulated markers of antigen presentation and co-stimulation on Flt3L-recruited cDC1s, indicating maturation of cDC1. Mice bearing fibrosis-related HCC and treated with ISV displayed significantly delayed tumor growth and prolonged survival compared to non-vaccinated animals. While depletion of CD4+ T cells and NK cells did not impair vaccine efficacy, CD8+ T cell depletion abrogated the tumor-controlling effect of the ISV, resulting in similar survival and largest tumor diameters as non-vaccinated mice. Due to high checkpoint expression in the immune microenvironment (mainly PD-1 and PD-L1), ISV was combined with anti-PD1 and anti-PD-L1 treatment. While HCC tumors did not respond to checkpoint monotherapy, the combination of ISV with anti-PD1 significantly prolonged median survival. This effect was synergistic as survival was increased compared to ISV alone. In the human TCGA-HCC dataset, a higher expression of cDC1 signatures were associated with adaptive immune response signatures and higher progression-free 24-month survival, independent of tumor stage, grading, and resection status.
Conclusion: Flt3L-based in situ vaccination elicits anti-tumor immunity and induces response to checkpoint blockade in previously unresponsive HCC tumors.

Polymeric nanoparticles targeting conventional type 1 dendritic cells enhance antigen cross-presentation and CD8+ T cells by activation of the non-canonical inflammasome

Jorge Huete-Carrasco[1], Natalia Muñoz-Wolf[1], Ross W. Ward[1], Ed Lavelle[1]
[1]*Adjuvant Research Group, School of Biochemistry and Immunology, Trinity College, Dublin 2, Ireland, Dublin, Ireland*

Vaccination is considered one of the major milestones in modern medicine, facilitating the control of life-threatening diseases, even reaching eradication in case of smallpox. Subunit vaccine antigens require the addition of adjuvants to enhance immunogenicity and influence the nature of the adaptive immune response induced. In this context, there is a need for adjuvants that more effectively promote cell-mediated immune responses, particularly $CD8^+$ T cells. Additionally, resolving the mechanisms underlying adjuvant and vaccine mode of action is critical to provide a basis for rational adjuvanted vaccine design and allow tailoring of adjuvanted vaccines for specific diseases and target groups.
The size of particulate adjuvants has emerged as a key parameter influencing adjuvanticity. Previous work from the Lavelle lab with polymeric particles demonstrated that particle size was instructive in the induction of $CD8^+$ T cell responses by polystyrene and poly D,L-lactic-co-glycolic acid particles. We explored the mechanism of action of these adjuvants and identified a critical role of components of the non-canonical inflammasome- ROS, caspase 11 and gasdermin D (GSDMD), in the mediation of particle-induced cell-mediated immunity. Furthermore, we demonstrated that antigen-specific $CD8^+$ T cells and IFN-y responses were dependent on type 1 conventional dendritic cells (cDC1) *in vivo* by using Batf3 deficient mice and results were confirmed using a cDC1-$CD8^+$ *in vitro* co-culture model. In addition, 50nm polymeric nanoparticles with ovalbumin (OVA) were used as a therapeutic vaccine in mice bearing either MC38 colon adenocarcinoma (hot tumour) or B16F10 melanoma (cold tumour) expressing OVA. Vaccination led to a significant reduction in tumour growth and increased probability of survival. Furthermore, this polymer-based particulate vaccine adjuvant outperformed the effect of anti-PD1 monotherapy in both tumour models, and demonstrated a synergistic effect when both therapies were used together in B16F10 tumours. Therefore, this work enhances our understanding of the mechanism of action of 50nm polymeric particulate adjuvants having a direct application in prophylactic vaccines against intracellular pathogens, as well as therapeutic cancer vaccines.

MV130 as a new innate memory-based mucosae vaccine against cancer

Luna Cordeiro Minute[1], Laura Bravo Robles[1], Pablo Mata Martinez[1], Francisco Javier Cueto[1], Jaime Fernandez-Pascual[1], Eduardo Lopez-Collazo[1], Carlos Del Fresno[1]
[1]*IdiPaz-Hospital Universitario La Paz, Madrid, Spain*

Trained immunity (TI), known as innate immune memory, is described as the ability of innate immune cells of responding to a homologous or heterologous secondary challenge with enhanced proinflammatory response upon the exposure to certain TI-inducing stimuli. The most studied TI-inducers are the BCG vaccine and the fungal β-Glucan. However, BCG and β-Glucan have limitation for their clinical application. MV130 is a mucosal immunotherapy based on heat-inactivated bacteria indicated for recurrent respiratory infections. MV130 was demonstrated to induce TI in pre-clinical models against respiratory viruses included Sars-Cov2 or *C. albicans*. However, the role of MV130 in conferring cancer protection is unexplored. We observed that C57BL/6J mice subjected to the prophylactic regimen of six doses of intranasally administered MV130 exhibited delayed tumor development and improved tumor control against subcutaneously injected LLCs (Lewis Lung Carcinoma) cells, administered seven days after the last immunization. The protection is maintained with a higher tumor burden or when tumor cells are injected 60 days after the last MV130 administration, indicating that MV130 induces a long-lasting memory, which is a main feature of TI. Furthermore, MV130-treated mice, present protection against orthotopically lung tumors and melanoma spontaneous lung metastasis as well as a pro-inflammatory lung microenvironment. Upon *ex vivo* heterologous restimulation of lung innate populations, alveolar macrophages and neutrophils presented an enhanced proinflammatory phenotype (TNF production), revealing a potentiated response due to TI. Moreover, chromatin remodelling by ATAC-seq shows the training effect on an epigenetic level. In conclusion, our data indicate that MV130 induces TI in innate immune cells by potentiating a proinflammatory antitumor response, paving the way for the induction of innate memory through mucosae as a novel cancer immnunotherapy strategy.

Can immunotherapies engaging the CD3/γδ TCR complex help reactivate exhausted γδ T cells in a tumoral microenvironment?

Morgane Chauvet[1;2;3], Emmanuel Scotet[1;3], Dorothée Bourges[2]
[1]Nantes Université, Inserm UMR1307, CNRS UMR 6075, Université d'Angers, CRCI2NA, Nantes, France; *[2]SANOFI R&D, Vitry-sur-Seine, France*; *[3]LabEx IGO « Immunotherapy, Graft, Oncology », Nantes, France*

Recent successes of cancer immunotherapies have generated a renewed interest in understanding the contribution of gamma delta T cells (γδ T cells) in the immune response against cancer. γδ T cells have been initially described to play a broad role in responses against infections and cancer, making them good candidates for specific redirection against tumor cells. Human γδ T cells and conventional alpha beta T cells (αβ T cells) share some common features such as the expression of a TCR linked to the CD3 signaling complex, composed of three dimers (CD3δε, CD3γε, ζζ). However, they differ regarding the molecular mechanisms involved in CD3 engagement and activation, paving the way for potential strategies to activate specific subpopulations of T cells. Targeting CD3-based activation processes could represent a solution to activate γδ T cells more specifically and avoid high toxicity and lack of specificity that are triggered in many immunotherapeutic strategies (eg. bispecific antibodies). However, as other types of immune cells, γδ T cells undergo a state of exhaustion while in the tumoral microenvironment. This exhaustion can be caused by several factors, such as TCR overstimulation, immunosuppressive cytokines (TGF-β) or hypoxia for example. Here, we show that human γδ T cells exhibit a higher sensitivity for CD3ε-mediated activation, as compared to αβ T cells. We compare three different types of exhaustion protocols, either by TCR over-stimulation, TGF-β cytokine treatment or co-culture with Zoledronate-activated SKOV3 tumor cells. In each case, we assess the exhausted phenotype and the reactivation potential of γδ T cells in presence of anti-CD3 mAbs and we show that CD3 stimulation can be a trigger to overcome exhaustion and regain anti-tumor effector functions. Mastering the CD3-based activation processes of γδ T cells could help us design new immunotherapies. This project has been funded by Sanofi Aventis R&D.

Enhancing oncolytic virus-infected cellular vaccines with tumor-rejecting lymphocyte transfer for the immunotherapy of triple-negative breast cancer

Guillaume St-Cyr[1], Lauren Daniel[1], Hugo Giguère[1], Lee-Hwa Tai[1;2]
[1]*Immunology and Cellular Biology, Faculty of Medicine and Health Sciences, University of Sherbrooke, Sherbrooke, Canada*; [2]*Research Centre of the University of Sherbrooke Hospital Centre (CRCHUS), Sherbrooke, Canada*

Triple-negative breast cancer (TNBC) is a highly heterogeneous disease characterized, in part, by its relative immunogenicity and propensity for recurrences. This can be targeted therapeutically through personalized immunotherapies capable of eliciting a durable antitumor immune response. To this end, we are developing an oncolytic virus (OV)-infected cell vaccine (ICV) comprised of irradiated cancer cells infected by the oncolytic vesicular stomatitis virus (VSVd51). We have previously shown that the ICV can stimulate antitumoral immune responses and improve survival in a preclinical murine model of TNBC. We have also highlighted the critical importance of CD8+T cells for the survival of vaccinated mice. However, despite the ICV inducing a systemic antitumor immune response, complete responses (CR) are still limited to 50%. Therefore, we hypothesized that enhancing antitumor T cell immunity through optimal amplification *ex vivo*, away from the immunosuppressive tumor microenvironment, followed by adoptive transfer can augment rates of CR.
Thus, we explored the immunostimulatory capacity of the ICV *ex vivo* and sought to convert peripheral blood immune cells into tumor-rejecting lymphocytes (TRL) to provide a more convenient and powerful alternative to tumor-infiltrating lymphocytes. To accomplish this objective, we established a protocol for TRL activation and expansion relying on the co-culture of peripheral blood T cells with the ICV.
Preliminary data reveal the generation of a mixed population of T cells, including central memory T cells, which are associated with improved *in vivo* persistence. Additionally, CD8+T cells and the expression of granzyme B were increased suggesting enhanced cytotoxicity, as validated by tumor-killing assays. Tumor-reactivity assays demonstrated that TRL cultures can be activated to express CD137, IFNg and PD1 upon stimulation with TNBC cells. These findings suggest that TRL cultures are enriched for tumor-reactive T cells. Future studies will evaluate their efficacy in xenograft mouse models.
TRL and therapeutic cancer vaccines, together, have the potential to induce a strong and curative antitumor immune response that deter disease recurrence. Our research aims to translate such personalized immunotherapies into future clinical applications for patients with TNBC.

Research funded by a grant from the CIHR project grant and CCS emerging scholar grants.

MafB regulates monocyte-to-macrophage differentiation and imprints tissue resident macrophage identity and function

Domien Vanneste[1;2], Wen Peng[1;2], Joan Abinet[1;2], Malik Hamaïdia[3;4], Alexis Balthazar[5], Alexandre Hego[6], Philippe Compère[7;8], Bénédicte Machiels[5], Thomas Marichal[1;2;9]

Purpose: The transcription factor MafB is specifically expressed by monocytes/macrophages. It has been shown that MafB restricts Csf1-dependent proliferation in myeloid progenitor cells, as well as the self-renewal ability of differentiated macrophages. Recently we discovered that monocytes were able to first proliferate in a vacant tissue niche in a Mafb-restricted way before undergoing differentiation into one or the other subset of lung interstitial macrophages. To further understand resident tissue macrophage (RTM) development and homeostasis, it is fundamental to investigate the role of MafB in RTM differentiation, identity and function.
Methods: By applying intracellular flow cytometry, we examined the expression of MafB in blood monocytes and RTM across different tissues. We created *Lyz2*^{Cre}*Mafb*$^{fl/fl}$ mice with myeloid-restricted *Mafb* deficiency and used a combination of bone marrow competitive chimeras, high-dimensional flow cytometry, bulk RNA-sequencing (RNA-seq) and single-cell RNA-seq to study the effect of Mafb knock-out on macrophage differentiation and function, *in vitro* and *in vivo*. To identify transcriptional programs directly regulated by MafB, we performed CUT&RUN on bone marrow monocyte-derived macrophages (BMDM) and blood monocyte-derived macrophages (MDM) from mouse and human, respectively.
Results: MafB was found to be highly expressed in RTM across different tissues as compared to blood monocytes and MafB expression was found to be upregulated along the monocyte-to-macrophage differentiation axis. The *in vitro* and *in vivo* macrophage differentiation was heavily affected in *Lyz2*^{Cre}*Mafb*$^{fl/fl}$ mice as compared to littermate controls. In *Mafb* knock-out macrophages, the expression of monocyte signature genes increased, while the expression of macrophage signature genes decreased. In addition, the expression of tissue specific identity genes was reduced in *Mafb* deficient RTM. We identified MafB binding sites in promoters and close enhancers of many genes in a gene set that has been shown to be upregulated during macrophage differentiation. Moreover, MafB was also found to directly regulate core macrophage identity genes.
Conclusion: MafB plays a key role in macrophage differentiation by regulating conserved core transcriptional programs that imprint macrophage identity and function.

Pentose Phosphate Pathway derived NO orchestrates macrophage immunometabolic responses through TCA cycle crosstalk; a target for Mycobacterium tuberculosis immune evasion

John McGrath[1], Anna Ledwith[1], Cian Horneck Johnston[1], Frederick Sheedy[1]
[1]*Trinity Biomedical Sciences Institute, Dublin, Ireland*

Background: Glycolytic metabolism has emerged as a key feature in macrophage antimicrobial responses against Mtb infection. Recent work within our group demonstrates a Mtb mediated deceleration of macrophage bioenergetic metabolism, a process dependent on upregulation of anti-inflammatory microRNA-21 and subsequent targeting of glycolysis. Here, we further characterise this immuno-evasive phenomenon as means to regulate PPP-derived NO and subsequently target TCA cycle metabolism. NO is a soluble endogenous gas produced by iNOS and proposed to have direct bactericidal activity. However, this model is poorly understood and moreover dismissed in the context of Mtb infection of macrophages, with traditional dogma suggesting an inability of human macrophages to generate substantial NO in response to infection when compared to murine models. Recent evidence challenging this perspective in addition to the mycobactericidal capacity of NO necessitates a more comprehensive view of processes influenced by NO, including the orchestration of metabolic reprogramming.
Results/Methods: Isotope tracing models demonstrate that upon infection of both human and murine macrophages, Mtb specifically represses host-cell glycolysis and reroutes central carbon metabolism towards induction of a cyclic-PPP. This in turn promotes iNOS derived NO production through PPP mediated accumulation of enzyme co-factor, NADPH. Further models working to supplement and sequester cellular NO reveals this Mtb mediated manipulation as means to target TCA cycle metabolism in addition to further promoting PPP activity through positive feedback. Here, we find through inhibition of TCA cycle ACO2 and generation of isocitrate, Mtb derived NO results in compensatory upregulation of IRG1 and generation of itaconate, a metabolite facilitating reduced secretion of anti-mycobacterial cytokine IL-1β, thus enhancing Mtb survival. Exogenous supplementation of itaconate, in addition to use of *irg1*$^{-/-}$ models further highlight the ability of this metabolite to regulate cellular NO levels and consequently influence bacterial survival by means of regulating IL-1β.
Conclusion: Mtb demonstrates a unique capacity to evade innate responses, particularly that of its primary target cell of infection – the macrophage. Here, we describe a novel mechanism of metabolic crosstalk between PPP and TCA cycle activity, coordinated through cellular NO. Furthermore, we describe how Mtb employs this pathway as a means to elude host immunometabolic responses.

CXCR3 mediates CD49a+ NK cell differentiation in colorectal cancer liver metastasis by promoting tissue residency in supportive macrophage niches

Eleonora Russo[1], Chiara Di Censo[1], Chiara D'Aquino[2], Luana Tomaipitinca[1], Giuseppe Sciumè[1], Giovanna Peruzzi[3], Valerio Licursi[4], Mattia Laffranchi[1], Francesca Sozio[1], Silvano Sozzani[1;5], Stefano Garofalo[6], Cristina Limatola[6], Angela Santoni[1;5], Giovanni Bernardini[1]

Purpose: NK cell phenotype and activity in tumors is highly context-specific and both dysfunctional CD49a+ ILC1-like and preserved anti-tumor phenotypes have been described so far. This study aims at dissecting the mechanisms governing type 1 innate lymphoid cells (ILCs) function in metastasis engraftment and progression by investigating their phenotypic plasticity and behaviour in a metastatic model of colorectal cancer (CRC).
Methods and Results: By taking advantage of a MC38-induced CRC mouse model of liver metastasis, we show that NK cell/ILC1 are involved in controlling hepatic metastasis formation. We report poor infiltration of ILC1 and expansion of a CD49a^{+} NK cell population among metastasis-infiltrating (MI) lymphocytes. CD49a+ NK cells displayed preserved killing capacity against CRC cells, while other MI NK cell subsets were functionally impaired. By bulk RNA-seq of sorted type 1 ILCs and by multiparametric FACS analysis, we show that CD49a+ NK cells have increased expression of several molecules associated to immunoregulation and tissue retention, including PD-L1, CD73 and CD69, CXCR3.
In addition, we found that a population of CXCL9-producing F4/80^{hi} macrophages expands in metastatic nodules and promotes CD49a+ NK cell expansion through TGF-β. Anti-CSF1R antibody-mediated depletion of metastasis-associated macrophages (MAM) resulted in a marked reduction of CD49a+ NK cell metastasis infiltration, supporting an *in vivo* role for MAM in shaping NK cell phenotype. Along with this, an alternative SL4-induced liver metastasis model showed failed accumulation of CXCL9+ macrophages mirrored by a reduced generation of CD49a+ NK cells.
Finally, conditional deletion of Cxcr3 in NKp46+ cells markedly affected CD49a+ NK cell differentiation in MC38-induced metastasis, indicating that CXCR3 is required for correct NK cell localization in macrophage-supporting niches. Correspondingly, Ncr1ΔCxcr3 mice showed accelerated metastasis formation, indicating that CXCR3 expression by NKp46+ cells has a protective role.
Conclusion: Our data indicates that MI NK cells acquire ILC1-like features under the effect of metastasis environmental factors. Deficiency in accumulation of CD49a+ NK cells in Ncr1ΔCxcr3 mice suggests that CXCR3 plays a major role in promoting NK cell metastasis infiltration and/or in their crosstalk with MAM, thus influencing NK cell conversion and impacting liver metastasis development.

Myeloid type i IFN sensing facilitates stress erythropoiesis

Florian Deckert[1;2], Asma Farhat[1;2], Alina Fokina[1], Lisabeth Pimenov[1], Riem Gawish[1], Sylvia Knapp[1]
[1]Medical University of Vienna, Vienna, Austria; *[2]Center for molecular medicine (CeMM), Vienna, Austria*

Infections and inflammation can impair steady-state erythropoiesis and induce alternative extramedullary stress erythropoiesis in organs like liver or spleen. To date, there is limited understanding of how the erythroblastic islands' microenvironment facilitates stress erythropoiesis.
Here, we studied erythropoiesis in the murine spleen upon exposure of mice to the synthetic TLR9 agonist CpG ODN. We sorted myeloid and progenitor cells for single cell transcriptome sequencing (scRNA-seq) and modelled erythroid development by combining RNA-velocity and trajectory inference methods. To functionally determine the role of myeloid type I interferon (IFN) signaling, we challenged $CD169^{cre/+}$ and $LysM^{cre/+}$ $IFNAR^{fl/fl}$ (interferon alpha/beta receptor) mice and analyzed the impact on stress erythropoiesis at different time points.
Exposure to CpG strongly enhanced the transition of pro-erythroblasts towards the erythroblast stage at single cell level. Interestingly, dysregulation of Gata1/2 and altered IFN signaling in pre-erythroblasts explained enhanced erythropoiesis under stress condition. Further, we confirmed that effective stress erythropoiesis required type I IFN mediated activation of pre-red pulp macrophages (pre-RPM) by challenging $CD169^{cre/+}$ $IFNAR^{fl/fl}$ mice with CpG. Strikingly, IFNAR activated pre-RPM expressed the chemokine ligand 2 (CCL2), an agonist of the atypical chemokine receptor 1 (ACKR1) expressed on erythroblasts, which had been shown to be an essential regulator of hematopoiesis. Consequently, we challenged $LysM^{cre/+}$ $IFNAR^{fl/fl}$ mice and confirmed that loss of IFNAR signaling in monocytes strongly reduced CCL2 expression and prevented induction of stress erythropoiesis at day 1 and day 3.
Our results indicate that stress erythropoiesis depends on myeloid IFNAR signaling and uses alternative transcriptional programs compared to steady state erythropoiesis. Early monocyte recruitment enhances erythroblastic island formation and pro-erythroblast expansion while later scavenging of CCL2 by erythroblast ACKR1 might serve as a negative feedback loop to terminate stress erythropoiesis. To further dissect the temporal dynamics of the erythroblast microenvironment, we are currently analyzing a bulk-Seq time course experiment of challenged $IFNAR^{fl/fl}$ and $LysM^{cre/+}$ $IFNAR^{fl/fl}$ mouse with sorted cell type populations (monocyte, pre-RPM, PRM, erythroblasts). We anticipate that our results provide fundamental insights to improve our understanding of anemia of inflammation in the clinical setting.

Mutual immunomodulatory effect of a high-sodium diet and antihypertensive drugs on mouse macrophages

Martyna Cieślik[1], Spencer D. Strobel[1;2], Bernadeta Nowak[1], Krzysztof Bryniarski[1], Katarzyna Nazimek[1]
[1]*Jagiellonian University Medical College, Department of Immunology, Krakow, Poland*; [2]*Geisinger Medical Center, Palliative Care Department, Danville, PA, United States*

Purpose: The development and maintenance of hypertension are associated with chronic systemic inflammation, and both processes drive each other. Additionally, excessive sodium intake triggers both elevated blood pressure and inflammatory processes. Since mechanisms of interaction of hypotensive drugs with the immune system are still not fully understood,
we focused on the investigation of impact of hypertension-associated high-sodium diet and six antihypertensive drugs on the modulation of peritoneal exudate macrophages (PEMs) function in mice.
Methods: Mice, fed since weaning with either standard (STD) or high-sodium diet (HSD), were intraperitoneally administered, for 8 consecutive days, with one of the drugs: captopril (5mg/kg), olmesartan (1mg/kg), propranolol (10mg/kg), carvedilol (5mg/kg), amlodipine (3mg/kg), or verapamil (5mg/kg). Mineral oil-induced PEMs were assessed for secretion
of ROIs (chemiluminescence), NO (colorimetric method) and cytokines (ELISA), surface marker's expression by flow cytometry as well as for phagocytic activity followed by induction of the humoral immune response against corpuscular antigen (SRBC) in vivo. Moreover, diet- and drug-induced modulation of contact hypersensitivity (CHS) response (PEM-induced CHS, adoptively transferred CHS, and actively induced CHS) was determined. Results were statistically analyzed using two-way ANOVA.
Results: HSD elevated both systolic blood pressure and heart rate, however, the effects were modulated by drugs. The assayed medications increased the generation of ROIs and NO secreted by macrophages from STD-fed donors, but they reversed both HSD-induced oxidative burst and enhanced secretion of pro-inflammatory cytokines. Some drugs increased macrophage phagocytic activity and enhanced macrophage-mediated activation of B cells for antibody production. Moreover, the assayed medications augmented macrophage-mediated effector phase of CHS, but suppressed the sensitization phase of cell-mediated hypersensitivity under HSD conditions. In certain circumstances, drugs with similar mechanisms of action, amlodipine and verapamil especially, exerted opposite effects.
Conclusion: Our current findings clearly support reports about high sodium-associated interference with development of hypertension and pro-inflammatory processes, which may be reversed by hypotensive drug treatment. Modulation of Th1- and Th2-dependent immune responses may have important clinical significance due to the additional anti-inflammatory effects of hypotensive drugs in the hypertension-related dysregulation of immune system.

CD109 as a target for lung cancer and tumor-associated macrophages

Tine Haesen[1;2], Maximilian Schinke[1;3], Vanessa Neuhaus[1], Susann Dehmel[1], Mania Ackermann[1;3], Pirjo Laakkonen[4;5], Armin Braun[1], Katherina Sewald[1]
[1]Fraunhofer Institute for Toxicology and Experimental Medicine ITEM, Hannover, Germany; *[2]University of Bielefeld, Bielefeld, Germany*; *[3]Hannover Medical School, Hannover, Germany*; *[4]Translational Cancer Medicine Research Program, Faculty of Medicine, University of Helsinki, Helsinki, Finland*; *[5]Laboratory Animal Centre, Helsinki Institute of Life Science (HiLIFE), University of Helsinki, Helsinki, Finland*

Purpose: Due to oncogenic mutations and resistance development, there is a persistent need for novel targeted therapies to combat lung cancer. The glycoprotein CD109 has been shown to contribute to tumorigenesis and presents an appealing target for anti-cancer therapy. We hypothesize that CD109 supports the M2 macrophage phenotype, and thereby promotes a pro-tumorous micro-environment. Herein, we apply a primary human *ex vivo* setting to reveal the expression of CD109 on tumor-associated macrophages (TAM) and explore the use of RNA therapeutics *in vitro*.
Methods: Expression of CD109 was visualized *ex vivo* in primary human lung tissue (i.e. precision-cut (tumor) lung slices, PCLS/PCTLS) using confocal microscopy. Flow cytometry was applied to determine CD109 expression on macrophages isolated from donor-paired tumor and non-tumorous human lung tissue. Macrophages with pro (M1)- and anti (M2)-inflammatory phenotypes were differentiated from either $CD14^+$ selected monocytes (M1/M2 R&D differentiation kits) or induced pluripotent stem cells (iPSC, M1-IFNg, M2a-IL4), and CD109 expression was confirmed by flow cytometry or whole transcriptome analysis.
Results: Comparison of tumor tissue and donor-matched, non-tumorous tissue confirmed a higher expression of CD109 within the tumor tissue. Additionally, a higher expression of CD109 on TAMs compared to non-tumoral macrophages (55.6%±0.1 vs. 16.4%±0.9 $CD45^+CD109^+$ cells, n=2) was revealed. Moreover, monocyte-derived M2-like macrophages (median fluorescence intensity (MFI) fold change 2,8±1.1, n=4) and iPSC-derived M2a macrophages displayed a higher CD109 expression compared to their M1-like phenotypes. Furthermore, effective CD109 downregulation was achieved using target-specific small interfering RNA (siRNA) in A549 cells (MFI protein fold change 0.21±0.07, n=5 and 96% gene knockdown, n=1), in monocyte-derived M1 and M2 macrophages (MFI fold change 0.46±0.11 and 0.28±0.03 respectively, n=2) and in iPSC-derived macrophages with a M0, M1 and M2a phenotype (MFI fold change 0.39±0.02, 0.41±0.05 and 0.50±0.06 respectively, n=2).
Conclusion: Our results confirm overexpression of CD109 in lung tumor tissue and reveal an increased expression on *ex vivo* TAMs and *in vitro* M2-like macrophages. Moreover, a decrease in CD109 expression was achieved *in vitro* via siRNA-targeted knockdown. Henceforth, further experiments will investigate the immunomodulatory effects of CD109 downregulation on both cancer as well as macrophage functionality.

The tumor microenvironment drives mitochondrial metabolic reprogramming in neutrophils during non-small cell lung cancer

Marah Runtsch[1], Oliver Kindler[1], Thomas Eichmann[1], Ana Santiso[1], Kathrin Maitz[1], Luka Brcic[1], Joerg Lindenmann[1], Julia Kargl[1]
[1]*Medical University of Graz, Graz, Austria*

Lung cancer is among the most common and deadly cancers, and neutrophils are a key immune cell found in high abundance within lung tumors. Neutrophils are generally pro-tumoral due to their immunosuppressive functions, but display heterogeneity and plasticity. A better understanding of their roles in the lung tumor microenvironment (TME) is thus needed. In particular, how cellular metabolism dictates neutrophil function, and especially the role of mitochondria, within the lung TME is not well-elucidated. Here, we investigated the metabolic state of neutrophils from human lung and tumor tissue of non-small cell lung cancer (NSCLC) patients. Results reveal altered mitochondrial metabolism, oxygen utilization, and ROS production in tumor-associated neutrophils compared with those of non-tumor lung tissue. This correlated with changes in neutrophil subpopulations within human lung tumors, including of degranulating, immature, aged, and immunosuppressive neutrophils. Mitochondrial function, ROS, and the cellular metabolome were also altered in human neutrophils treated with NSCLC tumor-conditioned media *in vitro*, which also induced immunosuppressive functions. Further, single-cell RNA sequencing analyses revealed that specific neutrophil subsets of the NSCLC TME have modified metabolic gene expression and heterogeneous metabolic flux, including of glucose and glutamine. Finally, inhibition of the mitochondrial complexes differentially altered ROS production and immunosuppressive functions of neutrophils, suggesting that mitochondria are essential switches that dictate pro- or anti-tumoral responses of neutrophils in the lung TME. Altogether, these metabolic alterations drive the development/polarization of heterogeneic subsets that support or restrict tumor progression. Our work thus highlights potential novel therapeutic outlooks for lung cancer in conjunction with current immunotherapies.

This project was funded by a START Grant from MEFO and MedUniGraz to Dr. Runtsch.

Tackling tumor microenvironment metabolism: unveiling IL4i1's role and therapeutic potential

Marco Gargaro[1], Giulia Mencarelli[2], Andrea Marra[3], Estevão Carlos Silva Barcelos[1], Andrea Astolfi[1], Giorgia Manni[2], Giulia Scalisi[4], Doriana Ricciuti[2], Benedetta Pieroni[2], Francesco Sarnari[2], Alessandro Pinzi[2], Giuseppe Manfroni[1], Marco Colonna[5], Robert Schreiber[5], Maria Letizia Barreca[1], Peter Murray[6], Kenneth M Murphy[5], Francesca Fallarino[2]
[1]Department of Pharmaceutical Science, University of Perugia, Perugia, Italy; *[2]Department of Medicine and Surgery, University of Perugia, Perugia, Italy*; *[3]Department of Medicine and Surgery, University Campus Biomedico of Rome, Rome, Italy*; *[4]Genethon, Unit of Genomic, Inserm Integrare Research Unit, Evry, France*; *[5]Department of Pathology and Immunology, Washington University in St. Louis, School of Medicine, St. Louis, United States*; *[6]Max Planck Institute of Biochemistry, Martinsried, Germany*

Purpose: The metabolism of amino acids, especially tryptophan, is strongly linked with immune tolerance and unfavorable outcomes in the tumor microenvironment (TME). IL4i1, one of the enzymes involved in tryptophan degradation, has recently been identified as a crucial factor that makes the TME less resilient. IL4i1 sustains several tumor hallmarks, including immune suppression and resistance to ferroptosis. However, the mechanism and biology of IL4i1's action are not fully understood.
Methods: A poorly immunogenic fibrosarcoma cell line was analyzed through single-cell analysis 10 days after the tumor cell inoculation. Mass spectrometry was used to conduct the metabolite analysis derived from tryptophan degradation. To investigate the role of IL4i1 in the myeloid lineage, Il4i1 flox mice were bred with specific cre mice for enzyme deletion in macrophages and dendritic cells. Lastly, bioinformatic RNAseq data analysis was carried out on a cohort of 231 patients with different sarcoma subtypes.
Results: Single-cell RNA sequencing analysis showed that IL4i1 is only expressed in regulatory dendritic cells (mregDCs) in the TME of a transplantable fibrosarcoma cell line. These IL4i1+ mregDCs are mature dendritic cells that express markers such as CCR7 and Zbtb46. We also found that the TME is rich in metabolites derived from tryptophan conversion to I3P and 3-IAld by IL4i1. When we deleted IL4i1 in mice, we observed a reduction in tumor growth and an increased CD8 T cell-mediated response. Interestingly, when we used conditional models to delete IL4i1 in mregDCs, we saw a decrease in tumor cell growth and IL4i1-derived metabolites in the TME. We also found that IL4i1 metabolites suppress CD8 T cell response and conferred resistance to ferroptosis in tumor cells. Finally, we discovered that AhR-expressing target cells respond to IL4i1-produced metabolites, expanding our understanding of how IL4i1 shapes a metabolic network with profound effects on the TME and host anti-tumor response. Our findings show that IL4i1 is an adverse prognostic factor in specific sarcoma subtypes in the TCGA-SARC dataset, further highlighting its relevance in cancer contexts.
Conclusion: Our research identifies IL4i1 as a promising target for cancer therapy in the complex interplay of metabolism within the TME.

Extracellular α-ketoglutarate potentiate myeloid cells' capacity to induce Th17 and Tregs

Marijana Milanović[1], Luka Pavlović[2], Marina Bekić[2], Aleksandar Bisenić[3], Jelena Đokić[3], Miodrag Čolić[4], Sergej Tomić[2]
[1]Medical Faculty of the Military Medical Academy, University of Defense, Belgrade, Serbia; *[2]Department for Immunology and Immunoparasitology, Institute for the Application of Nuclear Energy, University of Belgrade, Belgrade, Serbia*; *[3]Institute for Molecular Genetics and Genetical Engineering, University in Belgrade, Belgrade, Serbia*; *[4]Serbian Academy of Sciences and Arts, Belgrade, Serbia*

Purpose: Alpha-ketoglutarate (αKG) emerged as a potent regulator of energetic and redox metabolism in immune cells. However, it is still unclear how exogenous αKG affects the metabolism and functions of key myeloid cells regulating the inflammation and T cell response, such as dendritic cells (DCs) and myeloid-derived suppressor cells (MDSCs).
Methods: The models of human monocyte-derived DCs and MDSCs induced by GM-CSF/IL-4 and GM-CSF/IL-6, respectively, were used to assess the effects of exogenous αKG *in vitro*. Cell survival, OXPHOS, Glycolysis, ROS, Akt/FoxO1 signaling, autophagy, cytokines production and phenotype of MDSCs and DCs were monitored by qPCR, WB and multi-color flow cytometry, whereas their functions were analyzed in different co-culture assays with allogeneic T cells.
Results: Non-toxic doses of exogenous αKG (<50mM) acted via Akt/FoxO1 and Nrf2/KEAP1 signaling pathways in DCs and MDSCs leading to an increased HIF-1α stabilization, ROS production and autophagy. Thereby, αKG-treated myeloid cells displayed down-regulated HLA-DR and PD1L expression, as well as an increased production of IL-1β, IL-23, IL-10 and TGF-β. αKG-DCs displayed an altered differentiation pathway compared to control DCs, according to their impaired up-regulation of CD1a on $CD14^{-}HLA\text{-}DR^{+}$ DCs. Functionally, αKG-DCs displayed a reduced allostimulatory and Th1 polarization capacity, but an increased capacity to induce Th17 cells, and conventional Tregs and IL-10-producing T cells in an IDO-1 and ILT-3-dependent manner. On the other hand, αKG potentiated differentiation of $HLA\text{-}DR^{low}CD14+$ MDSCs, as well as their capacity to induce both Th17 and Tregs *in vitro*.
Conclusion: Alph-ketoglutarate displays a potent capacity to alter the redox signaling in monocyte-derived cells, thereby potentiating their capacity to induce Th17 and Treg response, which could be a relevant mechanism for the establishment of persistent and chronic inflammation.

Overcoming the limitations of α4-1BB/PD1 dual treatment by exploring the metabolic programming of therapy-responsive T-cells

Fréderique de Graaf[1], Nils Mülling[1], Felix Behr[1], Ward Vleeshouwers[1], Macha Beijnes[1], Quint Blom[1], Lucas Brock[1], Ramon Arens[1]
[1]*LUMC, Leiden, Netherlands*

Purpose: Costimulatory agonists in combination with PD1/PD-L1 blockade has been an extensively studied approach in treating cancer patients. Although several clinical trials have demonstrated the potential of activating costimulatory pathways as evidenced by increased response rates the eventual clinical effectivity seems limited. To overcome the possible limitations of costimulatory agonists we explored the metabolic programming of therapy-responsive T-cells upon combinatorial PD1/PD-L1 blockade with α4-1BB agonist therapy.
Methods: *In vivo* studies were performed with colon carcinoma MC-38 bearing mice treated with either an α4-1BB agonist and/or PD1/PD-L1 blockade. The metabolic state and expression of rate-limiting enzymes of the cellular metabolic pathways were determined in circulating, tumor- draining and -infiltrating $CD8^+$ and $CD4^+$ T-cells. *Ex vivo* studies were performed with human T-cells isolated from blood and colon carcinoma to identify possible metabolic targets in α4-1BB/PD1 dual treatment. Crispr/Cas-based gene editing was used to knock-out key metabolic enzymes in T-cells.
Results: Combinatorial treatment with α4-1BB and PD1/PD-L1 blockade resulted in the induction of therapy-responsive circulating $CD8^+$ T-cells of which each unique subset expressed their own metabolic enzyme profile. Specifically, glycolysis-related enzymes and transporters were increased in $CD8^+$ T-cells by 4-1BB stimulation while PD-L1 blockade enhanced the magnitude of the circulating subsets. Moreover, T-cells isolated from the tumor and tumor-draining lymph nodes acquired similar metabolic phenotypes. Human $CD8^+$ and $CD4^+$ T-cells treated with α4-1BB and αPD1 recapitulated the profiles observed *in vivo*. However, particularly $CD8^+$ T-cells isolated from colon carcinoma were unresponsive to 4-1BB stimulation, implying dominant suppressive cues.
Conclusion: Costimulatory agonists are widely used in the clinic in combination with checkpoint inhibitor therapy, such as PD1/PD-L1 blockade. However, the clinical effects of these combinatorial immunotherapies seem limited. Here, we demonstrate that although T-cells in the circulation are responsive to α4-1BB/PD1 dual therapy, tumor-infiltrating, especially $CD8^+$, T-cells became less responsive and altered their metabolic profile. These findings may contribute to improved understanding of current immunotherapies in the clinic.

Assessing Immune Cell Infiltration and Metabolic Activity During Immunotherapy in vivo through Immuno-Metabolic PET/MRI Imaging

Sixing Li[1;2], Marie-Aline Neveu[1], Laura Kübler[1;2], Manfred Kneilling[1;3], André Martins[1;2]
[1]Werner Siemens Imaging Center, Department of Preclinical Imaging and Radiopharmacy, University of Tübingen, Tübingen, Germany; *[2]Cluster of Excellence iFIT (EXC 2180) "Image-Guided and Functionally Instructed Tumor Therapies," University of Tübingen, Tübingen, Germany*; *[3]Department of Dermatology, University of Tübingen, Tübingen, Germany*

Purpose: Immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment by aiding pre-existing T cells. However, their efficacy is limited in most solid tumors. In this study, we explored the synergistic potential of combining sorafenib, a multi-kinase inhibitor (MKI), with ICIs to elicit enhanced antitumor responses. We aimed to unravel the mechanisms behind this combined therapy in triple-negative breast cancers, which are resistant to ICIs or MKIs. Additionally, we developed a non-invasive multimodal imaging methodology to enable precise image-guided therapy.
Methods: Orthotropic tumor mouse models were generated by inoculating 4T1 breast cancer cells under the mammary fat pad. Tumor-bearing mice were treated with ICIs (anti-PD-1 + anti-CTLA-4), sorafenib, or both. Isotypes-treated mice were included as a control group. Multimodal imaging methods, including [^{89}Zr]Zr-DFO-αCD8 PET, [^{19}F]perfluorocarbon (PFC) MRI, [^{18}F]FDG PET, and hyperpolarized ^{13}C MRI, were applied to detect dynamic changes in CD8+ T cells and phagocytes infiltration, as well as tumor glucose uptake, glycolysis, respectively.
Results: Combining ICIs and sorafenib drastically prevented tumor progression, while monotherapy with ICIs or sorafenib did not yield tumor growth inhibition. [^{89}Zr]Zr-DFO-αCD8 PET showed an increase of CD8+ T cell infiltration in the sorafenib group (p=0.02) and combined therapy group (p=0.02) 3 days post-treatment. From [^{19}F]PFC MRI, the combined therapy group presented the highest ^{19}F signal at the late reaction phase (p=0.009), suggesting a high phagocyte accumulation in the tumor. These results were further supported by flow cytometry. [^{18}F]FDG PET and hyperpolarized ^{13}C MRI showed a uniform FDG uptake and an increasing lac/pyr ratio trend during the combined therapy. These findings strongly indicate that the combined therapy induces a proinflammatory tumor microenvironment (increased glycolysis; immune-cell activation) compared to monotherapies (aerobic oxidation; immune-cell exhaustion), underscoring its potential to enhance immune response and improve treatment outcomes.
Conclusion: Our findings demonstrate for the first time that combining ICIs and sorafenib effectively prevents the progression of triple-negative breast cancer in 4T1 mouse model, which can be attributed to the infiltration and activation of immune cells in the tumor microenvironment. This study highlights the unique role of multimodal immune-metabolic imaging in accurately discerning the different stages of immune-systemic therapy response *in vivo*.

Mitochondrial respiratory complex III sustains IL-10 production in macrophages and promotes tumor-mediated immune evasion

Alessia Zotta[1], Shane O'Carroll[1], Eva Palsson-McDermott[1], Juliana Toller-Kawahisa[1], Emily Day[1], Ross W. Ward[1], Dylan Ryan[2], Marah Runtsch[3], Kathrin Maitz[3], Anna Lueger[3], Julia Kargl[3], Mark Watson[4], Martin Brand[4], Ed Lavelle[1], Luke O'Neill[1]
[1]Trinity College Dublin, Dublin, Ireland; *[2]University of Cambridge, Cambridge, United Kingdom*; *[3]Medical University of Graz, Graz, Austria*; *[4]Buck Institute for Research on Aging, Novato, United States*

The anti-inflammatory interleukin (IL)-10 is a cytokine produced by activated immune cells and it is necessary for the dampening of the immune response and the resolution of acute and chronic inflammation. Because of its ability to switch off the activation of leukocytes, IL-10 upregulation is a common feature of tumor progression and metastasis. Most recently, IL-10 regulation has been shown to depend on mitochondria and redox-sensitive signals. We have found that Suppressor of site III_{Q_o} Electron Leak (S3QEL) 1.2, the specific inhibitor for reactive oxygen species (ROS) production from mitochondrial complex III, and Myxothiazol, a Complex III inhibitor, decrease IL-10 production from macrophages activated after priming with different ligands and by affecting basal mitochondrial respiration. IL-10 downregulation is likely to be mediated by the suppression of C-Fos, which is a subunit of Activator protein (AP)-1 transcription factor. S3QEL 1.2 impairs IL-10 production *in vivo* after Lipopolysaccharide (LPS) challenge and ameliorates the survival of mice bearing B16F10 melanoma, thus lowering tumor growth. Our data identify a new link between Complex III-dependent ROS generation and IL-10 production in immune cells and suggest S3QEL 1.2 as a compound with clinical relevance for the treatment of tumors and the advancement of mitochondria targeted anti-cancer therapies.

Understanding TCR specificity could open up novel avenues for target treatment of autoimmune diseases and diagnostics. Our study aims at benchmarking established tools for the antigen-specific TCR identification from a single repertoire snapshots, highlighting their limitations, and providing recommendations for analysis and experimental design.
We designed the "TCRgrapher" R library for the identification of specific TCRs. TCRgrapher includes a unified framework that can run ALICE, TCRNET, tcrdist3, and GLIPH2 with a flexible set of controls and parameters. We applied TCRgrapher to three sets of TCR repertoires: post-LCMV infection data published by Shlesinger et al., our data of mice vaccinated with Sputnik V, and our data of lung-infiltrating CD4+ T cells collected at the peak of tuberculosis infection. Each dataset had an experimentally obtained repertoire enriched with antigen-specific TCRs, used as a positive set.
Among the single-repertoire analysis methods scrutinized, ALICE and TCRNET performed best on mice TCRβ repertoires. Furthermore, we found minor differences between ALICE performance with different TCR generation models and with corrections to clonotype abundance. TCRNET performance by clonotype grouping was mostly identical. TCRNET showed higher precision in the area of low recall with real data used as the control sample compared to the OLGA-generated control. GLIPH2 gave satisfactory results only in cases of clusters formed by one nucleotide mismatch and only being run locally.
TCRgrapher provides a user-friendly way to find condition-specific clonotypes and compare the results from different tools. We hope that our work will be useful to a wide range of researchers in the field.

Modeling Variations in Antibody Response Magnitude and Longevity

Paola Stolfi[1], Filippo Castiglione[2], Enrico Mastrostefano[1], SIlvia Scarpetta[3], Antonella Prisco[4]
[1]*Instute for Applied Computing, CNR, Rome, Italy*; [2]*Biotech Research Center, Technology Innovation Institute, Abu Dhabi, United Arab Emirates*; [3]*Department of Physics, University of Salerno, Salerno, Italy*; [4]*Institute of Genetics and Biophysics CNR, Naples, Italy*

Long-lasting antibody responses are pivotal for both protective immunity and autoimmunity. Yet, the intricate mechanisms that dictate the duration of these responses remains only partially elucidated.
By employing an agent-based in silico model, we simulated the generation of short-lived and long-lived plasma cells during the immune response to an adenoviral COVID-19 vaccine, postulating that antigen-specific plasma cells have a certain probability of attaining an extended half-life. This hypothesis implies that the quantity of antigen-specific plasma cells generated in the initial immune response, coupled with their likelihood of becoming long-lasting, influence the magnitude of the antibody response months after immunization. Interestingly, our simulations unveiled two distinct clusters among individuals several months post-vaccination, delineating markedly divergent dynamics in antibody titers: one group exhibited sustained elevated antibody levels (sustainers), while another witnessed a decline (decayers). Notably, the absence of long-lived plasma cells in the decayers distinguished them from the sustainers. Leveraging machine learning clustering on antibody titers, we achieved an accuracy of 0.925 in identifying the decayers 28 weeks following the initial dose.
Presently, we are comparing the predictions of our model with clinical data on the antibody response to SARS-CoV-2 Nucleoprotein and Spike post-COVID-19 infection or vaccination, with the aim of validating and refining our model.
Specifically, we are harnessing machine learning methodologies on data sourced from published immunological studies to discern patterns in the dynamics of the antibody response.

High-dimensional cytometry (HDC) is a powerful technology for studying single-cell phenotypes in complex biological systems. Although technological developments and affordability have made HDC broadly available in recent years, technological advances were not coupled with an adequate development of analytical methods that can take full advantage of the complex data generated. While several analytical platforms and bioinformatics tools have become available for the analysis of HDC data, these are either web-hosted with limited scalability or designed for expert computational biologists, making their use unapproachable for wet lab scientists. Additionally, end-to-end HDC data analysis is further hampered due to missing unified analytical ecosystems, requiring researchers to navigate multiple platforms and software packages to complete the analysis.
To bridge this data analysis gap in HDC we developed cyCONDOR, an easy-to-use computational framework covering not only all essential steps of cytometry data analysis but also including an array of downstream functions and tools to expand the biological interpretation of the data. The comprehensive suite of features of cyCONDOR, including guided pre-processing, clustering, dimensionality reduction, and machine learning algorithms, facilitates the seamless integration of cyCONDOR into clinically relevant settings, where scalability and disease classification are paramount for the widespread adoption of HDC in clinical practice. Additionally, the advanced analytical features of cyCONDOR, such as pseudotime analysis and batch integration, provide researchers with the tools to extract deeper insights from their data. We used cyCONDOR on a variety of data from different tissues and technologies demonstrating its versatility to assist the analysis of high dimensionality data from preprocessing to biological interpretation.

Bw4 ligand and direct T-cell receptor binding induced selection on HLA A and B alleles

Yoram Louzoun[1], Reut Levi[1]
[1]*Bar Ilan University, Ramat Gan, Israel*

Introduction: The HLA region is the hallmark of balancing selection, argued to be driven by the pressure to present a wide variety of viral epitopes. As such selection on the peptide-binding positions has been proposed to drive HLA population genetics. MHC molecules also directly binds to the T-Cell Receptor and killer cell immunoglobulin-like receptors (KIR).
Methods: We here combine the HLA allele frequencies in over six-million Hematopoietic Stem Cells (HSC) donors with a novel machine-learning-based method to predict allele frequency.
Results: We show for the first time that allele frequency can be predicted from their sequences. This prediction yields a natural measure for selection. The strongest selection is affecting KIR binding regions, followed by the peptide-binding cleft. The selection from the direct interaction with the KIR and TCR is centered on positively charged residues (mainly Arginine), and some positions in the peptide-binding cleft are not associated with the allele frequency, especially Tyrosine residues.
Discussion: These results suggest that the balancing selection for peptide presentation is combined with a positive selection for KIR and TCR binding.

Quantitative comparison of cellular trajectories from single-cell transcriptomics data

Lisa Maria Steinheuer[1], Kevin Thurley[1]
[1]*Institute of Experimental Oncology, University Hospital Bonn, Bonn, Germany*

Single-cell transcriptomic analysis has greatly improved our understanding of immunological processes by uncovering the detailed dynamics of cell development. Developmental trajectories, which show how cells progress along differentiation pathways, are crucial for comprehending immune cell lineage commitment, activation, and function, offering insights into genetic mutations, diseases, and external influences. Despite the availability of numerous tools for inferring developmental trajectories, quantitative comparisons remain challenging due to limitations associated with single-cell RNA sequencing data, such as its high dimensionality, complexity, and sample heterogeneity.
Our study aims to develop a method for systematically comparing trajectory graphs and obtaining quantitative measures to comprehensively analyze single-cell data. Collaborating with various research groups at the University Hospital Bonn and the University of Bonn, we established trajectories using diverse datasets, including PBMC samples from individuals with Bardet-Biedl syndrome and COVID-19 patients. While many trajectory inference tools generate graphs in the low-dimensional UMAP space, we initially focus on comparing different trajectories within this embedding. To thoroughly analyze the data, we project the graph structures back into the high-dimensional data space, compare the differences, and assess the significance of variations between graphs at lower and higher dimensions.
This framework has the potential to provide valuable insights into immunological dynamics, particularly in patient-derived time-series datasets like those from COVID-19 patients. Identifying differences in disease progression could greatly affect clinical outcomes, shaping treatment decisions and patient care. We aim to establish a reliable framework for analyzing single-cell data, enabling a more thorough examination and deepening our understanding of immunological dynamics. Ultimately, the quantitative insights gained can be leveraged to develop data-driven mathematical models to explore cell-cell communication within the immune system and conduct *in-silico* perturbation studies.

The National Research Data Infrastructure for Immunology in Germany (NFDI4Immuno): Building a framework for comprehensive immunological data integration and analysis, collaboration and Open Science.

Sebastian Ferrara[1], Amro Abbas[1], Axel, Ronald Schulz[1], Christian Busse[2], Henrik, E. Mei[1], Hyun-Dong Chang[1]
[1]DRFZ, Berlin; *[2]DKFZ, Heidelberg, Germany*

In the era of advanced single-cell technologies, including flow cytometry, mass cytometry and single cell sequencing, capable of generating very information-rich datasets, the necessity for data sharing and reuse has grown significantly in immunological research. The National Research Data Infrastructure for Immunology (NFDI4Immuno) initiative funded by the German Federal Ministry of Education and Research tries to address this need.
Here, we present how the NFDI4Immuno initiative aims to integrate immunological data and metadata from various experimental technologies, including cytometry, sequencing, immunoassays, and imaging, to provide a holistic view of immunological processes. The initiative strives to enhance scientific collaboration by harmonizing data representations, metadata standards, ontologies, and programmatic interfaces with other NFDI consortia, promoting seamless queries and cross-referencing. The project is committed to support users in effectively utilizing its resources and to foster the adoption of FAIR principles (findability, accessibility, interoperability and reusability) within the immunological community to contribute to the broader cultural shift towards Open Science. Finally, NFDI4Immuno plans to establish and manage a network of federated repositories for immunological data, to develop tools and services that facilitate standardized and reproducible data analyses, reinforcing scientific rigor and transparency.

The project is funded by the Federal Ministry of Education and Research under the grant number 501875662.

Lin-CD117+CD34+FceRI+ progenitor cells in chronic spontaneous urticaria and atopic dermatitis

Katie Ridge[1], Barry Moran[1], Cliona O'Farelly[1], Alan Irvine[1], Mark Little[1], Conor Finlay[1], Niall Conlon[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Purpose: Chronic spontaneous urticaria (CSU) is a common, debilitating skin disorder characterised by recurring episodes of raised, itchy and sometimes painful wheals lasting longer than 6 weeks. CSU is mediated by mast cells which are absent from peripheral blood. However, lineage$^-$CD34^{hi}CD117$^{int/hi}$FcεRI$^+$ cells in blood have previously been shown to represent a mast cell precursor.
Methods: We enumerated FcεRI$^-$, FcεRI$^+$ and FcεRI^{hi} lineage$^-$CD34$^+$CD117$^+$ cells using flow cytometry in blood of patients with CSU (n=55), including 12 patients receiving omalizumab and 43 not receiving omalizumab (n=43). Twenty-two control samples were studied. Disease control and patient response to omalizumab was evaluated using the Urticaria Control Test. We performed single cell RNA sequencing (scRNA-seq) on lineage$^-$CD34^{hi}CD117^{hi} blood cells from a subset of patients with CSU (n=8) and healthy controls (n=4). We also assessed lineage$^-$CD34$^+$CD117$^+$ cells in patients with atopic dermatitis.
Results: CSU patients had more Lineage$^-$CD34$^+$CD117$^+$FcεRI$^+$ blood cells than controls. Lineage$^-$CD34$^+$CD117$^+$FcεRI$^+$ cells were significantly higher in patients with CSU who had an objective clinical response to omalizumab when compared to patients who had poor disease control 90 days after initiation of omalizumab. scRNA-seq revealed that lineage$^-$CD34$^+$CD117$^+$FcεRI$^+$ cells contained both lymphoid and myeloid progenitor lineages, with omalizumab responsive patients having proportionally more myeloid progenitors. The myeloid progenitor lineage contained small numbers of true mast cell precursors along with more immature FcεRI$^-$ and FcεRI$^+$ myeloid progenitors.
Conclusion: Increased blood CD34$^+$CD117$^+$FcεRI$^+$ cells may reflect enhanced bone marrow egress in the setting of inflammatory CSU. High expression of these cells strongly predicts better clinical responses to the anti-IgE therapy, omalizumab.

Single-cell responses to mTOR inhibition in patients with cutaneous sarcoidosis

Kveta Brazdilova[1;2], Anna Redl[1;2], Luisa Unterluggauer[1], Lisa Kleissl[1;2], Thomas Krausgruber[2;3], ThomasW Weichhart[4], Christoph Bock[2;3], Georg Stary[1;2]
[1]Medical University of Vienna, Department of Dermatology, Vienna, Austria; *[2]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria*; *[3]Medical University of Vienna, Institute of Artificial Intelligence, Center for Medical Data Science, Vienna, Austria*; *[4]Medical University of Vienna, Institute of Medical Genetics, Center for Pathobiochemistry and Genetics, Vienna, Austria*

Background: In a recent clinical trial, systemic, but not topical, mTORC1 (mechanistic target of rapamycin complex 1) inhibition resulted in a long-lasting remission in a subset of patients with cutaneous sarcoidosis, a granulomatous inflammatory disease. Skin and blood samples from different timepoints of the trial were assayed by single-cell RNA sequencing and spatial transcriptomics. We are investigating this dataset to uncover the transcriptional changes in the tissue upon mTOR inhibition and underlying patterns which determine treatment response.
Methods: After thorough quality control, high-quality cell transcriptomes from skin and blood were integrated using an scVI model, clustered, and cell types were annotated based on marker genes. Changes in cell-type composition throughout treatment were assessed using the scCODA model. Differential expression analysis between timepoints per cluster was performed using limma on pseudobulked counts. The results were used for gene set enrichment analysis.
Results: We find all expected cell subsets in our transcriptomics data as well as distinct granuloma-specific cell populations, which significantly decrease in abundance throughout treatment. The expression of many genes changes in macrophages, helper T cells and fibroblasts after systemic treatment, including cytokines, chemokines, transcriptional regulators, and genes previously linked to sarcoidosis. This is not the case for topical treatment. Pathways downregulated by systemic treatment are mostly related to metabolism, antigen presentation and autoimmune diseases, with the strongest effect on metabolism observed in macrophages. While macrophages show a strong response already immediately after treatment, T cells only undergo major expression changes at a later timepoint. Comparison of responders and non-responders throughout treatment reveals differences in pathways related to metabolism but also lymphocyte chemotaxis and activation.
Conclusions: The cell composition and expression profile of granulomatous tissue appear to change markedly after mTOR inhibitor treatment. mTOR inhibition results in changes of metabolic pathways in immune and structural cells, but also immune function is strongly affected in these populations. Different cell types respond on different time scales and we will further investigate details of these specificities. Additionally, by disentangling differences between responders and non-responders we aim to predict response of future patients.

The hair canal serves as an EGFR-regulated antimicrobial gatekeeper

Lena Artner-Gent[1], Regina Jin[1], Karoline Strobl[1], Dana Krauss[1], Joana Silva[2], Petra Pjevac[2], David Berry[2], Tatiana Chontorotzea[1], Jörg Klufa[1], Thomas Bauer[1], Maria Sibilia[1]

Hair follicles are crucial to maintain mammalian skin barriers and protect against physical stressors of the environment. They represent a unique niche for commensal skin bacteria but unchecked proliferation of microbiota within hair follicles initiates folliculitis and fosters cutaneous dissemination of infections. This clinical implication is exceptionally displayed in cancer patients receiving anti-EGFR therapy that evokes papulopustular eruptions with concomitant bacterial *Staphylococcus aureus* superinfections.
In this study, we identified the specific cell population facilitating the pivotal microbial gatekeeping function of the hair follicle. We exploited single-cell datasets, deciphered epidermal growth factor receptor (EGFR)-dependent transcriptional signatures, and conducted targeted knock-out experiments in genetically engineered mice to pinpoint the significance of the EGR2/K79-positive hair canal as essential antimicrobial bastion. EGFR orchestrates the expression of antimicrobial peptides (AMPs) such as beta-defensin1/6 and SPRR1a/4 within the hair canal via the ERK signaling pathway. Notably, our data suggests that the presence of EGFR in fully differentiated sebocytes is expendable for the homeostatic defense mechanism of the hair follicle.
Our investigation further revealed that the identified AMP profile translates to the human skin, as AMP homologues are also concentrated in K79-expressing cells, and their overexpression is evident in EGFR-ERK-dominant psoriatic skin conditions. These findings provide crucial mechanistic insights into the microbial defense strategy employed by the hair follicle, with direct therapeutic implications for addressing folliculitis associated with EGFR-inhibitor-based anti-cancer therapy.

Regulatory T cells (T_{regs}) are a critical immune component guarding against excessive inflammatory responses, but current understanding of T_{reg} heterogeneity and function in non-lymphoid tissues in humans is limited. In this project we characterized unique types of T_{reg} signatures in the context of tissue-confined inflammatory responses in human skin and gut. During chronic inflammation, T_{regs} fail to control effector T cell responses. Causes of T_{reg} dysfunction in these diseases are poorly characterized and therapies are aimed at blocking aberrant effector responses rather than rescuing T_{reg} function. We hypothesized that impairment in tissue-specific immune regulation leads to exacerbated T cell responses and chronic inflammation in these diseases. Therefore, we utilized single-cell RNA sequencing data from patients suffering from chronic skin and colon inflammation to show that diseased tissue-T_{regs} have a strong, specific, tissue-resident signature. We uncover *SAT1*, the gene encoding spermidine/spermine N1-acetyltransferase (SSAT), as a novel marker and driver of skin-specific T_{reg} dysfunction during T_H17-mediated inflammation. T_{regs} expressing high levels of *SAT1* are specifically enriched in chronic skin inflammation and show a proinflammatory effector-like transcriptomic profile. Using CRISPRa in healthy human skin-derived T_{regs}, we validated that expression of *SAT1* leads to loss of suppressive function and a switch to a T_H17-like phenotype. This phenotype is induced by co-receptor expression on keratinocytes exposed to a T_H17 environment. Lastly, we highlight the potential therapeutic impact of targeting SSAT in a mouse model of skin inflammation by inhibiting SSAT pharmacologically, which rescued T_{reg} number and function in the skin and systemically. Together, our results reveal a novel interface of polyamine catabolism and T_{reg} function in the skin which leads to impaired control of effector T cell responses. Ultimately, our findings significantly contribute to basic understanding of T_{reg} function and shed light on immune regulation during chronic inflammation in human tissue and reveal SSAT as a potential novel target for chronic inflammatory skin disease.

Single cell transcriptomics reveals two fates of Hair Follicle Stem Cells in patients with hidradenitis suppurativa and sheds light on the mechanisms of keratinisation and inflammation

Audrey Onfroy [1], Jean-Louis Francette[2], Etienne Audureau[3], Philippe Lecorvoisier[3], Caroline Boucle[3], Fanny Coulpier[1], Véronique Godot[2], Pierre Wolkenstein[3], Yves Lévy[2], Piotr Topilko[1], Sophie Hue[2]
[1]INSERM U955 Team 9, Creteil, France; *[2]INSERM U955 Team 16, Creteil, France*; *[3]Henri Mondor hospital, APHP, Creteil, France*

Purpose: Hidradenitis suppurativa (HS) is a devastating skin disorder that affects 1% of the world's population. Although the pathogenesis is multifactorial and poorly understood, the pathomechanisms of HS are intimately associated with aberrantly activated keratinization and autoinflammation. It is unknown whether the autoinflammatory events precede or follow the hyperkeratotic changes in the hair follicle (HF) epithelia. An intrinsic dysregulation of the hair follicle stem cell (HF-SCs) compartment leads to replication stress stimulating type I interferon responses. To further dissect the role of HF-SCs, we performed single cell RNA Seq using freshly isolated total HF cells.
Methods: HF samples were from discarded plastic surgery specimens from 2 controls and 5 HS patients. To obtain single-cell suspension, the isolated HFs were digested in Trysin-EDTA. We used the Seurat R package to analyze the scRNA-seq data.
Results: We identified three main clusters: i) HF matrix lineage enriched for *MSX2* (HF matrix marker), ii) non-matrix lineage enriched for *KRT14* and iii) immune cells enriched for *PTPRC*. To determine whether differences could be observed between HF cells from controls and HS patients, unsupervised clustering was performed based on the proportion of cells in each cluster. The most striking differences were observed in non-matrix cells and could segregate patients into 2 groups. The first group is enriched in cluster 1 (IBL), while the second is enriched in clusters 0 (mORS). These two clusters displayed fundamental transcriptomic changes. Noteworthy, GSEA revealed significant enrichment for genes involved in keratinization in IBLs, whereas mORS showed enrichment for interferon response genes. The trajectory analysis revealed that the HF-SCs differentiated in either IBL or mORS. We were able to confirm our results on 47 HS patients included in Fol-HYDRA cohort (CPP# n°2021-A02352-39) and show that these two pathways are associated with two different clinical phenotypes of patients.
Conclusion: Our results provide an unprecedented view of HS pathology and identify two pathways involved in HS, one involved in the keratinization process and the other in inflammation. Based on these pathways, two endotypes of HS patients were identified, which could serve as a potential marker for personalized medicine.

Multimodal and Longitudinal Single-Cell Analysis of Local Innate Immune Response to Vaccine in Ex Vivo Natural Human Skin Modules

Manon Scholaert[1], Mathias Peries[1], Emilie Braun[1], Jeremy Martin[2], Nadine Serhan[2], Alexia Loste[2], Bruner Audrey[2], Lilian Basso[2], Benoit Chaput[3], Eric Merle[4], Pascal Descargues[4], Emeline Pages[1], Nicolas Gaudenzio[1;2]
[1]Genoskin SAS, Toulouse, France; *[2]Toulouse Institute for Infectious and Inflammatory Diseases (Infinity) INSERM UMR1291, Toulouse, France*; *[3]Department of Plastic, Reconstructive and Aesthetic Surgery, Rangueil Hospital, CHU Toulouse, Toulouse, France*; *[4]Genoskin Inc, Salem, United States*

Purpose: In the rapidly evolving landscape of vaccine research, the quest for innovative methodologies with single cell resolution that accurately investigate human immune responses at the site of injection prior to clinical trials is of utmost importance.
Methods: In response to this challenge, we used bio-stabilized, injectable *ex vivo* human skin modules (HypoSkin®) to closely investigate mRNA vaccine-induced immune response within its natural environment and at the single cell level. We developed a framework that combines MANTIS spatial biology and single-cell RNA sequencing to detect subtle changes in immune landscape dynamics and track mRNA incorporation after vaccination with mRNA-1273 COVID-19 vaccine.
Results: In preparatory experiments, we confirmed the transcriptomic stability of *ex vivo* human skin modules at the single cell level. To delve deeper into the innate mechanisms of the vaccine at the injection site, we conducted single-cell RNA sequencing analysis on dissociated human skin modules enriched in skin-resident CD45+ immune cells. Our findings unveiled the presence of SARS-CoV-2 spike mRNA sequences primarily in DC/macrophage and mast cell clusters at 8 hours post-injection, accompanied by significant transcriptomic changes in multiple skin-resident immune cells post-vaccination. Furthermore, to assess protein-level changes, we utilized the Multiplex ANnotated Tissue Imaging System (MANTIS®) to analyze the activation status and redistribution of skin-resident antigen-presenting cells. Our analysis revealed that, upon vaccination, LCs and Langerin+ dDCs upregulate activation/maturation markers while redistributing in specialized dermal areas and enhance their capacity to interact with neighbor CD4+ T cells.
Conclusion: In summary, our comprehensive investigation underscores the efficacy of HypoSkin® combined with single cell analysis in capturing the intricate dynamics of vaccine-induced immune responses within native tissue environments. This innovative approach not only enhances our understanding of vaccine efficacy but also holds promise for expediting the development of novel vaccination strategies, thereby propelling the field of human innate immune response to vaccines forward.

Purpose: Human cytomegalovirus (HCMV) is associated with atherosclerosis and destabilization of atherosclerotic plaques. In some patients, HCMV promotes a marked reconfiguration of the natural killer (NK) cell compartment characterized by a distinct phenotype and antibody-dependent enhanced functional capabilities, including antibody-dependent cell-mediated cytotoxicity (ADCC), and cytokine production. IFN-γ producing NK cells have been implicated in atherosclerosis progression, apparently in association with infection to human cytomegalovirus (HCMV). Yet, the precise role of NK cells in atherosclerotic plaque destabilization and the molecular mechanisms underlying HCMV-associated atherosclerosis progression remain open issues. This study aims to investigate the potential impact of the HCMV-induced reconfiguration of the NK cell compartment in the pathogenic mechanisms underlying atherosclerotic plaque instability.
Methods: A total of 64 patients were enrolled in a follow-up protocol for carotid artery stenosis. Patients were classified following conventional criteria as bearing high-risk plaques (High-risk patients- HR patients) or low-risk plaques (Low-risk patients- LR patients). High-risk patients underwent carotid endarterectomy according to the European Society for Vascular Surgery (ESVS) guidelines. Carotid plaques and pre-operative blood samples were obtained from all patients to be processed. Multiparametric flow cytometry was used to evaluate NK cell phenotype and functionality.
Results: Adaptive- non-conventional NK cells are enriched in high-risk atherosclerotic HCMV seropositive patients and display an increased expression of NKG2D. Remarkably, we observed that FCεR1γ^{-} non-conventional NK cells increase upon plaque destabilization in peripheral blood and accumulate in carotid plaques of high-risk atherosclerotic patients by upregulating tissue resident markers (CD103, CD49a). Moreover, NK cells from High-Risk HCMV seropositive patients have enhanced antibody-dependent effector functions compared to Low-Risk patients and antibody-dependent IFN-**γ** release correlates with the frequency of FCεR1γ^{-} in high-risk atherosclerotic patients. Remarkably, masking of NKG2D receptor significantly reduces antibody-dependent IFN- **γ** release by FCεR1γ^{-} NK cells, suggesting that NKG2D might act in conjunction with CD16 to trigger NK cell activation thus representing a crucial axis for atherosclerotic plaque progression.
Conclusion: In conclusion, we provide new data involving memory-like NK cells and NKG2D in atherosclerotic plaque destabilization, further suggesting that their analysis may provide useful indications to identify high-risk patients that might benefit from early surgical intervention and/or closer follow-up.

Comparative analysis of interferon (IFN) signalling reveals an IFNy-Jak1 axis in the selective control of intestinal stem cell niche damage and fetal injury

Megan O' Brien[1], Caoimhe Cadden[1], Eóin McNamee[1]
[1]*Maynooth University, Co. Kildare, Ireland*

The Inflammatory bowel diseases (IBD: Crohn's disease and Ulcerative Colitis) are characterised by idiopathic inflammation with a central pathologic hallmark being the dysregulation of the epithelial stem cell niche (including loss of paneth cells, crypt atrophy, etc). While both infiltrating and tissue resident immune subsets play a role in the pathogenesis, how immune-epithelial stem cell crosstalk impacts on disease course is not fully defined. A defining feature of multiple clinical data sets has highlighted enhanced interferon (IFN) signalling associated with elevated disease activity and further with treatment refractory patients. This is of clinical relevance as biologic therapeutics targeting Jak-STAT signalling are in clinical use for IBD (e.g.: Tofacitinib). Yet, these therapeutics present with complications for some patients in addition to non-responsive cohorts. Currently, a clear understanding of how the different IFN classes specifically effect intestinal epithelial biology is not well defined.
To address this knowledge gap we utilised small intestinal organoid cultures to screen the effects of recombinant IFN classes (IFN-alpha, IFN-beta, IFN-gamma, IL-28a [IFN-lambda2]) and assessed the impact on growth, cell cycle, cellular composition and function. While organoids cultured in the presence of IFN-alpha, IFN-beta and IFN-lambda2 displayed no adverse effects, IFN-gamma had a marked detrimental impact on epithelial stem cell function, selectively depleting mature stem cell (*lgr5, olfm4*) and paneth cell markers (*lyz, defa21*). Notably, enterocyte, goblet cell and enteroendocrine cells were unchanged. We next performed RNA-sequencing and profiled organoids longitudinally using automated morphometric analysis to define the functional consequences of this on stem cell function. Of note, IFN-gamma selectively reverts the stem cell niche to an injury associated, fetal-like stem cell program (*ly6a, sprr1a*). We investigated the signalling events that IFN-gamma elicits to drive this gene program and performed a targeted small molecule pharmacologic screen to identify possible signalling hubs. While blocking hallmark injury, stress and damage-associated pathways had no impact, Jak1 (and not Jak2) inhibition reversed this fetal-stem cell programme and restored morphological growth patterns and organoid function. Thus, IFN-gamma has a selective negative impact on intestinal epithelial stem cell biology and further mechanistic understanding of this process has implications for IBD therapeutics.

Immune cells play a critical role in cytokine- and endotoxin-mediated endothelial permeability

Samira Ortega Iannazzo[1], Patricia Gogesch[1], Nicole Rupp[1], Joachim Rom[2], Markus Kreuz[3], Kristin Reiche[3], Martina Anzaghe[1], Zoe Waibler[1]
[1]*Paul-Ehrlich-Institut, Langen, Germany*; [2]*Varisano Klinikum Frankfurt Höchst, Frankfurt am Main, Germany*; [3]*Fraunhofer Institute for Cell Therapy and Immunology, Leipzig, Germany*

Purpose: Vascular leakage is a severe pathology occuring in a broad range of scenarios, e.g. as secondary disease induced by sepsis, infections, cytokine storms, or as side effect of immunotherapies. Its severity is underlined by the high lethality rate of 20-30% for the systemic capillary leakage syndrome (CLS). The unspecific symptoms during the acute phase of CLS and the rapid progression into the massive leak-phase often cause misdiagnosis or a diagnostic delay, which contributes to the high mortality. While many compounds are reported to affect endothelial cell (EC)-activation, the exact mechanisms resulting in increased permeability, including the role of immune cells, are not fully understood.
Methods: In this study, we generated a comprehensive dataset analyzing activation, vitality, cytokine secretion, and permeability of human umbilical vein endothelial cells (HUVEC) upon stimulation with 16 different stimuli (cytokines, vasoactive substances, and danger signals). HUVEC-permeability was analyzed in a trans-well-based leakage assay with or without human peripheral blood mononuclear cells (PBMC).
Results: Activation of HUVEC is characterized by upregulation of intercellular adhesion molecule-1 (ICAM-1), vascular cell adhesion molecule-1 (VCAM-1), and E-selectin with production of interleukin (IL)-8, monocte chemoattractant protein-1, and partly IL-6. Strong HUVEC-activation and reduced vitality was observed upon treatment with IL-1β, TNF-α, a TGN1412-induced cytokine cocktail ($SN_{TGN1412}$), thrombin, and lipopolysaccharide (LPS). Interestingly, only thrombin, and to a lesser extent $SN_{TGN1412}$ and VEGF, induced increased permeability of HUVEC-monolayers. On the other hand, compounds reported to be associated with vascular leakage such as TNF-α, IL-1β, or LPS had no direct effect on HUVEC-permeability. Remarkably, inclusion of stimulated PBMCs in the leakage assay induced elevated HUVEC-permeability mediated by IL-1β, TNF-α, $SN_{TGN1412,}$ and LPS.
Conclusion: Our results demonstrate that strong activation of EC not necessarily results in increased permeability. Especially for cytokine- and endotoxin-mediated vascular leakage, immune cells are required to induce increased permeability of HUVEC in our *in vitro* assay. In depth analyses of the mechanisms underlying the development of increased permeability will uncover potential treatment-targets for patients suffering from vascular leakage and help to improve safety-assessment of leakage-associated immunotherapies.

IL-18-induced HIF-1α in ILC3s ameliorates the inflammation of C. rodentium-induced colitis

Lucía Sancho[1], Raquel Castillo-González[1], Ana Valle[1], Cristina Villa[1], Aranzazu Cruz-Adalia[1]
[1]*UCM Faculty of Immunology, Madrid, Spain*

Group 3 innate lymphoid cells (ILC3s) are vital for defending tissue barriers from invading pathogens. Hypoxia influences the production of intestinal ILC3-derived cytokines by activating HIF. Yet, the mechanisms governing HIF-1α in ILC3s and other innate RORγt$^+$ cells during in vivo infections are poorly understood. In our study, transgenic mice with specific Hif-1a gene inactivation in innate RORγt$^+$ cells (RAG1KO HIF-1α$^{\Delta Rorc}$) exhibit more severe colitis following Citrobacter rodentium infection, primarily due to the inability to upregulate IL-22. We find that HIF-1α$^{\Delta Rorc}$ mice have impaired IL-22 production in ILC3s, while non-ILC3 innate RORγt$^+$ cells, also capable of producing IL-22, remain unaffected. Furthermore, we show that IL-18, induced by Toll-like receptor 2, selectively triggers IL-22 in ILC3s by transcriptionally upregulating HIF-1α, revealing an oxygen-independent regulatory pathway. Our results highlight that, during late-stage C. rodentium infection, IL-18 induction in the colon promotes IL-22 through HIF-1α in ILC3s, which is crucial for protection against this pathogen.

Complement-mediated severe hypersensitivity reaction to Paclitaxel

Jennifer Bolaños[1], Mariona Pascal[1;2;3], Rosa Muñoz-Cano[2;3;4], Francisco Lozano[1;2;5]
[1]Immunology Department, Biomedical Diagnostic Center, Hospital Clínic de Barcelona, Barcelona, Spain; *[2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain*; *[3]RETICS Asma reacciones adversas y alérgicas (ARADYAL) and RICORS Red De Enfermedades Inflamatorias (REI), Barcelona, Spain*; *[4]Allergy Department, Hospital Clinic de Barcelona, Barcelona, Spain*; *[5]Universitat de Barcelona, Barcelona, Spain*

Background: Every day practice reveals the relative high frequency of non-IgE mediated severe hypersensitivity reactions (SHR). Since the 80s, Paclitaxel, more specifically it's vehicle Cremophor EL has been associated with SHR, some of them fatal, which is why patients receiving this treatment must be pre-treated with corticosteroids and antihistamines, even though this measure has not been proven 100% effective. Herein we present a case of anaphylaxis to Paclitaxel associated to direct complement activation (DCA).
Case summary: A 62 years old female diagnosed with grade IVB endometrial carcinoma (endometrioid type), underwent complete cytoreduction surgery and subsequent adjuvant treatment with Paclitaxel-Carboplatin. After first infusion of Paclitaxel she presented anaphylactic shock with skin, cardiorespiratory and digestive system involvement that reverted after treatment with corticosteroids, antihistamines, three doses of adrenaline and cardiorespiratory support. Analytical results at 20 min post-reaction showed: tryptase 8.0 ug/L, tIgE 642.0 kU/L, C3 1.13 g/L (nv 0.87-1.70 g/L), C4 0.28 g/L (0.11-0.54 g/L) and CH50 17 U/mL (nv 28-60 U/mL). Prick test and basophil activation test (BAT) to paclitaxel were negative after 1 week of the reaction. Further Complement studies in the acute phase also detected increased levels of anaphilotoxins C3a (24.4 µg/mL; nv 6.7-11.7 ng/ml) and C5a (103 ng/mL; nv 11.5-77.8 ng/mL), as well as of membrane attack complex (MAC) sC5b-9 (1298 ng/mL (nv 187-525 ng/mL). For drug readministration, desensitization could not be achieved since a new anaphylactic shock appeared. Therefore, an alternative chemotherapy with non-pegylated doxorubicin was well tolerated.
Conclusion: Based on SHR occurring upon the first contact with paclitaxel, no evidence of specific IgE could be obtained and significantly increased anaphylotoxins and soluble MAC serum levels, we consider this to be a SHR mediated by DCA. Non-IgE mediated SHR involving DCA are relatively frequent, but little considered when making in vitro diagnosis. So far there is no difference in the medical management of IgE-mediated and non-IgE-mediated anaphylaxis. Therefore, it would be important to differentiate them and to consider the possibility of implementing preventive treatments directed against complement that seem to work in small *in vitro* studies and could prove to be more effective than current preventive treatment.

Anti-Ig-E treatment in patient with severe asthma and eosinophilic granulomatosis with polyangiitis: A case report

Nurgul Naurzvai[1], Haluk Turktas[2]
[1]Acibadem Atakent University Hospital, Istanbul; *[2]Losante Hospital, Ankara, Turkey*

Eosinophilic granulomatosis and polyangiitis (EGP), is a rare systemic small vessel vasculitis characterized by eosinophilia and typically accompanied by asthma. Patients typically present with symptoms related to asthma exacerbations, such as dyspnea, cough, and wheezing, as well as features of vasculitis such as neuropathy, skin lesions, and cardiac involvement. The exact cause of EGP is not fully understood. Both genetic and environmental factors are thought to contribute to its development. EGP is believed to be a T helper (TH) 2 mediated disorder, characterized by the upregulation of TH-2 related cytokines such as IL-4, IL-13, and IL-5. Eosinophilia in both blood and tissue is driven by eotaxin-3, produced by epithelial and endothelial cells. Glucocorticoids (GC) are the primary treatment for EGP and often lead to remission of the disease. Managing EGP can be challenging, particularly when patients are unresponsive or intolerant to standard therapies like GC. Omalizumab, an anti-Ig-E monoclonal antibody, is used in patients with severe asthma and can also be considered in EGP due to its ability to decrease eosinophil growth factors and increase eosinophil apoptosis. By targeting Ig-E and modulating eosinophilic inflammation, omalizumab offers a targeted approach with the potential to reduce reliance on systemic steroids and improve outcomes.
The 54-year-old patient had a history of asthma for 7 years before being diagnosed with EGP in 2014. Initially, the patient received steroid treatment for an extended period to manage EGP. However, he experienced recurrent asthma attacks and continued eosinophilia during follow-up. Due to the patient's severe symptoms, serious side effects from GC treatment, and frequent hospital admissions, omalizumab treatment was deemed appropriate. After initiating omalizumab treatment, the patient's symptoms were effectively controlled. He did not experience any serious asthma attacks requiring hospitalization during this 2 years period of time.
This case highlights the successful use of targeted therapy (omalizumab) in controlling EGP symptoms and preventing severe asthma exacerbations requiring hospitalization. The presentation of this case contributes valuable insights into the management of rare and refractory diseases, emphasizing the importance of personalized treatment approaches and the potential of novel therapies to improve patient outcomes.

IL-15 drives NK-receptor mediated cytotoxicity in senescent CD8 T cells

Olivia Bracken[1], Luciana Covre[2], Wing Tung Ma[1], Luisa Chocarro De Erauso[3], Roel De Maeyer[4], Christina Rollings[5], Linda Sinclair[5], Carlos Henrique Fantecelle[2], Yanchun Peng[4], Doreen Cantrell[5], Tao Dong[4], Daniel Gomes[2], Arne Akbar[1]
[1]University College London, London, United Kingdom; *[2]Universidade Federal do Espirito Santo, Vitoria, Brazil*; *[3]Universidad Publica de Navarra, Pamplona, Spain*; *[4]University of Oxford, Oxford, United Kingdom*; *[5]University of Dundee, Dundee, United Kingdom*

Purpose: Alongside reduced proliferative capacity, senescent T cells upregulate Natural Killer receptors (NKR) and are able to kill NK-target cells. We hypothesise that within inflammatory microenvironments, T cells, can induce non-specific tissue damage via NK-like cytotoxicity. We have explored the role of IL-15 in inducing senescent T cells to perform NK cytotoxic killing as a potential mechanism for non-specific pathology.
Methods: Peripheral blood mononuclear cells from males and females (30-80 years) were sorted into CD8 naïve (CD27+CD28+) and senescent (CD27-CD28-) T cell populations, followed by proteomic analysis. Cytotoxicity assays were performed using these cells cultured with and without 10 ng/ml IL-15 for 48 hours prior to co-culture with K562 target cells. Virus-specific CD8+ T cells and autologous fibroblasts were provided by Prof. Tao Dong.
Results: Upstream pathway analysis showed that IL-15 was predicted to be the master regulator of the proteome of senescent but not naïve T cells. Incubation of naïve and senescent T cells with IL-15 increased NKG2D and DAP-12 expression, facilitating antigen-independent cytotoxicity. IL-15 induced CD8+ senescent T cells to kill the K562 NK-target cell line. We investigated if virus epitope specific CD8+ T cytomegalovirus (CMV) and influenza virus (Flu) specific cell clones, which had a similar phenotype to senescent T cells, could kill autologous fibroblast targets. These cells were able to, but only at early time points after activation. This suggests that antigen-specific CD8+ T cells may only possess NK-like activity at the height of activation. To determine if this mechanism of non-specific killing was relevant *in vivo*, we studied patients with cutaneous leishmaniasis (CL) who develop skin lesions after parasitic infection. As the disease progresses there are few parasites, but an accumulation of NK-like CD8 T cells. We showed that a cocktail of cytokines, mimicking those that were within the lesions, could induce CD8 T cells to kill autologous fibroblasts and this was blocked by preventing NKG2D signalling.
Conclusion: Therefore, senescent CD8+ T cells can perform antigen-independent cytotoxic activity. This may be a mechanism for antigen non-specific pathology in clinical situations where intense inflammation and the accumulation of senescent T cells coexist.

Persistent exposure to cancer-derived granulocyte colony stimulating factor leads to aberrant bactericidal functionality of neutrophils

Ekaterina Pylaeva[1;2], Olga Shevchuk[1], Lea Tollrian[1], Jana Riedesel[1], Irem Ozel[1], Cornelius Kürten[1], Jan Kehrmann[1], Daniel Robert Engel[1], Helmut Hanenberg[1], Stephan Lang[1], Jadwiga Jablonska[1;2]
[1]University Hospital Essen, Essen, Germany; *[2]German Cancer Consortium (DKTK) partner site Düsseldorf/Essen, Essen, Germany*

Bacterial infections exert a profound impact on the morbidity and mortality rates among cancer patients. Besides the variety of disease- or treatment-dependent factors, modulation of immune responses by tumor itself potentially fosters the persistence of pathogenic microorganisms. While short treatment with granulocyte colony stimulating factor (G-CSF) effectively increases neutrophil counts and stimulates antibacterial properties of neutrophils both *in vitro* and *in vivo*, the controversial effects of persistent exposure to tumor-derived G-CSF on neutrophil functionality have been previously underestimated.
Our investigation revealed an increased susceptibility to infections associated with Gram-negative pathogens in previously untreated patients with head and neck cancer characterized with elevated expression of G-CSF. To investigate the impact of tumor G-CSF on impaired antibacterial responses, we established a murine model of oropharyngeal carcinoma characterized by low and high G-CSF production (MOPC and G-MOPC, respectively). We confirmed the role of persistent tumor-derived G-CSF stimulation in decreased resistance of such animals to lower respiratory tract infection caused by *Pseudomonas aeruginosa*.
Through analysis of proteome landscapes of lung neutrophils, we identified the affected pathways involved in cytoskeleton reorganization, response to reactive oxygen species, and regulation of aging and apoptosis in neutrophils isolated from G-MOPC-bearing animals (G-neutrophils). Accordingly, isolated G-neutrophils exhibited aberrant functionality related to these processes, with the most prominent impairment in aged cells. Notably, the alterations induced by persistent G-CSF exposure manifested at the neutrophil progenitor stage and persisted even after withdrawal of G-CSF from the system. Modulation of G-CSF downstream signaling pathways restored neutrophil maturation and functionality *in vitro*, leading to improved bacterial clearance *in vivo*.
Thus, the disregulated functionality of neutrophils, orchestrated by tumor-derived G-CSF, can be persistent over time and have an extended impact on the bactericidal clearance. Clinically, heightened attention to neutrophil functionality in cancer patients, also after surgical removal of the tumor, is required.

Loss of SARM1 attenuates chemokine production & immune cell infiltration during retinal degeneration

Luke Gibbons[1], Chris Greene[1], Charlotte Leane[1], Sarah Doyle[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Retinal degenerative diseases are a leading cause of incurable vision loss worldwide. Photoreceptors are the cells responsible for sensing light and initiating visual signalling, many retinal degenerative diseases are characterised by photoreceptor cell death resulting in irreversible sight loss. SARM1 is a TLR adaptor with an additional role in induction of axonal degeneration and neuronal cell death in response to various insults. Our lab has previously described a role for SARM1 in promoting photoreceptor cell death in models of retinal degeneration. Additionally, SARM1 regulates an immune response in injured neurons prior to cell death, resulting in the release of chemokines from neurons and recruitment of peripheral immune cells to the site of injury.

We aimed to characterize photoreceptor immune responses during retinal degeneration using the sodium iodate ($NaIO_3$) model of oxidative stress. $NaIO_3$ was administered by a single intravenous injection to induce retinal degeneration in C57BL/6J and *Sarm1*$^{-/-CRISPR}$ mice. *In vivo* optical coherence tomography (OCT) imaging was carried out at day-1 post $NaIO_3$ administration to assess immune cell infiltration. Chemokine levels in retinal lysates were quantified by ELISA. Immune cell infiltration into the retina was examined by flow cytometry. Photoreceptors were isolated from the retina and qPCR analysis was carried out to assess photoreceptor chemokine production in response to $NaIO_3$.

At day-1 post intravenous administration of $NaIO_3$, photoreceptor cells upregulate a range of chemokines, including CCL5, CCL7, and CXCL12 demonstrating that photoreceptors can generate an immune response to damage. Interestingly, at day-1 post $NaIO_3$, *Sarm1*$^{-/-CR}$ mice have reduced levels of CCL2 compared to C57BL/6J counterparts, as measured by ELISA. Likely as a result of this reduced chemokine secretion we observed fewer cells infiltrating into the retina of *Sarm1*$^{-/-CRISPR}$ mice compared to C57BL/6J, following NaIO3 administration by *in vivo* OCT imaging. Notably, we found by flow cytometry analysis that *Sarm1*$^{-/-CR}$ mice had significantly decreased numbers of infiltrating monocytes and dendritic cells at day-3 post $NaIO_3$ injection compared to C57BL/6J counterparts.

Taken together these data point towards SARM1 regulating a photoreceptor immune response prior to retinal degeneration which drives immune cell infiltration into the retina via upregulation of chemokines.

Senescence related phenotypic alterations of lymphocytes are affected by dialysis prescription and can predict mortality in dialysis patients

Georgios Lioulios[1], Aliki Xochelli[2], Theodoros Tourountzis[3], Michalis Christodoulou[4], Eleni Moysidou[4], Stamatia Stai[4], Aikaterini Papagianni[4], Ioannis Theodorou[5], Maria Stangou[4], Asimina Fylaktou[2]
[1]Department of Nephrology, 424 General Military Hospital, Thessaloniki, Greece; *[2]National Peripheral Histocompatibility Center, Department of Immunology, Hippokration Hospital, Thessaloniki, Greece*; *[3]Protypo Dialysis Center, Hemodialysis Unit, Thessaloniki, Greece*; *[4]1st Department of Nephrology, Hippokration Hospital, School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece*; *[5]Laboratoire d'Immunologie, Hôpital Robert Debré, Paris, France*

Purpose: Senescence-resembling alterations on lymphocytes of dialysis patients have been widely described. However, pathophysiology behind these phenomena has not been clarified. In this study, we examine the impact of dialysis prescription and residual urine output (RUO) on T and B lymphocytes, in dialysis patients
Methods: T and B cell subsets were determined with flow cytometry in 36 hemodialysis (HD) and 26 hemodiafiltration (HDF) patients, according to the expression of CD45RA, CCR7, CD31, CD28, CD57 and PD1 for T cells, and IgD and CD27 for B cells. Immune phenotype was associated with dialysis modality, hemofiltration volume (HFV), RUO and mortality
Results: Compared to HD, HDF patients had significantly decreased percentage of CD4+CD28-CD57- T cells [3.8(2.4-5.3) vs 2.1(1.3-3.3)%, respectively, P = 0.002] and exhausted CD4+ T cells [14.1(8.9-19.4) vs 8.5(6.8-11.7)%, respectively, P = 0.005]. Additionally, HFV was negatively correlated to CD8+ EMRA T cells (r = -0.46, P = 0.03). Moreover, retained RUO and shorter dialysis vintage were both independently associated, and also had synergistic effect, to increased count of total and naïve CD4+ T cells. Finally, exhausted CD4+ T cells percentage could predict all-cause mortality in dialysis patients, independently of age. Kaplan-Meier survival analysis for patients with proportion of CD4+PD1+ above and below median was significant (log rank P = 0.002). Moreover, significant effect of exhausted CD4+PD1+ T cells proportion remained in Cox Regression either when examined alone as a continuous variable (P = 0.003, 95% CI: 1.0, 1.2), or in combination with age (CD4+PD1+ proportion: P = 0.03, 95% CI: 1.01, 1.23, age: P = 0.02, 95% CI: 1.01, 1.44).
Conclusion: HDF especially with high HFV may have beneficial effects on senescence-related immune phenotype. RUO may also contribute to retarding immune senescence. Immune phenotype may also be a predicting factor for mortality in dialysis patients.

Sustainable T and B cell immunity in long-lived rodents (Spalax)

Maria Metsger[1], Alexey Davydov[1;2], Pavel Shelyakin[3], Mark Izraelson[2], Aleksei Mazalov[4], Irina Shagina[4;5], Jessica. Nordlund[6], Ulrika Liljedahl[6], Valeriia Kriukova[7], Kseniia Lupyr[4;8], Imad Shams[9], Dmitriy Chudakov[1;4;5], Olga Britanova[4;7]

Healthy aging represents one of the global challenges nowadays. Preservation of immunological memory contributes to the successful survival of both mice and humans. However, in some cases, immunologic memory could lead to erroneous adaptive immune responses resulting in chronic inflammation and autoimmunity. Recently emerging data show that age-related changes in adaptive immunity include accumulation of regulatory T cells, expansion of cytotoxic memory T cells, and significant reduction of naive T cell subset within CD8+ and CD4+ T cell pool in humans and mice.
In this study, we aim to explore the adaptive immune organization of an exceptionally long-lived and cancer-resistant rodent, Spalax. In contrast to mice and humans, repertoire diversity of T cell receptors remains stable with age in Spalax. Following our previous findings on Spalax adaptive immunity (Izraelson et al., Nature Aging, 2021), we focus on the age-related changes in transcriptomic programs of T and B lymphocytes using single-cell RNA and TCR sequencing of cells from the spleen and lymph nodes of young and aged animals.
Our results show that in contrast to mice, Spalax immunity has the following features:

- Exhausted memory CD8+ T cell clones do not accumulate with age and do not express GZMK;
- T cells lack accumulation of expression signatures of immune checkpoints (*Ctla4, Pdcd1, Tigit, Lag3*) and Tregs with aging.
- B cells have stably high level of SHM that do not increase with age;
- B cells include a unique *Aicda* expressing subset. *Aicda* encodes activation induced deaminase (AID) that mediates the class switch recombination and somatic hypermutations in the V-region of BCR. The increased expression of AID in Spalax B cells might contribute to affinity maturation of immunoglobulins that apparently occurs faster than in mice.

Based on our results, we can conclude that the balanced functioning of adaptive immunity in aged Spalax is supported by several mechanisms, including maintaining a low proportion of highly specialized long-lived memory T cells - a distinct strategy that potentially underlies this animal's extraordinary longevity.

Aging drives dysregulation of regulatory T cells in the gut mucosa.

Jefferson Leite[1], Natalia Notarberardino Bos[1], Rebecca Jasser[1], Zeynep Ergun[1], Katlynn Carter[1], Aysan Pousardegh Zonouzi[1], Emmanouil Stylianakis[1], Nadine Hoevelmeyer[1], Ari Waisman[1]
[1]*University Medical Center of Johannes Gutenberg University of Mainz Institute for Molecular Medicine, Mainz, Germany*

Aging encompasses the gradual deterioration of physiological functions crucial for survival and reproductive capacity, driven by various factors including cellular senescence, genomic instability, and mitochondrial dysfunction. Cellular senescence, induced by diverse stress stimuli, involves intrinsic factors such as replicative stress and DNA damage, along with extrinsic factors like viral infections and UV exposure. Nuclear DNA damage activates the DNA damage response (DDR) pathway, leading to p53-mediated cell cycle arrest and senescence. With advancing age, immune senescence occurs, characterized by dysregulation of innate and adaptive immunity and a chronic low-grade inflammatory state termed inflammageing. This study aimed to evaluate the impact of aging on effector and regulatory T cell (Treg) functionality within the gut mucosa. We found that aged mice exhibited alterations in the CD4 T cell profile, including a decrease in naive CD4 T cells and an increase in effector CD4 T cells, particularly Th1 and Th17 cells. Despite an increase in Treg cell frequency, aged Treg cells showed signs of activation, with elevated expression of CD44. Furthermore, the aged gut mucosa displayed an increased population of Treg subsets, including Treg+ Helios+, Helios+KLRG1+, and RORγt+ cells. Assessment of Treg suppressive capacity in an experimental model of T-cell transfer colitis revealed diminished efficacy of Tregs from aged mice in suppressing intestinal inflammation compared to young Tregs. Additionally, aged Tregs exhibited increased DNA damage and oxidative stress, as indicated by elevated levels of H2AX and mitochondrial ROS expression. Reduced proliferation was observed in aged Tregs, indicative of senescence. Moreover, increased expression of IL-6 signaling molecules in aged Tregs suggested a potential role of IL-6 in driving Treg senescence. Further investigation into the relationship between gut microbiota composition and Treg response revealed differences in Treg accumulation between aged mice in SPF and non-SPF facilities, suggesting a potential link between gut microbiota composition and Treg alterations during aging. In conclusion, aging affects Treg functionality in the gut mucosa, leading to altered suppressive capacity and accumulation of DNA damage and oxidative stress, potentially contributing to immune dysregulation associated with aging.

Highly multiplexed and 3D microscopy of the bone marrow microenvironment reveals rapidly expanding immature vasculature and PD-1+CD8+ T cell niches driving leukemic progression

Lanzhu Li[1], Geoff Ivison[2], Isabelle Rottmann[3], Jan C. Schröder[4], Yury Goltsev[5], Garry P. Nolan[5], Aaron T. Mayer[2], Bettina Weigelin[3;6], Christian M. Schürch[1;6]
[1]Department of Pathology and Neuropathology, University Hospital and Comprehensive Cancer Center Tübingen, Tübingen, Germany; *[2]Enable Medicine Inc., Menlo Park, CA, United States*; *[3]Werner Siemens Imaging Center, Department of Preclinical Imaging and Radiopharmacy, University of Tübingen, Tübingen, Germany*; *[4]Department of Internal Medicine II, Hematology, Oncology, Clinical Immunology and Rheumatology, University Hospital Tübingen, Tübingen, Germany*; *[5]Department of Pathology, Stanford University School of Medicine, Stanford, CA, United States*; *[6]Cluster of Excellence iFIT (EXC 2180) "Image-Guided and Functionally Instructed Tumor Therapies", University of Tübingen, Tübingen, Germany*

Purpose: The bone marrow microenvironment (BMME) critically regulates hematopoiesis. In leukemias, the BMME is remodeled towards a pro-leukemogenic niche, and the interplay of leukemic cells with their niche is critical for leukemia initiation, disease progression, and immune evasion. Therefore, an in-depth characterization of the BMME in 3D and at spatially resolved single-cell resolution will improve our understanding of leukemic progression and antitumoral immunity.
Methods: Femoral bones from wild-type and chronic myeloid leukemia mice 7, 14 and 21 days after leukemia induction were analyzed using 54-marker CODEX highly multiplexed microscopy and full-thickness 3D light-sheet microscopy.
Results: A total of 2,033,725 cells from 3 mice per group were imaged by CODEX. Using unsupervised clustering and manual annotation, we identified 41 cell types, including myeloid, erythroid, lymphoid, vascular and stromal cells, megakaryocytes, hematopoietic stem/progenitor cells (HSPCs), and leukemic subsets. During leukemic progression, the BMME was dramatically rearranged. Besides the expected expansion of leukemic cells, we found massive increases in immature vessels and megakaryocytes, whereas B cells were significantly reduced. CD8+ T cells shifted towards an immunosuppressive phenotype and upregulated PD-1 as disease advanced. Furthermore, in advanced-stage CML, PD-L1 was not only expressed by leukemic cells but also by non-malignant antigen-presenting cells (APCs), such as macrophages and dendritic cells. Neighborhood analysis revealed 14 BMME niches, and PD-1+CD8+ T cells were mostly enriched in the leukemic niche. CD34+CD117- HSPCs were predominantly located in bone and vascular niches, whereas CD34+CD117+ HSPCs were significantly enriched in the leukemic niche. Compared to wild-type mice, PD-1+CD8+ T cells were in close contact with PD-L1+ APCs in advanced leukemia. Moreover, during disease progression, PD-L1+ leukemic cells increasingly interacted with PD-1+CD8+ T cells. Leukemic stem cells were localized closer to megakaryocytes in advanced compared to early leukemia. In addition, 3D light-sheet microscopy revealed intimate cell-cell contacts between immature vessels and megakaryocytes, which increased in advanced leukemia.
Conclusion: We created a spatiotemporal landscape of the BMME during leukemic progression at an unprecedented resolution. We demonstrate that leukemic cells remodel the BMME to form specialized niches supporting their expansion and counteracting antitumoral immunity. Our findings could pave the way for novel leukemia immunotherapies.

Colorectal cancer ranks among the most prevalent malignancies worldwide, and frequently progresses into colorectal cancer liver metastasis (CRLM), resulting in a 5-year survival rate ranging from 30 to 50%. For those patients, partial hepatectomy is the therapeutic approach with the highest success rate, but the eligibility for surgery is restricted to merely 20% of patients. Neoadjuvant chemotherapy (NAC) is used as standard of care to facilitate the feasibility of curative surgery, as it can convert up to 30% of initially unresectable CRLMs into resectable metastases. However, the underlying reasons of why some patients fail to benefit from neoadjuvant treatment are currently unknown. The success of immunotherapeutic interventions hinges upon the presence and functional activity of infiltrating lymphocytes, which is tightly governed by the metastatic microenvironment. In this study, we collected CRLM samples from patients treated with NAC and studied the unicity of three spatially distinct patient-matched regions: the metastatic nodule, the invasive margin, and the distal liver tissue. Using high dimensional flow cytometry, we revealed distinct immune landscapes characteristic of each region. As such, we observed a scarcity of effector lymphocytes in the metastatic nodule, concomitant with an enrichment of exhausted, regulatory and memory T cells. Subsequent correlations of these immune features with NAC response revealed that patients with a high tumor burden and low fibrosis exhibited a more suppressive/exhausted lymphocytic landscape. Conversely, metastases that regressed in response to NAC were highly infiltrated by unique subsets of memory T cells. The integration of whole transcriptome analysis with proteomics revealed distinct signatures for these memory T cell subsets, which predicted prognosis in publicly available data sets for metastatic CRC. Our findings provide valuable insights into the biology of CRLM and unveil immune signatures associated with response to NAC. Based on this study, we suggest new therapeutic strategies to enhance NAC efficacy in CRLM management.

Beyond Helpers: Unraveling the Potential of CD4+ Cytotoxic T Cells in B cell lymphoma

Ivana Spasevska[1;2;3], Karoline Kongsrud[1;2;3], Ankush Sharma[1;2;3], Eveline Scherer[1], Hanna Julie Hoel[1;3], Marianna Vincenti[1;3], Monica Bostad[4], Heidi Ødegaard Notø[4], Idun Dale Rein[4], Claire Dunn[1], Kanutte Huse[1;2;3], June H. Myklebust[1;2;3]
[1]Department of Cancer Immunology, Institute for Cancer Research, Oslo University Hospital, Oslo, Norway; *[2]KG Jebsen Centre for B-cell malignancies, Institute of Clinical Medicine, University of Oslo, Oslo, Norway*; *[3]Precision Immunotherapy Alliance, University of Oslo, Oslo, Norway*; *[4]Flow Cytometry Core Facility, Department of Core Facilities Institute for Cancer Research, Oslo University Hospital, Oslo, Norway*

$CD4^+$ T cells exhibit remarkable heterogeneity and consist of several subsets. While most $CD4^+$ T cells exhibit either helper or immunoregulatory function, emerging evidence points to the existence of a unique subset of $CD4^+$ T cells with direct cytotoxic potential. Recently, there has been growing interest in these $CD4^+$ cytotoxic T lymphocytes (CTLs) due to their potential involvement in anti-tumor immune responses and their relevance in immunotherapy.
In a recent study, we employed cutting-edge single-cell RNA sequencing (scRNAseq) and T-cell receptor (TCR) sequencing to explore the landscape of $CD4^+$ T cells in lymphoma. We included diagnostic biopsies of diffuse large B-cell lymphoma (DLBCL, n = 3) and follicular lymphoma (FL, n = 3), alongside non-malignant tonsils (n = 3). Among the $CD4^+$ T cell clusters, one was characterized by high expression of a cytotoxic gene signature (*GZMK*, *NKG7*, *CST7*, *GZMA*, *GZMB*) and high expression of checkpoint receptors (*LAG3*, *HAVCR2*, *TNFSF9*). The $CD4^+$ CTLs accounted for over 20% of $CD4^+$ T cells within DLBCL and over 10% in FL tumors. Strikingly, the $CD4^+$ CTLs were almost absent in non-malignant tonsils. Their tumor-specific nature was further highlighted by TCR clonality analysis as $CD4^+$ CTLs had the highest clonal expansion among $CD4^+$ T cell subsets.
We further validated the presence of $CD4^+$ CTLs within an independent series of DLBCL tumors using flow cytometry by identifying $CD4^+$ CTLs as Granzyme B^+ Perforin$^+$ cells within the $CD4^+CD8^-FOXP3^-CD56^-$ population, excluding cytotoxic $CD8^+$, regulatory T cells and NK cells. $CD4^+$ CTLs ranged from 1-23% of intratumoral $CD4^+$ T cells in DLBCL and consistently with the scRNAseq findings, these cells were absent in non-malignant tonsils. More extensive phenotyping of intratumoral $CD4^+$ CTLs by spectral flow cytometry and functional assessments are currently ongoing.
In conclusion, by employing state-of-the-art technologies we have characterized $CD4^+$ CTLs in lymphoma and demonstrated substantial clonal expansion in DLBCL. Our findings might have implications for therapeutic strategies that leverage the yet untapped potential of this $CD4^+$ T cell subset in cancer immunotherapy.

Distinct spatiotemporal dynamics drive CD8+ T cell fate decision in tumor microenvironment

Valentina Russo[1;2], Carlo De Intinis[1;2], Gaia Montacchiesi[1;2], Luca Petiti[1], Nadia Brasu[1;2], Denis Baev[1;3], Lucia Lopez[4], Federica Benvenuti[4], Anna Sapino[3;5], Luigia Pace[1;2]
[1]Italian Institute for Genomic Medicine (IIGM), Candiolo (Turin), Italy; *[2]Armenise Harvard Lab of Immunity and Cancer, FPO-IRCCS Candiolo, Candiolo (TO), Italy*; *[3]FPO-IRCCS Candiolo, Candiolo (Turin), Italy*; *[4]Cellular Immunology, International Centre for Genetic Engineering and Biotechnology, ICGEB, Trieste, Italy*; *[5]University of Turin, Turin, Italy*

The immune system plays a critical role in fighting cancer initiation and progression. Tumor infiltrating lymphocytes (TILs), indeed, are essential components of the tumor microenvironment and play a critical role in immunotherapy responses. However, there are still a lot of open questions about TIL heterogeneity and effector functions before and after immunotherapy treatment. Understanding lineage relationships between naïve, effectors, memory and exhausted T cell subsets, and the underlying molecular pathways that regulate gene expression programs during the transitions between these distinct states, is essential for the rational design of novel vaccines and the development of new immunotherapy protocols.
In this study, we have examined $CD8^+$ T cell heterogeneity during different stages of cancer progression, by developing an integrative approach based on the combined single cell (sc) multi-omics analysis of surface markers at protein level (scCITE-seq), gene expression and abTCR (scRNA-seq) profiles, in both highly and poorly immunogenic mouse tumour models *in vivo*. The results highlight a complex TIL heterogeneity, with the identification of new neoantigen-specific $CD8^+$ T subsets, among which, $PD1^{low}$ cycling, $PD1^{high}$ exhausted and tissue resident memory (T_{RM}) $CD8^+$ T cells. We also found that both the immunogenicity and abundance of cancer neoepitopes have an impact on the transcriptional programs associated with tumour rejection. Of note, the expression of these new intra-tumoral gene expression signatures correlates with the progression free survival in solid tumour patients.
Taken together these results highlight new inter-clonal relationships between different $CD8^+$ T subsets in tumours, with distinct self-renewal and functional properties when comparing poorly vs highly immunogenic tumours, as well as during the different phases of cancer progression.

Tissue resident T cell responses to immunotherapies at the patient derived tumor-lung tissue interface

Tonia Bargmann[1;2], Sebastian Konzok[1;2], Dirk Schaudien[1], Christopher Werlein[3], Patrick Zardo[4], Lavinia Neuebert[2;3], Danny Jonigk[2;5], Hans-Gerd Fieguth[6], Katherina Sewald[1;2], Susann Dehmel[1;2], Armin Braun[1;2]
[1]Fraunhofer Insitute for Toxicology and Experimental Medicine (ITEM), Hannover, Germany; *[2]Member of the German Center for Lung Research (DZL), Biomedical Research in Endstage and Obstructive Lung Disease Hannover (BREATH) research network, Hannover, Germany*; *[3]Hannover Medical School, Institute of Pathology, Hannover, Germany*; *[4]Department of Cardiac, Thoracic, Transplantation and Vascular Surgery, Hannover School of Medicine, Hannover, Germany*; *[5]Institute of Pathology, School of Medicine, University Hospital RWTH Aachen, Aachen, Germany*; *[6]Klinikum Siloah and Klinikum Nordstadt Pathology, Hannover, Germany*

Purpose: A high infiltration of $CD39^+/CD103^+/CD8^+$ resident T cells in solid tumors is associated with improved response to immune checkpoint therapy. CD39 is an Ecto-ATPase, which contributes to an enzymatic cascade converting eATP into adenosine, thus shaping an immunosuppressive tumor microenvironment (TME). To counteract this, therapeutic anti-CD39 antibodies are being tested to drive the TME into an inflammatory state. We aim to evaluate the effectiveness of anti-CD39 and anti-PD-1 on lung cancer by analyzing patient-specific immune responses using precision-cut lung tissue slices.
Methods: Tumor far and tumor-front slices were prepared from human lung resections. Tumor-front tissue was distinguished from tumor far tissue by macroscopic and microscopic analysis. Tissue viability was assessed by metabolic activity using WST-1 assay and plasma membrane integrity by Lactate Dehydrogenase Release Assay with and without immune checkpoint treatment. After treatment with anti-CD39 (1 µg/mL) or the anti-PD1 antibody Nivolumab (50µM), we leveraged histological profiling, flow cytometry of T cell subsets, eATP levels and cytokine analysis in the culture supernatant to understand how anti-CD39 impacts immune regulation within TME after 30h *ex vivo*.
Results: Tumor slices contained significantly higher frequencies of $CD8^+/PD\text{-}1^+$ (1.6-fold) and $CD8^+/CD39^+/CD103^+$ (2.2-fold) cells. Treatment with anti-CD39 effectively inhibited CD39 activity, evidenced by a 4.3-fold increase in eATP levels in the culture supernatant of tumor-far tissue. In tumor tissue, 1 µg/mL anti-CD39 significantly increased activation of $CD8^+/CD103^+/CD39^+$ cells, denoted by an increase $CD107a^+$ expression (1.3-fold change in frequency). Additionally, $CD3^+$ T cells upregulated the early activation marker CD137 after treatment (1.43-fold) in two of four donors. As treatment reference, Nivolumab treated tumor tissue induced an increase in the activation marker CD107a on $CD8^+$ T cells (1.4-fold) in one of four donors. However, all donors displayed significantly higher total secretion of IFNγ (12-fold) and lowered secretion of TGFβ2 (1.5-fold) compared to the medium control.
Conclusion: Treatment of lung tumor tissue with anti-CD39 induces activation of T cells in and may specifically target the anti-tumor reactive $CD39^+/CD103^+/CD8^+$ T cells. Presently, we demonstrated the added value of viable patient-derived lung tumor tissue, providing data on the efficacy of immunotherapies in context of patient specific TMEs.

Distinct immune resistance profiles of malignant subpopulations contribute to intra-tumoral heterogeneity of pancreatic cancer

Abir Hussein[1], Ayse Nur Menevse[1], Julian Sax[1], Leonard Bellersheim[1], Antonio Sorrentino[1], Mostafa El-Tager[2], Daniele Ferrari[3], Andrea Markus[3], Ahmed Mahfouz[2], Marcel Reinders[2], Frauke Alves[3], Philipp Beckhove[1;4]
[1]Leibniz Institute for Immunotherapy (LIT), Regensburg, Germany; *[2]Delft University of Technology, Delft, Netherlands*; *[3]Max-Planck-Institute for Multidisciplinary Sciences, Göttingen, Germany*; *[4]University Hospital Regensburg, Department of Internal Medicine III, Regensburg, Germany*

Purpose: Identification and characterization of hitherto unknown immune resistance genes that are actively expressed and exploited by pancreatic ductal adenocarcinomas (PDAC) to escape immune evasion and refract current immunotherapies.
Methods: To systematically identify immune resistance genes, we performed high-throughput RNA interference screens of tumor-T cell co-cultures on human primary PDAC cells alongside five other tumor entities. We explored the expression profiles of 235 validated genes by analysing publicly-available transcriptome data from primary PDAC patients. The degree of heterogeneity between tumor subjects and in comparison to control pancreases was investigated based on bulk data. Intra-tumoral heterogeneity was explored by merging and integrating single-cell RNA-seq datasets from 36 patients. Candidate genes were selected for functional in vitro testing in several primary PDAC cell lines. Murine cells were transduced with viral-based shRNA to generate the stable knockdown of promising candidates for in vivo testing and validation of the impact of immune resistance gene expression on tumor progression and response towards peptide-based nano-vaccination in syngeneic pancreatic cancer mouse model.
Results: We obtained subpopulations of malignant ductal cells reflecting distinct biological states and characterized by a differential co-expression of immune-resistance genes driven by upstream transcription factors. Candidates selected for deeper functional analyses proved to protect against the immune rejection mediated by tumor-specific cytotoxic T lymphocytes. Tested genes mediate tumor-intrinsic resistance to T cell-derived cytotoxic molecules such as TRAIL, FasL and TNFa with differential impacts on distinct downstream death-receptor signaling pathways. Downregulation of some genes resulted in elevated death receptor expression on tumor cells sensitizing them towards immune rejection. Murine PDAC cells with the stable knockdown of three candidates were tested in a KPC orthotopic mouse model. In vivo experiments proved that immune resistance gene expression promotes tumor progression in immune-competent mice. Combination of gene inhibition with peptide-based PDAC nano-vaccine improved the therapeutic efficacy over monotherapies. The tumor micro-environment of mice that received the combination therapy showed an induced T cell activation as well as cytokine secretion.
Conclusion: In this work, we have identified and validated novel therapeutic targets for inhibition in PDAC for an enhanced tumor-sensitivity towards cytotoxic immune responses.

Engineered nanobodies as tools to visualize and direct antigen specific tolerance

Novalia Pishesha[1;2]
[1]*Boston Children's Hospital, Boston, United States*; [2]*Harvard Medical School, Boston, United States*

Autoimmune disorders affect approximately 10% of the global population, presenting symptoms ranging from mild to life-threatening. Current treatments largely involve broad immunosuppression, which can leave patients vulnerable to infections. We introduce an immunomodulatory strategy that targets the immune response to specific antigens while preserving overall immune functionality.

Our work centers on developing single-domain antibody fragments (nanobodies or VHHs) derived from alpacas. These nanobodies specifically target major histocompatibility complex class II (MHCII), allowing them to interact with all professional antigen-presenting cells (APCs). We developed a method for site-specific modification of these VHHs at their C-terminus using various chemo-enzymatic techniques, enabling the attachment of a broad spectrum of autoantigens, including citrullinated peptides, and anti-inflammatory drugs, e.g., dexamethasone (DEX). We demonstrated that a single dose of a VHH_{MHCII} conjugated to myelin oligodendrocyte glycoprotein (MOG) peptides and DEX (VHH_{MHCII}-MOG-DEX) provides long-lasting protection against experimental autoimmune encephalitis (EAE), a model for multiple sclerosis (MS), and can reverse paralysis in symptomatic mice without compromising their immunity against pathogens. This approach can be adapted for other autoimmune diseases like type I diabetes and rheumatoid arthritis by simply changing the autoantigens. This strategy is also applicable in suppressing unwanted immune responses against viral gene therapy vectors, permitting gene therapy redosing. Remarkably, all these benefits are achieved with a single dose.

To explore the mechanisms behind inducing antigen-specific tolerance, we employed comprehensive flow cytometry and transcriptomic analyses, which indicated an increase in antigen-specific regulatory T cells and evidence of bystander immune suppression mechanism. Additionally, we utilized positron emission tomography (PET)-based imaging to non-invasively monitor the biodistribution and tolerogenic activity of our engineered nanobodies in real-time. Furthermore, we developed anti-idiotypic nanobodies that recognize specific T-cell receptors (TCRs), i.e., 2D2 TCR, which interacts with the I-$A^b$$MOG_{35-55}$ complex. These nanobodies were used as imaging agents in immuno-PET to detect infiltrating T cells in the spinal cord of symptomatic EAE mice, helping us trace the efficacy of our antigen-specific tolerance approach. In conclusion, our engineered nanobodies offer a promising and versatile tool for both the specific modulation and real-time tracking of immune responses in autoimmune diseases, providing targeted treatments and future diagnostic avenues.

Anti-citrullinated histone antibody CIT-013: Targeting neutrophil extracellular traps as an anti-inflammatory therapy in hidradenitis suppurativa.

Stephanie van Dalen[1], Josephine Stein[1], Tirza Bruurmijn[1], Martyn Foster[2], John Ingram[3], Jacek Szepietowski[4], Piotr Krajewski[4], Errol Prens[5], Kelsey van Straalen[5], Maarten van der Linden[1], Renato Chirivi[1], Eric Meldrum[1]
[1]Citryll B.V., Oss, Netherlands; *[2]Experimental Pathology Consultancy, Benfleet, United Kingdom*; *[3]Cardiff University, Cardiff, United Kingdom*; *[4]Wroclaw Medical University, Wroclaw, Poland*; *[5]Erasmus Medical Centre, Rotterdam, Netherlands*

Purpose: Neutrophils are scarce in healthy skin but infiltrate lesions of Hidradenitis Suppurativa (HS) patients. Activated neutrophils release neutrophil extracellular traps (NETs) which contribute to the pathophysiology of many immune-mediated inflammatory diseases, including HS. CIT-013 is a first-in-class monoclonal antibody that targets the citrullinated histones H2A and H4, specifically present in NETs. CIT-013 has a unique NET-targeting dual MoA, suppressing the proinflammatory properties of NETs, and shows therapeutic efficacy in several pre-clinical models of neutrophil associated inflammation. In this study we validate HS as therapeutic target for CIT-013 by demonstrating the presence of proinflammatory NETs in lesional and perilesional biopsies and by showing a relationship between serum NETs and increasing HS clinical score.
Methods: The possible presence of the NET component citrullinated histone H3 (citH3) was assessed in HS lesional, perilesional and unaffected skin by immunohistochemistry. Several markers of NETs (CIT-013's epitope, citH3, calprotectin, and nucleosome content) were assessed in HS serum with ELISA.
Results: The presence of the NET component citH3 is significantly increased across several layers of HS skin lesional and perilesional regions compared to unaffected skin. Furthermore, CIT-013's epitope, citH3, calprotectin, and nucleosome content were significantly elevated in the serum of HS patients compared to healthy volunteers. Detection of these markers for NETs in serum increased in association with increasing International Hidradenitis Suppurativa Severity (IHS4) clinical score.
Conclusions: NETs are abundantly present in inflamed HS skin lesions. Moreover, markers of pro-inflammatory NETs are significantly elevated in HS serum in a manner that associates with increasing HS clinical score. This data reinforces the position of CIT-013 as a therapeutic approach for NET-associated diseases with unmet therapeutic needs, such as HS. CIT-013 will enter a phase 2 proof-of-concept trial in HS during 2024.

Elimination of CD45RChigh T and B cells by anti-CD45RC mAb lead to efficient control of experimental rheumatoid arthritis

Cécile Bergua[1], Marine Besnard[1], Ghenima Ahmil[2], Laure-Helene Ouisse[2], Nadege Vimond[1], Apolline Salama[2], Bérangère Evrard[2], Elise Brisebard[3], Alexis Collette[1], Frédéric Blanchard[4], Thibaut Larcher[3], Benoit Le Goff[5], Ronald Van Brempt[1], Ignacio Anegon[2], Carole Guillonneau[1;2]
[1]AbolerIS Pharma, Nantes, France; *[2]Nantes Université, INSERM, Center for Research in Transplantation and Translational Immunology, UMR 1064, CNRS, Nantes, France*; *[3]APEX-UMR703 PAnTher INRA/ONIRIS, Nantes, France*; *[4]INSERM UMR1229, Nantes, France*; *[5]CHU Nantes, Nantes, France*

Purpose: RA is a chronic relapsing/remitting disease characterized by synovitis, joint deformity, loss of function and increased mortality involving T and B cells. We demonstrated that administration of an anti-CD45RC mAb targeting B cells and a subset of T cells (Th1 and their precursor and TEMRA cells) leads to prevention or control in preclinical models of transplant rejection, GvHD, Duchene dystrophy or APECED. In this study, we deciphered the mechanism of action of the anti-human CD45RC mAb and in vitro and in vivo and potential in an experimental model of rheumatoid arthritis.
Methods: Cells were isolated from peripheral blood. Apoptosis, ADCC, ADCP and CDC were assessed by Annexin V/DAPI staining and cell count. In vivo studies were performed in CD34+-humanized NSG mice, in a GVHD model in humanized NSG mice or in a model of collagen-induced arthritis (CIA) in rat.
Results: We demonstrated that the humanized anti-human CD45RC mAb induced CD45RC^{high} T and B cell death mainly by direct apoptosis, inducing signaling but not cytokine release and ADCP. Using in vivo studies, we showed that a single iv administration of anti-CD45RC mAb induced an efficient killing of CD45RC^{high} T and B cells as soon as day 1, this effect was dose and time-dependent and targeted cells recovered by day 24. We also showed a dose dependent efficacy in a model of GVHD. Treatment with an anti-rat CD45RC mAb in a rat model of CIA efficiently prevented weight loss, mean arthritis severity, maximum score and AUC, in contrast to control mAb. Anti-CD45RC mAb completely inhibited anti-collagen antibody production, inflammation of the paws and GM-CSF secretion in the sera. Efficacy of the anti-CD45RC mAb correlated with depletion of CD45RC^{high} T and B cells by d3 and until sacrifice with conserved Treg numbers. Analysis of RA patients showed in the blood presence of CD45RC^{high} cells and a strong infiltration by CD45RC^{high} cells of synovial tissues using IHC.
Conclusion: Our study demonstrates that anti-CD45RC mAb treatment is a potent immunomodulatory agent rebalancing the Treg/teff ratio to reduce joint inflammation and disease activity in RA and a potential alternative for first line DMARD.

RP23: a novel peptide-based therapeutic for inflammatory skin diseases

Jack Rawlings[1], Anneliese Ashhurst[1], Skye Stockdale[1], Daniel Ford[2;3], Joshua Maxwell[2;3], Rachael Ireland[1], Richard Payne[2;3], Scott Byrne[1;4]
[1]School of Medical Sciences, University of Sydney, Sydney, Australia; *[2]Australian Research Council Centre of Excellence for Innovations in Peptide and Protein Science, Sydney, Australia*; *[3]School of Chemistry, University of Sydney, Sydney, Australia*; *[4]Westmead Institute of Medical Research, Westmead, Australia*

Inflammatory skin diseases such as psoriasis and atopic dermatitis represent a significant and ever-increasing health burden globally. Conventional steroid therapies are ill-suited for long-term continuous usage as they are accompanied by adverse effects. While biologics such as monoclonal antibodies are highly effective in severe disease, they are not prescribed in the vast majority of mild-moderate cases and are largely inaccessible due to their high cost.
RP23 is a modified human self-peptide with novel anti-inflammatory properties. Topical formulations of this peptide effectively treat both imiquimod-induced psoriasis and oxazolone-induced atopic dermatitis models in mice. Unlike steroids which have systemic effects, RP23 only suppresses local immune responses where it is needed. Importantly, RP23 is well tolerated by mice with no adverse events unlike steroids which reduced body weight and caused skin atrophy. Using fluorophore conjugated RP23, we determined that the peptide is primarily taken up by neutrophils, macrophages, and dendritic cells. Confocal microscopy of murine bone marrow-derived macrophages (BMDM) also demonstrated that RP23 was readily taken up by these cells and co-localised with lysosomes, consistent with phagocytosis. *In-vitro* BMDM assays, as well as studies in human monocyte-derived macrophages, demonstrated that RP23 reduced IL-6 and IL-12p40 release, which likely explains its mechanism of action in these diseases.
Thus, RP23 represents a promising new therapeutic for inflammatory skin diseases. It enjoys many clinical advantages over existing therapeutics, including being a cheaper, convenient, safer, and potentially more effective treatment option for psoriasis and atopic dermatitis.

Slamming the Brakes on Autoimmunity: Inhibition of the CD40:CD40L Pathway utilizing Fab Fragments and Nanobodies

Kathrine Pedersen[1], Nick Stub Laursen[2], Yaseelan Palarasah[3], Søren Egedal Degn[1], Steffen Thiel[1]
[1]*Department of Biomedicine, Aarhus University, Aarhus, Denmark*; [2]*Commit Biologics ApS, Aarhus, Denmark*;
[3]*Department of Molecular Medicine, University of Southern Denmark, Odense, Denmark*

Purpose*:* Break of tolerance and production of autoantibodies by autoreactive B cells are central aspects in autoimmune diseases such as Systemic Lupus Erythematosus (SLE). Signaling through the CD40:CD40L pathway provides a pivotal co-stimulatory signal for the activation of auto-reactive B cells. We aim to inhibit the CD40-CD40L pathway to dampen the disease-causing reactions leading to symptoms in autoimmune diseases, specifically the B cell driven disease SLE. This therapeutic strategy has previously been attempted with antibodies with serious off-target effects. We aim to utilize Fab fragments (50 kDa) and nanobodies (15 kDa) to take advantage of their significantly smaller size (compared to the 150 kDa of IgG) and the possibilities for molecular manipulation of the constructs.
Methods: We have developed CD40L-targeting Fab fragments and nanobodies. To develop Fab fragments, we first developed 30 different monoclonal mouse anti-human CD40L antibodies. The antibodies were tested for reactivity to CD40L by immunoassays and flow cytometry, and the capacity for inhibiting the CD40-CD40L interaction was tested by flow cytometry. The best inhibitory candidates were redesigned as Fab fragments and tested for retained binding and inhibitory capacity in in vitro assays (TRIFMA, flow cytometry and coculture assays). We have also immunized an alpaca with human CD40L to produce anti-human CD40L nanobodies. Different nanobody candidates have been selected using yeast-surface display and phage-display. Selected nanobodies were tested for their ability to bind CD40L and to inhibit the CD40-CD40L interaction using TRIFMA and flow cytometry.
Results: The Fab fragment successfully inhibited the CD40-CD40L interaction in vitro, both preventing a soluble version of CD40 in binding to CD40L on the surface of stimulated T cells as well as in a B cell-coculture assay. We also identified nanobody candidates that demonstrate the ability to inhibit CD40-CD40L interaction.
Conclusion: In conclusion, nanobodies and Fab fragments represent a new potential treatment with definite advantages over monoclonal antibodies. The inhibitory Fab fragments and nanobodies will be tested for the ability to ameliorate autoreactive symptoms in vivo, possibly without the risk of Fc-mediated side effects. We believe this represents a new treatment strategy and expanded opportunities for patients with SLE and other autoimmune diseases.

Rheumatoid Arthritis (RA) is an autoimmune chronic disease characterized by inflammation affecting multiple joints, ultimately resulting in deformity, pain and swelling. Available therapies target late stages of the inflammation process, when the microenvironment is highly inflammatory and therefore more challenging to control. Developing therapies targeting inflammation upstream (i.e. proinflammatory cytokine secretion) would benefit RA patients.
We have previously identified, through an unbiased high-throughput screening of small molecule chemical libraries, 27 molecules (23 novel and 4 repurposing drugs) with previously unknown anti-inflammatory capabilities.We validated their effects in PBMCs stimulated with different PAMPs/DAMPs, pharmacological concentrations and time points, and identified 14 molecules capable of reducing the secretion of TNF-α and/or IL-1β without affecting cell viability.
These molecules underwent characterization in PBMCs from healthy donors and treatment-naive RA patients. We observed that two molecules (#28 and #7, novel) reduce TNF-α secretion, another two (#1 and #15, novel) reduce IL-1β secretion, and six molecules (two of them repurposing drugs) reduce the secretion of both cytokines. Flow cytometry for lineage markers and cytokines allowed for the identification of the cell subtype(s) responsible of the decreased secretion. Molecules were prioritized based on reduction of cytokine secretion and number of donors who exhibited these effects, and proceeded to the determination of their mechanism of action (MoA) and in vivo analyses. For the novel molecules, a chemoproteomic approach is being used: compound #28, one of the best molecules, was derivatized to a fully functionalized fragment (FFF). After confirming that the FFF still maintained its anti-inflammatory properties, its MoA will be studied through chemoproteomics. In parallel, the prioritized molecules are being tested in the KxB/N serum transfer arthritis mouse model.
In summary, we developed an untargeted high-throughput drug discovery platform for the identification of novel and repurposing drugs capable of reducing the secretion of proinflammatory cytokines. The validation, characterization and prioritization steps have identified eight molecules with previously unknown immunomodulatory capabilities, which work in cells from RA patients. Therefore, our small molecule portfolio bears the potential to improve the treatment of RA, and potentially other inflammation-related diseases, by providing novel molecules capable of halting inflamamtion at early stages.

Obesity-induced dysbiosis impairs type 2 immune responses

Inaya Hayek[1], Viviane Schmidt[1], Lea Semmler[1], Roman Gerlach[1], Padraic Fallon[2], Christian Schwartz[1;3]
[1]Microbiology Institute - Clinical Microbiology, Immunology and Hygiene, Universitätsklinikum Erlangen, Friedrich-Alexander-Universität (FAU) Erlangen-Nürnberg, Erlangen, Germany; *[2]School of Medicine, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland*; *[3]FAU Immunomedicine (FAU I-MED), Erlangen, Germany*

Obesity has become a major global health concern, affecting millions of individuals directly or through associated comorbidities. Notably, obesity leads to significant changes in the cellular composition of adipose tissue and peripheral regions. These alterations subsequently influence the immune system, impacting the maintenance of adipose tissue balance. Moreover, the gut microbiome plays a crucial role in obesity and the regulation of the immune system. However, many aspects of these interactions remain poorly understood. In our study, we aimed to investigate how obesity alters the microbiome and its implications for type 2 immune responses, specifically focusing on tissue repair mechanisms.
To this end, we induced obesity in mice using a high fat diet (HFD) and analysed the microbiome by 16S rRNA sequencing. Additionally, we depleted the microbiome with broad-spectrum antibiotics before we infected the mice with the gastrointestinal helminth *Nippostrongylus brasiliensis*. Intestinal and pulmonary immune responses were assessed through flow cytometry, ELISA and qPCR.
Our longitudinal analysis of the microbiome revealed early and long-lasting changes in microbial composition induced by HFD, partly dependent on regulatory factors of the immune system. Immunopathology in the lung was increased during obesity, correlating with an exaggerated Th1-biased immune response and reduced markers for pro-resolving macrophages. Upon microbiome depletion with antibiotics, we observed significant differences between helminth-infected mice on HFD compared to those on a standard diet, both in the intestinal and pulmonary type 2 responses.
In summary, our findings demonstrate that obesity-induced dysbiosis affects type 2 immunity. Further studies will investigate the mechanisms affected by this dysbiosis, particularly those impairing wound healing during obesity thereby contributing to a deeper understanding of obesity-related comorbidities.

Loss of adipose tissue protects mice from intestinal inflammation

Toka Omar[1], Marilena Letizia[1], Britta Siegmund[1], Carl Weidinger[1]
[1]*Charité – Universitätsmedizin Berlin, Berlin, Germany*

Background: Crohn's disease (CD) is associated with creeping fat, characterized by hyperplasia of mesenteric adipocytes and increased secretion of adipokines, including leptin. Leptin promotes intestinal inflammation by inducing pro-inflammatory cytokines such as TNFα in murine and human lymphocytes. Meta-analyses have shown that obesity increases the risk of developing CD. However, whether the surgical removal of mesenteric fat could improve the outcome of CD patients and the impact of fat-derived signals on intestinal autoimmunity remain elusive.
Method: To decipher the role of adipose tissue, we investigated here how the absence of adipose tissue affects epithelial barrier functions and immune cell homeostasis. Therefore, we studied lipoatrophic Ppargfl/fl-Adipoq-Cre mice, that completely lack adipose tissue, under steady-state conditions and after induction of chronic dextran sodium sulfate (DSS)-mediated inflammation, as well as in allogeneic fat transplantation models. We characterized our models using flow cytometry, RNA sequencing, and ELISA.
Results: At steady state, lipoatrophic mice showed a decrease in CD4 IL-17+ T cells in the ileum, and lower frequencies of CD8 T cells and CD4 FoxP3+ cells in the colon, suggesting that fat-derived signals are required for T cell homeostasis in mice. To understand how the absence of adipose tissue affects intestinal inflammation, we challenged lipoatrophic or WT littermates with 3 cycles of 1.5% DSS, which induced weight loss in both WT and lipoatrophic mice. However, only fat-proficient WT mice developed severe colitis, whereas lipoatrophic animals had significantly reduced intestinal inflammation and displayed disturbances in the differentiation and function of pro-inflammatory T cells including Th1 and Th17 cells. Importantly, these defects in T cell function could be rescued by allogeneic transplantation of adipose tissue from lean wild-type mice but not by adipose tissue from leptin-deficient ob/ob mice, highlighting that the role of the adiopokine leptin as an important pro-inflammatory factor in IBD.
Conclusion: Our data demonstrate that adipose tissue acts as an important regulator of intestinal autoimmunity by controlling the differentiation and function of pro-inflammatory T cells through the secretion of adipokines including leptin. We believe that these observations may help explain why obese individuals are at a higher risk of developing intestinal inflammation and CD.

Obesity-induced changes in perivascular adipose tissue fibroblasts in a mouse model of atherosclerosis

Lea Mikkola[1;2], Ivana Mikocziova[1;2], Minna Piipponen[1], Mira Valkonen[3;4], Jimmy Fagersund[1], Senthil Palani[5], Anne Roivainen[2;5], Ana Hernández de Sande[6], Merja Heinäniemi[6], Pekka Ruusuvuori[3;4], Tiit Örd[7], Minna U Kaikkonen[7], Tapio Lönnberg[1;2]
[1]Turku Bioscience Centre, University of Turku, Turku, Finland; *[2]InFLAMES Research Flagship Centre, University of Turku, Turku, Finland*; *[3]Institute of Biomedicine, University of Turku, Turku, Finland*; *[4]Faculty of Medicine and Health Technology, University of Tampere, Tampere, Finland*; *[5]Turku PET Centre, University of Turku, Turku, Finland*; *[6]School of Medicine, University of Eastern Finland, Kuopio, Finland*; *[7]Faculty of Health Sciences, A.I. Virtanen Institute for Molecular Sciences, University of Eastern Finland, Kuopio, Finland*

Purpose: Atherosclerosis is a chronic inflammatory disease exacerbated by obesity. Using an atherosclerosis murine disease model, our objectives were to map the presence of immune and structural cells, to explore their potential interactions, and to investigate how obesity impacts them in different tissues.
Methods: We used ten Ldlr-/- Apob100/100 mice: five non-obese mice with a standard chow diet and five obese mice with a high-fat diet. We collected perivascular adipose tissue (PVAT), aorta, spleen, and epididymal white adipose tissue (eWAT) from each mouse, creating eight samples pooled by the tissue types. Following the tissue dissociation and enrichment of CD45+ cells from aorta samples, single-cell RNA-sequencing was performed using a 5' gene expression immune profiling protocol, combining it with a panel of 138 antibodies, resulting in a multimodal data of ~ 46k cells. For spatial validation we used immunohistochemistry and immunofluorescence in an independent cohort of similar mice.
Results: In addition to identifying various immune cell populations and their subtypes, we observed marked diversity in structural cells, with particularly notable gene expression changes in fibroblasts between the non-obese and obese states. The most substantial changes were evident in the aorta, PVAT and eWAT. PVAT- and eWAT-derived fibroblast populations were especially interesting as a gene set enrichment analysis, based on the genes that were differentially expressed between the obesity states, revealed multiple immune-related functions. We validated the location of one PVAT-derived fibroblast populations with immunohistochemistry/immunofluorescence and observed a difference in their abundance between the obesity states: these fibroblasts were more abundant in average in the non-obese mice in comparison with the obese mice. This could be due to morphological changes in the PVAT towards a white adipose tissue phenotype during obesity evident in a morphometric analysis.
Conclusion: Our findings provide novel insights into obesity-related alterations in adipose tissue-derived fibroblasts during atherosclerosis and their potential immune-related responses during the disease. Our results emphasize the significance of PVAT in atherosclerosis during obesity and how obesity might abolish the functionality of specific fibroblasts that could otherwise support normal immune responses during the disease.

Structural variations and developmental characteristics of adipose-associated serosal lymphoid tissues in mice

Xinkai Jia[1], Peter Balogh[1]
[1]*University of Pécs, Pécs, Hungary*

The peritoneal cavity in mice represents a separate lymphoid compartment with unique cellular composition and leukocyte homeostasis, dispersed into fluid and adipose-associated lymphoid congregates. In our work we studied the structural pattern, stromal organization and developmental features of adipose-associated lymphoid structures capable of binding normal as well as malignant B cells.

Using high-grade mouse B-cell lymphoma lines A20 (centroblastic DLBCL) and Bc.DLFL1 (extrafollicular DLBCL) we found that, in addition to the mesenteric fat-associated lymphoid congregates (FALC) and omental milky spots (MS) with subserosal diffuse T/B cell distribution, both lymphoma cell lines accumulated within a more compacted formation we termed foliate lymphoid aggregates (FLAgs), owing to their lymphocyte-filled body and slender stalks. The FLAg body part was arranged around reticular fibroblasts expressing VCAM, ICAM and FAP, embedded in extracellular matrix containing ER-TR7-positive Collagen type VI and fibronectin. Within FLAgs, T cells congregate in the central zone, surrounded by a B-cell-rich rim at the periphery, which pattern corresponds to the arrangement of CXCL13 and CCL21-positive chemokine domains, respectively. LYVE-1-positive macrophages sensitive to clodronate-mediated depletion mediate the binding of lymphoma cells to the FLAgs following intraperitoneal injection.

The developmental analysis of FLAgs demonstrated that these structures develop in the postnatal period. No obvious leukocyte cluster formation is observed in one-week-old postnatal mice, whereas by the second week, CD45-positive leukocytes aggregate at the bursal membrane and omentum, forming MS/FALCs at both locations. Subsequently, mature FLAgs occur. The onset of leukocyte clustering in the mesenteric adipose streaks follows a delayed appearance compared to other sites. The number of FLAgs and MS/FALCs becomes stable by week six under normal conditions.

FLAg development is absent both in RAG KO and nonobese Scid-gamma chain mutant (NSG) mice, whereas LTa deficient mice contain only small MS/FALCs; in contrast, mice with nude mutation or lacking RORgt the entire adipose-associated lymphoid tissue spectrum is present.

These observations indicate that the serosal adipose tissues in mice harbor various lymphoid structures with complex developmental determinants, and these sites contribute to the lymphoid recirculation for both normal and malignant B cells.

Obesity and sex differences: An overlooked reality in preclinical studies

Lisa Schuetz[1;2;3], Gayel Duran[1;4], Paulien Baeten[1;4], Doryssa Hermans[1;4], Sarah Chenine[1;4;5], Janne Verreycken[1;4], Tim Vanmierlo[1;4;5], Kristiaan Wouters[2;3], Bieke Broux[1;4]
[1]Neuro-Immune-Connections and Repair Lab, Department of Immunology and Infection, Biomedical Research Institute, Hasselt University, Diepenbeek, Belgium; *[2]CARIM - School of Cardiovascular Diseases, Maastricht University, Maastricht, Netherlands*; *[3]Internal Medicine, Maastricht University, Maastricht, Netherlands*; *[4]University MS Center, Diepenbeek, Belgium*; *[5]MHeNs - Mental Health and Neuroscience Institute, Maastricht University, Maastricht, Netherlands*

Obesity is a major worldwide health problem that increases the risk of developing neurodegenerative diseases including multiple sclerosis (MS) and Alzheimer's disease (AD). Current preclinical studies often only look at the effect of diet-induced obesity (DIO) in male mice as their weight gain is stable and fast. However, the risk for developing MS or AD is higher in women with obesity. Given the inflammatory changes induced by obesity, and the importance of the immune system in MS and AD, sex differences in immunological changes due to obesity should be taken into account.
Therefore, we investigated sex differences in a DIO model focusing on changes within the adaptive immune system in visceral and subcutaneous adipose tissue (vAT and scAT). We induced obesity in male and female ASC-citrine-C57BL/6J mice by feeding a high fat diet (HFD), and compared adipose tissue (AT) inflammation at the same adiposity stages (% AT/bodyweight) between both sexes. In vAT, the absolute number of T helper cells (Th, CD3+CD4+) increased sooner in females related to similar adiposity development. The same was observed for absolute numbers of the highly pro-inflammatory subsets Th17 (CCR6+) and Th17.1 (CCR6+CXCR3+). However, the effect of HFD is diminished with higher adiposity in female mice. Interestingly, only female mice showed an increase in immune cells in the subcutaneous AT after HFD. Additionally, uniquely in male mice, myeloid cells in the visceral AT showed a higher inflammasome activation upon HFD.
In summary, we showed that adiposity differently regulates immune cells in fat depots based on sex. Future experiments are warranted to assess how this affects neuroinflammation in a sex-dependent manner.

High fat low carbohydrate is linked to protection against the development of CNS autoimmunity

Duan Ni[1], Jian Tan[1], Julen Reyes[1], Alistair Senior[1], Caitlin Andrews[1], Jemma Taitz[1], Camille Potier[1], Claire Wishart[1], Alanna Spiteri[1], Laura Piccio[1], Nicholas King[1], Stephen Simpson[1], Ralph Nanan[1], Laurence Macia[1]
[1]*The University of Sydney, Camperdown, Australia*

Multiple sclerosis (MS) is an autoimmune disease, characterised by axon demyelination, clinically leading to paralysis. The exact aetiology is still unknown but both genetic and environmental factors are involved, with the latter being the major contributors. Diets, particularly western-like diets, are emerging player in MS. However, a comprehensive understanding towards the underlying mechanisms involved is lacking.
By using state-of-the-art nutritional geometry analytic methods, we first investigated globally the association between nutrient exposure via food environments and MS disease burden. Here, increased carbohydrate supply was associated with increased MS disease burden, while fat supply had an opposite effect. Furthermore, in a preclinical MS model, experimental autoimmune encephalomyelitis (EAE), we found that an isocaloric diet high in carbohydrate aggravated disease severity, while a diet enriched in fat was fully protective. This protection was reflected by reduced neuroinflammation and skewing towards generation of anti-inflammatory regulatory T cells away from encephalitic Th1 and Th17 cell subsets. The beneficial effects of high fat feeding specifically involved transcriptomic, epigenetic and metabolic immune changes.
Together, we showcased that manipulating diets might be an efficient and cost-effective approach to ameliorate the development of EAE, potentially explaining the link between high fat low carbohydrate dietary environment and reduced MS disease burden.

This study was supported by the Australian Research Council grant APP160100627, and Multiple Sclerosis Research Australia/Incubator Grant 204-0000000057.

Epigenetic imprints in human T cells reveal DNA replication speed as a driver for memory differentiation

Dania Hamo[1], Ghazaleh Zarrinrad[2], Anne Schulze[1], Kristy Ou[3], Paula Linh Kramer[4], Judith Gottfreund[4], Cornelia Peitsch[1], Marcel Finke[1], Mingxing Yang[1], Frederik Hamm[1], Abdulrahman Salhab[4], Pascal Giehr[5], Leila Amini[2], Verena Wolf[4], Jörn Walter[4], Julia K Polansky[1]
[1]Berlin Institute of Health for Regenerative Therapies (BCRT), Berlin, Germany; *[2]Berlin Institute of Health (BIH), Berlin, Germany*; *[3]EMBL, Heidelberg, Germany*; *[4]University of Saarland, Saarbrücken, Germany*; *[5]University Munich LMU, Munich, Germany*

Epigenetic mechanisms are known drivers of T lymphocyte development and function. This has been so far mainly attributed to epigenetic changes on gene regulatory elements like promoters and enhancers, which control the expression patterns of their target genes. In previous studies, we observed a surprising DNA methylation loss in large, heterochromatic parts of the genome in human T cells, which was a lasting epigenetic imprint resulting from proliferation episodes in the history of T cells. The molecular mechanisms and functional consequences of this heterochromatic DNA demethylation so far remained unclarified.
In human T cell cultures, we were now able to show that the DNA replication speed during proliferation events was the driving force for heterochromatic DNA methylation loss and that maintenance of the DNA methylation profile could be achieved by interfering with DNA replication timing. Interestingly, we observed that increased loss of heterochromatic DNA methylation levels was also a marker for TCM populations prone to undergo TEM differentiation, even in the absence of a TCR stimulus, indicating that past proliferation episodes predispose TCMs for TEM differentiation. Also, we were able to reduce the frequency of cells undergoing TEM differentiation by modulation of the DNA replication speed, indicating that the proliferation speed of T cells is causally involved in driving memory differentiation. Finally, our preliminary data suggest that this newly discovered mechanism might be exploited to improve therapeutic T cell products, as reducing proliferation-induced DNA methylation loss during the manufacturing process improved functionality of immunosuppressive regulatory T cell products.

With these data, we reveal that the proliferation behavior of T cells is monitored and recorded in the epigenome and has a causal impact on the future differentiation and functional potential of T cells.

Iron deficiency and acquired immunity: novel perspectives on the effects of iron restriction on immunological memory and protective immune responses

Shamsideen Yusuf[1], Giulia Pironaci[1], Hannah Murray[1], Dana Costigan[1], Philip Holdship[1], Megan Teh[1], Alexandra Preston[1], Andrew Armitage[1], Fadi Issa[1], Ronjon Chakraverty[1], Alexander Hal Drakesmith[1]
[1]*MRC Weatherall Institute of Molecular Medicine, Oxford, United Kingdom*

Immunological memory is a fundamental feature of the adaptive immune system. It allows the immune system to remember previous encounters with pathogens or antigens, which results in a faster and more effective secondary immune response. This response is facilitated by long-lived memory cells and helps manage re-infections and establish a protective state for the organism. Optimal immune responses require adequate levels of bioavailable iron, especially when T cells switch from a quiescent (catabolic) to an activated (anabolic) state for clonal expansion. However, it is not well understood how the adaptive immunity functions in the absence of adequate supply of iron. This study examines the impact of iron deficiency on CD8 T cell responses during influenza infection using *in vitro* and *in vivo* models where iron availability is restricted through genetic modifications or pharmacological inhibition of ubiquitous iron transporter called Transferrin Receptor 1 (TfR1).

Paradoxically, our *in-vivo* models showed an unexpected increase in the generation of antigen-specific ($NP_{366+}CD44^{+}CD62L^{-}$) CD8 T_{EF} cells following the primary immune response and greater survival of antigen-specific ($NP_{366+}CD44^{+}CD62L^{+}$) CD8 T_{CM} cells up to 95 days post-infection in Iron deficient mice. The primary CD8 T cell response also appeared to be delayed rather than impaired in our genetic models, suggesting that the severity of iron restriction is negatively correlated with the speed of the CD8 T cell response. Lastly, Iron-deficient CD8 T cells were more predisposed towards a memory fate over an effector fate, and this was not attributable to defects in cellular activation or apoptosis resistance during the immune contraction phase. The ongoing research aims to determine whether this increased generation and maintenance of memory CD8 T cells confer enhanced protection during a heterotypic PR8 challenge and to elucidate the mechanisms responsible for this augmented memory formation.

In conclusion, our findings contest the prevailing belief that iron deficiency necessarily impairs the primary immune response. Instead, they introduce a nuanced perspective wherein the detrimental effects of iron deficiency might exist along a continuum. Notably, there appears to be a threshold at which iron deficiency could enhance the establishment of the antigen-specific memory pool within the organism.

Leveraging the strategic positioning of central memory CD8+ T cells in steady state lymph nodes for enhanced secondary recall

Brigette Duckworth[1;2], Benjamin Broomfield[1;2], Raymond Qin[1;2], Carolina Alvarado[1;2], Chin Wee Tan[1;2;3], Gabrielle Belz[4], Verena Wimmer[1;2], Melissa Davis[2;3;5], Joanna Groom[1;2]
[1]The Walter and Eliza Hall Institute of Medical Research, Parkville, Australia; *[2]Department of Medical Biology, University of Melbourne, Parkville, Australia*; *[3]Frazer Institute, Faculty of Medicine, The University of Queensland, Brisbane, Australia*; *[4]The University of Queensland Diamantina Institute, Faculty of Medicine, Woolloongabba, Australia*; *[5]South Australian immunoGENomics Cancer Institute, University of Adelaide, Adelaide, Australia*

Purpose: The next generation of vaccines against infectious disease, chronic infection and cancer will require robust T cell memory. Currently, vaccines that consistently induce robust and durable $CD8^+$ T cell memory remain elusive. There is increasing evidence that memory $CD8^+$ T cells are strategically positioned to enhance recall capacity. Therefore, defining the niche for central memory $CD8^+$ T cells (T_{CM}) and revealing the factors that regulate this location may provide novel insights to harness T cell memory for improved vaccine outcomes.
Methods: In this study, we combined tissue clearing and 3D-lightsheet fluorescence microscopy of intact murine lymph nodes (LNs) to determine the location of T_{CM} following the resolution of acute infection models. To identify the cellular interactions that occur within the LN memory niche, we employed high-resolution confocal microscopy, along with spatial photo-labelling, scRNA sequencing and network analysis to reveal the environmental factors that underpin T_{CM} location and longevity.
Results: In steady-state LNs, T_{CM} cells occupy a conserved niche distinct from naïve T cells. T_{CM} were quantified at a higher density in the cortical ridge and interfollicular regions than naïve T cells, which primarily reside in the paracortex. The T_{CM} niche was consistent across multiple diverse infection models, including LCMV, HSV-1 and *Listeria*. We identified a subset of dendritic cells (DCs) which specifically interact with T_{CM} cells in this niche and maintain their long-term location. Furthermore, specifically targeting this DC subset can influence the immune response to re-challenge.
Conclusion: This study lays the foundation to improve vaccine and boosting strategies grounded in robust and long-lived T cell memory.

Staphylococcus aureus colonisation expands respiratory tissue-resident memory CD4+ T-cells, with the potential for heterologous immunity.

Cliodhna Daly[1], Seán Cahill[1], Rachel McLoughlin[1]
[1]*Trinity College Dublin, Dublin 2, Ireland*

Purpose: While *Staphylococcus aureus* (*S. aureus)* is primarily recognized as an invasive pathogen, it is also known to persistently colonise the anterior nares of a significant proportion of healthy individuals. CD4+ T-cells play an important role in controlling *S. aureus* colonisation, however the impact of *S. aureus* colonisation on shaping local T-cell populations in the nasal mucosa is poorly defined.
Methods: To investigate local tissue resident immune cell development and memory responses, we used mouse models of *S. aureus* nasal colonisation. Analysis of cell functional and phenotypic changes was performed using flow cytometry.
Results: We identified CD4+ Tissue Resident Memory (TRM) T-cells in the *S. aureus*-colonised nasal tissue, which remain primed at the tissue site for rapid reactivation upon secondary exposure to *S. aureus.* Intra-nasal administration of LPS or *Klebsiella pneumonia* (*K. pneumoniae*) to *S. aureus*-colonised mice also activated nasal tissue IL-17+ CD4+ TRM cells, suggesting *S. aureus* specific CD4+ TRM cells have the capacity for bystander activation, which is driven by Th17 cell polarizing cytokines and not achieved by *K. pneumonia* antigen presentation alone. A model of persistent colonisation was developed in a population of germ-free mice, allowing us to characterize the impact of colonising *S. aureus* on nasal tissue CD4+ TRM cell responses in mice stably colonised with *S. aureus* from birth. *S. aureus* mono-colonised mice challenged with *K. pneumoniae* exhibited lower bacterial burden in the lungs than germ-free controls, as well as increased IL-17 production from nasal tissue CD4+ TRM cells, indicating enhanced protection against a novel invasive respiratory pathogen mediated by the TRM cells.
Conclusion: Our findings demonstrate that nasal colonisation with *S. aureus* can prime and expand local CD4+ TRM cells, with the potential for bystander activation to enhance heterologous immunity to an unrelated respiratory pathogen.

A diverse pool of oral mucosa-resident memory T cells protects against viral infection at the site of entry

Florian Winkler[1], Fischer Carmen[2], Laura Marie Gail[1;3], Florian Deckert[3], Georg Stary[2;3], Johanna Strobl[1;3]
[1]Department of Dermatology, Medical University of Vienna, Vienna, Austria; *[2]Department of Oral and Maxillofacial Surgery, Vienna, Austria*; *[3]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria*

Purpose: A reliable, long-lasting protection against viral infections including SARS-CoV-2 is particularly based on the generation of memory T cell populations within the affected tissues. As one of the first sites of contact with infectious aerosols, the assessment of specific T cell subpopulations in the oral mucosa is of utmost interest for the evaluation of adaptive cellular immune responses to vaccinations or natural infections.
Methods: We performed flow cytometry analysis and single cell RNA sequencing via the 10X-Genomics protocol on blood and oral mucosa samples from healthy, SARS-CoV2 recovered individuals one month after infection. Three donors were vaccinated against *Yellow-Fever-Virus* prior to sampling. Cell types were annotated based on widely accepted marker genes and Python package CellTypist. Differential gene expression and TCR receptor analysis were performed using the Python toolkits SCANPY and SCIRPY.
Results: We found that the majority of SARS-CoV2-specific T cells in blood samples were central memory T helper cells (TCM) and, in oral mucosa samples, cytotoxic tissue-resident memory T cells (TRM) and type-1 helper T cells. While SARS-CoV2-specific mucosa T cells had a balanced ratio of Type-1 helper cells and cytotoxic TRM cells, *Epstein-Barr virus*- and *Yellow-Fever-virus*-specific cells consisted predominantly of cytotoxic TRM cells. The differential gene expression between SARS-CoV2-specific T cells and other virus-specific T cells enabled the distinction between gene programs involved in early tissue residency, circulating virus-specific cells and genes expressed by long-lived mucosa-resident cells. Cell-cell communication demonstrated a strong incoming signaling for TRM cells and a key role for fibroblasts in outgoing signaling.
Conclusion: Our data provide valuable insights into the distribution of T cell subpopulations and their respective TCR-specificity in healthy oral mucosa shortly after COVID-19 infection. The differential gene expression and cell population distribution enabled detailed insights into the function, functional capacity and longevity of the different virus-specific T cell subpopulations. In addition, communicative networks led by oral mucosa fibroblasts supported TRM survival within the tissue. This ongoing project may contribute to further understanding of T cell responses at effector sites following viral infection and vaccination.

A tissue-specific molecular program governs the formation and function of brain-resident CD8+ T cells

Tarek Elmzzahi[1;2], Darya Malko[1;2], Mehrnoush Shakiba[1], Doaa Hamada[1], Martin Fuhrmann[3], Kevin Man[2], Axel Kallies[2], Marc Beyer[1]
[1]Immunogenomics and Neurodegeneration, German Center for Neurodegenerative Diseases (DZNE), Bonn, Germany; *[2]Department of Microbiology and Immunology, Peter Doherty Institute for Infection and Immunity, University of Melbourne, Melbourne, Australia*; *[3]Neuroimmunology and Imaging Group, German Center for Neurodegenerative Diseases, Bonn, Germany*

T cells populate the brain at steady state, where they contribute to its physiology and protect the host against reinfection. T cells residing in peripheral non-lymphoid tissues are known to adopt tissue-specific transcriptional programs shaped by the tissue microenvironment. Whether brain-resident T cells similarly acquire a tissue-specific transcriptional landscape, and to what extent this molecular signature is altered in neuropathology, remains to be determined. Here we unravel the cellular and molecular heterogeneity of brain T cells in mice using single-cell RNA-sequencing and high-parameter flow cytometry. Specifically, we profile brain T cells under homeostatic conditions and in the contexts of cerebral amyloidosis, systemic viral infection, and aging. From these studies, a framework of a predominantly tissue-specific CD8+ T cell landscape has emerged, largely defined by the expression of the inhibitory receptor PD-1, the surface molecule Ly6C, and the transcription factor TCF-1. In spite of the transcriptional overlap across conditions, CD8+ T cells adopted context-specific phenotypic and functional properties. Interrogating the molecular determinants of brain CD8+ T cell differentiation and maintenance, we found that TCF-1 and PD-1 negatively regulate the population expansion of brain CD8+ T cells. In addition, PD-1 signaling was necessary for robust effector function and antigen-specific recall response. Furthermore, the cytokine transforming growth factor (TGF)-β was required for the differentiation of brain-resident CD8+ T cells. Taken together, these findings highlight common, tissue-specific as well as context-specific features of brain CD8+ T cells, and provide insights into the molecular mechanisms governing their formation and function.

Inducing tick immunity by vaccination as a novel strategy to prevent Lyme borreliosis

Melissa van Gool[1;2], Alexis Burnham[1;2], Francisca Bixirao Ferreira Andersen[1;2], Hannelore Beaart[1;2], Jacqueline van Eck[1;2], Abhijeet Nayak[1;2], Joppe Hovius[1;2;3]
[1]Center for Experimental and Molecular Medicine, Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands; *[2]Amsterdam institute for Immunology and Infectious diseases, Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands*; *[3]Department of Internal Medicine, Division of Infectious Diseases, Amsterdam UMC Multidisciplinary Lyme borreliosis Center, Amsterdam, Netherlands*

Lyme borreliosis is a vector-borne disease caused by *Borrelia burgdorferi* sensu lato (Bbsl) bacteria transmitted by *Ixodes* ticks. Over half a million new cases of Lyme borreliosis are diagnosed in the Northern hemisphere each year. Clinical manifestations include early and chronic skin infection as well as disseminated disease such as Lyme arthritis, neuroborreliosis, or carditis. Since there is currently no human vaccine available, we are investigating the innovative approach to prevent both Lyme borreliosis and other tick-borne diseases by targeting the tick vector, rather than targeting the pathogen itself as conventional vaccines do.
We identified and biologically validated 20 tick salivary gland genes that were consistently and abundantly expressed during early tick feeding and therefore likely to play a role in pathogen transmission. To assess their role in host-pathogen interactions and immunogenicity, 12 corresponding tick salivary gland proteins (TSGP) were produced recombinant in *Drosophila* and insect cell expression systems. TSGPs significantly inhibited human complement mediated killing of Bbsl and monocyte-derived dendritic cell activation by reducing the expression of co-stimulatory markers CD40 and CD86 as well as TNF-α and IL-6 release *in vitro*. Mice immunized with TSGPs and challenged with Bbsl-infected ticks showed no skin infections and Bbsl qPCR loads in deeper tissues such as the bladder and heart were significantly lower compared to mice receiving PBS adjuvants. These results indicate partial protection against Lyme borreliosis by an anti-tick vaccine in experimental models.
To investigate tick immunity in humans, we set up a unique human tick-challenge model in which eight human volunteers were challenged three to four times in two-week intervals with 10 pathogen free nymphal ticks per challenge, placed on the forearm and contained in a plastic eyepatch. Local skin reactions, including redness and itch significantly increased whereas tick-feeding parameters decreased after each challenge. IgG titers against TSGPs in serum were detected up till eight weeks after the last challenge. Altogether, this might indicate the development of tick immunity in humans and provide preliminary results for the use of TSGPs for an anti-tick vaccine to prevent Lyme borreliosis.

Purpose: A vaccine to prevent tuberculosis is urgently needed. In our group, we have developed and characterized two vaccine candidates with potential to replace and/or boost immunity against mycobacteria. In this work, we studied a combined vaccination scheme composed by BCGΔBCG1419c, a modified BCG that afford protection against tuberculosis in mice and guinea pigs, and a booster with the H1-TT subunit vaccine formulation, which has shown to induce protection against mycobacteria by inducing antibodies against EsxG/EsxH proteins in mice. We proposed that this scheme could induce cellular and humoral response resulting in better protection against tuberculosis. The purpose of our studies was to evaluate both the immunogenicity and the efficacy of the vaccination with BCGΔBCG1419c + H1-TT against tuberculosis in mice.
Methods: To evaluate immunogenicity of the BCGΔBCG1419c + H1-TT scheme, we vaccinated BALB/c mice subcutaneously with BCGΔBCG1419c and then we boosted them with H1-TT intranasally. After vaccination, we measured the cellular T response against *M. tuberculosis* antigens developed in lungs and the antibodies produced in sera and bronchoalveolar lavage (BAL). To evaluate the efficacy of protection BCGΔBCG1419c + H1-TT we challenged vaccinated and boosted mice with *M. tuberculosis* H37Rv. Here, we evaluated the effect of BCGΔBCG1419c + H1-TT on the progression of the disease by measuring the bacterial burden in lungs and we evaluated the cellular response against mycobacterial antigens in blood and lungs.
Results: The combined vaccination with subcutaneous BCGΔBCG1419c and intranasal booster with H1TT induces memory T cells responders to mycobacterial antigens in lungs, a cytolytic and helper T cell response against mycobacterial antigens in spleen and IgG, IgA, and IgM against mycobacterial antigens in sera and BAL. In the efficacy experiments, BCGΔBCG1419c + H1-TT reduced the bacterial burden in lungs in an 82% compared to unvaccinated and unboosted mice. This protection is associated with an increase of blood T cells responders to mycobacterial antigens and increased central memory T cells responders to mycobacterial antigens in lungs.
Conclusion: The combined vaccination with subcutaneous BCGΔBCG1419c and intranasal booster with H1TT induces cellular and humoral response which results in protection against the progression of tuberculosis in mice.

Chitin-derived polymers are promising cGAS-STING dependent mucosal vaccine adjuvants for respiratory pathogens.

Dorian Dederko[1], Kate Roche[1], Jorge Huete-Carrasco[1], Nicole Roche[1], Jeremy Aboagye[1], Lorena Garcia del Rio[1], Roisin Lynch[1], Hui Ma[1], Nicole O'Sullivan[1], Liam Murray[1], Grainne O'Rourke[1], Ed Lavelle[1]
[1]*Trinity College Dublin, Dublin, Ireland*

SARS-CoV-2 remains a pathogen of global significance even with the success of currently approved vaccines. Injectable vaccines have been effective at reducing mortality and morbidity, but breakthrough infections and reinfections are common. Increasingly, mucosal cell-mediated immunity (CMI), including $CD8^+$ T cells, is implicated as a critical facet of protection in individuals with asymptomatic and symptomatic COVID-19. Mucosal vaccines have the potential to curtail initial infection through induction of CMI and IgA responses at the foci of pathogen entry. However, despite significant progress the development of mucosal vaccines is hindered by the lack of effective mucosal vaccine adjuvants. Our lab has identified chitin derived polymers as effective adjuvants for injectable vaccines and demonstrated that these promote cell mediated immunity by engaging the cGAS-STING pathway. Here, chitin-derived polymers with various degrees of deacetylation were investigated as potential intranasal vaccine adjuvants for SARS-CoV-2 spike antigen *in vivo.* A fully deacetylated chitin-derived polymer, C100, emerged as a promising mucosal vaccine adjuvant capable of inducing antigen-specific $CD8^+$ T cells in the lungs, in addition to antigen-specific mucosal IgA and systemic IgG. To interrogate C100 as a potential platform-adjuvant, it was combined with the invariant NK T cell activator α-galactosylceramide (α-GalCer). The combination adjuvant further enhanced antigen-specific $CD8^+$ T cells in the lungs and spleen, and IFNγ recall responses in the lungs. Our findings suggest that C100 is a highly promising mucosal vaccine adjuvant capable of inducing mucosal immune responses increasingly correlated with protection from SARS-CoV-2. Moreover, C100 emerges as a potential platform adjuvant for the design of mucosal vaccine adjuvant systems with increased potency.

Preclinical immunological characterization of GMMA-based vaccine candidates against invasive nontyphoidal Salmonellosis

Marta Benincasa[1], Daniele De Simone[1], Maria Grazia Aruta[1], Martina Carducci[1], Roberta Di Benedetto[1], Carlo Giannelli[1], Francesco Berlanda Scorza[1], Miren Iturriza[1], Francesca Mancini[1], Rocio Canals[1], Omar Rossi[1]
[1]*GSK Vaccines Institute for Global Health (GVGH), Siena, Italy*

Purpose: *Salmonella enterica* serovars Typhimurium and Enteritidis are responsible for invasive non-typhoidal Salmonellosis (iNTS), a leading cause of bloodstream infections in <5-year-olds in sub-Saharan Africa. The emergence of multidrug-resistant non-typhoidal *Salmonella* (NTS) strains urges the development of affordable, effective vaccines.
GSK Vaccines Institute for Global Health (GVGH) is developing two vaccines: "iNTS-GMMA", a Generalized Modules for Membrane Antigens (GMMA)-based vaccine against iNTS, composed by GMMA purified from *S.* Typhimurium and *S*. Enteritidis; and "iNTS-TCV", a combination of iNTS-GMMA vaccine with a WHO-prequalified typhoid conjugate vaccine component (TCV), Vi-CRM_{197}, against both iNTS and typhoid fever. GMMA are outer membrane vesicles able to present multiple antigens in their natural conformation, derived from Gram-negative bacteria engineered to provide over blebbing and reduce potential systemic reactogenicity.
This work characterizes the immunological response of the NTS components of the two candidate vaccines and demonstrates their broad coverage.
Methods: CD1 mice were immunized intraperitoneally, New Zealand female rabbits intramuscularly; both with two doses, 4 weeks apart, of the two vaccines independently.
Sera were collected the day before and 2 weeks after the second immunization and were analyzed by ELISA to quantify antigen-specific immunoglobulins (IgG) and by luminescence-based SBA to assess antibody functionality.
Results: Immunogenicity studies showed the ability of iNTS-GMMA and iNTS-TCV to induce high IgG levels against the active ingredients of the NTS vaccine components, the O-antigens, and against the Vi of the TCV component. Both vaccines induced all the antigen-specific subclasses in mice against the NTS vaccine components. The antibodies induced complement-mediated killing against vaccine homologous NTS strains, and also against a broad panel of vaccine heterologous epidemiologically relevant *Salmonella* strains, including isolates associated to bloodstream infections and gastroenteritis, African and Southeast Asian representatives and strains belonging to different *S. enterica* serovars other than Typhimurium, Enteritidis and Typhi.
Conclusion: Preclinical data results strongly support the development of broad coverage GMMA-based vaccines to prevent iNTS. A Phase 1/2a for safety and immunogenicity of iNTS-TCV vaccine in healthy European and African adults is ongoing. For iNTS-GMMA, a Phase 2 age de-escalation dose-finding study for safety and immunogenicity in African adults, children and infants, has recently started.

The inhibition of IL-10 during immunization with a TLR agonist-based vaccine improves vaccine efficacy against the opportunistic pathogen *Staphylococcus aureus*

Alanna Kelly[1], Simon Carlile[1], Karen McCarthy[1], Tracey Claxton[1], Emilio Vozza[1], Kingston Mills[1], Rachel McLoughlin[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Staphylococcus aureus infections are a major global burden. Despite *S. aureus'* infectivity, it is also an important part of the natural human microbiome, primarily colonising the anterior nares. An effective anti-*S. aureus* vaccine remains elusive despite decades of research. A potential bottleneck is immunosuppressive imprinting during colonisation. *S. aureus* can induce immunosuppression to facilitate persistence by impeding effector T cell responses. The aim of this work is to investigate if commensal-driven immunosuppression impacts systemic antigen-specific T cells responses and whether targeting immunosuppression during immunization improves vaccine efficacy.
PBMCs and nasal fluid were isolated from a human cohort of healthy persistently colonised and uncolonised adults, and were assessed for alterations in antigen-specific T cell responses by flow cytometry and cytokine expression within the nasal mucosa by V-PLEX assay and RT-PCR. IL-10 production was significantly increased within the nasal tissue of colonised individuals, suggesting local *S. aureus*-induced IL-10 creates an immunosuppressive micro-environment promoting bacterial persistence. These local changes coincide with reduced systemic *S. aureus*-specific Th1 responses, which could be a significant challenge for effective vaccine function.
Using a murine immunization and infection model this study determined if modulating IL-10 signalling during vaccination could improve *S. aureus*-specific memory T cell responses during subsequent infection. C57BL/6 Wild-type mice were vaccinated with ClfA(of *S. aureus*) + CpG(TLR9 agonist) in the presence/absence of αIL-10. On day 3 & 7 post-immunization mice were challenged with intraperitoneal or subcutaneous infection. IL-10 inhibition during vaccination led to significantly improved IFN-γ+ IL17+ "Th1"-skewed T cell responses and enhanced bacterial clearance. In the subcutaneous setting, where an IL-17/IL-22 response is critical for efficient bacterial clearance, a novel Th17-skewing TLR2/STING agonist adjuvant was used. IL-10 inhibition led to significantly enhanced IL-17+ CD4, CD8 and γδ T cell responses and improved bacterial elimination.
This study reveals *S. aureus* nasal colonisation impacts systemic *S. aureus* antigen-specific T cell recall responses, and provides for the first time proof-of-concept that targeting IL-10 during immunisation may be a useful approach to improve vaccine efficacy against *S. aureus*. These results highlight how colonisation status may influence vaccine function and a novel strategy for improving anti-*S. aureus* vaccine efficacy.

Bacteria-targeting vaccine in prevention of cardiovascular and cardio thrombotic diseases

Jonna Alkula[1], Markus Ojanen[1], Vili Lampinen[1], Terho Lehtimäki[1;2], Pekka Karhunen[1], Vesa Hytönen[1]
[1]Faculty of Medicine and Health Technology, Tampere University, Tampere, Finland; *[2]The Finnish Cardiovascular Research Center Tampere, Tampere University, Tampere, Finland*

Purpose: Cardiovascular diseases (CVDs), such as myocardial infarction and stroke, are the leading cause of death in the world, causing ~18 million cases annually. Although high levels of LDL-cholesterol and unhealthy lifestyle are known risk factors for CVDs, also bacteria have been demonstrated to induce atherogenesis and platelet aggregation *in vivo*. In addition, molecular microbial techniques have been used to identify several DNA sequences from oral and gut bacteria in atherosclerotic plaques and thrombus aspirates of patients with myocardial infarction or acute ischemic stroke. Here our aim is to develop bacteria-targeting vaccines that could prevent cardiovascular complications.
Methods: Bacterial targets were selected based on metagenomic and immunohistochemical findings from human coronary artery plaques and thrombus samples. Antigens were chosen based on literature, and online databases of protein sequence and structure were used for the design of vaccine candidates. Recombinant proteins were produced in *E. coli* and their immunogenicity was studied using BALB/c mice. B cell response was studied from the serum by determining antigen-specific IgG endpoint titers with ELISA, and T cell response was determined from splenocytes using cytokine based FluoroSpot assay. SpyTag-decorated norovirus-like particles (noro-VLPs) will be used to display the antigens and improve their immunogenicity.
Results: We designed and produced five bacterial surface proteins from selected species to be used as antigens. Protein purity (~100%), endotoxin (<1.5 EU/µg) and DNA levels (<10 ng/dose) were acceptable for preclinical studies. While antigen-specific T cell responses were not detected in our immunizations, we obtained high IgG titers with three antigens (end point titer >100,000) and detectable levels of antibodies with the other two antigens.
Conclusion: For targeting selected bacteria, we designed and produced five vaccine candidates and achieved antigen-specific IgG antibodies against them in mice. Next, we aim to improve the immunogenicity of the antigens using VLP display and establish an infection model in mice to study whether the formation of atherosclerotic plaques or thrombi can be prevented by vaccination. Our study can lead to novel bacteria-targeted vaccine against cardiovascular diseases and have significant socioeconomical impact around the world.

Role of Foxo1 and inflammation on T-cell exhaustion in the course of anti-tumor responses

Amélie Lombès[1], Mathieu Germain[1], Aurélie Durand[1], Léa Giraud[1], Armelle Blondel[1], Cédric Auffray[1], Bruno Lucas[1]
[1]*Institut Cochin INSERM U1016 CNRS 8104, Paris, France*

T-cell exhaustion is a phenomenon commonly observed during aging and in persistent inflammatory conditions such as cancer and chronic infections. It is characterized by a progressive loss of effector functions and the expression of numerous immune checkpoint inhibitory receptors. Over the past decade, antibodies targeting these immune checkpoints have enabled considerable advances in cancer treatment. Unfortunately, these treatments are not efficient in all cancer types and only in a minority of patients. Our recent findings suggest that age-related inflammation (like exposure to pro-inflammatory cytokines such as type I interferons (IFN) and TNF-α) promotes the development of T-cell exhaustion via decreased expression of a transcription factor called Foxo1 (Durand A *et al*, Nat Commun 2024). This project aims to determine whether pro-inflammatory cytokines and Foxo1 downregulation could also be involved in T-cell exhaustion in the tumor microenvironment.
We observed a decrease in Foxo1 expression in intra-tumoral effector T cells, associated with an increase in the expression of several immune checkpoint receptors, in all mouse tumor models studied (transplanted, induced and spontaneous). We also studied tumor growth and T-cell infiltrate in different tumor models in mice deficient in type I IFN receptor expression ($IFNAR^{KO}$ mice) or TNFα expression (TNF^{KO} mice) compared with control mice.
We demonstrated the dual role of type I IFN in the MC38 transplanted tumor model by identifying accelerated tumor growth and reduced immune infiltrate in tumors in $IFNAR^{KO}$ mice compared to controls, but also a downregulation of exhaustion markers associated with increased Foxo1 expression in intra-tumoral $IFNAR^{KO}$ CD8 T cells.
We observed slower tumor growth in TNF^{KO} mice than in controls and a higher density of intra-tumoral CD4 T cells with a less exhausted phenotype in the MC38 tumor model.
Taken together, these results suggest a key role for pro-inflammatory cytokines in intra-tumoral T-cell exhaustion with a possible Foxo1-dependent effect for type I IFN. We would now like to test antibodies targeting these inflammatory signals to reduce T-cell exhaustion and improve anti-tumor immune responses.
This work is sponsored by an « Association pour la recherche sur le cancer » grant. Amélie Lombès is supported by an INSERM fellowship.

T cell Immunotherapy: thinking beyond inhibitory receptors.

Ludovic Martinet[1]
[1]*Cancer research center of Toulouse, Toulouse, France*

Although immune checkpoint blockade (ICB) such as anti-PD-1 has represented a turning point in cancer care, clinical responses are not observed in the majority of cancer patients. The mechanisms underlying this lack of responsiveness are still poorly understood and finding additional signals that regulate CD8+ T cell anti-tumor functions has become a major priority. While most studies focus on inhibitory receptors, signals transmitted through activating receptors also critically impact CD8+ T cell cancer immune surveillance and ICB efficacy. Indeed, we recently discovered that the loss of the activating receptor CD226 (DNAM-1) is a critical immune escape mechanism restraining CD8+ T cell function and affecting the clinical efficacy of cancer immunotherapy (Weulersse et al, Immunity. 2020, Braun et al, Immunity. 2020). We identified a subset of dysfunctional CD226-negative CD8+ T cells that progressively accumulated in the tumor microenvironment through a mechanism involving the transcriptional regulator Eomesodermin (Eomes). We found that CD226 loss was a critical mechanism altering LFA-1 functions and CD8+ T cell responsiveness to TCR stimulation. Finally, we demonstrated that the absence of CD226 was significantly limiting the therapeutic efficacy of ICB in preclinical mouse models.
More recently, we focused on CD137 (4-1BB) activating receptor, an enigmatic yet, promising target for immunotherapy. Using T cell-specific deletion and agonist antibodies, we found that CD137 modulates tumor infiltration of CD8+ exhausted T (Tex) cells expressing PD1, Lag-3 and Tim-3 inhibitory receptors (*Pichler et al, immunity. 2023*). T cell-intrinsic, TCR-independent CD137 signaling stimulated the proliferation and the terminal differentiation of Tex precursor cells through a mechanism involving the RelA and cRel canonical NF-kB subunits and the Tox-dependent chromatin remodeling. While Tex cell accumulation induced by prophylactic CD137 agonists favored tumor growth, anti-PD-1 efficacy was improved with subsequent CD137 stimulation in pre-clinical mouse models. Better understanding of T cell exhaustion has crucial implications for the treatment of cancer and infectious diseases.
Understanding the cellular process that drive T cell dysfunction has crucial implications for the treatment of cancer and infectious diseases. Thus, our study, that uncovers the importance of CD226 and CD137 pathways in T cell dysfunction, could have broad applications for immunotherapy.

Imiquimod induces gamma-delta T cell exhaustion in mouse psoriatic inflammation

Katarzyna Nazimek[1], Angelika Fedor[1], Bernadeta Nowak[1], Paulina Skalska[1], Martyna Cieślik[1], Magdalena Gębicka[1], Katarzyna Zaborowska[1], Krzysztof Bryniarski[1]
[1]*Jagiellonian University Medical College, Department of Immunology, Krakow, Poland*

Purpose: Complex pathogenesis of psoriasis involves yet understudied activities of Th1, Th17 and γδ T cells linked by cytokine circuits. Psoriatic dermatitis could be induced in mice by topical administration of imiquimod (IMQ) or intradermal administration of IL-23, and current studies aimed to compare these model mechanisms focusing on locally and systemically activated subpopulations of αβ and γδ T lymphocytes.
Methods: Psoriatic dermatitis was induced by IMQ administration for 7 consecutive days or ten intradermal injections of IL-23 performed every other day and assessed macroscopically by PASI scoring and ear swelling measurements in C57BL/6 mice. Serum cytokine concentrations were measured in ELISA and immune cells infiltrating lesional skin, draining lymph nodes and spleens were analyzed cytometrically.
Results: Mice treated with IMQ developed a more severe skin reaction than mice treated with IL-23, as reflected in significantly higher ear swelling responses and PASI values. Moreover, IMQ application caused the systemic inflammatory reaction with significant weight loss and severe splenomegaly. While serum levels of IL-12/IL-23p40 were similar in IL-23 and IMQ-administered mice, the latter treatment resulted in higher IL-17A and IFNγ concentrations. Moreover, IMQ increased the proportion of myeloid cells to T cells in lesional skin but not in draining lymph nodes and enlarged spleens. IFNγ-positive cells predominated among CD3ε-positive αβ and γδ T lymphocytes, while CD3ε-negative γδ T lymphocytes with impaired activation status were found more numerous than their CD3ε-positive counterparts, in enlarged spleens of IMQ-treated mice especially.
Conclusion: Our present findings suggest that intradermally injected IL-23 activates effector Th17 cells indirectly by stimulating the release of IFNγ by Th1 cells, and the initial activity of IFNγ-positive αβ and γδ T lymphocytes appears to be the common feature of both models studied. Moreover, the presence of CD3ε-negative γδ T cells with impaired activation status provides the first experimental evidence for γδ T cell exhaustion in psoriasis. Finally, one can conclude that IL-23-induced psoriasis model allows to study skin-related immune mechanisms with lower impact on animal welfare, while the IMQ-induced model enables holistic studies of psoriasis as a systemic disease with many comorbidities.

Activated hepatic stellate cells promote the retention and functional impairment of tissue-resident CD8+T-cells in the fibrotic liver

George Finney[1], Stephanie Kucykowicz[1], Emily Naish[1], Daniel Brown Romero[1], Walid Al-Akkad[1], Amir Gander[1], Krista Rombouts[1], Mala K Maini[1], Laura J Pallett[1]
[1]*University College London, London, United Kingdom*

The function and phenotype of liver compartmentalised T-cells - tissue-resident T-cells (T_{RM}) - have been well-defined in hepatotropic infections and cancer. We have defined a population of highly functional IL-2-producing intrahepatic $CD69^+CD103^+CD8^+T_{RM}$ that contribute to the control of hepatitis B infection. While in primary liver cancer the presence of T_{RM} associates with improved overall patient survival. However, whether T_{RM} are involved in the dysregulated cycles of tissue damage and repair characteristic of liver fibrosis remains unclear.

We are becoming increasingly aware that the liver stroma can orchestrate local immunity - imprinting cellular fate, producing immunomodulatory mediators, and promoting leukocyte tethering. Here we show that hepatic stellate cells (HSCs; liver fibroblasts, the master mediators of fibrosis) dictate the derivation and retention of hepatic $CD8^+T_{RM}$. As fibrosis progresses, primary HSCs increase secretion of active-TGFb, driving the increased retention of $CD8^+$T-cells with a T_{RM} profile ($CXCR6^{hi}CD69^+CD103^+$) in the fibrotic liver. Accordingly, hepatic $CD8^+T_{RM}$ exhibit an integrin profile capable of facilitating interaction with, and increased tethering to, activated HSCs and the extracellular matrix they lay down. For example, we show $CD8^+T_{RM}$ upregulate a1b1/CD49a and aLb2/CD11a, that bind to collagen-IV and HSC-expressed ICAM respectively, and downregulate a5b1/CD49e, that binds fibronectin. Additionally, our data suggest that activated HSCs not only imprint a program of residency on $CD8^+$T-cells, but also a functional impairment. *In vitro* primary fibrotic HSCs limit the functionality (IFNg/TNFa/CD107a) of peripheral $CD8^+$T-cells and highly functional hepatic $CD8^+T_{RM}$ from individuals without fibrosis. Correspondingly, *ex vivo* $CD8^+T_{RM}$ from individuals with fibrosis express more PD-1, produce less pro-inflammatory cytokines and have a reduced capacity for degranulation upon stimulation. Significantly, we also show increased PD-L1 expression on HSCs in advanced fibrosis, suggesting a potential axis for the functional impairment of intrahepatic $CD8^+T_{RM}$ in chronic liver disease.

Advanced liver fibrosis can lead to an increased infection risk, the development of primary liver cancer and ultimately liver failure if not addressed. Our data suggest that blocking the PD1/PD-L1 pathway may represent a therapeutic strategy to reinvigorate the function of these highly efficient antiviral/antitumour immune sentinels within the liver, therefore helping to reduce the risk of disease complications.

Immune checkpoint molecules control the local antigen-specific immune response in the liver

Thomas Guinebretière[1], Anaïs Cardon[1], Jean-Paul Judor[1], Richard Danger[1], Sophie Conchon[1], Amédée Renand[1]
[1]*Nantes Université, INSERM, Center for Research in Transplantation and Translational Immunology, UMR 1064, Nantes, France*

Purpose: Antigen presentation is regulated in the liver to limit inflammation and preserve liver functions in healthy condition. There is an increased incidence of conditions where the hepatic tolerance is altered, such as autoimmune liver diseases or immune checkpoint (IC)-related immunotherapies for cancer patients. Autoreactive $CD4^+$ T cells are considered as playing an active role in these alterations, however studying their emergence and biology is technically challenging. The objectives of this work were to define signaling pathways regulating antigen-specific immune response in the liver, with a special focus on $CD4^+$ T cells.
Methods: We developed a new murine model, in which the model antigen hemagglutinin (HA) expression is restricted to hepatocytes, thanks to inducible Cre recombinase under the control of hepatocyte-specific promotor (HA/iCre mice). Intraperitoneal injections of tamoxifen induce HA expression specifically in hepatocytes. Peripheral immunization is obtained by intramuscular injection of HA-coding plasmid. The role of IC in the liver antigen-specific response was investigated using IC blocking antibodies *in vivo*. Injections of depleting anti-CD4 antibodies were used to study the involvement of $CD4^+$ T cells in the induced immune responses. Hepatitis scoring method on liver sections was implemented to measure liver inflammation. HA-specific $CD4^+$ and $CD8^+$ T cells were tracked, measured, and characterized through tetramer staining, RNA-sequencing and flow cytometry analysis.
Results: HA-specific $CD4^+$ and $CD8^+$ T cells were detected in the spleen of mice after peripheral HA-specific immunization. After tamoxifen-induced HA expression by hepatocytes, a transient accumulation of HA-specific $CD4^+$ and $CD8^+$ T cells in the liver was detected. Flow cytometry and RNA-sequencing analysis of liver HA-specific $CD4^+$ T cells revealed up-regulation of IC molecules (PD-1, CTLA-4, TIGIT). In this condition, blockade of PD-1 and CTLA-4 induced severe hepatitis, including massive infiltration of HA-specific $CD8^+$ T cells, an effect reversed by $CD4^+$ T cell depletion.
Conclusion: Using a mouse model, we demonstrated that antigen-specific $CD4^+$ T cells acquire an immuno-exhausted profile, with up-regulation of IC molecules, when they accumulate in the liver after local antigen reactivity. Inhibition of IC pathways is associated to increased liver inflammation in a $CD4^+$ T cell dependent manner.

Purpose: HIV controllers (HIC) consist of a heterogeneous group of individuals who exhibit the capacity to sustain low plasma viral load with high CD4+ T-cell counts without antiretroviral therapy. Specifically, elite controllers (EC) show undetectable plasma viral load for several years. Which immunological mechanisms play a role in HIV control is not fully understood. We aimed to characterize the composition of circulating immune cells to identify an immune signature of HIV control.
Methods: High dimensional flow cytometry was performed to phenotype the major circulating immune cells and their maturation, activation, and exhaustion status, in 95 HIC and 1044 non-HIC (normal progressors on ART) of the 2000HIV study (NCT03994835). Differences in frequencies of the immune cell populations between HIC and non-HIC were investigated using a linear regression model.
Results: HIC were less often of European ancestry and showed higher CD4 nadir and HIV duration compared to non-HIC ($p<0.05$), while age and sex did not differ. HIC showed higher frequencies of total CD4+T-cells as well as several lineages of naïve cells (CD4+T, Treg and B cells) and CD8+TEMRA cells. In contrast, lower frequencies of CD4+ Th17, total CD8+T cells and memory subsets: CD4+Tcm, mTreg, CD8+Tcm, CD8+Tem and switched memory B cells were seen in HIC. Regarding immune cell status, CD4+T-cells of HIC were characterized by a reduced activation and exhaustion profile, evidenced by lower frequencies of cells positive for CCR5, HLA-DR+, CD38+ and PD1 ($p<0.05$). To dissect the populations linked to the long-term viral control, we independently analyzed the immune cell composition of 21 elite HIV controllers (EC, HIV-RNA <75 copies/mL/no-ART) and sought which cell subsets were enriched in EC. Notably, EC exhibited a higher frequency of TCRgdv2 cells and lower TCRgdv1 cells, as well as reduced exhaustion and activation within the T cell compartment, in comparison to non-HIC.
Conclusion: Our extensive immune cellular profiling suggests that HIC are characterized by increased proportions of naïve immune cells, reduced cellular exhaustion and activation with lower CCR5 expression. Increased proportions of TCRgdV2 cells in EC may contribute to maintaining the elite HIV controller status, highlighting their potential as a therapeutic target.

Understanding immunity at the site of embryo implantation – implications for women with recurrent pregnancy loss

Ana Kisovar[1], Ingrid Granne[1], Jennifer Southcombe[1]
[1]*Nuffield Department of Women's and Reproductive Health, University of Oxford, Oxford, United Kingdom*

Introduction: At the beginning of human pregnancy, an embryo implants into the endometrium, the inner most lining of the uterus. Like all mucosal tissues, the endometrium is enriched with immune cells providing pathogen defence, however alterations in the immune environment have been identified in patients with various disorders with associated subfertility. Recurrent Pregnancy Loss (RPL) effects 1-4% of couples and is defined as the consecutive loss of two or more pregnancies before 24 weeks' gestation. Although a significant proportion of RPL is linked with the autoimmune disorder antiphospholipid syndrome (APS), for the majority of patients (>50%) no reason is found but the immune system is implicated.
Methods: This study utilises a 35-parameter full spectrum flow cytometry panel (Cytek®Aurora), both bulk and single-cell transcriptomic sequencing (10X Genomics; 5'GEX/TCR/BCR immune-profiling) and Chip-cytometry (ZellScannerONE®) to characterise the T and B cell populations in the endometrium and blood of women with RPL. Samples were obtained when most relevant to embryo implantation, 7–11 days post Luteinising-Hormone surge.
Results: We analysed endometrial (n=10; 97K CD45+cells) and peripheral blood (n=10; 700K CD45cells) samples from RPL patients with miscarriage versus live birth in the subsequent pregnancy, and identified novel immune cell phenotypes, activation/regulatory markers, and cytokine receptors in matched samples. Endometrial naïve CD8+ T cells were increased in RPL patients that miscarried in their next pregnancy versus those with a live birth (p-adj = 0.021) and CD8+ T cell transcriptome was significantly altered with genes associated with chemotaxis, angiogenesis and vascular development. We present a detailed single cell transcriptomic analysis of the T and B cell compartments (n=8). Histology revealed CD8T cells were intraepithelial lymphocytes or in association with endometrial 'lymphoid aggregates', comprised of T, B, and macrophage cells.
Conclusions: This is the first study of endometrial mucosa using full-spectrum flow cytometry in combination with transcriptome analysis to identify immune modulation in RPL. Identification of the modulated pathways is key to the development of evidence-based treatments and diagnostics to enable detection of patients who would benefit from immunomodulators.

Studies to Determine Myelin Peptide-Specific Nanoparticle Tolerance Mechanisms and Clinical Translation

Joseph Podojil[1;2], Andrew Cogswell[1], Ming-Yi Chiang[1], Sandeep Kakade[2], Derrick McCarthy[1;2], Adam Elhofy[2], Stephen Miller[1]
[1]Northwestern University, Chicago, United States; *[2]Cour Pharmaceuticals, Skokie, United States*

Purpose: Self-antigen-specific T cells are the underlying cause of many autoimmune diseases. T cells are found at the site of tissue destruction, resulting not only in the exacerbation of disease, but also the release of self-epitopes in the context of inflammation resulting in the activation of additional T cell populations, *i.e.*, epitope spreading, thereby perpetuating disease. Treatment with Ag-containing biodegradable poly(lactide-*co*-glycolide) (PLGA) nanoparticles, *i.e.* tolerogenic immune-modifying particles (TIMP, also denoted as CNPs), has been shown to be both safe and induces Ag-specific tolerance in mouse models of autoimmunity and allergy, as well as in a celiac disease Phase I/IIa clinical trial. The present studies addressed three key objectives. (1) To further identify the cellular populations and molecular pathways required for Ag-specific TIMP-induced tolerance. (2) To investigate the ability of TIMP-induced tolerance to modulate spread epitope-specific CD4+ T cell activation, which is critical for the inhibition of autoimmune disease progression. (3) The present studies further identified novel pathways required for Ag-specific TIMP-induced tolerance.
Methods: Tracible TIMPs were used to determine the cell type that first phagocytosed TIMPs following injection in vivo, and confocal microscopy and flow cytometry used to determine the fate of these cells. A combination of in vitro and in vivo studies were completed to identify the requirement for STING/IFN-alpha receptor pathway for antigen-specific TIMP-induced tolerance utilizing transferred PLP139-151-specific and MOG35-55-specific T cell receptor transgenic CD4+ T cells in SJL and C57BL/6 mice respectively.
Results: The present data show that myeloid cells phagocytose TIMPs and undergo apoptosis via a caspase-dependent pathway. Subsequently, TIMP-induced Ag-specific tolerance therapy increases both $FoxP3^+$ regulatory T cells and $IL\text{-}10^+$ Tr1 cells in naïve mice and diseased mice via a STING/IFN-alpha receptor-dependent pathway. Furthermore, these data show TIMP treatment modulates T cells specific for spread epitopes associated with disease progression, but not encapsulated within the TIMP, *i.e.* tissue-specific bystander suppression.
Conclusion: Therefore, treatment activates various Ag-specific regulatory T cell subsets capable of regulating responses to disease-associated autoantigens not encapsulated within the TIMP via release of immunoregulatory cytokines, and treatment with multiple myelin-derived peptide epitopes has proven efficacious in preclinical mouse models of multiple sclerosis.

Tolerogenic dendritic cell-based immunotherapy to prevent unwanted immune response in enzyme replacement therapy for lysosomal storage disorders

Marta Fortunato[1;2], Daniela Tomasoni[1], Fabio Russo[1], Serena Gasperini[3], Simona Fecarotta[4], Maria Ester Bernardo[1], Giancarlo Parenti[4;5], Alessandro Aiuti[1], Laura Passerini[1], Silvia Gregori[1]
[1]San Raffaele Telethon Institute for Gene Therapy (SR-Tiget), IRCCS San Raffaele Scientific Institute, Milan, Italy; *[2]Vita-Salute San Raffaele University, Milan, Italy*; *[3]Metabolic Rare Diseases Unit, Pediatric Department, Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy*; *[4]Department of Translational Medical Sciences, Section of Pediatrics, Federico II University, Naples, Italy*; *[5]Telethon Institute of Genetics and Medicine, Pozzuoli, Italy*

Lysosomal storage disorders (LSDs) are caused by the lack of lysosomal enzymes. When available, enzyme replacement therapy (ERT) is the standard treatment for LSDs, although immune responses towards the infused enzyme can limit its therapeutic efficacy. Tolerogenic dendritic cells (tolDC) are pivotal in promoting antigen(Ag)-specific tolerance. We developed a protocol to generate tolDC using lentiviral-vectors encoding for human IL-10 and selected Ag-derived epitopes ($DC^{Ag/IL\text{-}10}$) and showed their efficacy in modulating Ag-specific T and B cell responses. With the aim of developing tolDC as enzyme-specific adjuvant immunotherapy for LSD patients undergoing ERT, we dissected the immune status of ERT-treated LSD patients (Mucopolysaccharidosis-IVA, Pompe disease and alpha-mannosidosis), generated tolDC from patients' monocytes, and tested the ability of $DC^{Ag/IL\text{-}10}$ to modulate adaptive responses to ERT (a-L-iduronidase, IDUA) in a mouse model of Mucopolysaccharidosis-I (MPSI).
We measured cytokines/chemokines in patients' plasma by Luminex, performed flow cytometry profiling of peripheral blood cells and generated tolDC from $CD14^+$ monocytes of LSD patients. We found increased inflammatory cytokines and chemokines in the plasma of LSD patients, compared to healthy controls (HC). In line with this, we observed the upregulation of activation markers on monocytes and $CD8^+$ T cells and down-regulation of inhibitory markers on T cells. The frequency of granulocytes, in particular neutrophils, and antibody-producing B cells was higher in LSD patients compared to HC. Despite the activated phenotype, patient-derived $CD14^+$ cells differentiated into functional tolDC that modulate allogenic $CD4^+$ T cells, and promoted Tr1 cells as efficiently as those differentiated from HC. In a preclinical ERT model in which MPSI mice received IDUA treatment, we detected IDUA-specific $CD4^+$ T cell responses early after ERT initiation and the induction of anti-IDUA antibodies. Repetitive injections of engineered DC expressing IDUA and IL-10 ($DC^{IDUA/IL\text{-}10}$) reduced circulating anti-IDUA antibodies, compared to control mice injected mice with DC^{IDUA}.
Our data indicate that, despite the pro-inflammatory signature of ERT-treated LSD patients, monocytes can differentiate into functional tolDC. Preliminary *in vivo* data suggest that tolDC immunotherapy effectively limit the immune response elicited by ERT, thus potentially fostering its efficacy.

Tolerogenic dendritic cells are strong producers of extracellular vesicles with immunomodulatory function

Mats van Delen[1;2], Amber Dams[1], Hans de Reu[1], An Jacobs[2], Pascale Berckmans[2], Judith Derdelinckx[1;3], Inge Nelissen[2], Nathalie Cools[1;4]
[1]Laboratory of Experimental Hematology, Faculty of Medicine and Health Sciences, University of Antwerp, Antwerp, Belgium; *[2]Health Department, Flemish Institute for Technological Research (VITO), Mol, Belgium*; *[3]Department of Neurology, Antwerp University Hospital, Edegem, Belgium*; *[4]Center for Cell Therapy and Regenerative Medicine, Antwerp University Hospital, Edegem, Belgium*

Introduction: While the potential of tolerogenic dendritic cells (tolDC) for the regulation of pro-inflammatory pathogenic responses in multiple sclerosis has been recognized, their mode-of-action (MOA) remains elusive. With preliminary data pointing towards an increase in the production of extracellular vesicles (EVs), we hypothesize a role for EVs in the MOA of tolDC.
Methods: tolDC-derived EVs were isolated from conditioned media using tangential flow filtration, characterized by nanoparticle tracking analysis (NTA), high-sensitivity flow cytometry (HS-FCM), transmission electron microscopy (TEM) and western blot and compared to EVs derived from conventional DC (convDC). The suppressive function of tolDC-EVs was evaluated using an allogeneic mixed lymphocyte reaction (allo-MLR) and evaluated for differences in T cell and B cell responses.
Results: Staining of the EV membrane with Cell Mask Green showed the successful isolation of EVs from cell culture medium with a higher number of EVs retrieved from tolDC culture media compared to convDC. The median size of tolDC-EVs seems to be larger as compared to convDC-derived EVs, while tolDC produced significantly more EV. Characterization of EVs was done according to the current MISEV guidelines. Furthermore, tolDC-EV were able to suppress the allo-MLR as shown by a significant decrease in secreted interferon-gamma, decreased expression of cellular activation markers by allogeneic T cells, and changes in the B cell compartement as compared to the allogeneic lymphocytes alone. Moreover, our assay shows that tolDC-EV were able to suppress the allo-PBL reaction to a similar extent as tolDC.
Conclusion: Altogether, our data show the secretion of EVs by tolDC and suggest an immunosuppressive role of tolDC-EV. More research is needed to characterize tolDC-EV according to MISEV guidelines and further explore their immunosuppressive function. Ultimately, we aim to deliver new insight in the mode-of-action of tolDC and the induction of tolerance. In addition, this research could lead to the development of a new EV-based therapeutic agent for the treatment of MS.

A new paradigm for the role of AIRE in the regulation of cytoskeleton

Dominik Filipp[1], Jana Petrusova[1], Jasper Manning[1]
[1]*Institute of Molecular Genetics, Prague 4, Czech Republic*

Autoimmune regulator (Aire), one of the most studied transcription factors, is well known for its critical contribution to the establishment of immunological tolerance, a phenomenon that takes place in the thymus. Since Aire loss-of function mutations can lead to the onset of multi-organ autoimmunity, Aire has been studied for nearly three decades almost exclusively in the context of medullary thymic epithelial cell (mTEC) function where it regulates mechanisms involved in the prevention of autoimmunity. Recently, we and others have shown that Aire also fulfils an analogous immune function in a rare subset of lymph node cells. In addition, accumulating evidence suggests that Aire is also expressed in other non-immune cell types and tissues. Our newly acquired data now provides unambiguous proof of the novel role of Aire in testes. In the absence of Aire, the process of spermatogenesis is spatially disordered resulting in markedly reduced and malformed sperm leading to sterility. This aberrant phenotype is not only caused by transcriptional deregulation but also a previously undescribed cytoplasmic function of Aire in relation to essential microtubule cytoskeleton regulation. Importantly, we have evidence that AIRE is also associated with microtubules in autoimmunity-preventing mTECs as well as rapidly dividing cancer cells. This strongly suggests that AIRE could have a much broader spectrum of activities implicated in the modulation of physiological as well as pathological processes. We believe that this data invites for a revised view on the function of the Aire protein and could provide novel approaches for therapeutic interventions in processes linked to sterility, autoimmunity, and malignancy.

The embryonic lymphoid cells permanently imprint the thymic epitelial compartment

Gonçalo Nogueira[1;2], Francisca Soares-da-Silva[1;2], Nuno Alves[3], Pablo Pereira[1;2], Ana Cumano[1;2]
[1]Institut Pasteur, Paris, France; *[2]Université Paris Cité, Paris, France*; *[3]i3S – Instituto de Investigação e Inovação em Saúde, Porto, Portugal*

Thymic epithelial cells (TEC) play an essential role in central tolerance, guided by medullary (m)TEC driving negative selection of self-reactive newly generated thymocytes. Between days 12-15 of gestation, the thymus is colonized by a first wave of hematopoietic thymic seeding progenitors (TSP) that have the unique capacity to generate invariant gd T cells and lymphoid tissue inducer (LTi) cells. These embryonic populations are the first to express RANK ligand (L) in the thymus. RANK-RANK-L interactions are required for the expression of autoimmune regulator (AIRE) by mTEC, which is essential for the negative selection of self-reactive T cells. Previous analyses showed that injection of anti-IL-7Ra antibody in mid-gestation largely decreased the first wave of TSP and resulted in a strong reduction of invariant gd T cells and LTi cells, as well as of mature mTEC around birth. We are now investigating the impact that the absence of the first wave of TSP has on thymic function later in life. At post-natal day (P)15, anti-IL-7Ra antibody-treated (aIL7Ra-AT) mice exhibit reduced numbers of thymic regulatory T (Treg) cells and normal numbers of other populations of thymocytes. By contrast with control mice that show a peak of mTEC at P30, aIL7Ra-AT mice maintain constant the numbers of mTEC between P15 and P270. Transcriptional analyses of TEC in aIL7Ra-AT mice showed the virtual absence of AIRE-expressing mTEC and a decreased population of immature mTEC at P30. aIL7Ra-AT mice also showed an abnormal thymic architecture with increased numbers of small medullary areas that fail to coalesce, a feature that persists in older mice. aIL7Ra-AT mice showed delayed thymocyte recovery and a lack of capacity to regenerate their TEC compartment when subjected to whole-body sublethal irradiation or dexamethasone treatment. 50% of the aIL7Ra-AT mice died before the age of 9 months and the survivors showed immune infiltrates in several organs, indicative of autoimmunity. We conclude that interactions between embryonic thymocytes and TEC are essential for normal thymic function in adults and their perturbation will result in life-long consequences for the immune system.

Inheritance of old mitochondria controls early CD8 T cell fate commitment and is regulated by autophagy

Mariana Borsa[1], Ana Victoria Lechuga-Vieco[1;2], Amir Kayvanjoo[3], Yavuz Yazicioglu[1], Ewoud Compeer[1], Felix C. Richter[1;4], Hien Bui[5], Emilia Kuuluvainen[5], Michael L Dustin[1], Linda Sinclair[6], Doreen Cantrell[6], Pekka Katajisto[5;7], Anna Katharina Simon[1;3]
[1]University of Oxford, Oxford, United Kingdom; *[2]Institute for Research in Biomedicine, IRB, Barcelona, Spain*; *[3]Max Delbrück Center, Berlin, Germany*; *[4]Medizinische Universität Wien, Vienna, Austria*; *[5]University of Helsinki, Helsinki, Finland*; *[6]University of Dundee, Dundee, United Kingdom*; *[7]Karolinska Institute, Stockholm, Sweden*

T cell immunity is impaired during ageing, particularly in memory responses needed for efficient vaccination. Autophagy and asymmetric cell division (ACD) are cell biological mechanisms key to memory formation, which undergo a decline upon ageing. Thus, we aimed to decipher whether autophagy regulates the early-rise of asymmetric T cell fates and investigate whether there is a causal link between ACD and *in vivo* T cell fate decisions, as evidence has remained highly correlative. Our results are consistent with the concept that initiation of asymmetric T cell fates is indeed regulated by autophagy.
Firstly, by analysing the proteome of first-daughter $CD8^+$ T cells following TCR-triggered activation, we observed that mitochondrial proteins rely on autophagy for their asymmetric inheritance and that damaged mitochondria are polarized upon first division. These results led us to evaluate the functional impact of unequal inheritance of different mitochondrial populations on T cell function. To achieve that, we used a novel mouse model that allows sequential tagging of mitochondria in mother and daughter cells, enabling their isolation and subsequent *in vivo* analysis of $CD8^+$ T cell progenies based on a pre-mitotic cell cargo. Autophagy-deficient $CD8^+$ T cells showed impaired clearance and symmetric inheritance of old mitochondria, suggesting that both segregation and degradation events promote asymmetry and are needed to generate T cells devoid of old organelles. Daughter cells inheriting old mitochondria are more proliferative, glycolytic and show poor survival in absence of TCR stimulation. Adoptive transfer of cells followed by antigen-specific infection revealed that progenies inheriting old organelles have reduced memory potential, whereas daughter cells that have not inherited old mitochondria from the mother cell are long-lived, able to re-expand upon cognate-antigen challenge and produce effector cytokines upon re-stimulation. Proteomic and single-cell transcriptomic analysis of cells inheriting aged mitochondria suggest that their early fate divergence relies on one carbon metabolism as a consequence of poor mitochondrial quality and function.
These findings increase our understanding of how T cell diversity is early-imprinted and will help foster the development of strategies to modulate T cell function, which is particularly relevant in the context of immune rejuvenation and regenerative medicine.

A subset of αvβ8-expressing CD4+ effector memory T cells restrain anti-viral CD8+ T cell responses and prevent tissue pathology via activation of latent TGFβ.

Craig McEntee[1;2], Stephanie Houston[2], Conor Finlay[1;2], Susan Christo[3], Stefano Rossi[2], Gang Liu[4], Tovah Shaw[2;5], Joshua Casulli[2], Mark Fife[2], Catherine Smedley[2], Thomas Griffith[6], Marion Pepper[7], Tracy Hussell[2], Philip Hansbro[4], Jean-Marc Schwartz[2], Laura Mackay[3], Helena Paidassi[8], Mark Travis[2]

Eliciting rapid responses to previously encountered antigen underpins immunological memory and is a cornerstone of durable immunity. Central to this are long-lived memory T cells, which rapidly respond following re-encounter with cognate antigen and have been shown to be indispensable for protection following heterologous Influenza challenge. Hence understanding the mechanisms regulating immune memory is essential to identify candidate targets for therapies aimed at boosting antigen-specific cellular immunity.
Transforming growth factor β (TGFβ) is a key regulator of mucosal homeostasis and has several cellular targets, including effector T cells. However, due to its potent immune-suppressive functions, together with the fact it is a mediator of tissue fibrosis, TGFβ is secreted as an inactive complex which must be activated extracellularly, a process in which cell surface integrins are integral. However, the role of such molecules during an active memory recall response remains unresolved. Using heterologous *in vivo* viral infection models, we show that a population of $CD4^+$ T_{EM} can activate latent TGFβ via expression of the integrin molecule αvβ8. This pathway appears crucial *in vivo*, as mice lacking αvβ8 on $CD4^+$ T_{EM} ($CD4.Cre^{\Delta Itgb8}$) exhibit exacerbated virus-specific effector $CD8^+$ T cell responses and enhanced viral clearance following a secondary influenza infection. However, this enhanced anti-viral recall response in the absence of αvβ8-expressing $CD4^+$ T_{EM} is associated with enhanced lung pathology following secondary Influenza infection, a phenotype which can be completely reversed via adoptive transfer of αvβ8-expressing $CD4^+$ T_{EM} into $CD4.Cre^{\Delta Itgb8}$ mice prior to rechallenge. Furthermore, we demonstrate that antigen-specific $CD8^+$ T cells in the small intestine are enriched in mice lacking αvβ8 on $CD4^+$ T_{EM} following heterologous viral challenge with LCMV, indicating that this pathway is not solely restricted to the lung. Finally, we also show the presence of αvβ8-expressing $CD4^+$ T_{EM} in human peripheral blood.
Taken together, our findings suggest that the activation of TGFβ by $CD4^+$ T_{EM} is crucial to prevent exacerbated, tissue damage-inducing effector responses and that's this feature of some $CD4^+$ T_{EM} may also serve as a viable therapeutic target to harness the potent cytotoxicity of $CD8^+$ memory T cells, a correlate of protective anti-viral and anti-tumour immunity.

Highly-functional myeloid-instructed CD8+ T-cells accumulate in the peritoneal cavity

Erich Freyer[1;2;3], Daniel Brown Romero[1], George Finney[1], Anandita Mathur[1], Lucy Cooper[1], Mala K Maini[1], Markus Cornberg[2;3], Laura J Pallett[1]
[1]Institute of Immunity & Transplantation; Division of Infection & Immunity, University College London, London, United Kingdom; *[2]Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School, Hannover, Germany*; *[3]Centre for Individualized Infection Medicine (CiiM), Hannover, Germany*

Peritoneal leukocytes play a role in immunoregulation, tissue homeostasis and repair. When peritoneal homeostasis is disturbed leukocytes are recruited to restore balance. Previously we described the reprogramming of liver-resident $CD8^+$T-cells upon interaction with neighbouring myeloid cells (Pallett_etal.,_Nature_2023). Upon interaction resident $CD8^+$T-cells 'steal' fragments of the plasma membrane acquiring constitutive immunomodulatory features at rest and an enhanced antiviral/antitumour capacity when activated through their T-cell receptor (TCR). Crucially, we can detect these 'super-responder', myeloid-instructed $CD8^+$T-cells by co-staining for CD8 and CD14.
In advanced chronic liver disease a build-up of fluid (ascites) can occur within the peritoneal cavity. Here we hypothesise that myeloid cells within the cavity reprogramme $CD8^+$T-cells to help maintain peritoneal homeostasis, providing local antiviral/anti-tumour immunosurveillance. Co-staining for CD8/CD14, we show myeloid-instructed $CD8^+$T-cells accumulate in ascites. Peritoneal $CD14^+CD8^+$T-cells produce more pro-inflammatory cytokines (IFNg/TNFa/IL-2) when TCR-stimulated than their CD14-negative counterparts despite unexpectedly high Tim3 expression, often considered a co-inhibitory receptor via interaction with ligand galectin9. However, another major Tim3 ligand is phosphatidylserine (PS) that when co-expressed with Tim3 promotes NFkB signalling and cytokine production following TCR stimulation. To investigate whether the Tim3/PS axis was responsible for the increased functionality of $CD14^+CD8^+$T-cells we assessed expression of PS by measuring annexinV, which in the presence of Ca^{2+} binds to anionic PS. $CD14^+CD8^+$T-cells express more PS than $CD14^-CD8^+$T-cells. Notably the plasma membrane is regulated to maintain asymmetric distribution of phospholipids, with anionic phospholipids (e.g. PS) restricted to the cytoplasmic leaflet. During apoptosis loss of plasma membrane integrity triggers translocation of PS to the outer leaflet, however, importantly we established that peritoneal $PS^+CD14^+CD8^+$T-cells were not apoptotic by staining for active caspase3. Instead, we propose the anionic PS has likely been removed from the surface of the instructing myeloid cell. Furthermore, the addition of a Tim3 antibody known to block PS binding diminishes the capacity of $CD14^+CD8^+$T-cells to produce cytokines when TCR-activated.
$CD14^+CD8^+$T-cells represent a resident T-cell capable of enhanced responses within the peritoneal cavity. By exploiting the ability of PS/Tim3 to augment T-cell signalling, myeloid-instructed $CD8^+$T-cells may better contribute to the maintenance of immune homeostasis, representing an important immune sentinel providing critical antiviral/antitumour immunosurveillance.

Long noncoding RNA-124 regulates CD8+ T cell response to infection

Julia Erber[1], Carmen Stecher[1;2], Valerie Plajer[2], Nina Braun[1], William Mallard[3], Loyal Goff[3], Jun Zhao[2], Johannes Reisecker[1], Thomas Mohr[1], John Rinn[3;4], Richard Flavell[2], Dietmar Herndler-Brandstetter[1;2]
[1]Medical University of Vienna, Vienna, Austria; *[2]Yale University, Department of Immunology, New Haven, United States*; *[3]Broad Institute of MIT and Harvard, Cambridge, United States*; *[4]University of Colorado, Boulder, United States*

Recent studies have identified long noncoding RNAs (lncRNAs) in key functions of immune cell regulation. However, the role of lncRNAs in regulating $CD8^+$ T cell responses against pathogens and tumors *in vivo* remains incompletely understood. Deep RNA-seq profiling of mouse $CD8^+$ T cell subsets at different stages of bacterial infection *in vivo* allowed us to identify differentially regulated lncRNAs, such as *lncRNA-124*. By using CRISPR/Cas9-mediated genome engineering, we generated *lncRNA-124* knockout (KO) mice. To analyze the *in vivo* function of *lncRNA-124* we performed adoptive co-transfer of *lncRNA-124* WT and KO T cells followed by infection with listeria monocytogenes. Our results demonstrate that *lncRNA-124* regulates effector $CD8^+$ T cell expansion as well as effector-to-memory $CD8^+$ T cell differentiation. We also show that *lncRNA-124* is evolutionarily conserved and the human ortholog of *lncRNA-124* is expressed in human $CD8^+$ T cells. In conclusion, *lncRNA-124* is a novel long noncoding RNA that regulates distinct phases of $CD8^+$ T cell differentiation *in vivo*.

Background: Programmed Death-1 (PD-1) blockade has transformed the treatment of late-stage metastatic cancer, particularly for patients with non-small cell lung cancer (NSCLC). Indeed, real-world data report durable clinical responses for 10-15% of cases, in part due to the reinvigoration of exhausted CD8 T cells in the tumour microenvironment. However, failure to reinvigorate terminally exhausted CD8 T cells could lead to clinical relapse. The characterization of the exhausted CD8 T cells in peripheral blood holds promise as a biomarker of clinical response, informing treatment changes during relapse. Furthermore, the relationship between circulating immune cell profiles and circulating tumour DNA (ctDNA) remains largely unexplored. Our aim was to characterize the phenotype and function of peripheral CD8 T cells while concurrently monitoring ctDNA dynamics after PD-1 blockade in patients with NSCLC.
Methods: Peripheral blood mononuclear cells were collected from 35 NSCLC patients pre- and post-treatment. Flow cytometry and CITE-seq was performed for phenotypic and transcriptomic analysis of CD8 T cells. Plasma ctDNA analysis was performed using SiMSen-seq, a simple multiplexed PCR-based barcoding of DNA for ultrasensitive mutation detection by next-generation sequencing. Response assessment (responder versus non-responder) was based on CT scan results and followed the iRECIST criteria with a cut-off of 9 months. All patients provided informed consent prior to enrolment to the study.
Results: Responders had higher baseline expression of TIGIT and PD-1 on CD8 T cells and an increased frequency of stem-like TCF-1+PD-1+ CD8 T cells post-treatment compared to nonresponders. Functional differences in peripheral CD8 T cells based on the transcriptional profile, between responders and nonresponders may explain treatment outcome. At baseline, nonresponders had high plasma ctDNA levels, compared to responders who had decreased or undetectable levels. Concurrent profiling of T cells and ctDNA analysis at matched time points within the same patient revealed a correlation between reduction in ctDNA load and an increase in the frequency of stem-like CD8 T cells following PD-1 blockade in a subset of patients.
Summary: The results of our study in NSCLC patients provide insights into the identification of biomarkers of clinical response in late-stage cancer, guiding treatment decisions and the development of combination therapies.

Activation phenotypes defined by coordinated expression of activation markers discriminate TCR-mediated and bystander T-cell responses

Tamara Schenk[1;2], Martijn Vos[1], Debbie van Baarle[1;2], Teun Guichelaar[1]
[1]National Institute for Public Health and the Environment, Bilthoven, Netherlands; *[2]University Medical Center Groningen, Groningen, Netherlands*

Identifying antigen-specific T-cell responses following T-cell receptor (TCR)-mediated activation during viral infection is fundamental to understanding virus-specific immunity. Using flow cytometry, activation of virus-specific T cells is commonly marked by the induction of activation-related CD-molecules and cytokine production. However, responses by non-specific bystander T cells to cytokines produced by T cells and infected cells complicate identification of antigen-specific T-cell activation. Since activation markers are sensitive to bystander activation, they lack specificity for antigen-activated T cells. Here, we aimed to gain insight on how activation markers can be applied to discriminate antigen-specific TCR-activated T cells from bystander-activated T cells. To this end, we studied how various markers are induced in response to stimulatory components of viral infections, and questioned if coordinated expression of markers could provide an activation phenotype that discriminates bystander-activated T cells.
We stimulated peripheral blood mononuclear cells (PBMCs) with anti-CD3 antibody to mimic TCR-mediated activation, supernatant of anti-CD3 activated T cells, or IL-2, IL-15, or IFNα as bystander cytokines. We then measured various activation-related characteristics in T cells, including CD69, CD25, CD137, CD154, IFNγ, and CD107a induction by flow cytometry. Based on coordinated expression of these markers, we defined activation phenotypes that pinpoint TCR-mediated and bystander T-cell responses. Subsequently, we translated our findings to anti-viral T-cell responses by stimulating PBMCs with peptides of influenza virus and SARS-CoV-2.
We observed significant induction of activation markers in response to both TCR-mediated and bystander stimulation. In comparison to TCR-mediated responses, bystander responsiveness was marked by lower co-expression of the different activation markers, and mainly included CD69 and CD107a expression. Such expression of markers without other markers being co-expressed defined activation phenotypes that indicated which T cells were activated by viral antigens or as bystander cells.
Together, our data show that defining activation phenotypes by coordinated expression of activation markers aids in pinpointing TCR-mediated versus bystander T-cell responses. The finding that a significant number of T cells respond as bystander cells indicates the relevance of considering such definition of bystander T-cell activation when studying antigen-specific T-cell responsiveness in viral infections.

Antigen-presenting autoreactive B cells activate regulatory T cells and suppress autoimmune arthritis in mice

Mike Aoun[1]
[1]*Karolinska Institutet, Stockholm, Sweden*

B cells undergo several rounds of selection to eliminate potentially pathogenic autoreactive clones, but in contrast to T cells, evidence of positive selection of autoreactive B cells remains moot. Using unique tetramers, we traced natural autoreactive B cells (C1-B) specific for a defined triple-helical epitope on collagen type-II (COL2), constituting a sizeable fraction of the physiological B cell repertoire in mice, rats, and humans. Adoptive transfer of C1-B suppressed arthritis independently of IL10, separating them from IL10-secreting regulatory B cells. Single-cell sequencing revealed an antigen processing and presentation signature, including induced expression of CD72 and CCR7 as surface markers. C1-B presented COL2 to T cells and induced the expansion of regulatory T cells in a contact-dependent manner. CD72 blockade impeded this effect suggesting a new downstream suppressor mechanism that regulates antigen-specific T cell tolerization. Thus, our results indicate that autoreactive antigen-specific naïve B cells tolerize infiltrating T cells against self-antigens to impede the development of tissue-specific autoimmune inflammation.

Elucidation of antigen-specific B cell dynamics after vaccination reveals activated B cell states that precede the classical memory B cell and plasmablast compartments

Lisan Kuijper[1], Laura Fernandez Blanco[1], Laura Kummer[1], Sabrina Pollastro[1], Tineke Jorritsma[1], Mariël Duurland[1], Amelie Bos[1], Niels Verstegen[1], Marit J. van Gils[2], Mathieu Claireaux[2], George Elias[1], Juan Garcia Vallejo[2], Taco Kuijpers[2], Filip Eftimov[2], Anja ten Brinke[1], Marieke van Ham[1]
[1]Sanquin, Amsterdam; *[2]Amsteram UMC, Amsterdam, Netherlands*

T-cell driven B-cell responses in extrafollicular and Germinal Center (GC) reactions are needed to induce antibody secreting cells (ASC) that produce protective antibodies upon infection and vaccination. It remains to be elucidated how B-cell differentiation occurs after antigen exposure, and how formation and maintenance of the different extrafollicular and GC B-cells subsets relate to each other and to formation of actual memory B-cells (Bmem) and ASCs. In this study, we characterized antigen-specific B responses longitudinally in PBMCs of persons receiving SARS-Cov-2 mRNA vaccinations or experiencing infection by using multiparameter high-dimensional flow cytometry. This deep immune phenotyping approach allowed us to distinguish different B-cell subsets and their dynamics.
Recently, we and others have described a CD71+ IgG+ Activated B-cell (ActBC) population that arises shortly after antigen stimulation and found indications that these might be B-cells that were derived from recent GC reactions. ActBC were also observed to be strongly expanded shortly after vaccination and could be further subdivided in the different B-cell states based on the deep profiling. Interestingly, the ActBC showed close phenotypic and dynamic relationships to CD11c+ B-cells previously described as 'atypical' B-cells. While the atypical and GC-derived B-cell populations have been described as separate entities, our data strongly point to interconnections between defined CD11c+ and classical populations in ongoing GC reactions. While it is unknown why B-cells differentiate towards a CD11c+ expression, these cells thus seem part of the normal immune response and together with the ActBC form the B-cell states that precede classical Bmem and/or ASC formation.
Currently, we are investigating the functional properties of ActBC and CD11c+ B-cell populations under influence of different antigenic and cytokine stimulation. In addition, the evolution of the BCR repertoire and clonotypes are being analysed over time along the various stages of B-cell differentiation. For this we link BCR analyses and transcriptomic expression to the defined proteomic phenotype of single cell sorted B-cells. These data may pave the way for strategies to target specific B-cell populations before Bmem or ASC formation has occurred in order to inhibit undesired humoral responses in transplantation or autoimmune diseases.

The brain-infiltrating B cell in multiple sclerosis: identifying triggers and receptors contributing to its effector program

Kirsten Kuiper[1], Jasper Rip[1], Laurens Bogers[1], Marie-Jose Melief[1], Annet Wierenga-Wolf[1], Liza Rijvers[1], Ursula Boschert[2], Ana Marques[1], Jamie van Langelaar[1], Romy Klein Kranenbarg[3;4], Beatrijs Wokke[3], Joost Smolders[1;3;5], Marvin van Luijn[1]
[1]Department of Immunology, MS Center ErasMS, Erasmus MC, Rotterdam, Netherlands; *[2]Ares Trading SA, Eysins, Switzerland, an affiliate of Merck KGaA, Darmstadt, Germany*; *[3]Department of Neurology, MS Center ErasMS, Erasmus MC, Rotterdam, Netherlands*; *[4]Department of Neurology, Albert Schweitzer Hospital, Dordrecht, Netherlands*; *[5]Neuroimmunology research group, Netherlands Institute for Neuroscience, Amsterdam, Netherlands*

Purpose: The effectiveness of anti-CD20 therapies highlighted B cells as a driving force behind multiple sclerosis (MS). Our group has identified distinctive, CXCR3$^+$ memory B cells that are triggered to infiltrate the MS brain and locally mature into antibody-secreting cells (ASCs). We aim to elucidate how T cell-dependent and –independent triggers mediate this process and which receptors enable CNS maintenance. This could aid in identifying MS patients who will benefit most from brain-penetrating drugs, such as next-generation Bruton tyrosine kinase (BTK) inhibitors.
Methods: In-depth *ex vivo* spectral flow cytometry analyses were performed with B cells from fresh post-mortem CNS compartments of MS donors and from the blood of healthy donors and untreated MS patients. B-cell responsiveness was determined based on phosphoflow cytometry (anti-BCR, sCD40L/IL-21) and *in vitro* T cell-dependent (CD40L/IL-21) differentiation assays, both with and without a BTK inhibitor. Single-cell RNA sequencing was performed for (precursors of) CXCR3$^+$ memory B cells at baseline and after *in vitro* differentiation.
Results: As compared to CXCR3- counterparts, CXCR3$^+$ memory B cells were more responsive to CD40L/IL-21-than BCR-related stimulation (phosphoflow), with an increased ability to mature into (CD38^{high}CD27^{high}) ASCs *in vitro*. Single-cell RNA-sequencing of *in vitro*-induced memory B cells confirmed these findings, showing a relatively enriched ASC cluster with co-expression of *CXCR3* and *ITGB1* (CD29, integrin-beta 1; VLA-4 subunit). BTK inhibition reduced induction of this ASC cluster. *Ex vivo* analyses revealed increased CD29 expression on CXCR3$^+$ versus CXCR3$^-$ memory B cells from untreated MS patients, which was even more pronounced in the CSF. This increase in CD29 expression was not seen for circulating CXCR3$^+$ ASCs. In single cell suspensions of post-mortem CSF, meninges, and brain tissues from 10 MS donors, CXCR3 and CD29 co-expression was found primarily on ASCs, in contrast to paired blood.
Conclusion: This work reveals enhanced sensitivity of CXCR3$^+$ memory B cells to T cell-dependent triggers, which likely underlies their increased ASC maturation capacity. Furthermore, we show that CD29 could serve as a phenotypic marker for their recruitment, persistence, and maturation into long-living ASCs in the MS brain.

Age-associated B cells drive loss of CD8+ T cells in systemic lupus erythematosus

Kristian Savstrup Kastberg[1], Lasse F. Voss[1;2], Gudrun Winther[1], Kenneth Green[1], Amanda Juul Howarth[1], Layla Pohl[1], Johanne Vium-Heinesen[1], Lea Fritz[1;3], Lisbeth Jensen[1], Cecilia Fahlquist-Hagert[1], Thomas R. Wittenborn[1], Yonglun Luo[1;4;5], Anne Troldborg[1;6;7], Lin Lin[1;5], Søren Egedal Degn[1]

Age-associated B cells (ABCs) are more prevalent with aging, infection, and autoimmunity. ABCs are characterized by their expression of T-bet and CD11c in mice and contribute to disease and inflammation by producing autoreactive antibodies, secreting inflammatory cytokines, and activating self-reactive $CD4^+$ T cells. However, no interplay between ABCs and $CD8^+$ T cells has been identified so far. In this study, epicutaneous application of resiquimod, a TLR-7 agonist, induced a systemic lupus erythematosus (SLE)-like autoimmune response in mice. This mouse model exhibits an increased frequency of plasma cells and germinal center B cells, increased levels of anti-DNA antibodies, and immune complex deposition in the glomeruli. The treatment also causes a loss of $CD8^+$ T cells confirmed by both flow cytometry and histology. Surprisingly, the $CD8^+$ T cell loss was rescued by a conditional knock-out of T-bet in activated B cells. Histological analyses showed that the loss of $CD8^+$ T cells could not be explained by homing to the resiquimod-treated areas. Single-cell sequencing indicated a hyperactivated or exhausted double-negative phenotype of the $CD8^+$ T cells. Ongoing experiments are aiming to elucidate whether the mechanistic link between ABCs and $CD8^+$ T cells depends on cytokines, cell-to-cell contact, or antibody production, leveraging additional genetic models, flow cytometry, cytometric bead arrays, and histological evaluation. Samples from SLE patients are also being examined to assess the applicability of these findings to clinical settings. This novel link between ABCs and $CD8^+$ T cells could give mechanistic insight into the heightened susceptibility of autoimmune patients to cancer and infection.

Contribution of memory B cells to the pool of bone marrow plasma cells through follicular and extrafollicular immune responses in health and disease

Marta Ferreira-Gomes[1], Pawel Durek[1], Frederik Heinrich[1], Gabriela M. Guerra[1], Franziska Szelinski[1;2], Tobias Alexander[1;2], Thomas Dörner[1;2], Andreas Radbruch[1], Mir-Farzin Mashreghi[1]
[1]German Rheumatism Research Centre Berlin (DRFZ), Berlin, Germany; *[2]Department of Rheumatology and Clinical Immunology, Charité-Universitätsmedizin Berlin, Berlin, Germany*

Memory B cells play a pivotal role in adaptive immunity by preserving immunological memory, yet the complexities of their organization and maintenance over time remain elusive. In previous work, we demonstrated that the majority of murine isotype-switched memory B cells localise to the spleen or bone marrow, with only a minority (20%) being in circulation. Whether this distribution holds true in humans remains unknown. Also unknown, is the real importance of memory B cells for plasma cell generation. Our analyses of bone marrow plasma cells (BMPC) revealed a distinct BMPC compartment characterised by a gene signature indicating an origin from memory B cell extrafollicular reactivation. These BMPC not only retain CD19 expression, but also exhibit higher levels of somatic hypermutation, raising questions about which memory B cells contribute to the pool of BMPC and the underlying processes involved. To address these questions, we analysed single-cell transcriptomes and B cell receptor repertoires of memory B cells and plasma cells isolated from paired blood and bone marrow samples. These samples were obtained from both healthy individuals and systemic lupus erythematosus (SLE) patients, the latter known for their propensity towards extrafollicular responses. Indeed, similar to mice, we report a considerable degree of heterogeneity among human memory B cells. Notably, selective repertoire overlaps in blood and bone marrow confirmed the probability of extrafollicularly reactivated memory B cells contributing to bone marrow plasma cell compartments. Utilising it as a model antigen, we exploited spike-specific public clones across individuals and devised a novel approach to analyse antigen-specific plasma cells. By "digitally sorting" bone marrow plasma cells expressing public clones with experimentally validated spike protein-binding BCR sequences, we investigated shared repertoires with blood and bone marrow memory B cells. Our findings edge closer to validating the intriguing hypothesis: do memory B cells undergo local differentiation into plasma cells within the bone marrow?

Distinct transcriptional profile drives enhanced activation responses in memory B cells compared to naive B Cells

Pietro Demela[1], Laura Esposito[1], Pietro Marchesan[1], Blagoje Soskic[1]
[1]*Human Technopole, Milan, Italy*

Long-lived memory B cells (Bm) arise from the differentiation of naive B cells (Bn). Antigen-experienced memory B cells are geared towards enhanced effector functions compared to their naive counterpart and provide long-term humoral immunity. To investigate the differences in responsiveness of naive and memory B cells, we profiled the transcriptome at the single cell level of human naive ($CD20^+CD27^-IgG^-IgA^-$) and unswitched memory B cells ($CD20^+CD27^+IgG^-IgA^-$) of four healthy donors. Cells were profiled in a resting state as well as at early and late stages upon in vitro T-dependent stimulation. Although both cell types underwent rapid proliferation and isotype switching, Bm proliferated more compared to Bn cells. However, isotype switching was more frequent in Bn cells. Already at a resting state as well as shortly after stimulation, Bn and Bm had considerably different transcriptional signatures suggesting that naive and memory B cells were in two different states poised to differentiate differently upon activation. At later time points, both Bn and Bm acquired multiple cell states thus recapitulating the highly dynamic process of immune response. To dissect the transcriptional determinants distinguishing Bn and Bm cells, we tested for differential expression analysis and we detected 2549 differential genes in resting cells and 1891 at day six following stimulation. Moreover, differential genes were highly time point specific, with only 32% of them overlapping between the time points. This suggests dynamic and large transcriptional differences in two similar B cell states. Interestingly, transcription of the secreting isoform of IgM was higher in the day six activated Bm cells compared to Bn, suggesting an intrinsic mechanism of fast differentiation of Bm cells to antibody producing cells. Moreover, the machinery required to sustain the high biosynthetic requirements such as genes involved in unfolded protein response, was highly expressed in memory B cells compared to naïve. Our data highlights differences in activation dynamics between naïve and memory B cells and sheds light on distinct cellular states that naive and memory B cells acquire during activation.

Mitochondrial perturbation in immune cells enhances cell-mediated innate immunity in Drosophila

Yuliya Basikhina[1], Laura Vesala[1;2], Tea Tuomela[1], Anssi Nurminen[1], Emilia Siukola[1], Tiina Salminen[1]
[1]*Tampere University, Tampere, Finland*; [2]*Umeå University, Umeå, Sweden*

Purpose: Mitochondria are key players in various cellular processes including energy metabolism, apoptosis, production of reactive oxygen species, stress responses, inflammation, and immunity. However, the role of mitochondrial metabolism in the innate immune responses is not yet fully understood. Our project investigates the effects of tissue-specific mitochondrial dysfunction on immune responses utilizing the fruit fly *Drosophila melanogaster* as a model.
Methods: We modelled mitochondrial dysfunction by knocking down oxidative phosphorylation (OXPHOS) complex genes in the two main immune tissues of *Drosophila*, the fat body and the immune cells (hemocytes). We used parasitoid wasp infection model to study the cell-mediated immune responses, as well as flow cytometry based assays to quantify immune cell populations and measure physiological parameters such as mitochondrial membrane potential and reactive oxygen species production. We utilized RNA sequencing to investigate the transcriptional response to OXPHOS knockdown in hemocytes.
Results: While OXPHOS disruption in the fat body was detrimental for the host viability and caused weakened immune responses, hemocyte-specific perturbation led to enhanced immunocompetence upon parasitoid infection, formation of melanotic nodules (immune cell aggregates, which are considered a sign of activated immune system) as well as immune cell activation and proliferation prior to immune challenge. Neither viability nor development of animals with hemocyte-specific OXPHOS knockdown was compromised. The hemocyte-targeted OXPHOS perturbation resulted in mitochondrial membrane depolarization and activation of the mitochondrial unfolded protein response, which is likely the reason for enhanced immune responses. The difference between the effects of mitochondrial dysfunction in these two key immune tissues is likely due to threshold effects and the tissue-specificity of mitochondrial metabolism.
Conclusion: Our results show that when mitochondrial dysfunction is mild enough, it can be beneficial in certain context, i.e. infection. We also show a link between the mitochondrial unfolded protein response and immune system activation, a phenomenon that appears to be conserved across various taxa. While the exact mechanisms are still unclear, the data we have obtained provides more insight into the tissue-specific role of mitochondrial metabolism in immune responses.

Glutamate dehydrogenase-Prostaglandin E2 axis controls Treg cell development with distinct features in maintaining immune tolerance

Fabien Prodjinotho[1], Neeraj Kumar[1], Jacob Lema[2], Cylia Crisand[1], Dominik Stelzle[3], Charles Makasi[2], Martin Haslbeck[4], Chummy SIKASUNGE[5], Veronika Schmidt[3], Andrea Winkler[3], Bernard Ngowi[2], Julia Esser-von Bieren[6], Clarissa Prazeres da Costa[1]
[1]Institute for Medical Microbiology, Immunology and Hygiene, Technical University of Munich (TUM), Munich, Germany; *[2]Muhimbili Medical Research Centre, National Institute for Medical Research (NIMR), Dar es Salaam, Tanzania*; *[3]Department of Neurology, University Hospital, Klinikum rechts der Isar, Technical University Munich (TUM), Munich, Germany*; *[4]Department of Chemistry, Technical University Munich (TUM), Munich, Germany*; *[5]School of Veterinary Medicine, Department of Paraclinicals, University of Zambia, Lusaka, Zambia*; *[6]Department of Immunobiology, Université de Lausanne, Epalinges, Switzerland, Lausanne, Switzerland*

Purpose: Distinct tissue-derived signals control regulatory T cell (Treg) induction in tissues and shape their heterogeneity and functionality in chronic inflammation. In the inflammatory parasitic brain disease, neurocysticercosis (NCC), we have recently identified that the lipid mediator PGE2 secreted from glutamate dehydrogenase (GDH)-modulated monocyte and microglia is a central driver of Treg development, essential to control disease in asymptomatic, non-epileptic NCC patients. Here, we characterize the epigenetic and transcriptional determinants of GDH-PGE2-modulated Treg cell development and the clinical implications in brain inflammation and silencing.
Methods: Targeted lipidomics and extensive LC/MS/MS profiling of lipid mediators in controls, asymptomatic and patients with epilepsy and neurological symptoms guided the identification of disease- and GDH-remodeling of eicosanoids, precursors and metabolites. In-depth immunophenotyping and pulsing of controls' and patients' peripheral cells with recombinantly expressed parasite GDH or PGE2 revealed the context-dependent Treg development with unique features. Subsequent mechanistic pathways of lipid mediator regulation of Treg induction were elucidated by transcriptional profiling of ex vivo sorted monocytes. The epigenetic and transcriptional determinants of Treg development and landscapes in asymptomatic patients were furthermore assessed via ATACSeq and RNASeq as compared to in vitro induced Treg and ex vivo sorted Tconv from healthy individuals
Results: Targeted lipidomics revealed a bias arachnoid acid metabolism in NCC patients with a pronounced COX-PGE2 pathway in asymptomatic disease. This is associated with distinct features of enhanced CNS migration and endothelial cell adhesion potency ($CD69^{hi}$, $CCR7^{+}$, VLA-4^{hi}, LFA-1^{+}) of $ST2^{+}$Tregs, with significant reduction of CD226 expression. The marked increase of PGE2 and precursor metabolites in patients' sera is positively correlated with pronounced EP2 and EP4 receptor expression on peripheral naïve $CD4^{+}CD25^{-}$ T cells. Integrative sequencing analyses interestingly revealed the non-canonical TNFR2-NF-kB and the JAK-STAT signaling pathways as important regulators controlling GDH-PGE2-driven Treg differentiation and thus a potential role during NCC.
Conclusion: This work highlights important insights into lipid mediators as novel regulators of Treg cell development with distinct features to maintain immune tolerance in NCC with relevance for other inflammatory brain diseases.

Targeting amino acid uptake on NK cells to limit pathogenesis of bacterial infections

Maxim Nosenko[1], Simon Carlile[1], Rachel McLoughlin[1], David Finlay[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Purpose: NK cells contribute to the pathogenesis of infections by producing IFNg, which is important for control of the pathogen, but its excessive production may lead to "cytokine storm" and tissue damage. Thus, moderating IFNg production by NK cells represents a therapeutic strategy for treatment of acute infections. Multiple studies demonstrate critical role of metabolic reprogramming for activation of immune cells. In particular, amino acid transport via Slc7a5 and glutamine uptake (mediated by Slc1a5 in NK cells) are essential for NK cell function *in vitro*. In this project we aim to test whether targeting amino acid uptake on NK cells suppresses IFNg production and thus limits pathogenesis of bacterial infections in mouse models.
Methods: We employ mouse models of peritoneal LPS-induced inflammation as well as bacterial infections with *E. coli* and *S. aureus*. Peritoneal NK cells are analyzed using flow cytometry, including click-based nutrient uptakes, mitochondrial assessment, as well as functional antibody staining. To dissect the role of amino acid transporters for NK metabolism and function, we employ mice with conditional inactivation of Slc7a5 or Slc1a5 in NK cells as well as pharmacological inhibitors of those transporters.
Results: In response to LPS challenge peritoneal NK cells underwent dynamic activation with early response (2-6 hours after LPS), indicated by upregulation of IFNg, CD69, and GzmB, as well as late response (24-48 hours after LPS), indicated by accumulation of perforin. Importantly, early response was associated with increased amino acid uptake via Slc7a5, while at the later timepoints uptake via Slc1a5 was significantly increased. Inactivation of Slc7a5 in NK cells resulted in suppressed metabolic and functional activation at both early and late timepoints, indicating crucial role of this transporter for NK activation. Furthermore, in bacterial infection models we observed a similar metabolic and functional activation of peritoneal NK cells in response to *E. coli* challenge, but not to *S. aureus* infection.
Conclusion: Altogether, our results indicate dynamic metabolic and functional response of NK cells in the context of inflammation and bacterial infections and provide novel strategy to limit pathogenic activation of NK cells via inhibiting amino acid uptake.

Deciphering the immunomodulatory effects of 4-hydroxynonenal in human monocyte-derived macrophages: size does not matter if the impact is radical

Melina Ioannidis[1], Sjors Maassen[1], Britt Coenen[1], Martijn den Ouden[1], Pieter Grijpstra[1], Danny Incarnato[2], Geert Van. den. Bogaart[1;3]
[1]Molecular Immunology Department, Groningen Biomolecular Science and Biotechnology Institute, University of Groningen, Groningen, Netherlands; *[2]Molecular Genetics, Groningen Biomolecular Sciences and Biotechnology, University of Groningen, Groningen, Netherlands*; *[3]Department of Medical Biology and Pathology, University Medical Centre Groningen, Groningen, Netherlands*

Purpose: Sepsis is a life-threatening syndrome and is a main cause of death worldwide. In 2017, 11 million people died of sepsis. Half of the 48.9 million reported cases in 2017 were children, with 2.9 million global deaths in children. Treatment and diagnostic options are limited, and morbidity and mortality remain high. Macrophages are important in sepsis. During inflammation, macrophages produce increased levels of pro-inflammatory cytokines and reactive oxygen species (ROS). ROS are essential in clearing pathogens and are highly reactive.
Lipid oxidation by ROS produces 4-hydroxynonenal (4-HNE). 4-HNE interacts with biomolecules, impacting crucial cellular processes. Considering the 4-HNE increase in inflammatory diseases, it raises the question of how 4-HNE affects the innate immune system to regulate inflammation. My project aims to identify modulatory properties of 4-HNE on human monocyte-derived macrophages (hMDM), hypothesizing that high concentrations of 4-HNE propagate inflammation as modified protein and biomolecules are expected to accumulate progressively.
Methods: Monocytes were isolated from the blood of healthy volunteers and differentiated into macrophages. Naïve macrophages were pre-treated with or without 4-HNE before adding lipopolysaccharide (LPS). RNA sequencing data were validated using reverse transcription-quantitative polymerase chain reaction. Cytokine production was measured by ELISA, and 4-HNE protein adducts and signaling were analyzed using flow cytometry and Western blot.
Results: LPS treatment significantly increased 4-HNE production. RNA sequencing revealed that 4-HNE treatment provokes a pronounced transcriptional reorganization of hMDM, including a decrease in Interleukin (IL)-10 and Interleukin-1 receptor antagonist production. Moreover, 4-HNE increased pro-inflammatory p38 signaling and blocked anti-inflammatory STAT3 activation. However, exhibited no impact on tumor necrosis factor-α and IL-6 production.
Conclusion: Thus, our data suggest that 4-HNE is an important immune system modulator that can stimulate inflammation by suppressing the IL-10 pathway. Understanding the immunomodulatory mechanisms of 4-HNE aids in understanding its role in ROS-related diseases, like sepsis, and identifying targets to restore damage by oxidative stress.

Metabolic shift of human (super)antigen-induced T cells in an ex vivo lymphoid cell culture based on tonsils.

Christopher Neullens[1], Ohl Kim[1], Klaus Tenbrock[1]
[1]*Clinic for Pediatric and Adolescent Medicine, RWTH Aachen University Hospital, Aachen, Germany*

Objective: Key metabolic processes such as glycolysis, fatty acid and mitochondrial metabolism are now recognized as crucial players in T cell activation and differentiation, and their modulation can differentially affect the development of T helper cell lineages. Especially memory T-cells (Tmem) are important for adaptive immunity since they assure long-lasting protection against pathogens, however, can also be harmful in chronic inflammation and autoimmunity. Until now, most studies addressed the metabolic phenotype of human T cells in peripheral blood, although most inflammatory and immunological processes occur in local tissues. We therefore made use of an ex vivo lymphoid cell culture based on tonsils. This ex vivo culture was recently established by the group of Baumjohann and in an analogous way by Wagar et al. and allowed us to metabolically profile memory T cells in a more physiological setting.
Methods: We metabolically analyzed CD4+ Tmem cells from adenoids after adenotomy and compared them with Tmem from peripheral blood.
Tissues from adenoids were cut and incubated as single cell cultures in well plates. They were then stimulated with different antigens including Pertussis Toxin and TSST-1.
Mitochondrial activity, fatty acid and glucose uptake and activation markers were measured using ex vivo assays and flow cytometry.
Results: Adenoids comprise of a remarkably higher CD4+ T memory population compared to peripheral blood CD4+ T cells. Fatty acid uptake is rather low with high mitochondrial activity when cells are freshly isolated in the non-activated state. Metabolism shifts upon reactivation from mitochondrial dependence to higher glucose demand. Compared to anti-CD3/CD28 stimulated cells which are fully dependent on Glucose, Pertussis Toxin and TSST-1 stimulated cells showed metabolic differences, including a higher fatty acid uptake and need for glutamine.
Conclusion: Metabolic characterization indicates a significant role of glucose dependent metabolism together with increased demands for fatty acids and glutamine during activation of adenoid derived CD4+ Tmem cells. Targeting metabolic pathways specifically in CD4+ Tmem cells can be a promising approach to improve vaccination or to treat autoimmune diseases.

ANGPTL3 deficiency-induced hypolipidemia triggers spontaneous interferon response

Alessandra Pinzon Grimaldos[1], Tiziano Giacomelli[1], Ilenia Pacella[1], Simone Bini[1], Alessia Di Costanzo[1], Ilenia Minicocci[1], Laura D'erasmo[1], Marcello Arca[1], Silvia Piconese[1;2;3]
[1]Sapienza university of Rome, ROMA; *[2]IRCCS Fondazione Santa Lucia, Rome, Italy*; *[3]Istituto Pasteur Italia, Rome, Italy*

Purpose: Familial Combined Hypolipidemia (FHBL2) is a genetic disorder characterized by low levels of plasmatic lipoproteins and caused by loss-of-function mutations in the Angiopoietin-like 3 (ANGPTL3) gene. This condition is not associated with an increased risk of immune-mediated diseases, and thus represents a unique contest to study the link between systemic lipid metabolism and the immune system.
Our purpose is to determine whether hypolipidemia impacts on monocyte energetic metabolism and interferon (IFN) response.
Methods: First, we studied monocyte frequency, lipid content and ISG15 expression *ex vivo* in FHBL2 subjects by flow cytometry. RNASeq analysis of peripheral blood mononuclear cells (PBMCs) of FHBL2 subjects was performed. To recapitulate *in vitro* the effects of poor lipid exposure on monocyte response, we cultured monocytes in conditions of LDL deprivation or supplementation. In this setting we studied the glycolytic and mitochondrial metabolism through the analysis of active mitochondrial mass, mitochondrial reactive oxygen species (ROS) production, and glucose uptake. To investigate how prenylation affects type I IFN signaling we analyzed IFNAR, STAT1 and phosphorylated STAT1 (pSTAT1) expression in presence or not of geranylgeranyltransferase I inhibitor (GGTI), to check the impact of mevalonate pathway-derived isoprenoids in immune signaling. Finally, we analyzed IL-1β production by lipid deprived monocytes in vitro in presence or not of type I IFN and/or LPS.
Results: We detected a trend for higher monocyte frequency containing lower amount of intracellular lipids in FHBL2 subjects *ex vivo*. RNASeq analysis of PBMCs of FHBL2 subjects showed that IFN and monocyte signatures were upregulated while genes encoding for mitochondrial electron transport chain were reduced.
Under lipid deprivation in vitro, monocytes showed lower levels of intracellular lipid accumulation, higher ISG15 expression and STAT1 phosphorylation. Mechanistically, lipid-deprived monocytes exposed to type I IFN showed higher glucose uptake and reduced active mitochondrial mass and mitochondrial ROS production. We observed a prenylation-dependent increase in IFNAR-STAT1 signaling and a specific suppression of IL-1β production in lipid-deprived condition.
Conclusion: In summary, we found a link among energetic metabolism and IFN response that could help understanding the immunoprotective effects of hypolipidemia.

Limited boosting and long-term immunity of SARS-CoV-2-specific CD8+ T cell responses after COVID-19 mRNA vaccination in people living with HIV

Vivien Karl[1;2], Anne Graeser[1], Anastasia Kremser[2], Liane Bauersfeld[1], Siegbert Rieg[1], Susanne Usadel[3], Christoph Neumann-Haefelin[1], Matthias Müller[1;3], Robert Thimme[1], Maike Hofmann[1]
[1]Department of Medicine II (Gastroenterology, Hepatology, Endocrinology and Infectious Diseases), Freiburg University Medical Center, Faculty of Medicine, University of Freiburg, Freiburg im Breisgau, Germany; *[2]Faculty of Biology, University of Freiburg, Freiburg im Breisgau, Germany*; *[3]Department of Infection Medicine, Medical Service Centre Clotten, Freiburg im Breisgau, Germany*

Purpose: People living with HIV (PLWH) are at higher risk to get severely sick after SARS-CoV-2 infection and have been therefore prioritized to get the COVID-19 vaccination. However, data on vaccine-elicited immune responses in PLWH is limited, in particular, about their virus-specific T cell responses induced by vaccination. In this study we, therefore, investigated whether SARS-CoV-2 spike-specific T cells are efficiently induced in PLWH after COVID-19 mRNA vaccination. Moreover, we also examined the fate and long-term SARS-CoV-2 spike-specific T cell immunity in PLWH focusing on the most vulnerable group with CD4 counts <300 cells/µl and, thus limited CD4+ T cell help.
Methods: SARS-CoV-2 spike-specific CD8+ T cell responses were followed in PLWH (n=18), receiving antiretroviral therapy, and healthy controls (HCs; n=24) throughout 3 to 4 mRNA vaccinations and breakthrough infection. Deep profiling of SARS-CoV-2 spike-specific CD8+ T cells was performed *ex vivo* by applying peptide-loaded MHC I tetramer technology and after *in vitro* expansion and cytokine production assays. SARS-CoV-2 spike-reactive CD4+ T cells (HCs n=20; PLWH n=22) and IgG levels (HC n=26; PLWH n=26) were determined by activation-induced marker (AIM) assay and ELISA, respectively.
Results: Our studies revealed that spike-specific CD8+ T cell responses are induced early after prime vaccination in PLWH and follow similar kinetics, however with reduced amplitude, after each vaccination as in HCs. Overall, PLWH with a CD4 count <300 cells/µl exhibited lower frequencies and a restricted breadth of the SARS-CoV-2 spike-specific memory T cell response compared to HC. The dampened SARS-CoV-2 spike-specific CD8+ memory T cell response was also reflected by a diminished induction of CD8+ T memory stem cells (T_{SCM}) in PLWH. Still, the vaccine-elicited SARS-CoV-2 spike-specific memory CD8+ T cells showed robust functional characteristics after *in vitro* recall response. In contrast to spike-specific IgG titers, CD8+ T cell frequencies were not durably boosted by repeated antigen contact and remained lower in the PLWH compared to HC.
Conclusion: Taken together, our findings demonstrate that mRNA vaccination elicited limited SARS-CoV-2-specific CD8+ T cell immunity in PLWH with low CD4 counts underscoring their vulnerability and indicating the potential requirement of different vaccination/boosting strategies.

Time of day influences the CD8+ T cell response to mRNA vaccination

Ward Vleeshouwers[1], Suzanne van Duikeren[1], Dominique M.B. Veerkamp[1], Macha Beijnes[1], Lucas M. Brock[1], Laura Kervezee[1], Ramon Arens[1]
[1]*Leiden University Medical Center, Leiden, Netherlands*

mRNA vaccines have recently emerged as a promising vaccine technology. $CD8^+$ cytotoxic T cells can play a central role in the immune response following mRNA vaccination and form protective immunological memory. Despite increasing evidence for circadian rhythmicity in $CD8^+$ T cell immunity, it remains unknown how the time of immunization affects the T cell response following mRNA vaccination. To investigate this, mice were vaccinated with the Spikevax SARS-CoV-2 vaccine at six different times across day and night and the Spike-specific $CD8^+$ T cell response was analyzed. We observed 24-hour rhythmicity in the expression of effector differentiation markers on Spike-specific $CD8^+$ T cells, with the highest expression after vaccination during the resting phase. Correspondingly, in animals vaccinated during the resting phase, Spike-specific $CD8^+$ T cells exhibited the highest capacity to produce IFN-γ upon restimulation. As costimulatory signals provided by dendritic cells (DCs) during T cell priming are known to shape effector T cell formation, we assessed the contribution of the molecular clock of DCs using a DC-specific conditional knock-out of the transcription factor BMAL1, which is essential for maintaining molecular circadian rhythms. We find that the time-dependent effects on $CD8^+$ T cell differentiation rely on the DC clock, indicating that a DC-intrinsic mechanism regulates rhythmic T cell responses. We show that CD80 and CD86, ligands for the costimulatory receptor CD28, regulate Spike-specific $CD8^+$ T cell differentiation and function. However, CD80 and CD86 expression does not exhibit 24-hour rhythmicity and the effect of vaccination time on T cell differentiation is maintained upon CD80 or CD86 blockade, indicating that CD28 ligation does not mediate time-dependent alterations in $CD8^+$ T cell responses. Collectively, these data demonstrate that the time of mRNA vaccination affects the effector quality of vaccine-specific $CD8^+$ T cell responses and provide insight into the underlying mechanisms. This could facilitate the development of a strategy in which timed administration is used to increase the protective capacity of mRNA vaccination.

Immunization with BM325, a preS-based recombinant grass pollen allergy vaccine can overcome non-responsiveness to HBsAg-based hepatitis B virus vaccines

Inna Tulaeva[1;2], Carolin Cornelius-Nikl[1], Margarete Focke-Tejkl[1], Milena Weber[1], Mikhail Tulaev[1], Felix Lehmann[3], Nora Goldmann[3], Alexandra Dubovets[2], Alexander Karaulov[2], Rainer Henning[4], Dieter Glebe[3], Rudolf Valenta[1;2;5]

Purpose: Non-responsiveness to HBsAg-based vaccination against hepatitis B virus (HBV) exceeds 10%. BM32 is a recombinant grass pollen allergy vaccine consisting of the HBV-derived preS antigen and hypoallergenic peptides from four major timothy grass pollen allergens. We have shown previously that allergic patients who received allergen-specific immunotherapy with BM32 developed antibodies capable of neutralizing HBV *in vitro*. Here we investigated if immunological non-responsiveness can be overcome by immunization with BM325, a component of BM32 in a subject with more than 30 years history of unsuccessful HBV vaccination.
Methods: A subject with a history of repeated vaccinations with HBsAg-based vaccines without developing HBV-specific immunity received five monthly injections of 20 microgram BM325 adsorbed to Aluminum hydroxide. preS-specific antibody responses were measured using preS and preS-derived peptides by ELISA and microarray technology. preS-specific T cell responses were measured by CFSE staining. HBV-neutralizing capacity was determined using cultured HBV-infected HepG2 cells.
Results: Subcutaneous vaccination with BM325 induced a strong and sustained preS-specific IgG response peaking already after the third injection. The antibody response was composed mainly of the IgG_1 subclass which reached 1.9 mg/ml preS-specific IgG_1 one month after the immunization and remained at a level of 0.7 mg/ml one year after the treatment. preS-specific IgG antibodies were mainly directed to the N-terminal part of preS which contains the attachment site of HBV to its receptor Na+-taurocholate co-transporting polypeptide (NTCP). IgG reactivity to peptides from the NTCP attachment site was comparable for HBV genotypes A-H. Continuous assessment of the preS-specific T cell proliferation showed a pronounced reactivity of CD3+CD4+ lymphocytes after the complete injection course which was still present one year after the last injection. The induction of preS-specific cytotoxic CD8+ T cells was low. Maximal HBV neutralization (98.4%) was achieved 1 month after the 5^{th} injection which correlated with the maximal IgG reactivity to the N-terminus of preS.
Conclusion: Our data suggest that the BM325 vaccine may be used as a preventive vaccination against HBV even in non-responders to HBsAg-based vaccines.

Development of an immunocompetent 3D-bioprinted skin-on-chip model

Alexeja Kleiter[1;2], Claudia Zelle-Rieser[2], Nora Kaiser[1], Judith Hagenbuchner[1], Michael Ausserlechner[1], Patrizia Stoitzner[2]
[1]Department of Paediatrics II, Medical University of Innsbruck, Innsbruck, Austria; *[2]Department of Dermatology, Venereology and Allergology, Medical University of Innsbruck, Innsbruck, Austria*

Due to the complexity of the skin, the development of *in vitro* models to study skin biology is challenging. Commonly used human skin equivalents consist of collagen with fibroblasts topped with epidermal layers composed of keratinocytes. We are interested in developing a 3D-bioprinted skin-on-chip model that will contain dendritic cells (DC) to develop an immunocompetent skin model that can be used as surrogate for human skin and replace animal models in future.
Currently, we are developing different chip designs allowing bioprinting of a dermal compartment containing fibroblasts in a gelatin-methacrylate (GelMA) mix as bio-ink. On top of this dermis we microjet-print a keratinocyte cell layer that after airlift develops into a multi-layered differentiated epidermis. We also investigated how DC can be embedded into the dermal compartment. For this purpose, we mixed human blood monocytes or in vitro differentiated monocyte-derived DC (moDC) together with fibroblasts in the GelMA bio-ink that upon blue light exposure polymerizes forming stable hydrogels. With flow cytometry analysis we investigated viability, differentiation and maturation of DC in hydrogels.
First of all, we observed that moDC stayed viable in hydrogels and displayed an immature phenotype when analyzed by flow cytometry and could be activated within hydrogels by addition of a maturation stimulus. When CD14+monocytes were differentiated by GM-CSF and IL-4 in the hydrogels for a week, they upregulated HLA-DR but still showed some low level of CD14, resembling an inflammatory monocyte or the recently described DC3. These preliminary results suggest that moDC are viable and monocytes can be differentiated into DC in hydrogels.
In the next step, we will add moDC and CD34+derived DC subtypes into our 3D-bioprinted skin-on-chip model to establish an immunocompetent skin model. The differentiation of DC from monocytes but also CD34+precursors directly within the bioprinted skin model will be examined. In future we hope to use the immunocompetent human skin model for drug testing and vaccine developments.

Skin routes of immunization with Langerin-targeted HIV1-gp140 vaccine impacts on germinal center activation and tailors antibody response

Juliane S. Lanza[1;2;3], Adele Hammoudi[1], Joanna De Chiara[2], Mathieu Surénaud[1], Mireille Centlivre[1], Bernard Malissen[2;3], Véronique Godot[1], Yves Lévy[1], Sandrine Henri[2], Sylvain Cardinaud[1]
[1]Vaccine Research Institute (VRI), INSERM-U955 (IMRB) Équipe 16, Université Paris-Est Créteil (UPEC), Creteil, France; *[2]Centre d'immunologie de Marseille-Luminy (CIML) - Parc Scientifique et Technologique de Luminy, Marseille, France*; *[3]Centre d'immuno-phénomique (CIPHE) - Parc Scientifique et Technologique de Luminy ISM-Biorobotics, Marseille, France*

Background: Targeting dendritic cells (DCs) with antigens is a promising strategy for modulating T follicular helper (Tfh) cells and germinal center (GC) reactions in lymphoid organs, enhancing the specific adaptive immune response to vaccines. Preclinical studies from our lab and others suggest a major role of Langerhans cells (LC) for inducing HIV-1 specific antibody responses. Our study explores: i) the immunogenicity of a Langerin-targeting vaccine consisting of an anti-Mouse Langerin mAb fused to HIV-1/gp140ZM96 (Env) (aLang.Env, Kervevan PLoS Path 2021) administered through different routes of skin immunization in mice; ii) the role of epidermal LC versus dermal cDC1s.
Methods: The lymph nodes (LN) draining each site of immunization were first assessed in C57BL/6 mice with ovalbumin (OVA) surrogate antigen after topical application (t.a.) or administration by subcutaneous (s.c.), intradermal (i.d.) and transcutaneous (t.c.) route through laser-guided microporation (PLEASE technology). The aLang.Env mAb (10mcg equivalent of Env) was administered without adjuvant in a Prime-Boost scheme (day 0 and day 21). Serum Env IgG titers were followed by Luminex overtime and GC/Tfh reactions were assessed by FACS phenotyping of dLN (day 28).
Results: All methods of administration proved effective, as evidenced by the proliferation of OVA-specific CD8+ T cells (OT-I) and CD4+ T cells (OT-II) in the dLN. While aLang.Env induced Tfh cells, GC B cells, and Env-specific GC B cells regardless of the immunization route, only the intradermal route resulted in a significant increase in systemic Env-specific IgG response. The GC/Tfh reaction and humoral responses through i.d. route were further validated in the Xcr1DTA mouse model, where cDC1 cells were depleted, suggesting that epidermal LCs were the primary DC subsets triggering these responses. However, we observed a reduction in effector CD8+ T cells in the absence of dermal cDC1.
Conclusion: Our study finds that i.d administration of HIV-1 Env antigen targeted to Langerin without adjuvant leads to GC reaction in proximal lymph nodes, and effective Ab responses. This effect was specifically related to the target of LCs since depletion of cDC1 did not impact humoral responses whereas $CD8^+$ effector response were predominantly mediated by dermal cDC1.

Exploring cross-functionality elicited by altSonflex1-2-3 vaccine candidate in different animal models

Valentina Caradonna[1], Marika Pinto[2], Renzo Alfini[2], Giacomo Vezzani[2], Carlo Giannelli[2], Omar Rossi[2], Miren Iturriza[2], Donata Medaglini[1], Francesca Micoli[2], Francesca Mancini[2]
[1]Laboratory of Molecular Microbiology and Biotechnology, Department of Medical Biotechnologies, University of Siena, Siena, Italy; *[2]GSK Vaccines Institute for Global Health, Siena, Italy*

Purpose: *Shigella* is a major cause of mortality especially in children in low-middle income countries (LMICs) and has been prioritized among the most dangerous antibiotic-resistant pathogens by the WHO. The O-antigen (OAg) component of the lipopolysaccharide is considered a protective antigen, posing challenges to vaccine development since more than 50 *Shigella* OAg structures have been identified. No vaccine eliciting broad protection against Shigellosis is currently avaiable. GVGH has developed a 4-component GMMA-based vaccine, altSonflex1-2-3, covering *S. sonnei* and *S. flexneri* 1b, 2a and 3a, identified among the most prevalent serotypes in LMICs.
Aim of this work is to investigate the ability of altSonflex1-2-3 vaccine to elicit cross-functional antibodies in different animal models and to match preclinical and clinical data. Sera from mice, rats and rabbits immunized with altSonflex1-2-3 vaccine candidate have been examined for their ability to bind to and kill relevant *S. flexneri* subtypes different from those included in the vaccine.
Methods: Animal sera were analysed by a Luminex-based multiplex binding assay and by FACS-based binding assay for the evaluation of antibody binding to purified OAg and to whole bacteria.
The functionality of antibodies present in sera from animals and human subjects was assessed using a high-throughput luminescence-based Serum Bactericidal Assay.
Results: Results clearly show ability of the antibodies elicited by the altSonflex1-2-3 vaccine to bind to and kill the tested *S. flexneri* X, Y, 6, 4a and 5b strains due to serotype-common epitopes within the OAg structure of the different *S. flexneri* serotypes. The 4-component vaccine shows a broader coverage compared to each corresponding monovalent formulation, confirming that all components included in the vaccine are necessary to achieve a good coverage. Numerically the relative level of bactericidal activity observed is different in the different animal species both against the vaccine homologous and heterologous strains.
Conclusion: This study demostrates the potential for altSonflex-1-2-3 vaccine to be broadly-protective. It will be important to understand if the preclinical results will be confirmed in humans, thus allowing validation of preclinical results with clinical data.

Purpose: The gastrointestinal tract contains a vast population of T cells, localized in the Gut-Associated Lymphoid Tissue (GALT), draining lymph nodes, and scattered in the lamina propria, and intestinal epithelium. These cells play crucial roles in promoting tolerance to dietary antigens and microbiota, as well as mounting protective immune responses against pathogens. Despite their importance, our understanding of the development, maintenance, and functional adaptations of diverse populations of gut resident T cells remains limited. While studies in mice have shed light on intestinal T-cell development and specialization, translating this knowledge to humans presents significant challenges. To address this gap, we constructed an integrated atlas of the T cell compartment across the human gastrointestinal tract.
Methods: Integrating publicly available datasets with newly generated multiomics single-cell and spatial data, we compiled an atlas spanning the entire intestinal tract, including different site-specific gut lymph nodes. We incorporated newly generated single-cell data from a unique transplanted setting allowing us to track resident T-cell maturation over time. In addition, we performed scRNA-seq from different intestinal regions from matched donors and included paired TCRαβ and TCRγδ sequencing to study the clonotype dynamics and T cell trafficking across regions.
Results: In summary, we have integrated a multiomics single-cell atlas of intestinal T cells providing a comprehensive analysis across regions of the gastrointestinal tract. Our analysis reveals unique regional adaptations and high degree of specialization, dissecting the heterogeneity of different populations of circulating and resident T cells, regulatory T cells and innate-like T cells.
Conclusion: A better understanding of the heterogeneity and regional adaptations of intestinal T cells holds promise for identifying therapeutic targets for inflammatory gut diseases and advancing vaccines and cancer immunotherapies aiming at the intestinal mucosa.

The frail immune system: a frailty DNA methylation surrogate in circulating immune cells predicts preclinical ageing and future clinical outcomes.

Matt McElheron[1;2], Jordan Davies[1], Etienne Patin[2], Belinda Hernandez[1], Lluis Quintana-Murci[2], Darragh Duffy[3], Cathal McCrory[1], Rose Anne Kenny[1], Aisling O'Halloran[1], Nollaig Bourke[1]

[3]*Translational Immunology Unit, Institut Pasteur, Université de Paris Cité, F75015, Paris, France, Paris, France*

Demographics are globally shifting towards older age. Frailty is an age-related state of functional decompensation characterized by decreased reserve and heightened vulnerability to stressors. Frailty encompasses physical, cognitive, and psychosocial domains. It also captures population-level immune variability associated with accelerated biological ageing, as indexed by inflammation, reduced anti-viral immunity, and vaccination efficacy. As populations age, variability increases in population health and immunity, underscoring the need to dissect underlying relations between frailty and immune dynamics.
We hypothesise that modelling population frailty dynamics using large-scale, longitudinal clinical data and system-wide immune metrics will facilitate profiling of the ageing immune system and assessment of immune-mediated ageing, particularly among individuals at higher risk of later-life poor health compared to peers of the same age with similar lifestyles.
This study utilizes extensive clinical and immune data collected during a 10-year, nationally-representative study, The Irish Longitudinal Study on Ageing (TILDA, n = 8,500; age 50y+). Elastic net modelling was employed to derive an epigenetic frailty surrogate using immune cell epigenome-wide methylation profiling and a validated 31-item Frailty Index. The frailty surrogate was then evaluated in Milieu Intérieur (MI, n = 1,000; age 20 – 69y) and public datasets as a predictor of accelerated ageing and used to investigate the ageing immune landscape.
The immune-based frailty surrogate consistently predicted frailty in test datasets (R = 0.46, $P = 2.2 \times 10^{-10}$), and fully adjusted models. The frailty surrogate identified non-frail individuals at risk of 10y frailty transitions. In independent human cohorts including MI, this immune-based frailty signature reflected variability in the methylome, circulating cytokine profile and viral infection status, identifying immune changes associated with accelerated ageing. Additionally, the score predicted health status at 10y follow-up in this healthy, mid-life population. Alongside modelling frailty transitions, comorbidities, and mortality in TILDA, the immune-based frailty surrogate characterised cellular changes associated with accelerated ageing in MI, including a strong neutrophil signature (β = 0.21, $P = 1.1 \times 10^{-5}$). Ongoing analyses are investigating viral infections in immune-mediated ageing. Overall, this research aims to leverage longitudinal clinical, epigenetic, and immune profiling to understand why the ageing process differentially manifests among members of society.

Diffusion-limited cytokine signaling in T cell populations

Brunner Patrick[1;2], Kiwitz Lukas[1;2], Li Lisa[1], Kevin Thurley[1;2]
[1]*Biomathematics, Institute of Experimental Oncology, University Hospital Bonn, Bonn, Germany*; [2]*Deutsches Rheuma-Forschungszentrum, Berlin, Germany*

Purpose: Effective immune-cell responses depend on collective decision-making mediated by diffusible cytokines. However, it remains poorly described how cytokines are spatially distributed in tissues, and how paracrine signaling efficacy is affected.
Methods: Based on response-time modeling [1], we designed a three-dimensional spatio-temporal modeling framework, to systematically investigate the origin and consequences of spatially inhomogeneous cytokine distributions in lymphoid tissues [2]. Further, we developed an open source, modular and scalable software package for quantitative analysis of CODEX multiplexed histology data.
Results: We found that spatial cytokine inhomogeneities are critical for effective paracrine signaling, and they do not arise by diffusion and uptake alone, but rather depend on properties of the cell population such as an all-or-none behavior of cytokine secreting cells. Furthermore, we assessed the regulatory properties of negative and positive feedback in combination with diffusion-limited signaling dynamics, and we derived statistical quantities to characterize the spatio-temporal signaling landscape in the context of specific tissue architectures. Our software package for processing multiplexed histology data allowed to derive cell-segmentation and subsequent feature annotation to individual cells for complex tumor tissue, which was not possible with available methodology and will set the stage for comparison to mathematical models.
Conclusion: Our simulations highlight the complex spatiotemporal dynamics imposed by cell-cell signaling with diffusible ligands, which entails a large potential for fine-tuned biological control especially if combined with feedback mechanisms. Moreover, insights from spatio-temporal simulations will be critical for interpretation of multiplexed histology and spatial transcriptomics data sets such as from lymphoid tissues and the tumor microenvironment.

Deep immune phenotyping of the ageing immune system

Lennart Riemann[1], Rodrigo Gutierrez[1], Ivan Odak[2], Joana Barros-Martins[3], Lennart M. Rösner[4], Ximena Leon Lara[1], Christine Falk[5], Thomas F. Schulz[6], Gesine Hansen[7], Thomas Werfel[4], Reinhold Foerster[1]
[1]Institute of Immunology, Hannover Medical School, Hannover, Germany; *[2]Icahn School of Medicine at Mount Sinai, New York, United States*; *[3]Columbia University, New York, United States*; *[4]Department of Dermatology, Hannover Medical School, Hannover, Germany*; *[5]Institute of Transplantation Immunology, Hannover Medical School, Hannover, Germany*; *[6]Institute of Virology, Hannover Medical School, Hannover, Germany*; *[7]Department of Paediatric Pneumology, Allergology, and Neonatology, Hannover Medical School, Hannover, Germany*

Purpose: Population ageing is a prominent feature of the global demographic change. Elderly people represent a vulnerable population group with an increased risk for infections, cancers, and other diseases. Studying the ageing immune system is important to understand biological ageing and age-related diseases, but challenging due to the high number of immune parameters and large inter-individual variability.
Methods: We conducted an in-depth immune system profiling of 550 elderly participants (≥60 years) and 100 young controls (20–40 years) of the RESIST Senior Individuals (SI) cohort. Participants were randomly selected via the local residents' registry office. We collected extensive demographical, clinical, and laboratory data and performed multi-color spectral flow cytometry and 48 plasma cytokine multiplex assays for a deep immune phenotyping, and analyzed the data using an unsupervised, computational clustering approach. This was complemented by a multi-omics integration analysis to jointly analyze cytometry, cytokine, and laboratory data.
Results: Our analysis approach allowed us to study 97 distinct innate and adaptive immune cell populations. We monitored their frequencies across ages and related them to clinical, laboratory, and cytokine data. Substantial age-related changes were observed in selected cytokines (e.g., CCL27 and CXCL10), and in both innate and adaptive immune cell compartments. The in-depth profiling revealed that often particular subsets within sub-lineage cell populations displayed age-related changes, while others remained stable, e.g. only two of five naïve CD4+ T cell clusters decreased with age. Furthermore, known associations (age, sex, CMV status, smoking) could be assigned to individual of the 97 immune cell subpopulations with high precision and novel associations (e.g., gout, COPD, obesity) were unveiled. Finally, using the multi-omics integrative analysis to combine the different datasets, we could identify immune signatures for common age-related diseases such as heart failure, gout and many others, enabling a systems biology view on disease-associated changes.
Conclusion: This study is one of the largest immune profiling studies conducted so far and the first one to focus on the elderly immune system. We provide a high-resolution picture of age-related immune system changes and unveil important associations with other clinical and laboratory data as well as diseases.

Pancreas-infiltrating T cells in Type 1 diabetes: an integrated investigative approach using spectral flow cytometry and bioinformatics analysis

Astrid Fabri[1], Lina Petersone[1], Natalie Edner[1], Chunjing Wang[1], Lucy Walker[1]
[1]*University College London, London, United Kingdom*

Type 1 diabetes (T1D) is an autoimmune disorder in which immune cells target the insulin producing β cells of the pancreas leading to hyperglycaemia. CD28 co-stimulation blockade has been tested as a therapeutic for T1D with mixed clinical results. A better understanding of the T cell populations present at the site of the autoimmune attack, and the extent to which these populations are sensitive to co-stimulation blockade or other interventions, would be helpful in designing approaches to inhibit T1D development.
In this study, we have compared mice that develop diabetes with their non-diabetic littermate controls over the timecourse of disease development. We designed and optimised two 33 colour spectral flow cytometry panels to perform detailed immunophenotyping of pancreas-infiltrating T cells. Diabetic mice were also treated with co-stimulation blockade reagents to assess the dependence of different immune populations on CD28 signalling.
The traditional method of manual gating proves to be insufficient for effectively analysing the complex datasets generated by spectral flow cytometry. Here, we have optimised a bioinformatics pipeline for the identification of novel pancreas infiltrating T cell populations and for the assessment of their sensitivity to co-stimulation blockade. After quality control of the data, we perform unbiased cell clustering and use marker enrichment modelling analysis for cell identification and explore cell population dynamics with differential abundance and state analysis. We further validate our results using an algorithm-guided gating strategy.
Overall, we have developed a workflow for the detection of candidate T cell populations in T1D and highlight the importance of using bioinformatic tools for the analysis of large spectral flow cytometry datasets.

Dissecting chromatin regulatory landscape during B cell activation

Pietro Marchesan[1], Pietro Demela[1], Laura Esposito[1], Blagoje Soskic[1]
[1]*Human Technopole, Milan, Italy*

Impaired B cell activation results in high susceptibility to infection, immune deficiency and autoimmune diseases. Genetic variants linked to immune-mediated diseases show enrichment in enhancers and promoters specifically active in B cell activation. Considering the dynamic nature of B cell activation and the diverse population of B cells, we mapped gene expression regulation and chromatin accessibility using single-cell transcriptomics (scRNA-seq) and single-cell sequencing assay for transposase-accessible chromatin (scATAC-seq) across three different stages of B cell activation. We stimulated human naïve and memory B cells with anti-IgM, CD40L and a cocktail of cytokines and performed immune profiling in the early and late stages of activation. The stimulation cocktail triggered B cell activation, proliferation and antibody class switching *in vitro*. As expected, the majority of activated memory B cells proceeded to later cell divisions than naïve B cells. Furthermore, memory B cells expressed a higher level of antibodies, suggesting a higher effector capacity. The chromatin accessibility and transcriptomic analysis of 64.513 high-quality cells demonstrated that a large number of transcriptional changes are detected in the early time point of activation. In addition, naïve and memory B cells clustered separately along activation, suggesting different differentiation paths. This demonstrated a rapid activation of B cells following activation, and a large diversification of activated naïve and memory B cells. Finally, to investigate transcription factor activity and gene-regulatory networks driving the differences in the activation responses between naïve and memory B cells we linked peaks of open chromatin to the activation-induced genes. Our results demonstrated cell type specific chromatin elements affecting differences in gene expression in naïve and memory B cells. This functional map of active chromatin regions, coupled with gene expression dynamics will inform prioritisation of autoimmunity-associated genetic variants and provide further insight into the dynamics of naïve and memory B cell activation.

The human leukocyte antigen (HLA) locus harbors translated lncRNAs with immunomodulatory functions

Ana Pinheiro Lopes[1], Alex van Opstal[1], Marina Reixachs Solé[1] , Jip T. Van Dinter[1] , Luuk A. Broeils[1] , Cornelis P.J. Bekker[2] , Sebastiaan Van Heesch[1]
[1]*Princess Maxima Center for pediatric oncology, Utrecht, Netherlands,*
[2] *Department of Rheumatology & Clinical Immunology | Center for Translational Immunology, University Medical Center Utrecht, Utrecht, Netherlands*

The evolution of the human leukocyte antigen (HLA) locus has helped promote immune adaptation specific to the human species. However, for many recently evolved genes in this locus it remains unknown whether they exert immune-related functionality. These include 72 long noncoding RNAs (lncRNAs) with unknown function and coding potential. Here, we combined RNA-seq and Ribo-seq data from human tissues and cell lines to detect new coding sequences in the HLA locus. We found 18 lncRNA-ORFs translated from 7 out of 72 lncRNAs and observed that the putative microproteins produced from these ORFs emerged *de novo* during primate evolution. One key example is a 42-amino acids long, and potentially secreted, alpha-helical microprotein, which shares genomic regulatory elements and a signal peptide nearly identical to classical HLA proteins. Silencing of this microprotein in immune cells impacts inflammatory cytokines production, such as IL-12, as well as the expression of the immune checkpoint receptor ligand PD-L1 and HLA class I proteins. Our work illustrates that evolutionarily dynamic genomic loci can harbour novel, potentially human-specific regulatory factors that modulate immune cell functions critical to cancer recognition by the immune system.

Study of the non canonical signalling induced by the binding of small molecules to CXCR4

Séverine Grinberg[1], Birgit Caspar[1], Ivana Stoilova[1], Mariette Matondo[2], Eleonore Bouscasse[2], Stephane Giorgiutti[3;4], Vincent Gies[3;4], Nikaïa Smith[5], Nassima Bekaddour[1], Dominique Cathelin[1], Anne-Sophie Korganow[3;4], Jean-Philippe Herbeuval[1]
[1]Université Paris Cité, CNRS, UMR8601, Paris, France; *[2]Université Paris Cité, CNRS, Institut Pasteur, Paris, France*; *[3]Université de Strasbourg, INSERM, UMR_S 1109, Strasbourg, France*; *[4]Hôpital de Strasbourg, CNR RESO, Strasbourg, France*; *[5]Université Paris Cité, CNRS, INSERM, UMR7057, Paris, France*

Purpose: The chemokine receptor CXCR4 is historically known to be involved in cell migration and adhesion. Our recent reports describe CXCR4 as a potentially promising target in immune regulation. Indeed, small molecules targeting the minor pocket of CXCR4, called minor pocket agonists (MiPAs), have been demonstrated to have anti-inflammatory activities, in particular reversing pathogen or small molecule mediated toll-like receptor (TLR) activation. This anti-inflammatory effect is probably mediated through a non-canonical signalling pathway that is further explored in this study.
Methods: The broad-spectrum inhibitory effect of MiPAs was confirmed by monitoring IRF7 phosphorylation using flow cytometry and NF-kB activation via HTRF following TLR activation with a TLR7/8 ligand. RNA silencing techniques were employed to identify potential key components.
Phosphoproteomics and cytometry by time of flight (CYTOF) techniques were utilized to get a broader view of cell activation states. A phosphoproteomics study examined the phosphorylation status of proteins in the presence and absence of MiPAs at different time points. Similarly, a panel of proteins involved in immune regulation was investigated using CYTOF. These techniques will allow us to identify prominent targets, subsequently validated by western blotting, flow cytometry and RNA silencing.
Results: MiPAs induced a reduction in IRF7 and NFkB phosphorylation, confirming their broad-spectrum anti-inflammatory effect. The phosphoproteomics study revealed approximately 100 proteins with altered phosphorylation status between treated and untreated conditions. Key targets identified were validated using western blotting and flow cytometry. CYTOF on PBMCs allowed us to get a clearer picture of the proteins involved in the TLR pathway under different treatments.
Conclusion: Our results indicate that MiPAs downregulate both TLR7/8 mediated phosphorylation of transcription factors such as NFkB and IRF7. This regulation of innate immune cell activation by MiPAs appears to be activated through a non-canonical pathway. Phosphoproteomics and CYTOF studies provided initial insights into possible key proteins involved in this pathway. Future efforts should focus on identifying points of cross-talk between the CXCR4 and TLR pathways.

Concentration dependent pro- and anti-inflammatory signaling by the SCFA butyrate

Muwei Jiang[1], Geert Van den Bogaart[1]
[1]*University of Groningen, Groningen, Netherlands*

Butyrate is a four-carbon short-chain fatty acid produced from microbial fermentation of dietary fibers in the colonic lumen. Current studies show anti-inflammatory properties of butyrate and suggest that it might have therapeutic applications in inflammatory bowel disease (IBD) and colonic cancer. The widely recognized molecular mechanisms causing the anti-inflammatory effects of butyrate include histone deacetylase (HDAC) inhibition and activation of G protein-coupled receptors (GPCRs). However, recently, butyrate has been reported to also bind to the transcription factor PPARγ, which might also result in immunomodulatory effects. Therefore, we hypothesized that butyrate activates PPAR signaling in human monocyte-derived macrophages of the immune system. Indeed, RNA-seq showed that butyrate induced the expression of PPARγ and CD36, a well-known gene downstream of PPAR signaling. In line with literature, ELISA showed that low concentrations of butyrate (0.1-1mM) can suppress production of the proinflammatory cytokine TNF-α by blood-derived macrophages. This was at least partly attributable to PPAR signaling, because the immunosuppressive effect of low concentration of butyrate was reversed by knockdown of PPARγ. However, high concentration of butyrate (10mM) surprisingly promoted the expression of TNF-α and IL-1β. Furthermore, the inhibition of the GPCR signaling pathway alleviated the secretion of IL-1β induced by 10 mM butyrate, but had no effect on TNF-α. Instead, our data show that butyrate promoted TNF-α production through CD36 and SRC signaling. Ultimately, the divergent immunomodulatory effects of butyrate on macrophages may be the result of a combination of mechanisms. As the concentration of butyrate varies in different regions of the human gut, and the concentrations of butyrate in the gut and tissues depend on health and disease, exploring the immunological mechanisms of different concentrations of butyrate will be helpful for the treatment of intestinal diseases and peripheral inflammation.

Identification of novel interactors of T cell specific adaptor protein TSAd - an adaptor molecule with elusive function

Hanna Chan[1], Pawel Borowicz[1], Brian Christopher Gilmour[1], Maria Stensland[2], Iván García Loza[1], Santosh Phuyal[1], Romina Matter[3;4], Lukas Jeker[3;4], Tuula Anneli Nyman[2], Anne Spurkland[1]

Signals from the extracellular milieu are received via cell surface receptors and relayed along a complex network of interconnected intracellular signalling pathways. T cell functions depend on tight regulation of these signalling pathways to respond in a flexible, dynamic and adequate manner. Adaptor proteins play a central role in modulating and fine-tuning intracellular signalling pathways by bridging protein-protein interactions, one of which is T cell specific adaptor protein (TSAd). Following activation of naïve T cells, TSAd is upregulated and believed to influence T cell receptor signalling by modulating Src family tyrosine kinase activity. TSAd-deficient mice display accelerated allograft rejection, suggesting that TSAd mediates regulatory T cell activity. However, the defined role of TSAd in T cell activation and function and the molecular details of the underlying mechanisms remains elusive. Here, we employ two independent approaches with an aim to better understand TSAd biology in an unbiased manner. Firstly, using affinity-purified mass spectrometry (AP-MS) and reverse genetics, we identified two novel ligands of TSAd, namely DOK2 and PTPN11. Binding of these ligands to TSAd was dependent on a functional TSAd Src homology 2 (SH2) domain binding to DOK2-pTyr402 and PTPN11-pTyr580 respectively. The interactions were further characterised and validated on the cellular level using bimolecular fluorescence complementation (BiFC) and proximity ligation assay (PLA). Secondly, using a publicly available dataset of healthy PBMCs, we identified genes co-expressed with TSAd. In particular, DOK2 expression correlated with TSAd expression in lymphocytes. Using CRISPR/Cas9 mediated ablation of TSAd and/or its ligands in primary T cells, we are currently exploring the affected signalling pathways and downstream events that these interaction partners are implicated in.

Peroxiredoxin 4 links redox homeostasis to innate antiviral immunity

Vasile Mihai Sularea[1], Jamie Sugrue[1], Andreea Atanasescu[1], Cliona O'Farelly[1]
[1]*School of Biochemistry and Immunology, Dublin, Ireland*

Purpose: Viral infection can lead to cellular oxidative stress through excessive production of reactive oxygen species (ROS). ROS homeostasis, regulated by ROS production and antioxidant enzymes, is crucial for modulating cell signalling and avoiding cell damage. ROS also appear to have important functions in regulating the innate immune response. However, how the redox system and the antioxidant enzymes are involved is not fully understood. Here we sought to determine how the antioxidant enzyme peroxiredoxin 4 (PRDX4) modulates RNA sensing and activation of the antiviral response.
Methods: We analysed publicly available RNA-seq and proteomic datasets of an *in vivo* hepatotropic infection model (LCMV) to identify differentially expressed genes involved in redox homeostasis. Using *in vitro* models (HEK293T and Huh7 cells) we assessed how PRDX4, whose expression was decreased in the viral infection model, modulates the antiviral response. We measured type I and III interferons, inflammatory cytokines, and interferon stimulated gene (ISG) expression upon stimulation with dsRNA or viral infection with Dengue virus in PRDX4-silenced cells.
Results: We found that expression of several antioxidant enzymes was altered following LCMV infection. PRDX4 was among those mostly strongly decreased at both the gene expression and protein level. Our in vitro studies showed that PRDX4 silencing leads to an increased antiviral response after stimulation with dsRNA or infection with the RNA virus Dengue. Moreover we found that PRDX4 silencing did not alter the activation of dsRNA sensors such as protein kinase R or RIG-I-like receptors, but it increased the IRF3 and IRF7-mediated interferons induction. Mechanistically, we found that PRDX4 deficiency upregulates ROS levels which lead to increased Activator Protein 1 (AP-1) activation, acting as enhancer for type I and III interferons expression and subsequent ISGs induction.
Conclusions: In our study we identified a novel role for the antioxidant enzyme PRDX4 in restraining the antiviral immune response by limiting AP-1 activation. Our results highlight the possibility of targeting PRDX4 as an antiviral immunomodulator.

A role for Natural Killer cells in establishment of non-reactivating latent HSV-1 reservoirs

Oscar Haigh[1], Kenza Breton[1], Paul Mazet[1], Jean Armengaud[2], Nolwenn Poccardi[1], Noemie Oziol[1], Roger Le Grand[1], Patrick Lomonte[3], Antoine Rousseau[1], Marc Labetoulle[1]
[1]Institut de biologie François Jacob, Fontenay-Aux-Roses, France; *[2]Institut des sciences du vivant Frédéric Joliot, Marcoule, France*; *[3]Institut NeuroMyoGène, Lyon, France*

Herpes simplex virus type 1 (HSV-1) is a common neurotropic human pathogen that establishes a life-long latent infection in sensory neurons. Recurrent outbreaks of a diverse range of disease stems from reactivation of latent reservoirs. Experimental HSV-1 vaccines elicit robust antibody responses, but are yet to achieve beneficial clinical outcomes, while available antiviral drugs offer only partial protection. Therefore there is a need to broaden our understanding of mechanisms that govern the latency and reactivation process; how to control reactivation may be crucial for developing effective vaccines or therapies. Using our clinically-relevant HSV1 mouse model, and reactivation triggering by explant culture, we previously defined a protective state that provokes the establishment of non-reactivating latent reservoirs. This is elicited by primary infection of mice with a thymidine kinase-deficient (TKdel) mutant before virulent WT challenge. Non-reactivating reservoirs of persisting HSV1 genomic DNA differ from classical latent reservoirs, by a lack of latency-associated mRNA transcription and loss of T cell accumulation. Herein we demonstrate an essential role for a subset of NK cells in the process that elicits non-reactivating latent reservoirs. Their depletion rescued the ability of challenge HSV1 to reactivate in TKdel-primed animals, which also induced a compensatory increase in B and CD4 T cell responses during early challenge. Phenotypic and functionality of NK cells compared between establishment of different latent states. Meanwhile, TG proteome analysis during the establishment of the different latent HSV1 reservoirs identified novel proteins and biological pathways associated with establishment of non-reactivating vs classic latent HSV1 reservoirs, and changes in the absence of the NK subset. These included suppression of inflammatory, metabolic and wound healing/repair pathways of the establishing classic reservoir, to pathways involving mRNA message and signalling regulation during non-reactivating latent reservoir establishment. This study demonstrated that TK-deficient primary HSV1 infection elicits NK cell-dependent immune responses during acute-phase challenge that dictate the reactivatability of establishing latent HSV1 reservoirs. These findings have direct implications for understanding the mechanisms that govern the latency and reactivation process, and their exploitation to extinguish HSV1 reactivation.

Background: Glioblastoma (GB) is the most common and aggressive primary brain tumor with limited efficacy of standard therapy. Analysis of the GB tumor microenvironment (TME) has shown prominent immunosuppression with PD-L1 expression on glioma cells and exhaustion of infiltrating immune cells. In early-stage tumors from the syngeneic GL261/HER2 mouse model, monotherapy with off-the-shelf NK-92/5.28.z CAR-NK cells targeted against HER2 was highly effective. However, CAR-NK cell monotherapy did not overcome the pronounced immunosuppressive TME of large tumors. Hence, we explored if combination of CAR-NK cells and anti-PD-1 checkpoint inhibition (ICI) induces tumor regression in advanced tumors.
Methods: Combination therapy with systemic ICI and local CAR-NK cell treatment were explored in subcutaneous and orthotopic GL261/HER2 tumors. Effects on tumor growth and survival were determined. The TME and infiltrating lymphocytes were characterized with highplex multi-spectral flow cytometry, multispectral histology and bulk RNAseq.
Results: Combination therapy with CAR-NK cells and systemic ICI resulted in strong synergistic effects, with tumor regression and long-term survival observed even in advanced-stage tumor-bearing mice. Analysis of tumor tissues revealed alterations in lymphocyte infiltration and TME upon combination therapy. Specifically, infiltrating lymphocytes displayed a more activated phenotype with predominance of NKT cells and reduction of regulatory T cells.
Conclusions: The data obtained demonstrate that efficacy of HER2-specific CAR-NK cells is increased in large tumors by combination with checkpoint blockade. The combination therapy reverted the immunosuppressive TME, resulting in successful treatment even of advanced tumors refractory to CAR-NK monotherapy. We are currently translating this combination therapy concept into early clinical testing by including a respective patient cohort in our ongoing CAR2BRAIN phase I clinical trial (NCT03383978).

Defective NK cell function in metastatic melanoma patients underpinned by metabolic abnormalities

Eimear Mylod[1], Jack Behan[1], Fergal Kelleher[2], Clair Gardiner[1]
[1]Trinity Biomedical Sciences Institute, Dublin, Ireland; *[2]St James Hospital, Dublin, Ireland*

Metastatic Melanoma (MetMel) is an aggressive cancer with a poor 5-year survival rate of less than 30%; however, the introduction of immunotherapy has contributed to dramatic improvements in survival. Previous data from our group demonstrated NK cell dysfunction in the circulation of metastatic breast cancer patients including reduced IFN-γ production and cytotoxicity, along with deficits in NK cell metabolism. Identifying NK cell dysfunction in other cancers such as MetMel is integral for the introduction and successful implementation of new NK cell-based immunotherapeutic approaches. We hypothesised that patients with MetMel have dysregulated circulating NK cell phenotype, function and metabolism.

Peripheral blood samples were collected from newly diagnosed MetMel patients prior to commencement of treatment, and healthy donor (HD) controls. PBMC were isolated and stimulated with IL-2 or IL-12/15 for 18 hours and profiled by flow cytometry or confocal microscopy.

Circulating NK cell frequencies were significantly lower in MetMel patients while the proportion of $CD56^{dim}$ and $CD56^{bright}$ NK cells between HD and MetMel patients was not different. MetMel patient NK cells upregulated activation markers CD69 and CD25 in response to cytokine, however their production of IFN-γ and TNF-α were significantly diminished. Furthermore, NK cell degranulation following stimulation was significantly lower on MetMel patient NK cells compared to HD. Upregulation of CD98, a nutrient receptor, was not significantly increased following stimulation with IL-12/15 on MetMel NK cells relative to HD NK cells. These parallel decreased mitochondrial mass and hints at mitochondrial dysfunction in these patients as mitochondrial mass and mitochondrial membrane potential do not correlate in MetMel patients.

Our data demonstrate that NK cells two key functions; production of cytokines and cytotoxicity are dysfunctional in MetMel patients. Our data provide the first indications that NK cell dysfunction in the circulation of MetMel patients extends to metabolic defects and highlight the need to explore methods to restore NK cell function in these patients. These data highlight some general and cancer specific facets of NK cell dysfunction in metastatic cancers and emphasises the need to identify methods to target these mechanisms to improve NK cell functionality in metastatic cancer patients.

Targeting intrinsic inhibitory checkpoints using nano-carriers to unleash NK cell anti-tumor activity

Batel Sabag[1], Guy Biber[1], Abhishek Puthenveetil[1], Mira Barda-Saad[1]
[1]*Bar-Ilan University, Ramat Gan, Israel*

Purpose: Current Natural Killer (NK) cell-based immunotherapy relies heavily on adoptive transfer and ex-vivo manufacture of NK cells, which has major limitations in achieving therapeutic impact. Moreover, NK cells express multiple inhibitory checkpoint receptors. Therefore, even if a given receptor is effectively blocked, NK cells may still be inhibited via alternative pathways, compromising the efficiency of this approach. These current limitations call for novel approaches for targeting prevailing intracellular inhibitory signaling cascades shared by multiple surface inhibitory receptors to unleash NK cell's anti-tumor responses.
Methods: In this study, we developed novel non-viral lipid-based nanoparticles (NPs)-based delivery system encapsulating small interfering RNAs (siRNAs) targeting three key negative regulatory genes SHP-1, Cbl-b, and c-Cbl. We validated the cytotoxic potential of the modified NK cells by degranulation, granzyme B, and killing assays. Furthermore, we established an in vivo system to assess the efficacy of these NPs in activating NK cells.
Results: We demonstrate that these NPs effectively enhance NK cell activity against HLA-matched cancer cells. Our data demonstrates the potential of NPs treated NK cells to exhibit increased cytotoxicity and moreover these NPs also provide an effective in vivo delivery system to enhance NK cytotoxicity in the tumor microenvironment (TME). Targeting NK cells in-vivo bypasses the need for ex-vivo isolation of NK cells.
Conclusion: This technology provides an innovative and broad therapeutic approach that includes both the active-modulating compounds and the systemic delivery platform. NK cells are attractive immunotherapeutic candidates due to their innate ability to target tumors without the requirement for prior antigen exposure or antigen specificity. They can complement T-cell immune surveillance, and recent data also demonstrate their ability to trigger substantial adaptive immune responses through crosstalk with dendritic and T-cells. Therefore, Utilizing NPs to enhance the cytotoxic capacity of NK cells by downregulation of key intrinsic inhibitory checkpoint molecules may provide a robust immunotherapeutic approach.

Dual blockage of PD-L/PD-1 and IL33/ST2 axes improves antitumor immunity by enhancing NK cells' tumoricidic potential

Marina Jovanovic[1], David Geller[2], Nevena Gajovic[1], Milena Jurisevic[1], Milan Jovanovic[3], Gordana Supic[4], Danilo Vojvodic[4], Ivan Jovanovic[1]
[1]Center for Molecular Medicine and Stem Cell Research, Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia; *[2]Department of Surgery, University of Pittsburgh, Montefiore, 7 South Pittsburgh, United States*; *[3]Department of Abdominal surgery, Military Medical Academy, Belgrade, Serbia*; *[4]Military Medical Academy, Belgrade, Serbia*

Purpose: During last decade, blockage of PD-L/PD-1 axis has had a great impact on immunotherapy of tumors. On the other hand, blockage of IL33/ST2 axis has shown to be benefitial in supressing tumor oncogenesis. However, co-blockage of these axes has not been thouroghly studied yet.
Methods: Breast cancer and colon cancer were inducted in BALB/C wild type and BALB/C ST2 knockout mice, after which mice underwent anti PD-1 and anti IL-33 treatment.
Results: Simultaneous blockage of IL33/ST2 and PD-L/PD-1 significantly postponed tumor appearance and slowed down breast cancer and colon cancer growth. We showed that enhanced NK cell cytotoxicity against breast cancer cells in ST2 knockout anti-PD-1 treated mice was followed with overexpression of miRNA-150 and miRNA-155, upregulation of NFκB and STAT3, increased expression of activation markers and decreased expression of immunosuppressive markers in splenic and tumor-infiltrating NK cells. In addition, NK cells from ST2 knockout anti-PD-1 treated mice tend to proliferate more and are less susceptibile to apoptosis. On the other hand, accumulation of immunosuppressive myeloid derived suppressor cells and regulatory T cells was significantly impaired in spleen and tumor microenvironment of ST2 knockout anti-PD-1 treated mice.
Conclusion: Simultaneous blockage of IL3/ST2 and PD-L/PD-1 axes stimulates anti – tumor immune response more efficiently, and therefore impedes tumor progression more efficiently in comparison to single blockage of either axes, which offers a new perspective to immunotherapy of tumors.

The NKG2A-HLAE immune checkpoint: novel-IC therapy based on mAb to specific HLAE-peptide complexes

Muhammad Abu Ahmad[1], Olga Radinsky[1], Kamran Manzoor Waidha[1], Frank Momburg[2], Angel Porgador[1]
[1]Ben-Gurion University of the Negev, Beer Sheva, Israel; *[2]German Cancer Research Center, Heidelberg, Israel*

Purpose: HLA-E, a non-classical MHC class Ib molecule, is overexpressed in Multiple Myeloma (MM). HLAE:NKG2A is one of the ICs that leads to the suppression of NK and $NKG2A^+$ T cells activity and enhances tumor progression. Currently, Immune Checkpoint Inhibitors (ICIs) target the NKG2A receptor which has a low specificity to cancer and high toxicity to the patient. nonetheless, a new ICI targeting the $HLAE^{pHLAG}$ complex could potentially improve cancer therapy outcomes.
Methods: mAb "4D7" was developed using a hybridoma system. mAb 4D7 affinity was assessed in-vitro with recombinant proteins and various cell lines that expressed zero to high levels of HLAE. Its functional impacts were examined in a system where MM cell lines were co-cultured with primary NK cells. pNK were isolated from the peripheral blood of 5 healthy donors, and their activity was examined in the presence of mAb 4D7 by CD107a degranulation assay. Also, the functional impacts of the mAb 4D7 on allogenic pNK and MM blast cells, isolated from the bone marrow of 6 MM patients were assessed.
Results: mAb 4D7 was determined to be an IgG-kappa isotype showing a high specific binding to recombinant $HLA\text{-}E^{pHLA\text{-}G}$. Cell lines with overexpression of membranal $HLA\text{-}E^{pHLA\text{-}G}$: RPMI8226, U266, 721.221 HLA-E, and 721.221 HLA-G positively stained with the mAb 4D7. Cell lines with low to zero expression of HLA-E like 721.221 WT showed low or negative staining with the mAb 4D7. The degranulation of $NKG2A^+$ pNK subset cells against MM target cells increased in the presence of mAb 4D7. However, adding mAb 4D7 to $NKG2A^-$ pNK subset cells co-cultured with MM target cells did not affect the pNK activity. Similar results were obtained when the target and effector cells were isolated from the bone marrow of active treatment-naive MM patients.
Conclusions: MAb 4D7 demonstrates a remarkably high affinity for binding to the $HLAE^{pHLAG}$ complex, ensuring the safety of its application. The ability of 4D7 mAb to effectively block the $HLA\text{-}E^{pHLA\text{-}G}$ complex and counteract the inhibition signal in NK cells. mAb 4D7 is a promising monoclonal antibody with substantial potential to serve as an ICI for clinical use in MM patients.

Primary NK cells modified by CD33-CAR insertion and CRISPR/Cas9-based disruption of the KLRC1 gene mediate high efficacy against acute myeloid leukemia

Tobias Bexte[1], Nawid Albinger[1], Ahmad Al-Ajami[2], Philipp Wendel[1], Jamal Alzubi[3], Alec Gessner[4], Sebastian Wolf[4], Hadeer Mohamed Rasheed[5], Beate Anahita Jung[5], Olaf Penack[5], Thomas Oellerich[4], Jan Henning Klusmann[1], Toni Cathomen[3], Michael Rieger[4], Katharina Imkeller[2], Evelyn Ullrich[1]
[1]Goethe University - Department of Pediatrics, Frankfurt, Germany; *[2]Goethe University - Edinger Institute, Frankfurt, Germany*; *[3]Institute for Transfusion Medicine and Gene Therapy, Freiburg, Germany*; *[4]Goethe University Hematology and Oncology, Frankfurt, Germany*; *[5]Charite University and Humboldt University, Berlin, Germany*

Purpose: Chimeric antigen receptor (CAR)-modified natural killer (NK) cells show strong antileukemic activity against acute myeloid leukemia (AML). However, NK cell-mediated tumor killing is often impaired by tumor-mediated immune suppression. We previously observed increased IFN-γ secretion by CAR-immune cells following target cell contact, which can induce upregulation of inhibitory molecules such as HLA-E. Here, we report a novel strategy to overcome CAR-NK cell inhibition mediated by the HLA-E-NKG2A immune checkpoint.
Methods: CD33-targeting CAR-NK cells were generated by lentiviral transduction of primary NK cells as recently reported (Albinger et al., *Blood Cancer J* 2022). Deletion of the NKG2A-encoding *KLRC1* locus was performed by nucleofection using CRISPR-Cas9 technology. The CAR33- and NKG2A-expression as well as cytotoxicity were analysed. *In vivo*-efficacy was evaluated in OCI-AML2 xenografted NSG-SGM3 mouse models. Furthermore, single-cell multi-omics analyses were used to characterize the genetically engineered NK products in comparison to non-transduced NK cells.
Results: Lentiviral transduction of NK cells resulted in up to 60% CAR33-positive cells, while *KLRC1* gene disruption resulted in a significant reduction of NKG2A cell surface expression. CAR33-*KLRC1*^{KO}-NK cells showed significantly higher elimination of CD33^{+}/HLA-E^{+} OCI-AML2 cells in *in vitro* cytotoxicity assays compared to *KLRC1*^{KO}- or CAR33-NK cells. Furthermore, a reduction of leukemic burden was observed *in vivo* following a single injection of a low dose of CAR33-*KLRC1*^{KO}-NK cells compared to *KLRC1*^{KO}-NK or CAR33-NK cell treatment in an NSG-SGM3 AML-xenografted mouse model. Two injections of 3x10^{6} CAR33-*KLRC1*^{KO}-NK cells each led to a complete elimination of AML and leukemia-initiating cells in the bone marrow, which was confirmed by bone marrow re-engraftment analysis. Finally, we were able to unravel transcriptional features of activation and maturation on single cell level in the CAR33-*KLRC1*^{ko}-NK product, which were preserved following exposure to AML cells.
Conclusion: Removing an inhibitory receptor in CAR-NK cells showed a highly beneficial effect for the treatment of AML. Finally, we conclude that dual-modified NK cells have the potential not only to bypass immune suppression in AML but also in a broad range of other cancer entities.

Macrophage-fibroblast crosstalk in the rheumatoid arthritis synovium is defined by sexually dimorphic extracellular matrix patterning and drives disruption of tissue homeostasis.

Linda Mies[1], Jean-Baptiste Richard[1], Moustafa Attar[1], Stephen Sansom[1], Sarah Short[2], Joanna Hester[2], Andrew Filer[3], Christopher Buckley[1], Kim Midwood[1]
[1]Kennedy Institute of Rheumatology, NDORMS, University of Oxford, Oxford, United Kingdom; *[2]Nuffield Deparment of Surgical Sciences, Oxford, United Kingdom*; *[3]Institute of Inflammation and Ageing, University of Birmingham, Birmingham, United Kingdom*

Purpose: Tenascin-C (TNC) is an immunomodulatory extracellular-matrix protein, that is expressed during the onset of rheumatoid arthritis (RA). High TNC-serum levels are associated with hard-to-treat disease and predicts patients whose pain will not improve with anti-TNF therapy. Conversely, in patients with spontaneously resolving synovitis, TNC levels decrease. Our lab has developed TNC-targeting antibodies, that were shown to prevent disease progression in a rodent arthritis model. The aim of this project is to determine which patients would benefit most from these antibodies, by better understanding the role of TNC in human RA pathology.
Methods: Single-cell RNA sequencing data was used to investigate the cellular source of TNC in RA and OA synovium. Multiplex imaging was used to determine the localisation and cellular targets of TNC in synovial biopsies. Spatial transcriptomics was used to investigate how TNC affects cells in the synovium, and these results were validated using confocal imaging and qPCR analysis of matrix-activated human macrophages.
Results: TNC is expressed exclusively by stromal cells, particularly fibroblasts, in the synovium. Gene expression amongst fibroblast subsets changes with disease type and stage. Multiplex imaging shows two distinct groups of patients, characterized by the presence or absence of TNC in the lining-layer. Female patients showed significantly higher levels of TNC in the lining-layer, compared to male patients. Moreover, male patients showed increased proportion of T-cells in lymphoid aggregates, and seropositive patients showed increased proportion TNC+ B-cells in the lymphoid aggregates. Regardless of tissue-niche, TNC-rich areas contained significantly more immune cells, particularly macrophages, compared to TNC-poor areas. GPNMB, an immunomodulatory protein, was down-regulated in TNC-rich areas. GPNMB is expressed in the lining-layer on remission-associated macrophages, and we confirmed that expression of GPNMB is regulated by TNC, through activation of TLR4.
Conclusion: There is a large variation in the location and synovial tissue levels of TNC. TNC was found to be associated with distinct cell neighbourhoods that drive the development and persistence of inflammation. Moreover, varying levels of TNC in the synovium may contribute to differences in the course of disease and treatment response between male and female RA patients, and seropositive and seronegative RA patients.

Elucidating the role of interleukin-4 receptor alpha signalling in the pathogenesis of haemophilic arthropathy.

Alexander Lawrence[1], Anne Chevalier[1], Peter Turecek[2], James O'Donnell[3], Padraic Fallon[1]
[1]School of Medicine, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland; *[2]Baxalta Innovations GmbH, A Member of the Takeda Group of Companies, Vienna, Austria*; *[3]Irish Centre for Vascular Biology, Royal College of Surgeons in Ireland, Dublin, Ireland*

Purpose: Haemophilia A is a rare X-linked congenital bleeding disorder caused by mutations in the *F8* clotting factor gene. These mutations lead to a deficiency in Factor VIII resulting in prolonged bleeding time. Repeated bleeding into major articular joints may led to the development of haemophilic arthropathy (HA), a degenerative chronic joint disease characterised by synovitis, cartilage degeneration and bone remodelling. Currently, there are no available disease modifying treatments for haemophilic arthropathy with patients with severe HA requiring joint replacement surgery.
Methods: A new *F8* deficient (*F8$^{em1-/-}$*) mouse model of severe haemophilia A, generated by CRISPR-Cas9 targeting of Exon 1 of *F8*, was developed that recapitulated the spontaneous HA observed in patients with haemophilia. To define the immunological basis of HA, *F8$^{em1-/-}$* mice were subjected to sub-patellar needle injury of the knee joint to induce synchronized acute articular bleeding leading to hemarthrosis. The synovium from damaged knee joints were analysed during acute and chronic disease phases to characterise cell populations and inflammatory gene expression in the joint by flow cytometry and NanoString technology.
Results: Needle injury to the knee joint of *F8$^{em1-/-}$* mice, but not to wild-type mice, led to local bleeding and acute inflammation in the synovium. This was associated with acute pro-inflammatory cytokines, such as IL-1β and TNF-α, and changes in immune cell populations and genes networks as injury resolved. KEGG pathway analysis revealed marked increases in the IL-4Rα signalling axis in the synovium of *F8$^{em1-/-}$* mice after injury. We defined the IL-4Rα expressing cells in the joint during HA. A dual IL-4Rα$^{-/-}$ x *F8$^{em1-/-}$* mouse was generated that confirmed IL-4Rα expressing cells have a role in the immunopathogenesis of HA.
Conclusion: A functional role for IL-4Rα axis in the pathogenesis of HA in a novel mouse model was demonstrated. The study raises options for therapeutic interventions addressing disease modifying inflammatory targets to treat HA.

Funding: This study was supported in part by a research grant from Science Foundation Ireland (SFI) under the SFI Strategic Partnership Programme Grant (16/SPP/3303) and research support from Takeda.

Staphylococcal Enterotoxin B Binding to CD28 mediates inflammatory T cell-dependent intestinal epithelial barrier dysfunction.

Carola Amormino[1], Emanuela Russo[1], Valentina Tedeschi[1], Maria Teresa Fiorillo[1], Alessandro Paiardini[2], Francesco Spallotta[1;3], Laura Rosanò[4], Loretta Tuosto[1], Martina Kunkl[1;5]

Purpose: *Staphylococcus aureus* is a gram-positive bacterium that may cause intestinal inflammation by secreting enterotoxins, which commonly cause food-poisoning and gastrointestinal injuries. Staphylococcal enterotoxin B (SEB) acts as a superantigen by stimulating T lymphocytes to produce inflammatory cytokines. We recently highlighted that SEB may induce the massive production of inflammatory cytokines by binding in a bivalent manner the TCR and CD28 costimulatory molecule. Here, we investigated the role of inflammatory cytokines elicited by SEB-mediated stimulation of T cells in the dysregulation of Caco-2 intestinal epithelial barrier function.
Methods: Primary T cells, isolated from the peripheral blood of healthy donors, were stimulated with SEB and co-cultured with of Caco-2 cells in trans-well plates and the following analyses were performed: 1) Inflammatory cytokine production in culture supernatants was quantified by ELISA; 2) actin cytoskeleton modifications, the localization of cell-cell junctions and the nuclear translocation of pSTAT3 and NF-kB transcription factors (TFs) were analysed by confocal microscopy; 3) the expression of epithelial markers, mesenchymal markers epithelial to mesenchymal transition TFs (EMT-TFs) were evaluated by western blotting and real time PCR; 4) the specific recruitment of pSTAT3 and NF-kB on the proximal promoters of EMT-TFs was analysed by chromatin immunoprecipitation.
Results: We demonstrated that inflammatory cytokines produced by T cells following SEB stimulation induce dysfunctions in Caco-2 intestinal epithelial cells by promoting actin cytoskeleton remodelling and epithelial cell-cell junction down-regulation. Moreover we also found that SEB-activated inflammatory T cells promote the up-regulation of SNAIL-1, TWIST-1 and ZEB-1 EMT-TFs in a NF-kB- and STAT3- dependent manner. Finally, by using a structure-based design approach, we identified a SEB mimetic peptide that, by blocking the binding of SEB to CD28, dampens inflammatory-mediated dysregulation of intestinal epithelial barrier.
Conclusion: Our results provide new insights into the enterotoxic activity of SEB during *S. aureus* infections, which may lead to the exacerbation of chronic inflammatory diseases, and we identified of a novel mimetic peptide able to attenuate inflammatory-dependent epithelial barrier dysfunctions.

Exploring the roles of γδ intraepithelial lymphocytes in gut physiology

Ambra Natalini[1], Vivien Kohlhaas[1], Robin Dart[2], Cara Brown[1], James Wilmouth Jr[1], Rocco D'Antuono[1], Lucinda Tullie[1], Colin Hutton[1], Vivian Li[1], Adrian Hayday[1;2]
[1]The Francis Crick Insitute, London, United Kingdom; *[2]King's College London, London, United Kingdom*

Purpose: The murine intestinal intraepithelial lymphocyte (IEL) compartment is dominated by Vγ7$^+$ γδ T cells, which rely on neighbouring epithelial proteins, Btnl1 and Btnl6 for their development. The role of intestinal Vγ7$^+$ T cells is still unclear but of note, mice lacking Vγ7$^+$ cells are more susceptible to colorectal cancer, while patients with Crohn's disease are more likely to develop penetrating B3 disease if they are homozygous for an hypomorphic allele of *BTNL3* and *BTNL8* that are the human homologues of *Btnl1* and *Btnl6.* In this context, we hypothesise that Vγ7$^+$ T cells promote tissue integrity at steady-state and tissue repair post-challenge. This essential property will be dependent on the cells' regulation by Btnl proteins.
Methods: The Btnl-dependent gene network regulating Vγ7$^+$ cells is investigated by analysing the immunophenotype, the functional response and the transcriptomic profile of Vγ7$^+$ cells after acute loss of *Btnl1*. Additionally, small intestinal organoids will be used to develop a system for quantifying IEL-IEC interactions at steady-state. The impact of Vγ7$^+$ cells post-challenge will be investigated by examining the susceptibility of Btnl1-deficient mice to gut-damaging insults that require epithelial repair.
Results: Acute loss of Btnl1 does not induce an immediate change in Vγ7$^+$ IEL frequency, but it does alter the cells' phenotype. Specifically, following acute loss of Btnl1, Vγ7$^+$ cells show diminished expression of CD69, commonly considered to be downstream of TCR signalling, but also associated with tissue-residence. Additional changes will be presented. Beyond the impact on T cells, acute Btnl1 loss seems to induce enterocyte apoptosis.
Conclusion: These results, which will be expanded upon, are already sufficient to point to a key importance of the Btnl-gd axis for steady-state intestinal physiology. Given the association of this axis in human IBD, specific findings in the mouse model system described might identify actionable targets.

Utilizing integrated spatial transcriptomics to elucidate localized immune responses within human coronary arteries throughout the progression of atherosclerosis

Joana Campos[1], Desley Neil[2], Pasquale Maffia[3], Claudio Mauro[2]
[1]Propath, Birmingham, United Kingdom; *[2]University of Birmingham, Birmingham, United Kingdom*; *[3]Universityof Glasgow, Glasgow, United Kingdom*

Aims: The contribution of immunity to human atherosclerosis is increasingly recognised. However, the anatomical organization and the specific roles of immune cells in the various stages of disease in the different vascular layers remain underexplored, underscoring the necessity for research to elucidate their function throughout disease progression. Moreover, research on human atherosclerosis has predominantly relied on samples obtained from endarterectomies of carotid arteries, representative of end-stage disease and confined solely to the plaque, offering little insight into disease progression.
Methods: Here, we performed combined Nanostring GeoMx® DSP and CosMx™ SMI on serial cross-sections of coronary arteries from human explanted hearts from subjects that underwent heart transplantation at University Hospitals Birmingham NHS Foundation Trust. The cross-sections include the full thickness of the vessel wall and surrounding adipose tissue with vasa vasorum. These show atherosclerosis progression from near-normal vessels to severe lesions, corresponding to AHA type II-V lesions. For GeoMx®, FFPE sections were stained with morphology markers (SYTO13, CD45 and CD4) and hybridised with the Whole Human Transcriptome Atlas RNA panel. A total of 55 Regions of Interest (ROIs) were placed across the cross-sections covering anatomical locations that were CD45+CD4$^-$ or CD45+CD4$^+$ in the adventitia or the atherosclerotic plaque. The collected barcodes were processed for Next Generation Sequencing (NGS). The NGS readout data was converted from FASTQ to DCC format, and the data uploaded to the GeoMx® DSP. Data analysis was performed using the DSP Analysis Suite and R packages available from Bioconductor and made available by NanoString. For CosMx™, serial FFPE sections (to those used for GeoMx) were hybridised with the CosMx Universal Cell Characterisation RNA Panel, which was customised with 20 additional targets to cover genes & pathways highlighted by the GeoMx study. We placed 235 Fields of View (FOVs) across the cross-sections in order to profile the full thickness of the artery layers, the atherosclerotic plaques and immune cell infiltrates. Data analysis was performed using the DSP Analysis Suite, AtoMx SPI, and R packages available from Bioconductor.
Results: We integrated GeoMx® and CosMx™ datasets, to perform a series of analyses, including pathway and neighbourhood analyses, and cell phenotyping.

Aims: To evaluate the effect of current and future therapies on HS fibroblast activation
Methods: Single cell RNA-sequencing (scRNA-seq) was performed on HS lesional and healthy control skin. Fibroblasts and myeloid cells were identified and characterised using Seurat. Myeloid-derived drivers of fibroblast activation were identified in silico using Nichenetr and validated in vitro on HS fibroblasts which were stimulated with recombinant cytokines or HS skin explant conditioned media.
Results: scRNA-seq identified inflammatory fibroblast subsets which may contribute to the highly inflammatory microenvironment of HS lesions and subsequent scarring which is characteristic of HS. Fibroblasts with high expression of podoplanin and CD90 also had elevated expression of neutrophil chemoattractants *CXCL1* and *CXCL8*, collagens and matrix metalloproteinase (MMP) genes and were unique to HS lesions. HS inflammatory fibroblasts had elevated expression of TNF and IL-1b responsive genes, suggesting that myeloid cells may promote an inflammatory phenotype in HS fibroblasts. Furthermore, myeloid cell derived IL-1b, TNF and TGFb were identified as potential regulators of inflammatory genes in HS fibroblasts. IL-1b, TNF and TGFb regulate the expression of MMPs and collagens in HS fibroblasts, suggesting that myeloid cell interactions with fibroblasts may promote fibrotic scarring in HS. Further, scRNA-seq analysis indicated that anti-TNF therapy reduced the expression of chemokines, cytokines, MMPs and anti-microbial peptides in HS fibroblasts but may not prevent HS scar formation. Finally, blocking IL-1b production in HS lesions using the NLRP3 inflammasome inibitor MCC950 failed to prevent the activation of HS fibroblasts.
Conclusion: These findings highlight an important role of myeloid cell derived TNF, IL-1b and TGFb in driving fibroblasts into an inflammatory phenotype. IL-1b, TNF and TGFb regulated the expression of the neutrophil attractants *CXCL1* and *CXCL8* which may, along with increased MMP and collagen production, contribute to HS scarring. While fibroblasts from HS patients on anti-TNF therapy had reduced expression of proinflammatory mediators, confirming the importance of TNF in the pathogenesis of HS, HS fibroblasts maintained an elevated expression of fibrotic factors. Taken together this data indicates anti-TNF therapy may not prevent the development of fibrotic scars in HS patients and highlights the complexity of HS pathogenesis.

Non-classical HLA-E class I molecule and its potential role in SARS-CoV-2 infection.

Mahsa Rafieiyan[1;2], Giusto Davide Badami[1;3], Mojtaba Shekarkar azgomi[1;3], Marco Pio La Manna[1;3], Francesco Dieli[1;3], Nadia Caccamo[1;3]
[1]Central Laboratory of Advanced Diagnosis and Biomedical Research (CLADIBIOR), Azienda Ospedaliera Universitaria Policlinico (AOUP) Paolo Giaccone, University of Palermo, Palermo, Italy, Palermo, Italy, Palermo, Italy; *[2]Department of Sciences for Health Promotion and Mother-Child Care "G. D'Alessandro", University of Palermo, Palermo, Italy, Palermo, Italy, Palermo, Italy*; *[3]Department of Biomedicine, Neurosciences and Advanced Diagnosis, University of Palermo, Palermo, Italy, Palermo, Italy, Palermo, Italy*

The SARS-CoV-2 pandemic has had a massive impact on global health and economies. While mRNA vaccines have effectively prevented disease, they do not guarantee long-term immunity, as neutralizing antibody titers decline. $CD8^+$ T cells recognize infected cells by binding T cell receptors to epitopes presented by human leukocyte antigen (HLA) Class Ia molecules, which are highly polymorphic. HLA-E, a low polymorphic molecule, presents limited peptides to $CD8^+$ T cells. In this study, we identified eight peptides from the 2019-nCoV/USA-WA1-A12/2020 (MT020880) complete genome SARS-CoV-2 that fit the HLA-E pocket and are recognized by $CD8^+$ T cells to provide long-term immunity against SARS-CoV-2 infection and future coronaviruses.
NetMHC-4.0 was used to predict peptide-HLA binding affinity, incorporating structural information from HLA molecules. The synthesized potentially immunogenic epitopes were validated for binding to the HLA-E molecule to generate an immunological response. We analyzed HLA-E-restricted $CD8^+$ T cells from peripheral blood mononuclear cells (PBMCs) of 20 COVID-19-recovered individuals, 20 SARS-CoV-2 seropositive hospitalized patients, and 20 people who received three doses of mRNA BNT162b2 vaccine, using flow cytometry to evaluate their phenotype and functional characteristics. To assess the functions of SARS-CoV-2-specific $CD8^+$ T cells, we used intracellular cytokine staining (ICS) to measure the expression of effector cytokines (IFN-γ, TNF-α, IL-2, IL-4) and the CD107a mobilization as a readout of cytotoxicity on isolated PBMCs, following stimulation by our designed peptide pool.
We found that a subset of $CD8^+$ T cells efficiently recognized and reacted to the pool of HLA-E-restricted peptides by producing different cytokines. The HLA-E–restricted SARS-CoV-2–specific $CD8^+$ T cell response was more frequently detected in recovered subjects than hospitalized PCR-positive patients. These $CD8^+$ T cells predominantly expressed TNF-α and IL-4 with lower expression of IFN-γ and IL-2. The detection of surface CD107a significantly differed between hospitalized and recovered individuals.

Our results suggest that HLA-E-restricted $CD8^+$ T cells may contribute to controlling SARS-CoV-2 infection, reducing disease severity, and producing long-term immunity. Hence, understanding HLA-E-restricted $CD8^+$ T cell-mediated immunity is crucial for improving therapeutic and vaccine strategies.

The complement system plays a crucial role in the innate defense against invading pathogens. The complement proteolytic cascade on the microbial surface generates potent proinflammatory molecules and opsonins, resulting in lysis of the opsonized microbe or its phagocytosis by innate immune cells. Many pathogens, including viruses, have thus evolved strategies to overcome the complement-mediated destruction, e.g., by hijacking host complement regulators or encoding their own analogues. Since persistent activation of the complement is considered to play a key role in the pathogenesis of in severe coronavirus disease 2019 (COVID-19), we hypothesized that severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) virions subvert normal complement recognition and/or lysis. To test that, we produced SARS-CoV-2 virions in a human cell line naturally permissive to infection and purified them by size exclusion. Analysis of the purified SARS-CoV-2 virions by liquid chromatography coupled to tandem mass spectrometry revealed that SARS-CoV-2 reproducibly incorporates a subset of host cellular proteins, including some of the known complement regulators, into its virions during budding from infected cells. We confirmed the presence of the complement regulators in SARS-CoV-2 virions by Western blotting. Subsequent functional assays using specific blocking antibodies and/or enzymatic cleavage confirmed the role of the hijacked host cellular proteins in prevention of the complement-mediated lysis of SARS-CoV-2 virions. In conclusion, our results reveal an intriguing immune escape mechanism of SARS-CoV-2 with possible implications in the immunopathology of COVID-19.

ORF3a is the largest SARS-CoV-2 accessory protein. While its role as a viroporin remains controversial, it is known that this transmembrane protein impairs immune responses and induces vesicle formation. In this study, we analysed the cellular landscape in ORF3a-transduced A549 lung epithelial cells, using a combination of imaging techniques and various omics approaches to gain insight into the molecular mechanism of ORF3a. Initially, Transmission Electron Microscopy confirmed an increase in the number of vesicles inside the cells and revealed a significant number of altered mitochondria with abnormal cristae compared to control A459 cells. Furthermore, cryo nano-tomography in the water window performed at full-field transmission X-ray microscopy (ALBA synchrotron) allowed us to grasp the effects of ORF3a in cells expressing a GFP N-terminal tagged version of this accessory protein. With the increased number of vesicles, there was almost no sign of ER or Golgi, indicating that ORF3a promotes their fragmentation. ORF3a was found to localize in some of these vesicles, which exhibited a characteristic tubular pattern inside. Transcriptomic analysis revealed a distinct transcriptome in ORF3a transduced cells, with genes involved in mitochondria morphology and function being notably downregulated. Interestingly, altered mitochondria were often found next to those ORF3a-tubular vesicles, and live-cell imaging showed an increase in the motion and speed of these organelles compared to those of control cells. Additionally, we also found an unusual increased amount of lipid drops both by tomography and lipid staining in confocal microscopy, correlating with the upregulation in lipid metabolism induced by ORF3a as observed by Genome-Scale Metabolic Models. Together, our results demonstrate that the individual expression of the SARS-CoV-2 accessory protein ORF3a is sufficient to alter cellular structure, suggesting that this protein may play an important role in viral pathogenesis.

Enhanced early type I interferon signaling is associated with resistance to SARS-CoV2 infection

Cian Reid[1], Jamie Sugrue[2], Federica Giangrazi[1], Adam Dyer[3], Sean Kennelly[3], Liam Townsend[4], Jean Dunne[5], Niall Conlon[5], Nollaig Bourke[3], Darragh Duffy[2], Cliona O'Farelly[1]
[1]School of Biochemistry and Immunology, Trinity College Dublin, Dublin, Ireland; *[2]Translational Immunology Unit, Institut Pasteur, Université de Paris Cité, Paris, France*; *[3]Discipline of Medical Gerontology, School of Medicine, Trinity College Dublin, Dublin, Ireland*; *[4]Department of Infectious Diseases, St James's Hospital, Dublin, Ireland*; *[5]Department of Immunology, St. James's Hospital, Dublin, Ireland*

An impaired type I interferon (IFN) response is associated with severe SARS-CoV2 infection, and we propose that a particularly effective early response might provide protection in individuals who do not get infected upon exposure to virus. This resistant phenotype is rarely studied as exposure is difficult to ascertain. Here, the high rates of COVID-19 infection in 3 Irish nursing homes provided a unique opportunity to study resistance to SARS-CoV2. Seven individuals out of 90 were repeatedly negative for SARS-CoV2 nucleocapsid antibody despite living in environments of high exposure. To further validate lack of prior infection, IFN-y release upon stimulation of whole blood with SARS-CoV2 antigens was completed to test for T cell memory responses. All 7 resistant individuals had low IFN-γ responses indicating a lack of T cell memory to SARS-CoV2. We then performed standardized *ex-vivo* whole blood stimulations for 4-hours with viral ligands to determine the early innate anti-viral responses of these individuals compared to 7 age and sex matched controls previously infected with SARS-CoV2 from the same nursing homes. Multiplex gene expression profiling technology was used to quantify transcripts of 785 genes involved in innate immune signaling. Digital protein quantification assays were used to measure cytokines involved in innate anti-viral signalling. We identified an increased early type I interferon signaling transcriptomic signature within the nursing home resistors in response to Poly:IC compared to controls. This included significant increases in expression of *IFNA8* and *IFNG*. Interferon stimulated genes *OAS3*, *ISG15*, *HERC5*, *IFI6* and *APOL6* were also increased in resistors, which are important in early control of SARS-CoV2 infection. This early enhanced innate immune response could contribute to resistance to SARS-CoV2 infection. Investigating the immune mechanisms of optimal control of SARS-CoV2 virus early after exposure may lead to development of new anti-viral treatments and therapeutic strategies.

Longitudinal serosurveillance of severe acute respiratory syndrome coronavirus 2 in urban and rural cohorts in Malawi: characterising population exposure and protective immunity to viral variants

Mhairi McCormack[1], Louis Banda[2], Stephen Kasenda[2], Ellen Hughes[1], Lina Leonard[1], Annie Mwale[3], Estelle McLean[2], Alison Price[2], Amelia Crampin[2], David Chaima[4], Abena Amoah[2], Tonney Nyirenda[4], Antonia Ho[1], Brian Willett[1]
[1]MRC-University of Glasgow Centre for Virus Research, Glasgow, United Kingdom; *[2]Malawi Epidemiology and Intervention Research Unit, Lilongwe/Karonga, Malawi*; *[3]Public Health Institute of Malawi, Lilongwe, Malawi*; *[4]Kamuzu University of Health Sciences, Blantyre, Malawi*

Purpose: In Malawi, the extent of SARS-CoV-2 exposure and transmission is unclear due to high rates of mild/asymptomatic infections and limited diagnostic capacity. Existing SARS-CoV-2 seroprevalence studies have utilised enzyme-linked immunosorbent assays (ELISAs), lacking functional immunity estimates. Here, we employed pseudotyped virus neutralisation assays (PVNAs) to measure SARS-CoV-2 neutralisation, evaluating community exposure and protective immunity elicited by infection and vaccination.
Methods: Sera were obtained from rural (Karonga, n=968) and urban (Lilongwe, n=938) communities in Malawi, at 3-monthly intervals (February 2021-April 2022). Median age was 23 years (IQR 12-40). Human immunodeficiency virus (HIV)-based SARS-CoV-2 PVNAs assessed neutralisation of B.1 (ancestral), B.1.1.7 (Alpha), B.1.351 (Beta), B.1.617.2 (Delta), BA.1 (Omicron) and BA.2 (Omicron). Positive samples identified from fixed-dilution screening were titrated (titre at 50% reduction in infectivity). Nucleocapsid ELISAs were performed on sera from vaccinated participants to distinguish "vaccinated" from "vaccinated and infected". Findings were restricted to HIV-uninfected participants due to HIV-infected sera interfering with the pseudotypes. Ethical approval was received from the Malawi College of Medicine Research Ethics Committee (P11/20/3177) and the University of Glasgow College of Medicine, Veterinary and Life Sciences Research and Ethics Committee (200200056).
Results: Seroprevalence increased over time and varied by location (Survey 1-Karonga 6.5%, Lilongwe 11.7% ($p<0.001$); Survey 4-Karonga 45.4%, Lilongwe 68.6% ($p<0.001$)). Variant exposure also differed with time and location – novel variants emerged earlier in Lilongwe. Seroreversion (neutralisation negative following being positive) peaked at Survey 3 – the highest percentage of seroreverted individuals were Delta-exposed (Karonga – 29%, Lilongwe – 38%). Among naturally infected participants, children <15 years had the lowest B.1 titres ($p<0.05$). A single dose of ChAdOx1-S (AstraZeneca) vaccine induced stronger Beta neutralisation than one dose of Jcovden (Janssen) vaccine ($p=0.006$). Individuals with hybrid immunity (vaccinated and infected) had higher antibody titres than participants solely **vaccinated or infected ($p<0.05$).**
Conclusion: SARS-CoV-2 seroprevalence increased over time, with variants emerging earlier in Lilongwe, the international travel hub. Low neutralisation levels in children, possibly due to high asymptomatic/pauci-symptomatic infection rates, may lead to increased reinfections among this demographic. The high neutralisation responses in those with hybrid immunity reinforces the importance of vaccination in protective immunity.

The long Pentraxin PTX3 serves as an early predictive biomarker of co-infections in COVID-19

Francesco Scavello[1], Enrico Brunetta[1], Sarah Mapelli[1], Emanuele Nappi[1], Ian Garcia[1], Marina Sironi[1], Roberto Leone[1], Giovanni Angelotti[1], Domenico Supino[1], Silvia Carnevale[1], Hang Zong[1], Elena Magrini[1], Matteo Stravalaci[1], Alessandro Protti[1;2], Alessandro Santini[1], Elena Costantini[1], Victor Savevski[1], Antonio Voza[1;2], Barbara Bottazzi[1], Michele Bartoletti[1;2], Maurizio Cecconi[1;2], Alberto Mantovani[1;2;3], Paola Morelli[1], Federica Maria Pilar Tordato[1], Cecilia Garlanda[1;2]

Purpose: COVID-19 clinical course is highly variable and secondary infections contribute to COVID-19 complexity. Early detection of secondary infections is clinically relevant for patient outcome. Procalcitonin (PCT) and C-reactive protein (CRP) are the most used biomarkers of infections. Pentraxin 3 (PTX3) is an acute phase protein with promising performance as early biomarker in infections. In COVID-19 patients, PTX3 plasma concentrations at hospital admission are a strong independent predictor of poor outcome. In this study, we assessed whether PTX3 contributes to early identification of co-infections during the course of COVID-19.
Methods: We analyzed PTX3 levels in COVID-19 patients with (n=101) or without (n=179) community or hospital-acquired fungal or bacterial secondary infections (CAIs or HAIs), comparing it with classical biomarkers used by clinicians, i.e., PCT and CRP.
Results: PTX3 plasma concentrations at diagnosis of CAI or HAI were significantly higher than those in patients without secondary infections. In a longitudinal analysis, PTX3 peaked at admission and significantly increased again at the co-infection time-point. In patients surviving the secondary infection, the protein concentration significantly decreased after co-infection diagnosis, whereas in non-survivors, only a trend of decrease was observed. In selected patients, for whom we had serial PTX3, PCT and CRP measurements in a time period close to the HAI diagnosis, PTX3 plasma levels almost doubled few days before the diagnosis, when PCT and CRP concentration were still in the range of moderate increase or normality. Compared to PCT and CRP, the increase of PTX3 plasma levels was associated with the highest hazard ratio for CAIs and HAIs (aHR 11.68 and 24.90). In univariable and multivariable Cox regression analysis, PTX3 was also a strong predictor of 28-days mortality or intensive care unit admission of patients with potential co-infections, faring more pronounced than CRP and PCT.
Conclusions: PTX3 is a promising predictive biomarker for early identification and risk stratification of COVID-19 patients with co-infections.

Enhanced long-term protective effects of CXCR4/IL10-expressing mesenchymal stromal cells in a preclinical model of inflammatory bowel disease

Mercedes Lopez-Santalla[1], Marta Covadonga Ordoñez-Velasco[1], Miriam Hernando-Rodriguez[1], Maria Fernandez-Garcia[1;2], Juan Antonio Bueren[1], Rosa Maria Yañez[1], Marina Garin[1]
[1]CIEMA/IIS-FJD/CIBERER, Madrid, Spain; *[2]Kiji Therapeutics, Paris, France*

Mesenchymal stromal cells (MSCs) have shown great promise as a treatment for inflammatory bowel disease (IBD), owing to their immunosuppressive and regenerative capabilities. However, their therapeutic efficacy is challenging in part due to their limited efficiency in entering the inflamed colon and their variable in vivo immunomodulatory capacity. In this study, genetically engineered adipose derived human MSCs constitutively expressing the chemokine receptor 4 (CXCR4) and interleukin-10 (IL-10) (CXCR4/IL10 MSCs) have been used to improve their migration to the inflamed colon and to enhance the immunosuppressive properties of MSCs. Compared to non-modified MSCs (native MSCs), CXCR4/IL10-MSCs exhibited enhanced trafficking to the inflamed colon in dextran sodium sulphate (DSS)-challenged colitic mice. Interestingly, the administration of the CXCR4/IL10-MSCs showed enhanced therapeutic effects when compared to native MSCs, as indicated by analyses of the pathological indices and inflammatory markers. Strikingly, upon chronic re-challenge with DSS, enhanced long-term protective effects were observed in CXCR4/IL10-MSCs treated mice when compared to native MSC-treated colitic mice and the non-MSC-treated colitic mice. Overall, these results highlight the importance of developing improved cell-based therapies with MSCs as a highly effective strategy to induce long-term protective immune memory in immune-mediated disorders in which the complete resolution of the inflammation is impaired. Overall, this strategy based on enhancing the homing and immunosuppressive abilities of MSCs may represent an optimized, with potential long-term effect, MSC-based cell product for IBD therapy.

Development of a 3D model of colorectal cancer to assess the stromal-mediated effects on T cells in a stromal-rich colorectal cancer tumour microenvironment.

Eileen Reidy[1;2;3], Lei Lei[3], Niamh Leonard[4], Louise Rabbitt[4], Merah Al Busaidy[4], Abhay Pandit[2], Aideen Ryan[1;2;3]
[1]Discipline of Pharmacology and Therapeutics, School of Medicine, College of Medicine, Nursing and Health Sciences, University of Galway, Galway, Ireland; *[2]CÚRAM, SFI Research Centre for Medical Devices, University of Galway, Galway, Ireland*; *[3]University of Galway, Lambe Institute for Translational Research, Galway, Ireland*; *[4]University of Galway, Galway, Ireland*

Purpose: Colorectal cancer (CRC) is the second leading cause of cancer related deaths worldwide. Elevated T cell levels can signify better prognosis, however activated T cells express immune checkpoint inhibitors, hindering immune-mediated responses and advancing CRC. CRC is classified into four Consensus Molecular Subtypes (CMS1-4), notably CMS4, with abundant mesenchymal stromal cells (MSCs) and an inflamed immune phenotype. Given CMS4's link to poor disease-free survival, this project explores the impact of a stromal-dense environment on T cell activation in a 3D model.
Methods: Our project describes the development of a 3D collagen embedded spheroid containing CRC cell lines, hMSCs to mimic stromal cell infiltration of CMS4 and PBMCs cultured with anti-CD3-CD28 beads. We used a variety of methodologies including flow cytometry, AlamarBlue™, real-time PCR and confocal microscopy to assess the impact of sialidase and PD1-sialidase on a multicellular 3D model in vitro.
Results: We have shown that mesenchymal stromal cells (MSCs) promote viability and outgrowth of cells from the co-culture spheroids. We have also demonstrated that MSCs increase production of fibronectin which is present in stromal rich areas *in vivo*. We have demonstrated that hMSCs induce production of exhaustion markers LAG3 and PD1 on T cells in co-cultures with HCT116 + hMSC + PBMC spheroids. Finally, we demonstrated that Sialidase and PD1-Sialidase can potentially reverse immunosuppression induced by hMSCs through decreasing the expression of PD1 on both CD4 and CD8+ T cells.
Conclusion: Overall, we have developed a multi-cellular collagen embedded spheroid, that can be used in interrogate stromal mediated immunosuppression in the TME of CRC. This model can also be used in a drug screening capacity allowing us to analyse the effects hMSCs have on the response to Sialidase treatment in a 3D CRC model. Overall, the model represents an effective screening platform to identify novel therapeutic targets and assess the impact of immunotherapies in vitro.

Ehf and Fezf2 regulate thymic tissue homeostasis and thymic tuft cell development

Kristin Rattay[1]
[1]*Pharmacological Institute, University of Marburg, Marburg, Germany*

Thymic epithelial cells are indispensable for T cell maturation and selection and the induction of central immune tolerance. The self-peptide repertoire expressed by medullary thymic epithelial cells is in part regulated by the transcriptional regulator Aire and the transcription factor Fezf2. Due to the high complexity of mTEC maturation stages (i.e., post-Aire, Krt10+ mTECs, and Dclk1+ Tuft mTECs) and the heterogeneity in their gene expression profiles (i.e., mosaic expression patterns), it has been challenging to identify the additional factors complementing the transcriptional regulation in the past.
We aimed to identify the transcriptional regulators involved in the regulation of mTEC development and self-peptide expression in an unbiased and genome-wide manner. We employed ATAC footprinting analysis as an indirect method to identify key transcription factors influencing mTEC gene expression, further substantiated by ChIP sequencing validation and analysis of conditional knock-out mice.
We show that Fezf2 and Ehf are involved in the regulation of late developmental gene signatures implicated in cornification and keratinization in mTECs and that Fezf2 regulates Tuft-mTEC-specific gene signatures. Moreover, using conditional knockout mice, we identify Fezf2 to be essential for the development of thymic Tuft cells and Aire+-mature mTECs. Additionally, it was discovered that members of the ELF, ESE, ERF, and PEA3 subfamilies of ETS transcription factors, along with the Krüppel-like family of transcription factors, are instrumental in regulating genes crucial for advanced mTEC development.
Our findings highlight Fezf2 as a pivotal regulator of the newly characterized thymic Tuft cells. The Fezf2-dependent development of Tuft-mTECs discovered in this study identifies an alternative role of Fezf2 during mTEC development in which Fezf2 regulates the development of late developmental mTEC stages and the Tuft-mTEC stage, thereby indirectly affecting the representation of self-peptides, which are normally expressed and presented by those mTEC subsets. This newly identified role of Fezf2 in regulating late mTECs, Aire+-mTECs and Tuft-mTECs enhances our understanding of the complex cellular landscape of thymic epithelial cells.

Characterization of an IL-33 expressing, immune active fibroblast subpopulation

Lisa Schmidleithner[1], Niklas Beumer[2;3;4], Frauke Hoffmann[1], Joachim Seebass[4], Thomas Hehlgans[1], Markus Feuerer[1]
[1]LIT - Leibniz Institute for Immunotherapy, Regensburg, Germany; *[2]Division of Personalized Medical Oncology (A420) and Division of Applied Bioinformatics (B330), Heidelberg, Germany*; *[3]DKFZ-Hector Cancer Institute and Department of Personalized Oncology, Heidelberg, Germany*; *[4]Faculty of Biosciences, Heidelberg, Germany*

Fibroblasts are diverse mesenchymal cells which play an important role in tissue homeostasis and repair through the production of a variety of different growth factors. In addition, they are also involved in many immune regulatory responses, where they have been implicated in both pro- and anti-inflammatory processes. Moreover, a deregulation of fibroblasts can lead to a plethora of different pathologies, such as fibrotic diseases and, in the tumor microenvironment, so-called cancer associated fibroblasts (CAFs) have been shown to support tumor growth. However, the inter- and intra-tissue heterogeneity of fibroblast populations remains unsolved. Therefore, we performed a single cell (sc) assay for transposase-accessible chromatin with sequencing (ATAC-Seq) of murine fibroblast populations isolated from the skin, lung, visceral adipose tissue, and lymph nodes and could confirm and further specify tissue-specific fibroblast subpopulations as well as fibroblast populations which we could identify across all analyzed tissues (pan-tissue fibroblasts). These data defined different prevailing footprints of transcription factor families between the populations and allowed inference of a developmental trajectory. Bulk RNA sequencing of pan-tissue and tissue-specific fibroblasts revealed that the pan-tissue fibroblast population represented a more immune-active subpopulation. Specifically, the expression of the cytokine IL-33, a member of the IL-1 family, could be attributed to the pan-tissue population. IL-33 reporter mice and conditional knock-out of IL-33 on fibroblasts revealed distinct functions. scRNA-seq of lung fibroblasts, T cells and metastatic cancer cells from the lung allowed us to identify potential ligand-receptor pairs. Our data have further characterized an immune active fibroblast subpopulation present in all tissues, a finding which helps to better understand the heterogeneity of fibroblasts and their interactions with the immune system.

Stromal cells shape the immune response to mycobacteria

Anne Lösslein[1;2;3;4], Jana Neuber[1;2], Leonhard Wagner[1;2], Roman Sankowski[5], Sagar Sagar[4], Philipp Henneke[1;2]
[1]Institute for Immunodeficiency, Center for Chronic Immunodeficiency (CCI), University Medical Center Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany; *[2]Institute for Infection Prevention and Control, University Medical Center Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany*; *[3]Institute of Medical Microbiology and Hygiene, University Medical Center Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany*; *[4]Department of Medicine II (Gastroenterology, Hepatology, Endocrinology, and Infectious Diseases), University Medical Center Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany*; *[5]Institute of Neuropathology, University Medical Center Freiburg, Faculty of Medicine, University of Freiburg, Freiburg, Germany*

Purpose: Mycobacterial tissue infections induce the formation of granulomas, which are complex immune cell structures. Macrophages (MΦ) are the key players of the granuloma. Nevertheless, a mature granuloma with a necrotic core not only leads to the accumulation of immune cells but also causes remodelling of the tissue with an impact on fibroblasts and stromal cells (SC). In this project, we aim to characterize the role of SC for granuloma formation and control of mycobacteria, as well as the interaction of MΦ and non-immune cells in mycobacterial infections.
Methods: To address these questions, we used *Mycobacterium bovis* BCG mouse infection models and *in vitro* co-cultures of SC and MΦ. We further characterized SC in mycobacterial infections by flow cytometry, confocal and live cell imaging as well as transcriptomic analyses.
Results: Mycobacterial infections lead to the accumulation of bone-marrow derived monocytes at the site of infection, which then further contribute to granuloma formation. We found high expression levels of CCL2 and CCL7 in SC up to 16 weeks post infection, indicating a regulatory role in monocyte recruitment. Transcriptome analysis further revealed an impact of SC on the cytokine environment, including IL-4, IL-13 and TNF production. Although mainly macrophages take up mycobacteria in infection, we observed by microscopy that BCG also infected SC *in vitro*. With the help of adoptive cell transfers, we were able to prove that mycobacterial infections of SC also occur *in vivo*. Additionally, killing assays suggested that the bacteria survived within SC over several days. SC accumulated lipids and showed changes in lipid metabolism during the infection, which might be beneficial for the intracellular survival of mycobacteria as those are highly lipid-dependent. Currently, we are performing single-cell-sequencing analysis to elucidate mechanisms of bacterial uptake in SC as well as MΦ-SC interactions.
Conclusion: Our data point towards an essential role of SC in mycobacterial infections. SC not only influence the MΦ immune response, but also serve as potential host cells for mycobacteria, which is of high relevance for the pathogenesis of latency and the treatment of mycobacterial infections.

A circadian clock compound selectively impairs inflammation-induced antifibrinolytic activity to restore clot breakdown pathways.

Paula Klavina[1;2], Aisling M. Rehill[2], Steven J. Humphreys[3], Claire S. Whyte[3], Nicola J. Mutch[3], Roger J. S. Preston[2], Annie M Curtis[1;4]
[1]Curtis Clock Laboratory, School of Pharmacy and Biomolecular Sciences (PBS), RCSI, Dublin, Ireland; *[2]Irish Centre for Vascular Biology, School of Pharmacy and Biomolecular Sciences (PBS), RCSI, Dublin, Ireland*; *[3]Aberdeen Cardiovascular and Diabetes Centre, Institute of Medical Sciences, School of Medicine, Medical Sciences and Nutrition, University of Aberdeen, Aberdeen, United Kingdom*; *[4]Tissue Engineering Research Group, Department of Anatomy and Regenerative Medicine, RCSI, Dublin, Ireland*

Purpose: Circadian rhythms are 24-hour cycles of human physiology that ensure processes occur at the most optimal time of day. However adverse cardiovascular events also show a time-of-day dependency. Stroke, characterised by aberrant blood clotting, has the highest incidence between 8:00 and 9:00am. Immunothrombosis is a phenomenon whereby inflammation triggers the coagulation system and vice versa. Proteins associated with immunothrombosis and inflammation including plasminogen activator inhibitor (PAI) 1, a potent inhibitor of clot breakdown (fibrinolysis), and IL-6 peak in the early morning hours. Therapeutic inhibition of immunothrombosis is challenging due to the complex network of interactions between pro-inflammatory, procoagulant, and fibrinolytic pathways. The aim of this project was to evaluate whether targeting the clock rather than the immune or haemostatic pathways can be a potential therapeutic approach to limit unwanted morning clotting events.
Methods: Bone marrow-derived macrophages (BMDMs) and primary human umbilical vein endothelial cells were stimulated with the clock modulating compound SR9009 followed by activation with the bacterial component lipopolysaccharide (LPS) or pro-inflammatory cytokine TNFα to mimic an immunothrombotic event. Following treatment, RNA from treated BMDMs was sequenced, gene and protein expression was analysed by RT-qPCR and ELISA respectively, fibrinolytic potential was analysed by plasmin generation assays.
Results: SR9009 alone did not affect plasmin generation in the presence or absence of endothelial cells or macrophages. However, under inflammatory conditions, SR9009 potently inhibited inflammation-induced expression of anti-fibrinolytic proteins PAI-1 (Serpine1) and PAI-2 (Serpinb2) in both macrophages and endothelial cells. Promoter analysis shows both Serpine1 and Serpinb2 possess binding sites for circadian transcriptional regulators. In an RNAseq screen in macrophages, SR9009 + LPS suppressed genes involved in leukocyte migration as well as fibrinolysis, with the most significantly suppressed gene being Serpinb2 when compared to LPS-treated cells. Consequently, inflammation-induced suppression of both macrophage and endothelial cell fibrinolytic activity was restored by SR9009 in a plasmin generation assay.
Conclusion: These data suggest SR9009 selectively restores fibrinolysis via inhibition of inflammation-induced anti-fibrinolytic protein generation. These therapeutic properties may have potential application in restoring normal plasmin generation and thus normal clot lysis in individuals with dysregulated fibrinolytic activity in the morning hours.

Antigen-specific dendritic cell immunotherapy to halt autoimmunity in Type 1 Diabetes

Aurora Forlani[1], Gloria Giacomello[1;2], Laura Passeri[1;3], Fabio Russo[1], Francesca Santoni de Sio[1], Anna Zanardini[4], Marina Scavini[4], Lorenzo Piemonti[5], Andrea Annoni[1], Laura Passerini[1], Silvia Gregori[1]
[1]Mechanisms of Peripheral Tolerance, SR-TIGET, IRCCS Ospedale San Raffaele, Milan, Italy; *[2]Università Milano Bicocca, Milan, Italy*; *[3]Medical Oncology Department, IRCCS San Raffaele Scientific Institute, Milan, Italy*; *[4]General Medicine – Diabetes and Endocrinology, Diabetes Research Institute (DRI), IRCCS San Raffaele Scientific Institute, Milan, Italy*; *[5]Beta-cell biology, Diabetes Research Institute (DRI), IRCCS San Raffaele Scientific Institute, Milan, Italy*

In Type 1 diabetes (T1D) insulin-producing b cells are destroyed by autoreactive T cells. Dendritic cells (DC) engineered with a lentiviral vector (LV) encoding for IL-10 and an insulin peptide ($InsB_{9-23}$) modulate Ins-specific T cells *in vitro* and *in vivo*. Our goal is to develop tolerogenic (tol)DC-based therapy to restore tolerance in T1D, we i) compared HLA-DQ8/A2-restricted epitopes to select the best autoantigen (autoAg) for DC engineering, ii) assessed the ability of T1D monocytes to differentiate in engineered tolDC, and iii) implemented a humanized mouse model (hu-mice) to test *in vivo* tolDC immunotherapy.
$CD14^+$ cells from HLA-$DQ8/A2^+$ T1D patients were transduced during DC differentiation with a LV encoding for the autoAg-derived peptide fused to the invariant chain and IL-10 (LV-Ag/IL-10). LV encoding for autoAg without IL-10 or invariant chain alone were used as controls. DC were characterized by flow cytometry and cytokine profiling. *In vitro* function was tested by stimulating autologous T cells and responses were evaluated by IFNg ELISA/ELISPOT and by the induction of type 1 T regulatory (Tr1) cells. To implement hu-mice, HLA-$DQ8^+$ cord blood (CB) cells were transplanted into newborn HLA-DQ8-trangenic NSG mice. Reconstituted mice were immunized. T cell response was monitored by flow cytometry.
We selected Hybrid-insulin-peptide 11 (HIP11), Neuropeptide Y_{60-75}, and a mimotope of $InsB_{9-23}$ (InsMIM) as the most HLA-DQ8 cross-reactive peptides. DC from T1D patients engineered with LV-autoAg/IL-10 ($DC^{Ag/IL-10}$) acquired tolDC phenotype ($CD14^+CD16^+CD163^+CD141^+ILT\text{-}4^+$), secreted high levels of IL-10, inhibited Ag-specific IFNg release by autologous $CD4^+$ T cells. Moreover, the frequency of Tr1 cells in culture with $DC^{Ag/IL-10}$ was increased as compared to control DC in T1D pts with detectable Ag-specific reactive T cells. $DC^{Ins/IL-10}$ dampened Ins-specific $CD8^+$ T cell response in HLA-$A2^+$ T1D pts. In hu-mice immunization with CB-derived Ins-pulsed B cells promoted the proliferation of autologous $CD4^+$ T cells *in vivo*. Preliminary data indicate that injection of $DC^{Ins/IL-10}$ modulate $CD4^+$ T cell response in this model.
We identified candidate autoAg-derived epitopes to generate tolDC in T1D patients, demonstrated that Ag-specific tolDC from T1D patients modulate Ag-specific $CD4^+$ and $CD8^+$ T cell responses *in vitro*, and developed a hu-mice model for assessing tolDC-based immunotherapy.

Conventional dendritic cells (cDCs) include functionally and phenotypically diverse populations, such as cDC1s and cDC2s. The latter population has been variously subdivided into Notch-dependent cDC2s, KLF4-dependent cDC2s, T-bet$^+$ cDC2As and T-bet$^-$ cDC2Bs, but it is unclear how all these subtypes are interrelated and to what degree they represent cell states or cell subsets. All cDCs are derived from bone marrow progenitors called pre-cDCs, which circulate through the blood to colonize peripheral tissues. Here, we identified distinct mouse pre-cDC2 subsets biased to give rise to cDC2As or cDC2Bs. We showed that a Siglec-H$^+$ pre-cDC2A population in the bone marrow preferentially gave rise to Siglec-H$^-$ CD8α$^+$ pre-cDC2As in tissues, which differentiated into T-bet$^+$ cDC2As. In contrast, a Siglec-H$^-$ fraction of pre-cDCs in the bone marrow and periphery mostly generated T-bet$^-$ cDC2Bs, a lineage marked by the expression of LysM. Our results showed that cDC2A versus cDC2B fate specification starts in the bone marrow and suggest that cDC2 subsets are ontogenetically determined lineages, rather than cell states imposed by the peripheral tissue environment.

Skin DCs display circadian (24 hour) rhythms in metabolic function which may be harnessed by dissolvable microneedle patch to improve vaccine efficacy

Cloé Payet[1], Christine Butler[1], Aoife Rodgers[2], Sandrine Henri[3], Ryan Donnelly[2], Annie M Curtis[1]

Several vaccines have demonstrated time-of-day dependent responses. Dendritic cells (DCs) are the main target as they process and present vaccine antigens to naïve T cells to elicit protective adaptive immunity. Peripherals DCs display a circadian rhythm in antigen processing and lymph node migration which is dependent on their metabolism. The skin is an ideal target for circadian vaccination because of its large network of DCs, which can be effectively reached using dissolvable microneedle (dMN) drug delivery technology. Thus, we aimed to create the first 'circadian-informed' skin DC vaccine using dMN.
Nanoparticles (NPs) were prepared using an oil-in-water emulsion method. Bone marrow derived DCs were used for *in vitro* work and assessed by flow cytometry (FC). Fluorescent-NP uptake by DC2.4 cells was studied by confocal microscopy. Skin circadian rhythmicity was assessed by Lumicycle using the circadian reporter Per2::Luciferase. Circadian whole skin metabolism was analysed by qPCR/Seahorse, while skin DCs metabolism was studied by spectral FC.
Fabricated NPs were ~200nm in diameter, and we obtained 30% encapsulation efficiency of the model antigen OVA. NP uptake by DCs caused upregulation of activation markers, such as CD40. Lumicycle analysis showed a strong circadian rhythm of core clock components. Seahorse analysis revealed a circadian rhythm in mitochondrial metabolism with a peak in the active phase. Spectral FC on skin DCs revealed circadian rhythmicity in glycolysis with a peak during resting phase.
We have identified that skin DCs are an ideal organ for circadian vaccination using dMN. Our dMN with encapsulated NPs promote DC activation and maturation. Within the skin, maximal basal respiration, which is associated with increased antigen processing and an immature state, occurs during the active phase. However, skin DCs show highest glycolysis, which is associated with maturation and migration, during resting phase. In future work, the circadian transcriptome of skin DCs will be assessed by single-cell RNA-seq to elucidate potential adjuvants to be incorporated into the dMN. We then hope to be able to formulate a dMN incorporating all these features and vaccinate mice at the optimal time of day in terms of skin DC metabolism, to achieve maximal protective immunity.

Claudin 1-mediated maturation of thymic dendritic cells type 1 promotes clonal deletion and Treg selection via antigen transfer

Jiri Brezina[1;2], Tomas Brabec[1;2], Matous Voboril[1], David Machac[1], Kristina Jancovicova[1], Vojtech Sykora[1], Ondřej Ballek[1], Jan Dobes[2], Martina Dobesova[1], Adela Cepkova[1], Michal Kolar[3], Petr Kasparek[4], Radislav Sedlacek[4], Sachiko Tsukita[5], Bernard Malissen[6], Graham Anderson[7], Dominik Filipp[1]
[1]Laboratory of Immunobiology, Institute of Molecular Genetics of the Czech Academy of Sciences, Prague, Czech Republic; *[2]Department of Cell Biology, Faculty of Science, Charles University, Prague, Czech Republic*; *[3]Laboratory of Genomics and Bioinformatics, Institute of Molecular Genetics of the Czech Academy of Sciences, Prague, Czech Republic*; *[4]Czech Centre of Phenogenomics and Laboratory of Transgenic Models of Diseases, Institute of Molecular Genetics of the Czech Academy of Sciences, Prague, Czech Republic*; *[5]Advanced Comprehensive Research Organization, Teikyo University, Tokio, Japan*; *[6]Centre d'Immunologie de Marseille-Luminy, Aix Marseille Universite´, Inserm, CNRS, Marseille, France*; *[7]Institute of Immunology and Immunotherapy, University of Birmingham, Birmingham, United Kingdom*

The presentation of self-antigens in the thymus by medullary thymic epithelial cells (mTECs) and dendritic cells (DCs) is crucial for the establishment of central tolerance. While mTECs produce and present self-antigens in an autonomous manner, DCs acquire them from mTECs by cooperative antigen transfer (CAT). Although CAT represents a key process of central tolerance, molecular determinants which define CAT's effectivity as well as the the capacity of DCs to subsequently present acquired antigens are largely unknown. To reveal the nature of these determinants, we compared the transcriptomes of CAT-experienced and inexperienced DCs via scRNAseq, which allowed us to redefine their heterogeneity and maturation. We focused on the candidate gene determinant, *Cldn1*, encoding the tight junction protein Claudin 1, which was found to be highly expressed among the CAT-experienced type 1 lineage DCs (DC1). Using DC1-specific Claudin 1 knockout, we found that mature DC1, which are the most effective in antigen presentation, are impaired. This translates to insufficient clonal deletion and Treg selection of self-reactive clones. A similar phenotype is observed when MHCII expression is specifically ablated in DC1 advocating that, in general, the deficiency of antigen presentation by mature DC1 leads to the impairment of Treg selection. In addition, we mapped the expression of the Claudin 1 ligand, Claudin 3, to mTECs which express the highest levels of self-antigens, suggesting the existence of a molecular bridge between mTECs and DC1. Hence, we propose a dual role for Claudin 1 in DC1: (i) mediating DC1, becoming part of the mTEC network (ii) having a critical role in maturation of DC1. Ultimately, Claudin 1 is a regulatory molecule which coordinates CAT and T cell selection processes. The comprehension of these processes will aid in the resolution of the current controversy concerning the role of DC1 in central tolerance.

Click chemistry allows the visualization of an immunogenic HLA-A2-restricted epitope on human monocyte-derived dendritic cells

Thijmen Mostert[1], Amy Kessler[2], Robbie Luijten[2], Diana Torres García[1], Ward Doelman[1], Sander van Kasteren[1], Sonja Buschow[2]
[1]*Leiden Institute of Chemistry, Leiden, Netherlands*; [2]*Erasmus Medical Center, Rotterdam, Netherlands*

Antigen processing and presentation by dendritic cells is essential for the induction of effective T-cell responses. Conventional T-cell based methods to study antigen processing and presentation do not provide information about the underlying processing processes. Having antigens that can be tracked throughout the processing pathway *and* activate a cognate T-cell would be highly insightful in correlating the mechanics of the antigen presentation pathway to the ability of a DC to activate a T-cell. However, the introduction of fluorophores into epitopes blocks T-cell activation and even prevents normal loading of the peptide onto an MHC.
We here show that click chemistry is a powerful solution to this problem. Click reactions are chemical reactions that can be performed selectively without interference of complex cellular environments. They can thus be used to introduce fluorophores selectively onto the specific sites in the epitope *after* processing and MHC-loading. In addition, the click handles used are so small that the clickable epitopes can still activate a T-cell.
Here, we generated clickable variants of the immunogenic, HLA-A2-restricted hepatitis B virus-derived epitope HBc18-27 by replacing each position with the clickable amino acid homopropargylglycine to study the cross-presentation of this epitope. HLA-A2 binding was assessed with the T2 cell HLA stabilization assay. Preservation of immunogenicity was determined with an HBc18-27-specific T cell assay. The accessibility of the handle in HLA-complex was determined on the surface of human monocyte-derived dendritic cells (moDCs) by flow cytometry. Moreover, the presence of the epitope on the surface of and within moDCs was visualized by confocal and superresolution microscopy. Furthermore, including the modified epitope within a synthetic long peptide allowed us to image the uptake, intracellular distribution and surface appearance of the epitope in moDCs.
This is, to our knowledge, the first study to visualize an epitope peptide within an MHC on the surface of an APC without loss of T-cell recognition during cross-presentation. The herein presented clickable epitopes provide a promising prospect for the study of epitope routing and presentation throughout the antigen presentation pathways and may enable direct and quantitative epitope studies in a T-cell-independent manner.

Factors determining dendritic cell identity in peripheral tissues

Sally Connolly[1], Elke Schwarzenberger[1], Carmen Tam-Amersdorfer[1], Magdalena Lang[1], Christina Passegger[1], Herbert Strobl[1]
[1]*Division of Immunology, Otto Loewi Research Center, Medical University of Graz, Graz, Austria*

Tissue-resident dendritic cells (DCs) are central to the maintenance of tolerance within peripheral tissues such as the skin, lung, and intestine. These DC populations exist in immature and migratory states, maintained and fine-tuned by microenvironmental signals. While several master transcriptional regulators of DC states have been identified, the complex interplay of these proteins and how tissue-derived signals are relayed remain poorly understood in both steady-state and inflammatory conditions. Transforming growth factor-β (TGF-β) family members are such tissue-derived signals that can alter DC subset specification and tolerogenicity. Following a microarray screen, we identified several TGF-β1-dependent transcription factors that were rapidly induced or repressed during the early stages of DC/epidermal Langerhans cell commitment. Lentiviral-mediated gain and loss-of-function experiments of these transcription factors reveal their role in DC subset identity. In the context of the skin, a picture emerges whereby monocyte and cDC2-lineage blood precursors are programmed by these factors to follow epithelial versus subepithelial DC fate decisions and that repression of TGF-β1-driven factors is required for maturation. Our data provides further insight into the complex transcriptional networks governing DC subset specification.

Regnase-1 KO B7-H3 CAR T cells for osteosarcoma: improved antitumor activity and potency to reprogram endogenous immune cells

Adeleye Adeshakin[1], Hao Shi[1], Phuong Nguyen[1], Scott Perry[1], Xiang Sun[1], Peipei Zhou[1], Jean-Yves Metais[1], Anil KC[1], Heather Sheppard[1], Liqing tian[1], Deanna Langfitt[1], Jason Yustein[2], Giedre Krenciute[1], Christopher DeRenzo[1], Hongbo Chi[1], Stephen Gottschalk[1]
[1]St. Jude Children's Research Hospital, Memphis, United States; *[2]Emory University School of Medicine, Atlanta, United States*

CAR T cell therapy has been successful for hematological malignancies leading to their FDA approval. However, CAR T cell therapy has been less effective in early-phase clinical studies for solid tumors, including osteosarcoma (OS), the most common bone cancer in children. We and others have demonstrated that Regnase-1 (Reg-1) knock-out (KO) CAR or TCR T cells have improved antitumor activity. However, the effects of Reg-1-KO on OS-specific CAR T cells is unknown. Thus, the goal of this project was to determine if Reg-1-KO CAR T cells have improved effector function and induce an immunostimulatory lung microenvironment in an immune-competent OS model with lung tumors, the most common site of metastases.
To target OS, we focused on B7-H3, an antigen that is reliably expressed in OS. Murine Reg-1-KO and Ctrl-KO B7-H3-CAR T cells recognized and killed murine OS cell lines in an antigen-specific manner as judged by cytokine (IFN-γ, GM-CSF, IL-2) production and cytotoxicity assays. To determine if Reg-1-KO improves the effector function of B7-H3-CAR T cells *in vivo*, mice received an intravenous (i.v.) injection of F331 cells to induce lung tumors, and on day 7 an i.v. dose of $1x10^6$ Reg-1-KO or Ctrl-KO B7-H3-CAR T cells, Reg-1-KO Sp6-CAR T cells or PBS. Reg-1-KO B7-H3-CAR T cells had improved antitumor activity and significant survival advantage. Flow cytometry and scRNAseq revealed that Reg-1-KO enhanced the expansion of B7-H3-CAR T cells on day 7 post-infusion and induced the expression of pro-inflammatory cytokines (IFN-γ, IL-13), cytokine receptors (IL-12R), increased OXPHOS and mitochondrial fitness. Endogenous immune cells revealed that Reg-1-KO B7-H3-CAR T cells induced immunostimulatory lung microenvironment with an influx of IFN-γ producing CD4 and CD8 T cells, and NK cells that was paired with a reduction of inhibitory cells, M2 macrophages. These effects lasted for at least 21 days post-CAR T cell infusion.
In conclusion, we demonstrate that Reg-1-KO improves the antitumor activity of B7-H3-CAR T cells and that Reg-1-KO CAR T cells reprogram endogenous immune cells without systemic toxicity. These promising results warrant further active exploration and if confirmed, early-phase clinical testing of Reg-1-KO B7-H3-CAR T cells in patients with recurrent/refractory OS.

FOXO1 enhances CAR T stemness, metabolic fitness and efficacy

Jack Chan[1], Christina Scheffler[1], Isabelle Munoz[1], Kevin Sek[1], Junyun Lai[1], Paul Beavis[1], Phillip Darcy[1]
[1]*Peter MacCallum Cancer Centre, Melbourne, Australia*

Chimeric antigen receptor (CAR) T cell therapy has transformed the treatment of hematological malignancies such as ALL, B cell lymphoma and multiple myeloma but the efficacy of CAR T cell therapy in solid tumors has thus far been limited. This is due to a number of factors including the immunosuppressive tumor microenvironment that gives rise to poorly persisting and metabolically dysfunctional T cells. Analysis of anti-CD19 CAR T cells used clinically have shown that positive treatment outcomes are associated with a more "stem-like" phenotype and increased mitochondrial mass. We therefore sought to identify transcription factors that could enhance CAR T cell fitness and efficacy against solid tumors. Here we show that overexpression of FOXO1 significantly promotes a "stem-like" phenotype in CAR T cells derived from either healthy human donors or patients, which correlates with improved mitochondrial fitness, persistence and therapeutic efficacy in vivo. This work thus reveals an engineering approach to genetically enforce a favorable metabolic phenotype that has high translational potential to improve the efficacy of CAR T cells against solid tumors. The study has recently been accepted for publication in Nature.

Generating CRISPR/CAS9 armoured CAR- and TCR-T cells for the treatment of solid tumours

Phoebe Dunbar[1;2], Paul Beavis[1;2], Phillip Darcy[1;2], Amanda Chen[1;2], KahMin Yap[1;2]
[1]*Peter MacCallum Cancer Centre, Melbourne, Australia*; [2]*Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, Australia*

Purpose: CAR T cell therapy has exhibited remarkable clinical success in the treatment of haematological malignancies, however, their efficacy in solid tumours is limited by antigen heterogeneity and immunosuppression imposed by the tumour microenvironment. In order to overcome these barriers, 'armoured' CAR T cells which secrete pro-inflammatory cytokines have been developed. However, toxicities related to the unrestricted expression of the armouring transgene has limited the application of these CAR T cells in the clinic. Our lab has previously demonstrated enhanced CAR T cell efficacy upon CRISPR/Cas9 mediate deletions of A2A (Giuffrida et al. *Nature communications* May. 2021), and here, our lab has developed a novel CRISPR knock-in strategy whereby we aimed to engage endogenous gene regulatory mechanisms drive transgene expression in a tumour-localised manner (*in review, Cell)*.
Methods: Genome-wide RNA-sequencing was used to identify genes in CAR T cells with tumour-specific expression. Promotors *NR4A2* and *RGS16* were identified as key candidates due to their inhibitory role in T cells. A novel CRISPR/Cas9-mediated homology directed repair (CRISPR HDR) strategy was then employed to knock in (KI) proinflammatory cytokines into these gene loci. This enabled the simultaneous deletion of an inhibitory gene while achieving tumour-specific control of cytokine expression.
Results: CRISPR HDR knock in of pro-inflammatory cytokines such as IL-12 and IL-2 into *NR4A2* and *RGS16* promoters supported the delivery of cytokines directly to the tumour site, leading to enhanced anti-tumour efficacy and long-term survival of mice in both syngeneic and xenogeneic models. This was concomitant with improved CAR T cell polyfunctionality, activation of endogenous anti-tumour immunity, a favourable safety profile and was applicable using CAR T cells from patients. Furthermore, with the aim to provide an even greater safety profile for this technology, this CRISPR HDR KI method was applied to tumour neoantigen specific TCR-T cells. These TCR-T cells induce T cell activation, produce pro-inflammatory cytokines upon T cell activation, and eliminate HLA-matched KRAS G12D expressing tumour cells.
Conclusion: CRISPR HDR enables the generation of armoured CAR T and TCR-T cells with tumour-restricted cytokine secretion. This is superior to analogous strategies currently used clinically such as artificial NFAT-based promoter systems.

Roquin is an RNA-binding protein that regulates the decay of mRNAs, many of which are proinflammatory targets. Expression of Roquin-1 and Roquin-2 proteins is crucial for T cell homeostasis and for the prevention of autoimmunity. Inactivation of Roquin-1/2 leads to spontaneous T cell activation and augments adoptive T cell functions in preclinical tumor models. During T cell activation, Roquin-1 and Roquin-2 undergo cleavage by the paracaspase MALT1, resulting in transient loss of function and subsequent derepression of various targets. Yet, the functional repercussions of Roquin cleavage on CD8+ T cells and CAR T cells remain inadequately understood.
To investigate the importance of Roquin cleavage, we engineered mice harboring MALT1 insensitive alleles of Roquin-1 and Roquin-2, termed "Double Mins" or “dMins”, to prevent cleavage events. Additionally, we developed a novel monoclonal antibody specific for the amino-terminal fragment of MALT1-cleaved human and mouse Roquin proteins.
CD8+ T cells from dMins/dMins mice displayed substantial impairments in T cell receptor (TCR) and co-stimulation induced activation, proliferation, and mTOR/S6 phosphorylation, alongside a markedly reduced production of Tumor Necrosis Factor-alpha (TNF-alpha). Investigation of Roquin cleavage in human and mouse T cells and CAR T cells revealed a correlation between Roquin cleavage and TCR strength, as well as enhanced effector functions. Notably, we demonstrate for the first time that Roquin cleavage regulates T cell-mediated killing of tumor cells *in vitro* and *in vivo*.
Taken together, this study unveils the significance of Roquin cleavage as a critical checkpoint in effectively controlling tumor growth and broadens our understanding of how to improve adoptive T cell therapy.

Learning the effect of CAR T cell design on single cell distributions

Alice Driessen[1;2], Rocio Castellanos Rueda[2], Sai Reddy[2], Marianna Rapsomaniki[3;4]
[1]IBM Research, Rüschlikon, Switzerland; *[2]ETH Zürich, Basel, Switzerland*; *[3]UNIL, Lausanne, Switzerland*; *[4]CHUV, Lausanne, Switzerland*

Introduction: Chimeric antigen receptor (CAR) T cells are a promising approach in cancer immunotherapy. Their safety, efficacy and functionality depend on the design of the CAR, which is a synthetic receptor that contains up to three intracellular signalling domains derived from a range of cellular signalling pathways. Due to its modular design and the multitude of possible domains, there is a vast combinatorial space of CAR designs. There are ongoing efforts to improve CAR T cell safety and efficacy based on CAR designs. However, testing the effect of each CAR design experimentally is resource and labour intensive, and not feasible beyond a few hundred combinations. Preliminary efforts on leveraging machine learning for CAR design have emerged, which focus on predicting bulk readouts. However, the underlying cell-to-cell heterogeneity is not considered.
Purpose: We aim to use single-cell multi-omic profiling and machine learning to model the effect and associated heterogeneity of CAR design on stimulating T cell states.
Methods: We developed a library of 30 CAR designs using combinations of five different intracellular domains. We also include two control designs, one that only contains the CD3zeta domain, and one without any signalling domains. CAR T cells were generated from two donors and characterised by single-cell CITE-sequencing at three timepoints in a 12-day repeated antigen stimulation (RAS). We used machine learning to map a single cell population of control cells to a population of cells expressing a CAR variant.
Results: We found that the major sources of heterogeneity are the donor, the time spent in RAS, and the cell state. CAR design affected the relative abundances of T cell states but CAR-related gene expression patterns where too subtle to identify. We show preliminary encouraging results on mapping single-cell profiles from the control to the CAR design populations, capturing the cell state distribution of the CAR population. Additionally, we predict the T cell state composition for unseen combinations of domains.
Conclusion: In the future, we aim to extend our method to unseen domains, which would give insights into the cell states associated with new CAR designs and guide CAR T cell therapy.

Microfluidic approach to study T and CAR-T confined and 3D cell migration

Jack Zhang Zhou[1], Carmen Oñate Salafranca[2;3], Nieves Movilla Meno[1;4], Maria José Gomez-Benito[1;4], Pedro Enrique Guerrero[4;5], Julian Pardo Jimeno[2;3], Jose Manuel García-Aznar[1;4]
[1]Department of Mechanical Engineering, University of Zaragoza, zaragoza, Spain; *[2]Faculty of Medicine, University of Zaragoza/IIS Aragon, Zaragoza, Spain*; *[3]CIBER of Infectious diseases, IS Carlos III, Madrid, Spain*; *[4]Instituto de Investigación en Ingeniería de Aragón (I3A), zaragoza, Spain*; *[5]Department of Biochemistry and Molecular and Cellular Biology, zaragoza, Spain*

Purpose: The immune system plays a decisive role in the defence against pathogens and aberrant cells, as tumoral cells. Nevertheless, the collective immune surveillance against solid tumours appears to be rather ineffective overall (Gonzalez et al., 2018). This lack of effectiveness is comprised by the physical barriers to infiltration and the active suppression by the tumour, resulting in poor migration (White et al., 2022). To overcome this limitation, it is essential to characterise this mechanism in physio-pathologically relevant scenarios to decipher the immune response.
Methods: In this context, we have developed novel microfluidic-based approaches that recreate the biomechanical aspects of solid tumours (Juste-Lanas et al., 2022; Movilla et al., 2022). Two distinct microfluidic geometries were used: one of them based on a central chamber which allowed hydrogel polymerization for 3D-migration (Hervas-Raluy et al., 2023), while the other one on microstructures of confined channels with varying widths (Paul et al., 2016). The microfluidic platforms were fabricated with polydimethylsiloxane (PDMS) due to its many benefits, including biocompatibility, transparency, flexibility and gas permeability. Then, same-donor T or CAR-T cells were seeded on the microchips, visualised via time-lapse microscopy and the obtained images were processed using ImageJ and Matlab to quantify cell migration.
Results: We found that T cells confined velocity is microchannel width-independent, while CAR-T cells show a great reduction in the highest confinement degree. Additionally, both types of immune cells display higher velocity under confinement compared to 3D migration.
Conclusion: These results highlight that CAR-T cell migration behaviour differs from T cells under confinement and that biomechanical cues, such as confinement, affect the correct infiltration of immune cells in solid tumours. As potential applications, our methodology will not only enhance the characterisation of immune cell migration but also enable the prediction of infiltration efficacy in patients. Additionally, it will facilitate the study of gene expression implicated in the decrement observed in CAR-T migration within confinement microchannels, paving the way to enhance immunotherapy targeting solid tumours. This work was supported by the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation programme (ICoMICS grant agreement No 101018587).

IL-1R8 acts as an immune checkpoint in CD8+ T cells, limiting cytokine-induced anti-tumor immune responses

Domenico Supino[1], Roberto Garuti[2], Andrea Mariancini[2], Chiara Perucchini[3], Silvia Carnevale[1], Andrea Ponzetta[4], Federico Simone Colombo[5], Elena Magrini[1], Anna Rigatelli[1], Luna Cordeiro Minute[2], Sarah Mapelli[1], Martina Molgora[6], Francesco Scavello[1], Irene Di Ceglie[1], Giovanni Pezone[1], Laura Falcone[3], Monica Casucci[3], Enrico Lugli[1], Sebastien Jaillon[1;2], Alberto Mantovani[1;2;7], Cecilia Garlanda[1;2]
[1]IRCCS Humanitas Research Hospital, Milan, Italy; *[2]Humanitas University, Pieve Emanuele*; *[3]IRCCS San Raffaele Scientific Institute, Milan, Italy*; *[4]Karolinska University Hospital, Stockholm, Sweden*; *[5]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy*; *[6]Washington University School of Medicine, St. Louis, United States*; *[7]Queen Mary University of London, London, United Kingdom*

Purpose: IL-1R8 is an atypical Interleukin-1 receptor (ILR) family member that controls inflammation by dampening ILR and Toll-like receptor (TLR) downstream pathways. Studies conducted on IL-1R8-deficient NK cells highlighted its pivotal role as immune checkpoint and negative regulator of IL-18-dependent activation. In particular, IL-1R8-deficiency has been shown to trigger NK cell-mediated immune surveillance against hematogenous metastasis, liver cancer and viral dissemination. Currently, genetic and pharmacological targeting of ILR and IL-18 are under investigation to improve $CD8^+$ T cell-based immunotherapy. The relevance of IL-1R8 in mitigating IL-18-driven activation and, conversely, the pathways instigated by the IL-1R8 loss-of-function in T lymphocytes are still elusive.
Methods: Combing transcriptomic analysis, high dimension flow cytometry, genetic silencing/inhibition, and *in vivo* models, we investigated IL-1R8 expression by $CD8^+$ T cells and its function in Tumor Infiltrating Lymphocytes (TILs).
Results: IL-1R8-deficiency led to anti-tumor immune resistance against colon carcinoma and fibrosarcoma by enhancing $CD8^+$ TIL fitness, synergizing with the immune checkpoint inhibitor anti-PD-1. TILs exhibited accelerated maturation\proliferation kinetic, induction of IL-2R complex and increased tumoricidal potential independently of antigen presenting cells (APCs). Mechanistically, we found that IL-1R8 controlled IL-18-mediated Type-1 polarization by affecting the Transcription Factor (TF) T-bet and, in turn, the effector molecules Interferon-γ (IFNγ) and Granzyme B (GZMB) in both antigen-specific and polyclonal T cell responses. Unexpectedly, IL-1R8 further curtailed the IL-2/EOMES/IL-2R signaling axis, tuning cell-autonomous mechanisms sustained by autocrine IL-2 signaling. In human, we demonstrated that IL-1R8 is rapidly induced in early-mature precursors and the central memory stage of $CD8^+$ T cells in healthy donors and cancer patients. Finally, an original anti-human IL-1R8 inhibitor and CRISPR-Cas9 mediated IL-1R8 ablation potentiated both primary human T lymphocytes and CAR-T cells against B-cell lymphoma.
Conclusions: Overall, the study revealed a profound impact of IL-1R8 deficiency or blockade on $CD8^+$ T lymphocyte immunobiology, which promoted cytokine-induced responses and conferred superior anti-tumor potential. Thus, IL-1R8 is a promising and targetable immune checkpoint of both NK and $CD8^+$ T cells to be exploited for implementing cancer immunotherapy.

Investigating regulators of CXCL9 and CXCL10 expression to improve T cell infiltration and immunotherapy responses in solid tumors.

Emily Derrick[1;2], Phillip Darcy[1;2], Paul Beavis[1;2]
[1]*Peter MacCallum Cancer Centre, Melbourne, Australia*; [2]*University of Melbourne, Melbourne, Australia*

Purpose: Immune checkpoint blockade (ICB) has revolutionised the treatment of numerous cancer types, including melanoma and non-small cell lung carcinoma. ICB targets immune-inhibitory molecules on the surface of T cells, unleashing their anti-tumour potential. Despite ICB's success, a high frequency of patients fail to respond to this therapy. A key limiting factor to ICB responses is the number of T cells that infiltrate the tumour microenvironment. T cell infiltration in the context of ICB has been shown to be dependent on chemoattractant molecules CXCL9 and CXCL10. The expression of these chemokines is also predictive of a positive response to ICB across multiple cancer types, highlighting their importance in ICB efficacy. We have previously demonstrated that these chemokines are predominantly produced by intratumoral macrophages. Therefore, we aimed to identify genes that we could target to enhance CXCL9/10 production in macrophages as a strategy to improve T cell infiltration and ICB responses in solid tumors.
Methods: We performed whole-genome CRISPR/Cas9 screening on a macrophage cell line to identify regulators of CXCL9 and CXCL10. To screen for secreted factors, we utilised a CRISPR-HDR technique we have previously validated to generate a macrophage cell line that expressed GFP and BFP as a bona fide readout of CXCL9/10 production. This screen identified PTPN2 as a key negative regulator of both CXCL9 and CXCL10 production.
Results: PTPN2 deletion enhanced CXCL9/10 production by primary murine/human macrophages *in vitro*, confirming our screen results. With PTPN2 inhibitors currently in clinical trials, we sought to define how PTPN2 depletion in macrophages plays a role in anti-tumor immunity. Myeloid-specific depletion of PTPN2 *in vivo* improved ICB efficacy and delayed tumor growth in a murine breast cancer model. CXCL9 expression was elevated in both intratumoral macrophages and dendritic cells, and improved T cell infiltration was observed without an increase in T_{reg} numbers when treated with ICB.
Conclusion: This work has uncovered that PTPN2 has a role in limiting CXCL9/10 expression in myeloid cells, which subsequently limits anti-tumor immunity. Myeloid-specific PTPN2 depletion led to improved responses to ICB, providing rationale to combine PTPN2 inhibitors with ICB for patients that are refractory to treatment.

Interferon epsilon limits ovarian cancer metastasis via regulation of peritoneal immune cells

Nicole Campbell[1;2], Linden J. Gearing[1], Jodee Gould[1], Georgie Wray-McCann[1], Nicole de Weerd[1;2], Paul Hertzog[1;2]
[1]*Centre for Innate Immunity and Infectious Diseases, Hudson Institute of Medical Research, Melbourne, Australia*;
[2]*Department of Molecular and Translational Science, Monash University, Melbourne, Australia*

Interferon epsilon (IFNε) is a unique type I interferon which is constitutively expressed by the female reproductive tract (FRT) epithelium. High grade serous ovarian cancer (HGSOC) is a cancer of the FRT which frequently presents with extensive metastasis throughout the peritoneal cavity, and carries a 5-year survival rate of <40%. We have determined that IFNε is highly expressed by healthy Fallopian tube epithelial cells (the cell of origin of HGSOC), but is lost in HGSOC tumours. In the ID8 mouse model of ovarian cancer, IFNε$^{-/-}$ mice developed a greater number of metastases compared to controls. Moreover, treatment of mice with exogenous IFNε, but not IFNβ, significantly reduced peritoneal metastasis and disease scores [1].
Mechanistically, IFNε demonstrated intrinsic anti-tumour activities when applied to HGSOC tumour cells, including increased apoptosis and reduced proliferation. The role of extrinsic anti-tumour activity by IFNε was investigated using an IFN-insensitive IFNAR1$^{-/-}$ ID8 cell line. Mice were injected intraperitoneally with wild-type (WT) or IFNAR1$^{-/-}$ ID8 cells, and treated with PBS or IFNε for six weeks. Analysis of disease scores revealed that IFNε treatment effectively limited HGSOC metastasis and progression, with no loss of efficacy observed in mice bearing IFNAR1$^{-/-}$ tumours versus WT. Furthermore, IFNε treatment was associated with marked alterations in peritoneal immune cells. IFNε treatment reversed the infiltration of immunosuppressive immune cells and suppression of immune cell proliferation observed in PBS-treated mice. Moreover, IFNε-treated mice displayed a greater frequency of activated immune cells such as CD8^{+} T cells [1].
To further elucidate the immunological mechanism of action of IFNε in the peritoneal cavity, single-cell RNA sequencing was performed on peritoneal cells from PBS- and IFNε- treated tumour-bearing mice. Significant remodelling of the peritoneal macrophage populations by IFNε was observed, suggesting these cells may regulate the immune response to HGSOC in the peritoneal cavity. Together, these results demonstrate that IFNε effectively inhibits metastasis of HGSOC, mediated primarily through its activity on immune cells, and may have potential as a novel cancer immunotherapy.

Targeting IL1R2+ tumor-infiltrating regulatory T cells with an anti-IL1R2 nanobody construct induces a strong anti-tumor effect in combination with anti-PD1 therapy

Sana Arnouk[1;2], Daliya Kancheva[1;2], Helena Van Damme[1;2], Yvon Elkrim[1;2], Jolien Van Craenenbroeck[1;2], Els Lebegge[1;2], Timo De Groof[2], Aleksandar Murgaski[1;2], Emile Clappaert[1;2], Ayla Debraekeleer[1;2], Jan Brughmans[1;2], Mate Kiss[1;2], Louis Boon[3], Nadja Van Boxel[1], Cecile Vincke[1;2], Bruno Dombrecht[1], Catelijne Stortelers[1], Geert Raes[1;2], Damya Laoui[1;2], Jo Van Ginderachter[1;2]

Immune checkpoint blockade (ICB) has revolutionized cancer therapy. However, ICB still suffers from low response rates and disease hyper progression. Several pieces of evidence point towards the involvement of a strongly immune-suppressive cell population called tumor-infiltrating regulatory T cells (tiTregs) in these phenomena. Hence, targeting Tregs has high potential in cancer therapy, specifically in combination with ICB. However, peripheral Tregs are essential to maintain tolerance and immune homeostasis, therefore, the therapy needs to specifically target the tiTregs. This can be achieved by targeting a tiTreg-specific marker. Interleukin 1 receptor 2 (*IL1R2*) gene has been shown to be specifically upregulated by tiTreg. Hence, we verified that IL1R2 protein is absent from peripheral Tregs and from anti-tumoral immune cells infiltrating mouse tumor models. We also showed that IL1R2 marks a highly activated and suppressive population of tiTregs. However, a deficiency of this receptor, either in the whole body or specifically within Treg, did not affect tumor characteristics nor tiTreg infiltration or phenotype, suggesting that this receptor is not functionally important on these cells in a cancer setting. Next, we generated nanobodies (Nbs), the smallest naturally occurring antigen-binding fragments, against IL1R2 and functionalized them with the Fc region of mouse IgG2a, known for its capacity to mediate antibody-dependent cell-mediated cytotoxicity (ADCC). This construct could indeed successfully deplete a proportion of the tiTregs which, in combination with ICB, caused a significant delay in mammary tumor growth. Furthermore, we enhanced the efficacy of the Nb construct by introducing point mutations in the Fc region known to potentiate the ADCC activity. We showed that the combination of ICB with this potentiated construct was superior to the combination with the original construct, causing full regression of 60% of the mammary carcinoma tumors with maintenance of immunological memory against a later challenge with the same cancer cells.

Role of the atypical chemokine receptor ACKR2 in the immune response to tumors

Francesca Albano[1], Elisa Zaghen[1], Raffaella Bonecchi[1]
[1]*Humanitas University, Pieve Emanuele, Italy*

ACKR2 is an atypical chemokine receptor that negatively controls inflammation being able to bind and lead to degradation most inflammatory CC chemokines. Previous results indicate that genetic deletion of ACKR2 resulted in increased tumor growth in inflammation-driven models. On the contrary, ACKR2 KO mice are protected in metastatic models of melanoma and breast cancer. To better understand the relative contribution of the cell types expressing ACKR2 in metastasis protection, an inducible and conditional reporter knockout mouse was generated.
ACKR2 expressed by hematopoietic progenitor cells regulates their metabolism and genetic deletion of ACKR2 induces long-term functional reprogramming of neutrophil differentiation that protects against cancer.
ACKR2 is also selectively expressed by capillary endothelial cells in the lung and deletion of ACKR2 from these cells resulted in protection from melanoma metastasis with increased lung extravasation of T lymphocytes.
These results indicate that targeting ACKR2 may be an innovative therapeutic strategy to unleash long-term functional reprogramming of neutrophil differentiation toward an antitumoral state. In addition, targeting ACKR2 could improve lung metastasis immunotherapy by improving lung lymphocyte extravasation.

Targeting IL-38 triggers γδ T cell-dependent anti-tumor immunity

Priscila da Silva[1], Javier Mora[1;2;3], Svenja Wiechmann[4], Mateusz Putyrski[4], Javier Garcia-Pardo[4;5], Xin You[1], Aimo Kannt[4], Andreas Ernst[4;6], Bernhard Brüne[1;7;8], Andreas Weigert[1;7;8]
[1]Goethe University Frankfurt, Faculty of Medicine, Institute of Biochemistry I, Frankfurt, Germany; *[2]Faculty of Microbiology, University of Costa Rica, San José, Costa Rica*; *[3]Centro de Investigación en Cirugía y Cancer (CICICA), University of Costa Rica, San José, Costa Rica*; *[4]Fraunhofer Institute for Translational Medicine and Pharmacology (ITMP), Frankfurt, Germany*; *[5]Institut de Biotecnologia i de Biomedicina (IBB) and Departament de Bioquímica i Biologia Molecular, Universitat Autònoma de Barcelona, Barcelona, Spain*; *[6]Goethe University Frankfurt, Faculty of Medicine, Institute of Biochemistry II, Frankfurt, Germany*; *[7]Frankfurt Cancer Institute, Goethe University Frankfurt, Frankfurt, Germany*; *[8]German Cancer Consortium (DKTK), Frankfurt, Germany*

Purpose: The IL-1 family receptor antagonist IL-38 acts as a suppressor of auto-inflammation. Given the connection between auto-immunity and anti-tumor immunity, we wondered if targeting IL-38 would affect the anti-tumor immune response.
Methods: The transgenic PyMT mammary carcinoma model, which is suitable for identifying strong immunomodulators due to being immunologically cold, was employed to target IL-38 genetically or with a self-generated neutralizing antibody. Immune cell profile and localization were determined by flow cytometry and immunohistochemistry, respectively. Whole transcriptome RNA sequencing, gene expression analysis and *in vitro* functional assays were used for mechanistic studies.
Results: IL-38-deficient (KO) PyMT mice presented a markedly delayed tumor growth compared to WT mice, accompanied by increased cytotoxic T cell infiltrates, including CD8+ T cells and γδ T cells. This phenotype was recapitulated upon the treatment with IL-38-neutralizing antibodies, where antibody-treated mice showed a major decrease in tumor growth compared to IgG-control treated animals, accompanied by increased CD8+ T cell and γδ T cell infiltrates. Particularly, the IFN-γ-producing Vγ1 γδ T cell subset was increased by targeting IL-38. In a therapeutic model of chemoresistance, anti-IL-38 antibodies in combination with doxorubicin increased tumor control followed by increase in CD8+ T cells and γδ T cells as well. Importantly, the delayed growth of IL-38 tumors was abolished upon γδ-TCR blockade with antibodies, accompanied by a strong decrease in both, CD8+ T cells and the Vγ1 γδ T cell subset, indicating a crosstalk between both populations. While mechanistic studies revealed no direct cross-talk between CD8+ T cells and γδ T cells, we found that γδ T cells recruit conventional dendritic cells (cDC1) into IL-38 targeted tumor via the specific chemokine Xcl1, which subsequently activate CD8+ T cells via the Notch pathway. Accordingly, in human mammary carcinoma, IL-38 expression negatively correlates with patient survival as well as CD8+ T cell and γδ T cell infiltrates.
Conclusion: Taken together, these results provide evidence for a therapeutic potential of anti-IL-38 antibodies to activate anti-tumor immunity in mammary carcinoma.

Purpose: Actin dynamics control early T-cell receptor (TCR) signalling during T-cell activation. However, the precise regulation of initial actin rearrangements is not completely understood. Here, we have investigated the regulatory role of the phosphatase Slingshot-1 (SSH1) in the regulatory signaling pathways driving this process.
Methods: The distribution of SSH1 at the immunological synapse was studied in human CD4 T lymphocytes using live-cell imaging. Knockdown of SSH1 expression by CRISPR/Cas9-mediated genome editing in Jurkat T-cells or small interfering RNA (siRNA) in primary human CD4 T lymphocytes were used to analyse the TCR early signalling and CD3ε conformational change by western blot and pull-down, and the distribution of F-actin and integrins towards the immunological synapse by confocal microscopy. Total Internal Reflection Fluorescence Microscopy was used to study the dynamics of actin cytoskeleton during synaptic contacts and T-cell effector function was determined by CD69 and CD25 expression by flow cytometry and IL-2 secretion by ELISA.
Results: Our data show that SSH1 rapidly polarises to nascent cognate synaptic contacts and later relocalises to peripheral F-actin networks organised at the mature synapses. Knockdown of SSH1 expression revealed a regulatory role for SSH1 in CD3ε conformational change, enabling Nck binding and proper downstream signalling and immunological synapse organisation. TCR triggering induced the SSH1-mediated activation of actin dynamics through a mechanism mediated by Limk1 inactivation.
Conclusion: These data suggest that during early TCR activation, Limk1-dependent early F-actin rearrangements are regulated by SSH1 phosphatase. This pathway fine-tunes the initial conformational changes of the TCR, integrin organization, and proximal signaling events to properly organize the immunological synapse and T-cell effector function.

Human immune responses differ across individuals, with age, sex and genetics playing major roles in this diversity. However, the variables that drive such differences remain poorly defined. We quantified 13 cytokines after 12 immune stimulations (bacterial, fungal, viral), and tested their associations with 136 variables from the Case Report Forms of the healthy donors of the "Milieu Intérieur" cohort. Through multi-variate data analysis and integration, we identified three novel variables associated with cytokine secretion variability - Smoking, Body Mass Index (BMI) and Cytomegalovirus (CMV) latent infection - with effects comparable to those of age, sex and genetics. We observed short-term effects of smoking on innate immunity and a previously unappreciated long-term effect of smoking on adaptative immunity[1]. The short-term effects of smoking were associated with increased CXCL5 cytokine induction and CEACAM6, a soluble blood protein that is involved in inflammatory processes and has been proposed as a clinical biomarker for multiple cancers. The long-term effects of smoking were increased induction of IL2 and IL13 in smokers and past smokers, compared to non-smokers, that were associated with long-lived B and T cells and DNA methylation levels of specific genes that encode signal trans-activators or metabolism regulators.
To extend upon these findings, we are now reconstructing the transcriptional networks involved in immune response differences from analysis of RNA-seq data of 200 donors after immune stimulations. We are also performing a longitudinal analysis of cytokine induction for 413 of the original 1,000 individuals of the cohort, sampled 10 years later. The study of the evolution of immune responses over time, depending on changes and pathologies experienced by the donors should help us refine the effects of aging, smoking, BMI, CMV infection and their interactions, and has potential clinical implications for the risk of developing infections, cancers or autoimmune diseases.
This programme is managed by the Agence Nationale de la Recherche and benefit from support of the French government's Invest in the Future programme ANR-10-LABX-69-01.

Humoral and cellular immune responses typically co-exist during viral infections. However, there are instances where one response predominates, determining the primary antiviral activity. For example, lymphocytic choriomeningitis virus (LCMV) infection elicits a pronounced cellular response, yet exhibits a suboptimal neutralizing antibody (nAb) response. This deficiency in nAb response hinders its clearance and facilitates persistent infection. Recent findings indicate that this preference for cellular immunity over humoral immunity is significantly regulated at the CD4+ T cell differentiation stage. Specifically, subcutaneous LCMV infection predominantly induces T helper 1 (TH1) differentiation, which augments cellular immunity, while largely neglecting T follicular helper (TFH) differentiation, a key driver of humoral immunity. Here, we investigated the mechanisms responsible for this inhibited TFH differentiation. We found that the TH1 cells induced by subcutaneous LCMV infection are heterogeneous. They encompass a terminally differentiated TH1 subset expressing Granzyme-B (GzmB) and a Tcf-1+ subset that retains the potential for TFH differentiation. While IL-12 appeared to be non-essential for this differentiation, T cell-derived IFN-γ facilitated the proliferation of the GzmB+ subset and inhibited the Tcf-1+ cells' progression into TFH. Consistently, inhibition of IFN-γ enabled robust TFH differentiation, leading to the formation of germinal centers and increased antibody production. Our study provides novel insights into the mechanisms inhibiting nAb production in response to specific viruses and offers a foundation for the development of advanced vaccine strategies.

Tlr7 bi-allelism defines a transcriptionally and functionally distinct B cell subset

Mélissa Nieucel[1], Charles-Henry Miquel[1], Léa Ferrayé[1], Anne-Laure Iscache[1], Magali Savignac[1], Julie Chaumeil[2], Jean-Charles Guéry[1]
[1]*Infinity, Toulouse, France*; [2]*Institut Cochin, Paris, France*

Evidence of sexual dimorphism in the immune response has been clearly established. Women develop a stronger immune response than men, giving them better protection against bacterial and viral infections, but this increased immunity makes them more susceptible to developing autoimmune pathologies such as systemic lupus erythematosus (SLE). While in women, one of the two X chromosomes is inactivated (XCI), some genes can escape XCI, leading to increased expression of these genes in female cells. Among them, the Toll-7 receptor (TLR7) encoding an endosomal receptor recognizing ssRNA from self and non-self, can escape X chromosome inactivation in human and murine female B cells. To address the phenotypic profile of B cells where Tlr7 evades X silencing, we generated an original dual reporter mouse model in order to track *Tlr7* biallelic cells referred as BiA7 B cells in vivo. We will present evidence that BiA7 B cells represent a functionally distinct subset of B cells. BiA7 B cell overexpressed various FO B cell markers, and are poised for immediate differentiation into antibody secreting cells and PC upon in vitro stimulation. To address the contribution of BCR- and TLR-signaling in the development of this distinct B cell populations, we generated MD4 dual reporter mouse model, expressing a monoclonal BCR against hen egg lysozyme. We also generated Tlr7 dual reporter mice on a Myd88-deficient background. Our data demonstrate that BCR-signaling is dispensable for BiA7 B cells development and function. The contribution of Myd88-signaling is under investigation. BiA7 B cells can be easily generated using an in vitro iGB cell expansion culture system. We will present data regarding the contribution of parental imprinting effects and epigenetic chromatin marks on the development of BiA7 B cells as well as the role of cytokines. Together our results provide evidence for the existence of a sub-population of B lymphocytes with biallelic expression of Tlr7 in female cells, poised for a rapid activation and differentiation into ASC and PC. The existence of BiA7 B cells could be an advantage by being preferentially selected during antiviral responses, but could also contribute to the development of B cell systemic autoimmunity.

Centromeric AA haplotype and -21 dimorphism in HLA-B T/T as powerful predictors for recurrent pregnancy loss

Raquel Gil Laborda[1], Nabil Subhi-Issa[1], María Guzmán-Fulgencio[1], Juliana Ochoa Grullon[1], Silvia Sanchez Ramon[1], Miguel Fernandez Arquero[1]
[1]*Hospital clinico san carlos, Madrid, Spain*

The role of NK cell alloreactivity in pregnancy outcomes remains uncertain. It is well-established that NK cells become activated through interactions with inhibitory KIR (iKIR) and NKG2A receptors, which recognize specific ligands on fetal cells. NKG2A specifically recognizes HLA-E bound by recipient HLA class I leader peptides, a process requiring methionine (M) at position 21 of the leader sequence. A rs1050458C/T dimorphism results in approximately 40% of individuals expressing at least one copy of 21 HLA-B (M/M or M/T), enabling ligand expression. We evaluated the impact of recipient HLA-B leader genotype (M+ versus M- (T/T)) and HLA-C group iKIR missing ligand (ML, C1C1/C2C2) on patients with recurrent pregnancy loss and compared them with a control group.
We conducted our study in a cohort of 77 patients with RPL and 75 healthy women, from whom we performed analysis of KIR, HLA-B, and HLA-C genes using peripheral blood samples and luminex technology. Our results showed that, as previously observed, the centromeric haplotype AA is increased in the RPL group compared to the control group, with a difference of 24%, with a p-value of 0.0056. Furthermore, upon analyzing the results through the iKIR missing ligand hypothesis, we observed that patients had significantly fewer KIR2DL1 ligand absences, with a p-value of 0.018. Lastly, we analyzed the dimorphism, and the results show that the -21 (T/T) dimorphism is significantly increased in the RPL group compared to controls, with a p-value of 0.0031. Additionally, when combining the Cen AA haplotype with the B dimorphism, we see that CenAA-T/T is much more prevalent in the RPL group with a p-value of 0.0005. Therefore, we confirm that the CenAA haplotype is a good marker for the diagnosis of patients with RPL, and furthermore, HLA-B could be a promising biomarker, as the results are conclusive, but we would need to increase the number of patients to confirm it.

Effect of rs2204985 polymorphism on human thymic T cell differenciation at the single cell level

Camille Kergaravat[1], Agata Cieslak[2;3], Abad Flores José David[4], Salvatore Spicuglia[4], Vahid Asnafi[2;3], Emmanuel Clave[1], Antoine Toubert[1]
[1]Université Paris Cité, IRSL, INSERM UMRS1160, Paris, France; *[2]Université Paris Cité, CNRS, INSERM U1151, INEM, Paris, France*; *[3]Laboratoire d'Onco-Hematologie, Hopital Necker, AP-HP, Paris, France*; *[4]Université Aix-Marseille, TAGC, INSERM UMR1090, Marseille, France*

Purpose: We previously described an association between human thymopoiesis and a common variant located within the TCRA/D T-cell receptor locus, the rs2204985 SNP, with the G allele associated with higher thymic output. This variant has recently been shown to be linked to the clinical outcome of hematopoietic stem cell transplantation, as well as to response to COVID-19. Our aim is therefore to understand how this genetic variation influences the thymocyte differentiation process and has a significant impact on human health.
Methods: In order to capture the transcriptional changes through thymopoiesis, we perfomed scRNA-Seq analysis on 8 postnatal thymi ranging from 1 week to 10 months, including 4 samples of each homozygous genotype (AA or GG). To analyze the entire thymic population, we included total thymic samples as well as sorted cells from the earliest and rarest subpopulations that were obtained by flow-sorting using CD34, CD38 and CD1a markers. From these populations, 16 scRNA-seq libraries for gene expression profiling were generated using the 10X Genomics platform.
Results: We obtained a total of 37936 cells that we visualized using the uniform manifold approximation and projection. Cell clusters were annotated into 19 different cell types representing the whole range of human thymocyte differentiation from thymus seeding progenitors to single positive cells.
CD34+ cells mapped to distinct clusters depending on their polymorphism status highlighting transcriptional differences. By differential analysis of gene expression according to the variant within CD34+ cells, we observed differences in expression of genes involved in Notch signaling (*NOTCH1, NOTCH3, RBJP*), in Notch target genes (*HES4*, *PTCRA*, *IL7R*) as well as in genes involved in stemness maintenance (*HES1, CD44, MEFC2*), cell proliferation and metabolism. These results suggest that progenitors initiate T cell specification differently depending on their genotype. To investigate these results further, SNP-dependant analysis of proliferation and recombination rate, β-selection and trajectories toward αβ or γδ lineages will be performed.
Conclusion: In summary, our findings support a SNP rs2204985-related "fine tuning" of thymopoiesis in the human postnatal thymus. Further exploration of the transcriptional networks and the epigenetics marks linked to the polymorphism will provide new insights in human thymopoiesis.

The memory phenotypic immunity of tumor-draining lymph nodes in ovarian carcinoma patients

Nachi Nathan[1], Philipp Paparoditis[1], Idan Milo[1], Leeat Keren[1], Adva Levy-Barda[2], Natalia Yanichkin[2], Oded Raban[2], Ram Eitan[2], Ziv Shulman[1]
[1]Weizmann Institue of Science, Rehovot, Israel; *[2]Rabin Medical Center, Petah Tikva, Israel*

The lymphatic system is strategically positioned at dedicated sites throughout the body to facilitate a rapid and efficient immune response. However, their involvement by solid tumors in the peripheral tissues is a hallmark of cancer and a strong indicator of poor prognosis. Emerging evidence suggests that tumor-specific humoral immune responses occur within the tumor tissue. Nonetheless, the contribution of tumor-draining lymph nodes (TDLNs) to this process in humans is not yet clear. Here, we studied TDLNs derived from high-grade serous ovarian carcinoma (HGSOC) patients. Comparatively, we included inflamed lymph nodes from IBD patients to underscore the TDLNs' unique state in cancer. We discovered that TDLNs are disrupted and inactive, hosting a deposit of memory lymphocytes that show tumor-binding potential. Through single-cell sequencing and multiplex imaging techniques, we observed that TDLNs in HGSOC patients lack germinal center structures and demonstrate limited T and B cell clonal expansion. Yet, the B cell phylogeny has shown extensive class-switch recombination and somatic hypermutation, indicating past tumor immune responses. Additionally, our research identified a specific population of macrophages that appear to hinder the formation of germinal centers. The lack of activity in TDLNs may explain the ineffectiveness of immune checkpoint blockade therapies in HGSOC. These results point to a novel population of TDLN-resident tumor-specific memory B cells, suggesting that their reactivation in the clinic could benefit HGSOC patients.

Prior Acute Influenza Infection Drives a Transient Pro-Tumoural State in the Lungs

Ryan Devlin[1], Chiara Pirillo[1], Jack McCowan[1], Amy Shergold[1], Alberto Bravo-Blas[1], Sarwah Al-Khalidi[1], Leo Carlin[1], Ed Roberts[1]
[1]*CRUK Scotland Institute, Glasgow, United Kingdom*

Following acute infection, an anti-viral state exists in the immune system that can impact the course of subsequent infections. Since this anti-viral state is broad, we hypothesised that prior infections could alter immune responses to tumours.
Mice were infected with influenza A virus (IAV) and, at 28-days post-infection with viral clearance, the lung and draining lymph node showed persistent changes in composition and organisation. Surprisingly at this point mice developed more lung tumours in models of both primary and metastatic disease. The same result was observed after infection with influenza B virus or intranasal challenge with lipopolysaccharide suggesting that ongoing post- viral inflammation may generate a pro-tumoural state.
To address this, mice were treated with anti-inflammatories during IAV infection, which not only prevented the subsequent increase in tumour burden but led to a reduction. This decrease suggests an underlying anti-tumoural mechanism in addition to the pro-tumoural inflammation. We therefore looked longer term following flu to where inflammation had fully resolved and found that when tumours were induced at 90-days post IAV infection, tumour burden was reduced.
At this later time point there was an increase in type 1 conventional dendritic cells (cDC1). To determine whether this increase was sufficient to replicate the protection from tumour induction mice were treated with FLT3L prior to tumour challenge. This treatment increased cDC1 numbers and led to a highly significant decrease in metastatic seeding.
Acute IAV infection drastically reshapes the lung and lymph nodes, driving a temporary post-viral inflammation which is pro-tumoural. Later this resolves, unmasking an anti-tumoural effect potentially related to persistently increased cDC1 and T-cell priming. We now aim to investigate the importance of cDC and T cell immunity in protecting from subsequent cancer development and to explore FLT3L as an anti-metastatic therapeutic.

Dissecting macrophage diversity in cancer to unveil distinct contributions to therapeutic resistance

Marta Pandini[1], Divya Mishra[2], Marta Iovino[2], Giulia Marelli[2], Federica Portale[2], Roberta Carriero[2], Desiree Giuliano[2], Gianluca Basso[2], Gabriele De Simone[2], Paolo Kunderfranco[2], Piergiuseppe Colombo[1], Marcello Manfredi[3], Paolo Casale[1], Massimo Lazzeri[4], Diletta Di Mitri[1;2]

Background and rationale: The efficacy of immune checkpoint inhibitors (ICIs) in cancer relies on the presence of an effective T cell-mediated immune response. However, multiple features of the tumor microenvironment constrain T cells activation thus contributing to therapy resistance. Importantly, emerging studies have shown that ICIs efficacy is in part dependent on tumor associated macrophages (TAMs). On this line, we recently discovered that lipid-laden macrophages (LLMs) infiltrate tumors, including prostate cancer, ovarian cancer and melanoma.
Methods: Here we applied single cell RNA sequencing to the immune infiltrate of prostate cancer and melanoma. We then implemented a multiparametric flow cytometry strategy to confirm transcriptional findings. In vivo, we set up transgenic and transplantable models of prostate cancer and melanoma to investigate the immune composition of tumors. Finally, we isolated tumor infiltrating lipid-loaded macrophages and we performed bulk RNA sequencing and mass spectrometry to dissect the transcriptional features and the proteome profile of LLMs.
Results: We demonstrated that the abundance of LLMs correlates with tumor size and we discovered that LLMs promote cancer progression in association with immune evasion and poor response to chemotherapy. Lipid intake in TAMs is partially dependent on scavenging by MARCO and MARCO neutralization in vivo deplete LLMs both in prostate cancer and melanoma models. Mechanistically, we also found that TAMs display a dysfunctional autophagy provoked by a deregulation of the TFEB-dependent CLEAR signalling pathway that is responsible of lipid accumulation. Finally, we demonstrated that LLMs infiltrate melanoma and ovarian tumors in patients that are refractory to ICIs. Importantly, this enrichment is even observed prior to treatment initiation, suggesting that LLMs may be predictive of ICIs response.
Conclusions: Together, our findings identify a heterotypic crosstalk involving LLMs and cancer cells that drives tumor aggressiveness and is implicated in resistance to immunotherapies.

Role of JNK in chronic intestinal inflammation and its relationship with tumor development

Benigno Rivas-Pardo[1], Beatriz Martín Adrados[1], Raquel González-García[1], Chaobo Chen[1], Adela Solsona-García[1], Elena Martínez-Zamorano[2], Yolanda Campos-Martin[2], Manuel María Gómez del Moral[3], Francisco Javier Cubero[1], Eduardo Martínez-Naves[1]
[1]*Department of Immunology, Ophthalmology & ENT, Complutense University School of Medicine, Madrid, Spain*; [2]*Department of Pathology, Hospital Universitario de Toledo, Toledo, Spain*; [3]*Department of Cell Biology, Complutense University School of Medicine, Madrid, Spain*

Purpose: The c-Jun N-terminal kinases (JNKs) are conserved proteins which regulate various cellular responses, including cell proliferation, differentiation or survival. Hyperactivation of the JNK signaling is observed in many inflammatory diseases, contributing to pathology through the regulation of multiple inflammation-related genes. The objective of this work was to identify specific mechanisms of the JNK signaling pathway involved in intestinal chronic inflammation and its relationship with tumor development.
Methods: Mice with conditional deletion of *Jnk1* and *Jnk2* in the intestinal epithelial cells ($JNK^{\Delta IEC}$) were generated by crossing $Jnk1/2^{flox/flox}$-mice with VillinCre-mice. We analyzed small and large intestine samples using histological techniques, flow cytometry, RNAseq and Western Blot. Intestinal permeability was assesed *in vivo* using FITC-Dextran. Moreover, we induced colitis-associated colorectal carcinoma (CRC) using AOM/DSS method.
Results: Samples from 10, 52, and 72 weeks old $JNK^{\Delta IEC}$ mice were analysed. Young $JNK^{\Delta IEC}$ mice developed mild spontaneous inflammation in the duodenum and colon, associated with an increase in the percentage of intraepithelial γδT lymphocytes and NKG2D-expressing γδT lymphocytes, NK cells, and NKT cells. Intestinal permeability and microbiota-epithelium contact were also increased. In 52-week-old mice, inflammation progressed to high-grade epithelial dysplasia with cellular infiltrates in the duodenum, culminating in spontaneous duodenal tumor formation by 72 weeks. Transcriptomic analysis revealed enrichment of the complement pathway in duodenal samples. C3-protein expression was restricted to intestinal crypts in healthy tissues, while it was expressed throughout tumor tissues. Colon samples exhibited a dramatic downregulation of defensins genes. Additionally, increased apoptosis, unchanged proliferation, and elevated levels of non-phosphorylated RIPK1, implicated in cell survival, were observed in the duodenum of $JNK^{\Delta IEC}$ mice. Furthermore, $JNK^{\Delta IEC}$ mice were more susceptible to CRC than control mice, developing a greater number of tumors with a more aggressive histopathology.
Conclusion: The deletion of *Jnk1* and *Jnk2* in IECs is associated with a clear pro-inflammatory and pro-tumor phenotype. The complement system, highly expressed in tumor tissues, may play a crucial role in this process, alongside dysregulated death-survival mechanisms.

Deciphering the myeloid cell landscape of neuroblastoma

Javiera Villar[1], Claudia Pasqualini[1;2], Margaux Gardet[1], Marco Moreira[1], Kevin Mulder[1], Dominique VALTEAU[2], Veronique MINARD[2], Florent GINHOUX[1]
[1]Gustave Roussy, INSERM U1015 - Paris Saclay, Villejuif, France; *[2]Gustave Roussy, Department of Pediatric and Adolescent Oncology, Villejuif, France*

Neuroblastoma (NB), a neoplasm of the sympathetic nervous system, is the most common solid extra-cranial tumor of infancy being located mostly in the adrenal glands. Its prognosis is extremely variable depending on disease features. High risk disease is associated with age (>18 months), metastatic stage and *MYC* amplification. Even though chemo and immune therapy are used as treatment, long-term survival is still poor and around half of all patients will relapse and die. Hence, a better understanding of its biology is urgently needed to develop new drugs that will improve long-term survival. Over the last decade, the presence of myeloid cells has been correlated with adverse outcome in several cancers, largely attributed to their suppression of T- and NK- cell mediated immune response. However, most of the immune profiling studies in NB have been performed by techniques that do not allow a comprehensive analysis of myeloid cell heterogeneity. Here, we integrated 9 single cell RNAseq dataset of biopsies from more than 50 patients and 10 fetal adrenal glands, and compared with in-house spatial and flow cytometry data. We observed the recruitment of monocytes and their differentiation to *TREM2-SPP1+* macrophages as it happens in non-fetal adult cancers. *TREM2+* macrophages as well as *IL1B+* monocytes were more abundant in patients of high-risk NB. Moreover, we observed the recruitment of conventional dendritic cells, which are less abundant in high-risk disease. Together this data suggests that high-risk NB are characterized by the inability to mount an efficient immune response against the tumor. Our study provides a deep cartography of the immune composition of NB environment with putative underlying mechanisms of immune escape.

Tissue-resident macrophages and circulating monocytes might contribute to bacterial infection susceptibility of lung cancer patients

Francesco Palestra[1], Gina Memoli[1], Anne Lise Ferrara[1], Leonardo Cristinziano[1], Noemi Maria Giorgiano[2], Alfornso Fiorelli[2], Stefania Loffredo[1;3]

[2]*Translational Medical and Surgical Science, University of Campania Luigi Vanvitelli, Naples, Italy, Naples, Italy*;
[3]*Institute of Experimental Endocrinology and Oncology (IEOS), National Research Council, 80131 Naples, Italy, Naples, Italy*

Background: Lung cancer (LC) remains a significant global health challenge, with a high mortality rate and limited treatment options. LC patients are more susceptible to infections due to their immune system, lung damage, comorbidities, and potential immunosuppressive treatments. *Staphylococcus aureus* (*SA*), *Streptococcus pneumoniae* (*SP*), and *Pseudomonas aeruginosa* (*PA*) are just some of the pathogens involved in pneumonia development and in infectious complications in cancer patients. Considering that human lung macrophages (HLMs) are the most abundant immune cells in the lung and that hypoxia is the most common microenvironment feature of LC tissue, the aim of this study was to investigate the effect of *SA*, *PA*, and *SP* infection on HLMs under hypoxic and normoxic conditions. Considering the impossibility to isolate HLMs from healthy donors (HDs), we also evaluated the effect of *SA*, *PA*, and *SP* on monocytes, circulating progenitors of macrophages, of patients with LC compared to HDs.
Methods: HLMs were isolated from tissue of patients undergoing lung resection and were incubated at different times and with different concentrations of heat-killed *SA*, *PA*, and *SP* under hypoxic and normoxic conditions. At the end of the experiments, we evaluated cytokine and ROS production and chemiotaxis. In addition, monocytes of LC patients and HDs were stimulated with HK-bacteria and cytokine release was measured in supernatants.
Results: HK-bacteria induced IL-6, IL-1β, TNF-α, and ROS production from HLMs after 6 h of incubation. Furthermore, HK-bacteria promoted chemiotaxis of HLMs. The effect of HK-bacteria on cytokine release from HLMs was stronger under hypoxic condition. Monocytes of LC patients displayed a higher pro-inflammatory response to HK-bacteria compared to HD monocytes.
Conclusion: HLMs and monocytes seems to contribute to the susceptibility and outcomes of infections in LC patients. The hyperactivation of these immune cells in response to pathogens underscores the intricate interplay between the immune system and LC progression. Further research is essential to elucidate the mechanisms driving the dysregulated immune responses in LC patients.

Prevotella timonensis enhances HIV-1 transmission by primary human blood dendritic cells

Marleen Y. van Smoorenburg[1;2], John L. van Hamme[1;2], Ester B.M. Remmerswaal[1;2], Julia L. Nerwinska[1;2], Celia Segui Perez[3], Karin Strijbis[3], Teunis B.H. Geijtenbeek[1;2]
[1]Amsterdam UMC, location University of Amsterdam, Department of Experimental Immunology, Amsterdam, Netherlands; *[2]Amsterdam institute for Immunology and Infectious Diseases, Amsterdam, Netherlands*; *[3]Department of Biomolecular Health Sciences, Division Infectious Diseases and Immunology, Faculty of Veterinary Medicine, University of Utrecht, Utrecht, Netherlands*

HIV-1 remains a serious global health problem with many newly acquired infections affecting young women and girls in sub-Saharan Africa. The main route of HIV-1 infection is via mucosal surfaces in the genital tract during sexual intercourse. Alterations in the vaginal microbiota enhance susceptibility to HIV-1 infection however, underlying molecular mechanisms remain largely unknown. Here, we investigated the role of vaginal dysbiosis associated bacteria in altering HIV-1 uptake and transmission by dendritic cell (DC) subsets. *Prevotella timonensis,* but not other microbiota, enhanced uptake of different HIV-1 strains in monocyte-derived DCs. Notably, *P. timonensis*-enhanced uptake seems specific for viruses as *P. timonensis* enhanced cellular uptake of different viruses, but not other antigens or pathogens, such as fungi or bacteria. Furthermore, *P. timonensis* enhanced HIV-1 uptake over time and this process is independent of cellular HIV-1 capture and entry (co-)receptors. In addition, HIV-1 localises to tetraspanin-positive intracellular compartments, that are thought to be involved in HIV-1 transmission. Clathrin but not caveolin specific inhibitors blocked HIV-1 uptake in *P. timonensis* treated cells. Strikingly, analysis of primary blood DC subsets showed that *P. timonensis* not only enhanced HIV-1 uptake, but this also resulted in increased HIV-1 transmission to T cells. Besides increasing HIV-1 uptake and transmission, we observed that *P. timonensis* enhanced clustering of DCs with CD4 T cells, providing an additional mechanism enhancing HIV-1 transmission. *P. timonensis*-induced transmission could contribute to the enhanced HIV-1 susceptibility observed in women with vaginal dysbiosis. To conclude, our study provides new insights into the role DCs play in HIV-1 uptake and transmission after bacterial exposure, how bacteria modulate DCs to efficiently transmit HIV-1, and underscores the importance of examining the role of the microbiome in viral pathogenesis. Identification of underlying mechanisms and potential targets could facilitate the design of therapies to reduce the risk of HIV-1 acquisition and AIDS.

Cross-Reactive Immune Responses Following Concomitant Immunization Against Flaviviruses

David Wullimann[1], Mira Akber[1], John Tyler Sandberg[1], Marcus Buggert[1], Hans-Gustaf Ljunggren[1]
[1]*Karolinska Institutet, Stockholm, Sweden*

Flaviviruses are distributed all over the world and pose a significant global health burden. Infection with heterologous flaviviruses generate cross-reactive immune response but the clinical outcome of pre-existing immunity to subsequent flavivirus infection is still not fully understood. To prevent disease from flaviviruses, there are commercially available vaccines that work effectively against several flaviviruses, including against yellow fever virus (YFV), Japanese encephalitis virus (JEV) and tick-borne encephalitis virus (TBEV). Exposure to multiple flaviviruses is common, and co-administration of different vaccines against flaviviruses could be a useful strategy to generate broad, cross-reactive, immunity. However, safety and immunogenicity have until recently not been appropriately evaluated upon concomitant delivery of flavivirus vaccines.

To describe safety and immunogenicity upon co-vaccination with different combinations of flaviviruses at the same time, we studied adaptive memory B and T cell responses in a cohort of healthy individuals vaccinated with single or multiple immunizations against flaviviruses, as part of an open label, non-randomized clinical trial (EudraCT number: 2017-002137-32, Sandberg et al., 2023).

We assessed the extent of the cross-reactive responses from antigen-specific memory B-cells, CD4+ T-cells and CD8+ T-cells in both single and co-vaccinated participants against YFV, TBEV, JEV, in both temporal and qualitative measurements.

Our results from our clinical trial demonstrated that inactivated TBEV or JEV vaccines could be co-administered with the live attenuated YFV vaccine without an increased risk of adverse events. Furthermore, the development of neutralizing antibodies to the respective viruses was not diminished by co-vaccination. Regarding cross-reactivity, we observed a high degree of cross-reactive antibody responses across single and co-vaccinated participants. Furthermore, extensive cross-reactivity between different structural and non-structural antigens of flaviviruses was observed among antigen-specific T cells.

In conclusion, this study characterized cross-reactivity of adaptive immunity against multiple flaviviruses and the impact of heterologous immunization.

Longitudinal antibody and T cell response to Ebolavirus disease amongst a cohort of survivors in Guinea

Tom Tipton[1], Joseph Akoi Bore[2], Grace Hood[3], Saa sabass Temessadouno[2], Emmanuel Sovogui[2], Saa 4 Kamano[2], Thomas Strecker[4], Piet Maes[5], Yasmin Jiwa[3], Verena Kraehling[4], Joseph Timothy[6], Mandy Kader KONDE[7], N'Faly Magassouba[8], Kim Fornace[9], Miles Carroll[3]
[1]CHG, Oxford, United Kingdom; *[2]CRAM, Macenta, Guinea*; *[3]Oxford, Oxford, United Kingdom*; *[4]Philipps-Universität Marburg, Marburg, Germany*; *[5]KU Leuven, Leuven, Belgium*; *[6]LSHTM, London, United Kingdom*; *[7]CEFORPAG, Conakry, Guinea*; *[8]Guinean Ministry of health, Conakry, Guinea*; *[9]Singapore, Singapore, Singapore*

Purpose: 10 years ago, an epidemic of *Ebolavirus* disease in West Africa resulted in over 28,600 cases and 11,325 deaths. Since the conclusion of this outbreak in 2016 we have been working with survivor groups from the affected regions to better understand immunological memory following natural infection. Working with the local community, we recruited 117 survivors and received blood donations at regular intervals between 2015-2024.
Methods: Using processed serum, we measured the live virus neutralisation response to Zaire Ebolavirus as well as the antibody response to recombinant glycoprotein (GP) and inactivated virus. Using peripheral blood mononuclear cells (PBMC) we performed IFNγ ELISpot and in-depth B and T cell phenotyping assays.
Results: We found that the mean anti-GP and T cell responses have remained remarkably stable over time, although individual results varied greatly. Modelling of the longitudinal antibody data suggested a half-life of ~10years. The mean T cell response, as measured by ELISpot, was 305 spot-forming units, this again remained stable over time. We found the dominant antigen specific CD8+ polyfunctional T cells showed a stem cell memory like phenotype whereas the CD4+ T cells showed a central memory phenotype and that Ebola virus glycoprotein specific memory B cell are detectable in the blood in the years following infection.
Conclusion: The continuous high titre of neutralising antibodies and T cell response supports the concept of long-term protective immunity in survivors.

Single-cell profiling reveals signatures of protective immunity to human SARS-CoV-2 challenge

Lorenz Kretschmer[1], Kaylee Worlock[2], Lisa Dratva[1;3], Susan Jackson[4], Andrew Mawer[4], Krzysztof Polanski[1], Josephine Barnes[2], Masahiro Yoshida[2], Kerstin Meyer[1], Christopher Chiu[5], Helen McShane[4], Marko Nikolic[2], Sarah Teichmann[3]

Human SARS-CoV-2 infection induces widespread cellular and molecular changes in the immune landscapes of exposed individuals. However, the role of pre-exposure immune variation and temporal dynamics of immune responses following SARS-CoV-2 infection remain insufficiently understood. To systematically map immune responses to a defined exposure of SARS-CoV-2, we performed longitudinal single-cell sequencing of nasopharyngeal swabs and blood samples, collected in the context of a highly controlled human infection model (CHIM). We expand upon previous single cell analysis of SARS-CoV-2 challenge in seronegative individuals by including a cohort of seropositive volunteers, with prior history of community-acquired infections and vaccinations. This integrated single cell resource allowed us to resolve primary immune responses, immunological memory and recall responses at unprecedented detail. Longitudinal analysis revealed highly diverse response dynamics, with several temporally and tissue-restricted cell states generated during abortive, transient and sustained SARS-CoV-2 infections. We track the clonal dynamics of adaptive immune cells and showcase evidence for mucosal germinal centre reactions, reflecting a potential mechanism of regulating B cell immunity at the local site of infection. In addition, we introduce Cell2TCR, a computational tool for adaptive immune receptor profiling, which identified public SARS-CoV-2 specific TCR motifs in subsets of activated T cells. Notably, baseline immune profiling revealed adaptive immune signatures in seropositive individuals, who resisted SARS-CoV-2 infection despite exposure to a high viral challenge dose. Taken together, we leverage single cell multi-omics and analyse unique samples from SARS-CoV-2 CHIMs to delineate immune signatures and cellular dynamics associated with protective antiviral immunity.

NK cell derived IFN-γ mobilizes free fatty acids from adipose tissue to promote B cell activation during viral infection

Mia Krapic[1], Inga Kavazovic[1], Sabine Helmrath[2], Bojan Polić[1], Tamara Turk Wensveen[3;4], Felix Wensveen[1]
[1]Department of Histology and Embryology, Faculty of Medicine, University of Rijeka, Rijeka, Croatia; *[2]Institute for Experimental Hematology, Center for Translational Cancer Research (TranslaTUM), School of Medicine, Technical University Munich, Munich, Germany*; *[3]Center for Diabetes, Endocrinology and Cardiometabolism, Thalassotherapia Opatija, Opatija, Croatia*; *[4]Department of Internal Medicine, Faculty of Medicine, University of Rijeka, Rijeka, Croatia*

Viral infection typically causes us to lose fat, but how and why this happens is unclear. The immune system plays a major role in the regulation of adipose tissue biology during homeostasis and in context of metabolic disease. Here, we investigated whether immune cells also modulate adipocyte metabolism during viral infection. We find that visceral adipose tissue transiently decreases adiposity following viral infection. Upon pathogen encounter, adipocytes upregulate surface expression of ligands for the receptor NCR1 on NK cells, which drives their secretion of IFNγ. This cytokine directly stimulates adipocytes to downregulate PPARγ, which leads to their release of lipids in circulation, most notably of free fatty acids (FFAs). The FFA oleic acid stimulates the early activation of B cells by promoting oxidative phosphorylation. Oleic acid induced their expression of costimulatory B7 molecules and promoted their ability to prime CD8 T cells. Prevention of lipid release by adipocytes during infection impaired B cell activation, leading to reduced CD8 T cell responses and increased viral replication. Our findings uncover a new mechanism of metabolic adaptation to infection and provide a physiological background for the activation of immune cells in adipose tissue in context of metabolic disease.

β-glucan immunometabolic rewiring enhances anti-viral immunity via Interferon-dependant anti-viral training (IDAT)

Cian Horneck Johnston[1], Anna Ledwith[1], John McGrath[1], Hannah Prendeville[1], Jamie Murphy[1], Frederick Sheedy[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Background: Early viral containment through a proper, balanced immune response is critical to drive successful immunity and avoid disease. It is now emerging that yeast β-glucans can improve innate immune responses to bacterial infections and cancer through a process termed "Trained Immunity". However, little is known about impact on anti-viral innate immunity.
Results/Methods: Using a yeast-derived β-glucan whole glucan particle (WGP), we first confirmed the ability to drive classical training responses in bone-marrow derived macrophages (BMDMs) with enhanced pro-inflammatory cytokine production (TNF, IL-6). However, the production of anti-viral cytokines (IFN-β, CXCL10) was also enhanced, particularly after restimulation with viral ligands. RNA-sequencing of BMDMs from WGP-supplemented mice revealed upregulated Oxphos and TCA cycling pathways. Heightened rates of oxidative metabolism was confirmed by Extracellular-flux analysis of similar cells, while in-vitro inhibition of Oxphos was shown to impede the training effects induced by WGP, highlighting the importance of Oxphos for maintaining a trained phenotype. These metabolic changes coincided with increases in mitochondrial membrane potential and IFN-β production after WGP-stimulation. These changes coincided with increased expression of interferon stimulated genes (ISGs) in macrophages from WGP-treated mice, with notable increases in two key anti-viral transcription factors, Irf7 and Ikßkε. BMDMs from mice-fed WGP also increased type-I interferon responses in response to viral ligand stimulation, including IFN-β and CXCL-10. We also saw enhanced expression of the immune-response gene 1 (IRG1) as well as a reduction in the expression of fumarate hydratase (Fh). These results suggest that enhanced responsiveness of WGP-trained cells was driven by immunometabolic IFN-β signalling. Using IFNAR-deficient cells to investigate this, we observed that while IFN-β signalling did not affect immunometabolic responses or alter TNF production induced by LPS or PAM, it was vital for enhanced responsiveness to viral ligand stimulation. Similarly, IFNAR-deficient mice supplemented with WGP lost their ability to drive enhanced myelopoiesis showing the importance of this immunometabolic phenotype both in-vitro and in-vivo.
Conclusions: Therefore, we posit a novel anti-fungal signalling pathway that confers cross protection against viral infections, termed interferon-signalling dependant anti-viral training (IDAT). This novel training pathway coupled with classical trained immunity may hold potential to tackle future viral pandemics.

Homeostatic balance of GUT resident pTregs and tTregs plays a pivotal role in maintaining bone health under post-menopausal osteoporotic conditions

Rupesh Kumar Srivastava[1], Asha Bhardwaj[1], Leena Sapra[1]
[1]*All India Institute of Medical Sciences (AIIMS), New Delhi, India*

Introduction: Osteoporosis is a skeletal disease that leads to the deterioration of bone tissue. Recent research has shed light on the potential involvement of the intestinal immune system in regulating bone-health throughout the body. Gut-Tregs play an essential role in the modulation of immune responses and prevent various inflammatory manifestations. Understanding how Gut-Tregs contribute to bone homeostasis in post-menopausal osteoporosis (PMO) could pave way for novel therapeutic strategies targeting "immune-gut-bone" axis.
Aims and Objective: To investigate the role of gut-resident Tregs in regulating bone-health in preclinical model of post-menopausal osteoporosis (ovx).
Material Methods: Female C57BL/6 mice were divided into two groups: Sham (control) and ovx (bilateral removal of ovaries). At day 45, mice were euthanized, feces, intestine and bone-marrow were harvested for various analyses using SEM, μCT, FACS, HPLC and ELISA/CBA. *in vitro*, assays were conducted to investigate the role of SCFAs on the differentiation of gut-Treg cells and their effect on osteoclasts and osteoblasts.
Results: We observed a notable shift in the composition of gut-resident-Treg subsets in PMO, characterized by a decrease in peripherally-derived Tregs (pTregs) alongside an increase in thymus-derived Tregs (tTregs). Expanding on these findings, we delved into the potential role of pTregs in modulating bone remodeling using *in vitro* assays. Our results demonstrated that gut-resident pTregs exert a significant positive-influence on osteoblastogenesis while concurrently inhibiting-osteoclastogenesis, highlighting their regulatory impact on bone-remodeling. HPLC data further confirmed that ovx mice had significantly lower levels of SCFAs (acetate, propionate, and butyrate) in the feces as compared to the sham-group. Intriguingly, we observed that SCFAs play a crucial role in replenishing gut-resident Tregs via promoting the differentiation of pTregs. Interestingly, pTregs primed/treated with SCFAs exhibited significantly enhanced potency in suppressing osteoclastogenesis compared to unprimed pTregs, underscoring the therapeutic relevance of SCFAs in bolstering Treg-mediated regulation of bone metabolism.
Conclusion: Our findings altogether represent a groundbreaking revelation regarding the critical role played by the pivotal balance of pTregs and tTregs in the pathophysiology of osteoporosis. This discovery marks a significant advancement in highlighting a previously unrecognized frontier centered around the "pTreg-tTreg" cell axis, with huge clinical implications.

Type 1 diabetes (T1D) is a chronic autoimmune condition characterized by an imbalance between pathogenic CD4+ and CD8+ lymphocytes on one side and regulatory T cells (Treg) on the other. Activating Treg and/or tolerogenic dendritic cells (tolDC) through various methods has shown benefits in animal models of T1D. Both cell types express high levels of the aryl hydrocarbon receptor (AHR), and AHR activation is typically associated with enhanced tolDC and Treg functionality. In this study, the novel fluorescent indole-containing compound AGT-5 was investigated for its potential to act as an AHR ligand and modulate immune cells both in vitro and in vivo. Through in silico docking analysis, AGT-5 demonstrated the ability to bind AHR, and its agonistic effects were confirmed using the reporter Caco-2 cell line. Additionally, due to its fluorescent properties, AGT-5 was visualized in macrophages in vitro and in the small intestine lamina propria ex vivo after oral administration using confocal microscopy. AGT-5 exhibited no toxicity towards murine macrophages and human tonsillar cells. Moreover, tests on zebrafish embryos revealed no nephrotoxicity, hepatotoxicity, or cardiotoxicity. Utilizing an ADME virtual platform it was confirmed that AGT-5 possesses drug-like characteristics. Subsequently, AGT-5 was orally administered to C57BL/6 mice that had received low doses of streptozotocin to induce T1D. Treatment with AGT-5 commencing from the first day of T1D induction and lasting for 20 days effectively prevented immune cell infiltration into the pancreas, preserved insulin production, and halted the progression of T1D. AGT-5 achieved this by promoting tolDC and Treg activity along the gut-pancreatic lymph node-pancreas axis. Mechanistically, AGT-5 upregulated indoleamine 2,3-dioxygenase 1 in tolDC and enhanced ATP-degrading enzyme expression on Treg, thereby promoting immunosuppressive action. The positive outcomes seen in T1D animals suggest that AGT-5 holds promise for a potential treatment for inflammatory conditions that can benefit from stimulation of the regulatory arm of the immune response.

Purpose: T cell production is essential for patients undergoing stem cell transplantation and for cancer immunotherapy. A functional thymus is needed for the maturation of T cells, but unfortunately the thymus is highly sensitive to injury. While the thymus does harbor an endogenous capacity to regenerate itself, the role of regulatory T cells (Tregs) in this process is unknown.
Methods and results: In our murine models of thymic injury (SL-TBI, cyclophosphamide, dexamethasone, LPS and MCMV), we observed numeric and fractional expansion of Tregs within the thymus, peaking at the thymic cellularity nadir after injury. Depletion of Tregs before injury using the Foxp3^{DTR} model impaired thymic regeneration, whereas adoptive transfer of sorted thymic Tregs improved thymic regeneration. Using RAG2^{GFP} mice, where GFP is expressed under the promotion of RAG2, we observed that the increase in Tregs was mainly due to mature RAG2^{GFP}- Tregs but not de-novo produced RAG2^{GFP}+ Tregs after injury. Brdu administration after injury indicated active proliferation of these Tregs, and a RAG2^{GFP}parabiotic system, where a RAG2^{GFP}.CD45.1 mouse is surgically joined to a RAG2^{GFP}.CD45.2 mouse, indicated active recirculation of these Tregs after injury. Single-cell sequencing of CD45+ RAG2- cells in RAG2^{GFP} mice before and at day 1, 4, and 7 after sublethal irradiation revealed a unique transcriptional signature in RAG2^{GFP}- Tregs, including the regenerative factor amphiregulin. Its cognate receptor was seen to be upregulated on thymic epithelial cells and spatial transcriptomics of the thymus revealed increased EGFR signaling after injury. Conditional depletion of amphiregulin in Tregs using Foxp3^{Cre}Areg$^{fl/fl}$ mice resulted furthermore in impaired thymic regeneration after injury. Applying machine learning derived transfer of murine gene orthologs of recirculating Tregs to single cell sequencing of human thymi from children undergoing open heart surgeries enabled us to identify an analogous population of Tregs in the human thymus. These human recirculating Tregs where clonally expanded, expressed high levels of CD39 and ICOS, and secreted amphiregulin after stimulation.
Conclusion: Altogether, our data indicates that 1) recirculating thymic Tregs mediate thymic regeneration, 2) their regenerative capacity is dependent on amphiregulin, and 3) the presence of an analogous population of Tregs exists in the human thymus.

Conventional type 2 dendritic cells license FoxP3+ regulatory T cells in a Ccr4-dependent manner to suppress allergic inflammation

Jenny Mannion[1;2], Creel Ng Cashin[1;2], Nandini Samanta[1;2], Alexandra-Chloé Villani[1;2], Rod Rahimi[1;2;3]
[1]Center for Immunology and Inflammatory Diseases, Massachusetts General Hospital, Boston, United States; *[2]Harvard Medical School, Boston, United States*; *[3]Division of Pulmonary and Critical Care Medicine, Massachusetts General Hospital, Boston, United States*

FoxP3+ regulatory T cells (Tregs) play an indispensable role in restraining aberrant immune responses, including allergen-specific Th2 cell immunity that drives allergic disease. Treg suppression of adaptive immune responses requires co-localization with antigen presenting cells (APCs) and/or effector T cells. Ccr4 is a chemokine receptor expressed by both Th2 cells and Tregs and implicated in promoting cell trafficking into non-lymphoid tissues. While APCs have been shown to express the Ccr4 ligands Ccl17 and Ccl22, the lung APC subsets expressing the Ccr4 ligands and the cell-intrinsic role of Ccr4 in Tregs during allergic inflammation remain unclear. Here, using a murine model of allergic asthma and single cell RNA-sequencing analysis of lung APCs, we demonstrate that a population of activated, type 2 conventional dendritic cells (cDC2s) are the dominant source of Ccl17 and Ccl22 during allergic inflammation. We show that the type 2 cytokines IL-4 and IL-13 promote the development of activated cDC2s expressing the Ccr4 ligands. Using a novel, conditional Ccr4 knockout mouse, we show that specific and inducible deletion of Ccr4 in Tregs during allergic inflammation does not impair Treg trafficking into the lungs, but impairs their suppressive function, leading to a dramatic increase in allergic inflammation, including increased numbers of activated cDC2s, Th2 cells, and eosinophils. Our results suggest that the type 2 cytokines promote the development of a cDC2-dependent hub to license Ccr4+ Tregs to suppress allergic inflammation. Thus, we define a critical circuit between cDC2s and Tregs in a barrier tissue with implications for developing novel therapeutic approaches to suppress chronic allergic disease.

Regulatory T cells drive OPC differentiation independent of MHC-II

Jessica White[1], Alerie Guzman de la Fuente[1;2;3], Andrew Young[1;4], Rebecca Ingram[1], Yvonne Dombrowski[1], Denise Fitzgerald[1]
[1]Wellcome-Wolfson Institute for Experimental Medicine, Queen's University Belfast, Belfast, United Kingdom; *[2]Institute for Health and Biomedical Sciences of Alicante (ISABIAL), Alicante, Spain*; *[3]Institute of Neurosciences CSIC-UMH, San Juan de Alicante, Alicante, Spain*; *[4]Patrick G Johnston Centre for Cancer Research, Queen's University Belfast, Belfast, United Kingdom*

Background: Multiple sclerosis (MS) is an immune-mediated inflammatory disease of the central nervous system (CNS), characterised by the loss of myelin and oligodendroglia (demyelination). Although myelin regeneration (remyelination) can occur in MS, it often fails, leading to disease progression and subsequent disability. While there are no treatments targeting myelin repair, our lab has shown that regulatory T cells (Treg) can drive oligodendrocyte progenitor cell (OPC) differentiation and remyelination. The mechanisms underlying this effect remain mostly unknown but have been linked to the T cell activator MHC-II. In MS, MHC-II is highly expressed in de- and remyelinating lesions and can be upregulated by glial cells important to myelin regeneration (microglia, astrocytes, and oligodendrocytes). Thus, we hypothesised that MHC-II is required for efficient OPC differentiation and remyelination.
Methods: To test this hypothesis, we used *in vitro* OPC-T cell co-cultures and an *in vivo* model of lysolecithin-induced demyelination in WT and MHC-II-deficient mice.
Results: *In vitro*, we found that non-activated Treg significantly drive OPC differentiation independent of MHC-II. This pro-regenerative effect was impaired when Treg were not exposed to MHC-II during T cell development. In a transwell assay, Treg directly co-cultured with OPCs significantly enhanced OPC differentiation and not when physically separated. Immunofluorescence staining of lesioned spinal cord sections *in vivo* also revealed the absence of MHC-II does not significantly affect the number of oligodendrocyte lineage cells, proliferating OPCs and differentiated oligodendrocytes, but may impair CNS remyelination.
Conclusion: Together, these findings suggest a novel MHC-II-independent mechanism for Treg-driven OPC differentiation. Ongoing work is investigating whether MHC-II is necessary for remyelination *in vivo* and the mechanism(s) by which Treg function beyond what is classically known in regeneration.

Revisiting the role of the transcription factor Foxo1 in the biology of thymic and peripheral regulatory T cell subsets

Léa Giraud[1], Aurélie Durand[1], Charlotte Guillou[1], Nelly Bonilla[1], Sonia Carvalho[1], Alexandra Lainé[1], Céline Charvet[1], Bruno Martin[1], Bruno Lucas[1], Cédric Auffray[1]
[1]*Institut Cochin, Université de Paris Cité, CNRS (UMR 8104), INSERM (U1016), Paris, France*

Regulatory CD4 T (Treg) cells are the main mediators of peripheral tolerance under physiological conditions. In the periphery, Treg cells include cells that have been naturally produced in the thymus, called thymic Treg (tTreg) cells, and cells that have differentiated from naive CD4 T cells after activation in secondary lymphoid organs (SLOs), called peripheral Treg (pTregs) cells. In addition to and within this ontogenic heterogeneity, Treg cell activation level, location in SLOs or tissues or the age at which they were produced further drives the diversity of this cell subset. Although they share equivalent functions, all these Treg cell subsets have been shown to play complementary roles in the prevention of autoimmune diseases. Importantly, the signals driving the generation of these subsets of Treg cells could differ. For instance, while TCR and IL-2 signaling pathways dictate the generation of tTreg cells, TGFβ signaling (through Smads activation and binding to Foxp3 CNS1 enhancer) is crucial for pTreg cell differentiation. Many other factors have been identified as controlling the homeostasis of Tregs in general, but only few of them have been shown to regulate specific Treg cell subsets.
We recently identified Foxo1 as a putative specific regulator of the perinatal tTreg cell subset homeostasis. Indeed, analysis of Treg cells from mice invalidated for Foxo1 specifically in T cells showed a major and specific alteration of this Treg cell subset. We have shown that in perinatal Foxo1-deficient mice, the most activated Treg cells die by apoptosis and fail to proliferate due to an intrinsic defect of $Foxo1^{KO}$ tTreg cells to sense IL-2 results. Interestingly, our results strongly suggest in $Foxo1^{TKO}$ neonates, an intrinsic defect of $Foxo1^{KO}$ tTreg cells to sense IL-2 results in the apoptosis of this Treg cell subset and ultimately leads to an inversion of the balance between tTreg and pTreg cell subsets. This hypothesis was further confirmed by our latest data showing that whereas $Foxo1^{TKO}$ mice only develop with age a mild autoimmune disease, limiting pTreg cell generation in $Foxo1^{TKO}$ $CNS1^{KO}$ mice leads to a severe multi-organ autoimmunity in this mouse model.

The interplay between innate Immunity mechanisms in advancing neurodegeneration

Elena Zenaro[1], Enrica Caterina Pietronigro[1], Bruno Santos-Lima[1], Eleonora Terrabuio[1], Anna Slanzi[1], Aferdita Suli[1], Somayehsadat Ghasemi[1], Nicola Lopez[1], Beatrice D'Ulivo[1], Gabriele Angelini[1], Alessandro Bani[1], Ermanna Turano[1], Matteo Calgaro[1], Gabriele Tosadori[1], Nicola Vitulo[1], Davide Risso[2], Sara Cremona[1], Francesca Di Norscia[1], Rajasekar Nagarajan[1], Vittorina Della Bianca[1], Barbara Rossi[1], Giulia Iannoto[1], Monica Castellucci[3], Bruno Bonetti[4], Gabriela Constantin[1]

Alzheimer's disease (AD) is a chronic, progressive neurodegenerative disorder and is the most common form of dementia in elderly people worldwide. The main pathological hallmarks of AD consist of the accumulation of extracellular senile plaques of amyloid-beta, intracellular neurofibrillary tangles, synaptic degeneration, and neuronal injury in areas of the brain that control cognition. In addition to the established role of the brain's resident glial cells, infiltrating peripheral leukocytes have been recently discovered to play a pivotal role in brain physiology and contribute to disease pathogenesis. Recent studies on AD patients and mouse models with AD-like pathology have suggested a role for T cell accumulation in the brain.
Our study aimed to characterize the interplay between innate immunity mechanisms in disease development in 3xTg-AD mice, a transgenic mouse model developing both amyloid and tau pathologies. The non-canonical population of T lymphocytes harboring γδ TCR chains represents a unique lymphocyte population with innate immunity characteristics. We first evaluated the extent of γδ T cell infiltration in the meninges and brain, and observed an increased number of γδ T cells in 3xTg-AD mice compared to wild-type control animals. Moreover, flow cytometry data revealed an activated, IL-17–producing phenotype of meningeal and brain infiltrating γδ T cells in 3xTg-AD mice. These data were confirmed by single-cell RNA sequencing showing γδ T-cell pathogenic signatures, including genes involved in T activation and IL-17 production. Then, to demonstrate a role for γδ T cells in disease induction, we generated an AD mouse model deficient in the TCR δ chain (3xTg-ADxTcrd$^{-/-}$). In 3xTg-ADxTcrd$^{-/-}$ mice, memory and neuroinflammation were improved, and the typical signs of AD were reduced. In addition, when γδ T cells were genetically ablated in 3xTg-AD mice, peripheral and central neutrophil dysregulation was reversed, suggesting that these IL-17+ γδ T cells lead to an inflammatory condition that relied on circulating neutrophils.
Our findings show a new role for IL-17-producing γδ T cells in AD development, suggesting that targeting the interaction between γδ T cells and neutrophils could be a promising approach for AD treatment, potentially leading to new therapies.

Post-translational modification of LL37, the autoantigen of psoriasis, polarize responder CD4-T-cells towards an alternative T helper phenotype

Roberto Lande[1], Anna Mennella[1], Giuseppe Ocone[1], Rebecca Favaro[2], Elisabetta Botti[3], Mario Falchi[1], Antonio Costanzo[2], Loredana Frasca[1]
[1]*Istituto Superiore di Sanità, Rome, Italy*; [2]*Centro di Ricerca Humanitas, Skin Pathology Lab, Rozzano (Milano), Italy*; [3]*Università Tor Vergata, Rome, Italy*

Psoriasis is a chronic skin disease evolving to psoriatic arthritis (PsA) in 30% of cases. LL37 is a psoriasis T-cell autoantigen, recognized by both CD4 and CD8 T-cells and, in complex with self-DNA/RNA, is a trigger of type I interferon (IFN-I) in plasmacytoid dendritic cells (pDCs) and of pro-inflammatory factors in myeloid dendritic cells (mDCs). LL37 can undergo irreversible post-translational modifications, namely citrullination and carbamylation, favored by a neutrophil-dominated inflammation. Of note, carbamylated and citrullinated LL37 (carb-LL37 and cit-LL37) are antibody targets in PsA
Purpose: Our goal was to understand whether cit-LL37 and carb-LL37 are detectable in psoriatic skin biopsies and to address whether T-cells of psoriasis patients react not only to LL37, but also to cit-LL37 and carb-LL37.
Methods: We used laser scan confocal microscopy (LSCM) to analyze skin biopsies of psoriasis patients and control healthy donors. We used Ki67 expression proliferation assays and intracellular staining to analyze CD4 T-cell responses in psoriasis and cytokine production by flow cytometry
Results: We detected carb-LL37 and cit-LL37 in lesional psoriasis skin. Of interest, both modified peptides co-localized with neutrophil infiltrates. Neutrophil extracellular traps (NETs) were visible in psoriatic dermis where carb-LL37 and cit-LL37 were present. Psoriatic CD4 T-cells proliferated and produced Th1/Th17 cytokines in response to LL37 and carb-LL37. Interestingly, only cit-LL37-specific CD4 T-cells tend more often to up-regulate CXCR5 and Bcl-6, markers of T helper follicular cells (Thf).
Conclusion: These data, obtained using LL37 as a model autoantigen, reveal for the first time in psoriasis that post-translational modifications of an autoantigen, which also exert its effect also on innate immune cells, can influence autoreactive T helper-cell-polarization and, possibly, their effector functions. Citrullination and carbamylation, occurring when neutrophil infiltrate the skin, may favor or exacerbate autoreactive responses and possibly play a role in PsA development.

Characterising Effector T-cell Responses to Novel Autoantigens in Rheumatoid Arthritis

Elizabeth Pook[1], Kathryn Steel[1], Sarah Ryan[1], Carl Coyle[1], Esperanza Perucha[1], Leonie Taams[1], Andrew Cope[1]
[1]*King's College London, London, United Kingdom*

Purpose: Antigen specific CD4+ T-cells play a key role in the early pathogenesis of rheumatoid arthritis (RA). Challenges to our understanding of these key subsets are underpinned by limited knowledge of putative autoantigens as well as a lack of assays to capture the full phenotypic and functional heterogenicity of the responding population. Here, we describe a multi-modal approach combining proliferation, surface marker expression and cytokine production to characterise CD4+ T-cells responding to novel RA peptides.
Methods: Peptides presented by HLA-DR in RA synovial tissue were identified by mass spectrometry (see abstract by Steel et al) and screened for reactivity in RA (n=11) and PsA (n=5) PBMC by 48hr IFNγ production measured by FluoroSpot. Peptides with the greatest reactivity were tested in PBMC from RA patients (n=12) by labelling with CFSE and culturing for 7 days. A pathogen-derived peptide pool (CEFT) was used as positive stimulation control. For positive responses (stimulation index >2) phenotypes of divided cells was assessed by multi-parameter flow cytometry and FlowSOM clustering. Cytokine secretion was assessed in Luminex assays.
Results: Following 48hr stimulation with synovial derived peptides, IFNγ production was higher in RA PBMC compared to PsA PBMC. Peptides derived from Desmoglein-2 (DSG2) and Immunoglobulin heavy constant gamma 1 (IGHG1) showed robust IFNγ responses. Stimulation with DSG2 and IGHG1 derived synovial peptides resulted in a higher proportion of either CD25/ICOS/OX40^{high} CCR4^{+} or CD25/OX40/ICOS$^{low/med}$ CXCR3^{+} populations at 7 days, dependent on the individual. 41BB^{+}PD1^{+} CD4 T-cells were significantly more abundant in the CEFT responding population compared to synovial peptide responding cells (p=<0.0001). A small population (1-2%) of ICOS^{high} CCR4^{+} cells was present in 3 individuals responding to DSG2 and IGHG1 derived peptides. Following 7-day stimulation with DSG2 and IGHG1, a substantial proportion of CD4+ T-cells responded with production of TNFα (65%), GM-CSF (85%) and IFNγ (40%).
Conclusions: Circulating CD4+ T-cells responding to novel autoantigenic peptides, have a pro-inflammatory CD25^{+}ICOS^{+}OX40^{+} phenotype and produce pro-inflammatory cytokines. Phenotypic signatures of antigen responding populations are heterogeneous, likely reflecting distinct TCR signals generated by each peptide, and the unique state of the host immune response.

Caveolin-1/PPARα axis restrains pathogenic T follicular helper cell response in primary Sjögren's syndrome

Xiang Lin[1]
[1]*The University of Hong Kong, Hong Kong, Hong Kong*

Purpose: Primary Sjögren's syndrome (pSS) is a common autoimmune disease characterized by exocrinopathy involving salivary and lacrimal glands. Our accumulated works have demonstrated the critical roles of Th17 and T follicular helper (Tfh) cells in the pSS pathogenesis. In this study, we investigated the role of a scaffold protein caveolin-1 (Cav-1) in disease development and effector T cell dysregulation.
Methods: pSS patients were recruited and circulating T cells were analyzed. Wildtype (WT) or Cav-1-/- mice were induced for experimental SS (ESS). Disease phenotype and immune responses were assessed. WT and Cav-1-/- CD4+ T cells were subjected to RNA-seq and metabolic analysis. WT and Cav-1-/- Tfh cells migration was assessed by two-photon intravital images *in vivo*. Humanized SS mice were established by engrafting PBMCs from pSS patients.
Results: Cav-1 deficiency in hematopoietic origin exacerbated ESS pathology and humoral autoimmunity, together with enhanced Tfh cell responses, while Th17 cells were unaffected. Cav-1-/- Tfh cells exhibited increased motility and follicular localization. RNA-seq revealed impaired peroxisome proliferator-activated receptor alpha (PPARa) pathway in the absence of Cav-1. PPARa served as a downstream transcription factor of Cav-1, which rapidly repressed *Icos* transcription upon Tfh polarization, interestingly, independent of lipid metabolism. Thus, PPARa-/- CD4+ T cells also showed elevated ICOS expression, which can not be restored by overexpression of the *Cpt1a*, the downstream metabolic factor of PPARa. Prevention of PPARa translocation into nucleus could abolish this transrepressive effect. Phenotypic analyses suggested that Cav-1 and PPARa expressions were decreased in CD4+ T cells from pSS patients and ESS mice, and thus negatively correlated with Tfh cell frequencies. Notably, pharmaceutical activation of PPARa with fenofibrate could suppress human and murine Tfh cells in culture, in ESS mice and in humanized SS mice. In ESS mice, oral administration of fenofibrate effectively ameliorated disease pathology at both acute or chronic stages.
Conclusion: These results revealed an unrecognized role of Cav-1/PPARa axis in Tfh cell tolerance and pSS pathogenesis, suggesting PPARa as a promising target in the treatment of humoral autoimmunity.

Rapamycin rescues loss-of-function in blood-brain barrier-interacting regulatory T cells

Paulien Baeten[1], Ibrahim Hamad[1], Cindy Hoeks[1], Michael Hiltensperger[2], Bart Van Wijmeersch[3], Veronica Popescu[3], Lilian Aly[2], Veerle Somers[1], Thomas Korn[2], Markus Kleinewietfeld[1], Niels Hellings[1], Bieke Broux[1]
[1]Hasselt University, Biomedical Research Institute, Diepenbeek; *[2]Technische Universität München, München, Germany*; *[3]Noorderhart, Revalidatie & MS Centrum, Pelt, Belgium*

In autoimmunity, it has been established that FOXP3+ regulatory T cells (Tregs) skew towards a pro-inflammatory, non-suppressive phenotype, making them unable to control the exaggerated autoimmune response. This largely impacts the success of autologous Treg therapy which is currently under investigation for autoimmune diseases, including multiple sclerosis (MS). There is a need to ensure in vivo Treg stability before successful application of Treg therapy. Using genetic fate-mapping mice, we demonstrate Tregs which have lost FOXP3 expression (exFOXP3 T cells) accumulate in the central nervous system during experimental autoimmune encephalomyelitis. In a human in vitro model, we discovered that interaction with inflamed blood-brain barrier endothelial cells (BBB-ECs) induces a loss of suppressive function in Tregs. Transcriptome and cytokine analysis revealed that in vitro migrated Tregs have a disrupted regenerative potential, a pro-inflammatory Th1/17 signature and upregulate the mTORC1 signaling pathway. In vitro treatment of migrated human Tregs with the clinically-approved mTORC1 inhibitor rapamycin restored their suppressive capacity. Finally, flow cytometric analysis identified an enrichment of inflammatory, less suppressive CD49d+ Tregs in the cerebrospinal fluid of people with MS. In sum, interaction with BBB-ECs is sufficient to affect Treg function, and BBB transmigration triggers an additive pro-inflammatory phenotype switch. These insights will help to improve the efficacy of autologous Treg therapy of MS.

The Effects of CXCR5, PD-1 and ICOS Molecules of Helper T Cells on B Cell Responses and the Implications in Myasthenia Gravis

Merve Cebi[1], Arman Çakar[2], Hacer Durmuş[2], Yeşim Parman[2], Güher Saruhan Direskeneli[1]
[1]Istanbul University Istanbul Medical Faculty Department of Physiology, Istanbul, Turkey; *[2]Istanbul University Istanbul Medical Faculty Department of Neurology, Istanbul, Turkey*

Follicular helper T (Tfh, CXCR5$^+$) cells regulate B cell responses mainly at the germinal centers by interacting with B cells via PD-1 and ICOS molecules as well as cytokines. Similarly, peripheral helper T (Tph) cells lacking CXCR5 provide help for B cell responses mainly in the periphery. Both cell groups are implicated in the pathogenesis of myasthenia gravis (MG). This study examined molecular interaction of T and B cell populations by comparing T cell subsets according to these molecules and aimed to determine therapeutic target molecules in this interaction for MG patients.
The study included 10 healthy controls (HCs) and 6 untreated acetylcholine receptor-antibody-positive MG (AChR-MG) patients. CD4$^+$ helper T cells were sorted by combinations of CXCR5, PD-1 or ICOS (using FACSAria), stimulated with CD3/CD28 antibodies and then co-cultured with sorted CD19$^+$ B cells of the same donors. The impact of separated T cell subgroups on the development of plasmablasts (CD27$^+$CD38$^+$ cells) in CD19$^+$ B cells, on the production of total IgG as well as anti-AChR IgG, IL-4, IL-21 and IL-17 in culture supernatants (ELISA and cytometric bead assay) were assessed.
In HCs, not CXCR5 alone, but the presence of PD-1 or ICOS molecules with CXCR5 (Tfh) on T cells induced higher plasmablasts and higher IgG production compared to co-cultures without these molecules. The effects of these molecules did not differ from each other. Similarly, T cells without CXCR5 (Tph) were effective in inducing B cell responses with PD-1 or ICOS and PD-1 was superior to ICOS in plasmablast induction.
In AChR-MG MG patients, CXCR5$^{+/-}$ PD-1$^+$ T cells also exhibited higher plasmablasts, IgG, as well as AChR-IgG, IL-4 and IL-17 compared to CXCR5$^{+/-}$ PD-1$^-$ cell cultures. This effect was predominant in the CXCR5$^+$PD-1$^+$ co-culture compared to the CXCR5$^-$PD-1$^+$ co-cultures.
Both PD-1-expressing CXCR5$^+$(Tfh) or CXCR5$^-$(Tph) cells exhibited a higher potential to enhance B cell responses compared to cells without PD-1. This effect is particularly evident in antigen-specific antibody production in AChR-MG patients. Modulation of PD-1 or CXCR5 in MG patients should be explored aiming to reduce AChR-IgG production.

iNKT cell immunomodulation and mucosal healing by microbiota-derived lactate

Federica Perillo[1], Chiara Amoroso[2], Alberto Baeri[3], Flavio Caprioli[2], Federica Facciotti[3], Francesco Strati[3]
[1]Departement of experimental oncology, European Institute of Oncology IRCCS, Milano, Italy; *[2]Gastroenterology and Endoscopy Unit, Fondazione IRCCS Cà Granda, Ospedale Maggiore Policlinico Milano, Milano, Italy*; *[3]Università degli Studi di Milano Bicocca, Milano, Italy*

Purpose: Invariant natural killer T (iNKT) cells play a critical role in mucosal immune homeostasis. Although iNKT cells release proinflammatory cytokines in response to the altered gut microbiota of IBD patients, exposure to microbiota-derived metabolites can promote homeostatic IL10-mediated iNKT cell responses resulting in better clinical outcomes in Crohn's disease (CD) patients. Thus, understanding the mechanisms leading to iNKT cells' functional shaping by microbiota-derived metabolites is important to design novel therapies for IBD patients.
We hypothesised that iNKT cells, serving as sentinels of tissue integrity, are the primary immune cells sensing microbiota-derived metabolic signals promoting the resolution of inflammation in IBD. In particular, we show that microbiota-derived lactate can control iNKT cell functions promoting iNKT cell-mediated mucosal tolerance while preventing T-cell-mediated overt inflammation and tissue injury.
Methods: We performed immunophenotyping of iNKT cells by multiparametric flow-cytometry from surgical specimens of CD patients and correlated NKT10 responses with intra-colonic levels of lactate, gut microbiome composition and tissue injury/healing. We studied the molecular pathway determining the NKT10 phenotype in a lactate-enriched microenvironment by RNA-seq and CHIP-seq. We validated our results by using in-vivo models and spatial transcriptomics on patient specimens.
Results: Our data suggest that microbiota-derived lactate plays a role in the epigenetic control of the immunoregulatory phenotype of iNKT cells through histone lactylation, thereby protecting animals from intestinal inflammation
Conclusion: On overall our data show i) how microbiota-derived lactate modulates the immunophenotype of iNKT cells, ii) the mechanisms underlying sensing of microbiota-derived lactate by iNKT cells, iii) iNKT cells role in inflammation resolution.

Microbial-derived metabolites promote NKT22 responses in colitis associated colorectal cancer patients

Federica Perillo[1], Alberto Baeri[2], Chiara Amoroso[3], Flavio Caprioli[3], Francesco Strati[2], Federica Facciotti[2]
[1]*Department of Experimental Oncology, European Institute of Oncology IRCCS ~ Milano ~ Italy, Milan, Italy*;
[2]*Department of Biotechnology and Biosciences, University of Milan-Bicocca ~ Milano ~ Italy, Milan, Italy*;
[3]*Gastroenterology and Endoscopy Unit, Fondazione IRCCS Cà Granda, Ospedale Maggiore Policlinico ~ Milano ~ Italy, Milan, Italy*

Purpose: Patients suffering from inflammatory bowel diseases (IBD) manifest an increased risk of developing colitis-associated colon cancer (CAC). Interleukin 22 (IL22) is a cytokine involved in the proliferation and survival of epithelial cells. However, it also correlates with the development of tumoral lesions. IL22 is secreted by different immune cell types, including iNKT cells, tissue resident cells possessing cytotoxic properties in colorectal cancer (CRC). In IBD patients, though, iNKT cells perform both pro-inflammatory or tolerogenic functions in a microbiota-dependent fashion, opening questions on their functional role in CAC development.
Methods: Immune cell composition and iNKT cell phenotype of inflamed and cancerous tissue lesions of CAC (n=49), IBD (n=20) and sporadic CRC (n=38) patients were analysed in samples obtained from Policlinico Hospital, Milan, and IOV-IRCCS, Padua. High-dimensional single-cell flow cytometry, metagenomics, RNAseq, spatial immunophenotyping and trascriptomic (Cosmx, Nanostring), ex vivo and in vitro experiments were performed to evaluate the phenotype and function of human iNKT cells. Metabolomics was performed to identify microbial-derived molecules involved in iNKT cells activation. Mechanisms were dissected in CAC murine models, either iNKT proficient or deficient.
Results: An increased expression of IL22 and a higher NKT22 infiltration was observed in CAC tissues, as well as an enrichment of *Odoribacter*, a gram-negative bacteria implicated in tryptophan metabolism. Stimulation of iNKT cells with *Odoribacter*-derived metabolites induced Ahr-dependent IL22 production by iNKT cells. Metabolomic analyses revealed an increased presence of tryptophan metabolites in the *Odoribacter* supernatant, promoting NKT22 differentiation both in vitro and in vivo models. Moreover, the administration of *Odoribacter* Supernatant or of the single purified metabolites were sufficient to increase tumorigenesis in CAC mouse models, but not in iNKT-deficient mice. Spatial proteomics and trascriptomic analyses of human CAC tissues confirms the microbiota-dependent functional skewing of iNKT cells residing closely to cancer cells.
Conclusion: iNKT cells in CAC patients are the major IL22 producing cells and are induced by the recognition of microbiota-derived metabolites implicated in tryptophan metabolism and Aryl hydrocarbon receptor (AhR) stimulation. NKT22-microbiota interaction in CAC patients plays a potential crucial role in tumor development.

Neutrophils mediate protection against colitis and carcinogenesis by controlling bacterial invasion and driving IL-22 production by γδT cells.

Silvia Carnevale[1;2], Andrea Ponzetta[1], Anna Rigatelli[1], Roberta Carriero[1], Simone Puccio[1;3], Domenico Supino[1], Giovanna Grieco[1;2], Piera Molisso[1;2], Irene Di Ceglie[1], Francesco Scavello[1], Chiara Perucchini[1], Fabio Pasqualini[2], Camilla Recordati[4], Claudio Tripodo[5], Beatrice Belmonte[5], Andrea Mariancini[1;2], Paolo Kunderfranco[1], Giuseppe Sciumè[6], Enrico Lugli[1], Eduardo Bonavita[1;2], Elena Magrini[1], Cecilia Garlanda[1;2], Alberto Mantovani[1;2;7], Sebastien Jaillon[1;2]
[1]IRCCS, Humanitas Clinical and Research Center, Rozzano, Italy; *[2]Humanitas University, Pieve Emanuele, Italy*; *[3]Institute of Genetic and Biomedical Research, UoS Milan, National Research Council, Rozzano, Italy*; *[4]University of Milan, Milan, Italy*; *[5]University of Palermo, Palermo, Italy*; *[6]University La Sapienza, Rome, Italy*; *[7]The William Harvey Research Institute, Queen Mary University of London, London, United Kingdom*

Purpose: Neutrophils are the most abundant leukocytes in human blood and play a primary role in resistance against invading pathogens and in the acute inflammatory response. However, their role in colitis and colitis-associated colorectal cancer is still under debate. This study aims to dissect the role of neutrophils in these pathological contexts by using a rigorous genetic approach.
Methods: Neutrophil-deficient mice (*Csf3r*$^{-/-}$ mice) were used in classic models of colitis and colitis-associated colorectal cancer (CAC) and the role of neutrophils was assessed by histological, cellular and molecular analyses coupled with adoptive cell transfer. We also performed correlative analyses using human datasets.
Results: *Csf3r*$^{-/-}$ mice showed increased susceptibility to colitis and colitis-associated colorectal cancer compared to control *Csf3r*$^{+/+}$ mice and adoptive transfer of neutrophils in *Csf3r*$^{-/-}$ mice reverted the phenotype. In colitis, *Csf3r*$^{-/-}$ mice showed increased bacterial invasion and a reduced number of healing ulcers in the colon, with lower tissue levels of IL-22, indicating a compromised regenerative capacity of epithelial cells. The activation state of γδT cells from *Csf3r*$^{-/-}$ mice was altered towards decreased production of IL-22 and increased production of IL-17. Both adoptive transfer of neutrophils and ABX treatment were sufficient to rescue the polarization and activation state of γδ T cells toward high expression of AhR and IL-22 and low expression of IL-17. In patients with ulcerative colitis, expression of *CSF3R* was positively correlated with *IL22* and *IL23* expression. Moreover, gene signatures associated with epithelial-cell development, proliferation, and antimicrobial response were enriched in *CSF3R*^{high} patients.
Conclusion: The findings reported here highlight the importance of neutrophils in maintaining intestinal homeostasis in response to inflammatory insults and describe a model where neutrophils control the susceptibility to intestinal inflammation and CAC by shaping the intestinal microbiota composition and the activation of an IL-22-dependent tissue repair pathway.

Differential effects on fecal microbiota, gut immunity and vaccine response conveyed by a natural environment vs. co-housing with wild or pet store mice

Henriette Arnesen[1], Signe Birkeland[1], Harriet Stendahl[1], Klaus Neuhaus[2], Ryan Langlois[3], David Masopust[3], Harald Carlsen[1], Preben Boysen[1]
[1]*Norwegian University of Life Sciences (NMBU), Aas, Norway*; [2]*Technische Universität München, Freising, Germany*; [3]*University of Minnesota Medical School, Minneapolis, United States*

Purpose: Laboratory rodents may fail to develop a diverse microbiome and immune training, risking poor translatability to humans. We have established a housing system exposing C57BL/6 (B6) mice to soil and domestic animal excrements, representing a realistic living habitat for house mice. These "feralized" mice shift their gut microbiota, obtain a matured immunophenotype and are more resilient to colorectal cancer development. In earlier studies we exerted microbial pressure by cohousing B6 mice with wild (WildCoH) or pet store mice (PetCoH) as microbial donors. The present study compared immunological performance following several such conditions. We also compared the burden of pathobiont exposures in pet store-bred and free-living wild mice, and B6 mice co-housed with the donors, and measured their ability to respond to an influenza vaccine.
Methods: B6 mice were exposed to various microbially rich conditions; a naturalistic habitat, and/or co-housing with wild-caught or pet store mice. Analyzed parameters included microbiota and virome sequencing, pathobiont immunity, gene expression in colon, flow cytometry, immunohistochemistry and serological response to parenteral influenza vaccine.
Results: A variety of environmental exposures revealed effects on the intestinal barrier, microbiota, gut immunity and vaccine response. Feralization moved the B6 fecal microbiota towards that of wild mice, while WildCoH brought the microbiota even closer to the "wild" type. Expression of genes for barrier integrity and antimicrobial functions increased accordingly. Feralization, and to a greater extent WildCoH, increased resident memory CD8+ T-cells in the colon mucosa. Antigen experience markers increased along similar trends in NK and T-cells, while T-reg numbers were unchanged. In a separate experiment, PetCoH mice showed a stronger exposure to pathobionts than feralized or WildCoH mice. Following influenza vaccination, PetCoh mice showed a dampened specific antibody production, not detected in feralized or WildCoH mice.
Conclusion: Exposure of model mice to soil and domestic animal excrements conveyed a shift of the gut-associated microbiota, antigen experience markers and colonic barrier function. Exposure to wild mice potentiated these changes. Finally, cohousing model mice with pet store animals, shown to carry a higher pathogenic burden, made the strongest impact on systemic immunity and compromised a vaccine response.

Integrating functional metagenomics to decipher microbiome-immune interactions

Puspendu Sardar[1], Amelia Soderholm[1], Sarah Whiteside[1], Benjamin Beresford-Jones[1], Paula Kuo[1], Rahul Roychoudhuri[1], Virginia Pedicord[1]
[1]*University of Cambridge, Cambridge, United Kingdom*

Purpose: Recent studies have linked the composition of the gut microbiota to various aspects of human health, including host metabolism, immunity and infection susceptibility. With shotgun metagenomic sequencing methods, inventories of the microbial residents of the gut have become more detailed and precise, but primary investigation of molecular mechanisms involved in key microbiome-immune interactions has remained challenging. Our research group recently built important biological and bioinformatic resources that facilitate functional and mechanistic studies of the gut microbiome and translation of findings between mice and humans. We have now leveraged these tools to understand how microbiota metabolites act as dynamic messengers to the host epithelium and underlying immune system in homeostasis and disease.
Methods: Shotgun metagenomic sequencing datasets generated in our lab and public datasets were functionally annotated using our functional metagenomics pipelines, UHGG and MGBC database and ToolKit to provide functional profiles of human patient and mouse microbiomes. Immune impacts of differentially abundant microbial functions and metabolic pathways were further explored *in vitro* and in mouse models using reporter assays, flow cytometry, bulk- and single-cell RNA-seq, proteomics and mass spectrometry-based metabolomics.
Results: Moving from humans to mice, we uncovered a taxonomy-independent association in melanoma patients between gut microbiota acylation of lipopolysaccharide (LPS) and response to the immune checkpoint inhibitor anti-PD-1. In *in vitro* assays, we went on to show that the balance of LPS acylation states determines the capacity of gut LPS to stimulate immune activation. In tumor-bearing mouse models, oral administration of immunostimulatory LPS significantly enhanced anti-PD-1 efficacy. Moving from mice to human patients, by pairing functional metagenomics, proteomics, metabolomics and transcriptomics with gut immune cell profiling, we revealed a role for a microbiota-derived fatty acid in driving epithelial antigen presentation and downstream anti-inflammatory intraepithelial lymphocyte abundance in mice. Corresponding microbiome and host transcriptomic signatures were then uncovered in Crohn's disease patients with lower disease severity, confirming an association with decreased inflammation.
Conclusion: Leveraging our generated resources and multi-omic functional approaches to microbiome research, we have utilized observations from both mice and human patients to mechanistically investigate how the microbiota-derived metabolite milieu impacts multiple aspects of host immunity.

Gut microbiota and maternal immune transfer at birth precede pre-allergic clinical outcome.

Remy Villette[1], Djelika Traore[1], Elise Dhilly[1], Marta Schuhmacher[2], Isabella Annesi-Maesano[3], Martin Larsen[1]
[1]CIMI Paris, Inserm U1135, Sorbonne University, Paris, France; *[2]Departament d'Enginyeria Química, Universitat Rovira i Virgili, Tarragona, Catalonia, Spain*; *[3]Institute Desbrest of Epidemiology and Public Health, University of Montpellier and INSERM, Montpellier, France*

Purpose: The gut microbiota of 2–3-month-old infants is associated with later pre-allergic signs, while the microbiota at the time of allergic manifestation is not. We hypothesized that the infant gut microbiota and immune system are primed shortly after birth, and that this is influenced by maternal transfer of humoral immunity.
Methods: Using biological samples from 187 mother-child dyads from a French-Spanish birth cohort we investigated the association between allergic outcomes and composition and humoral immunity to gut microbiota at birth, 2 months, and 2 years-of-age. Experimentally we employed flow cytometry to monitor the proportion of antibody-bound gut microbiota and 16S rRNA gene sequencing to evaluate the gut microbial composition. Finally, we sorted IgA+ and IgA- gut microbiota and identified microbes bound to IgA by 16S rRNA gene sequencing (IgAseq).
Results: Meconium microbiota clustered into three groups dominated by Escherichia, Enterococcus, and mixed genera, respectively. The Escherichia cluster was associated with protection against later allergic manifestations. We moreover studied the proportion and specificity of humoral immunity to gut microbiota. Breastmilk hugely affected the proportion of antibody-bound microbiota in early-life. The diversity of IgA-binding increased with age in concordance with general microbiota diversification.
Conclusion: Gut microbiota composition at birth was associated with future allergies. Future studies should evaluate whether interventions to alter gut microbiota and/or humoral immunity in early-life could protect against allergy.

Identification of serial killing natural killer cells

Jens Niemann[1], Maren Claus[1], Vanna Imsirovic[2], Carsten Watzl[1]
[1]*Leibniz Research Centre for Working Environment and Human Factors, Dortmund, Germany*; [2]*University of Rijeka, Rijeka, Croatia*

Natural killer (NK) cells are important for early and effective immune responses through cytokine production and by killing transformed and virally infected cells. NK cell cytotoxicity is regulated by different germline encoded activating and inhibitory receptors and executed by the release of cytotoxic granules or the engagement of death receptors. Human NK cells have been shown to be heterogeneous and differ in their ability to kill target cells. NK cells that are able to sequentially kill multiple target cells are called serial killers. The serial killing activity of NK cells is essential for their cytotoxic function since the majority of kills can be performed by a minority of cells. Consequently, serial killing NK cells are of particular interest for therapeutic applications. However, while it is known that only a fraction of NK cells perform serial killing, it is currently not possible to predict which NK cells will engage in serial killing.
To this end, we established a staining protocol that can differentiate between the timing and the count of multiple NK cell degranulation events occurring during target cell co-culture. NK cells are analyzed via flow cytometry which enables us to combine degranulation data with other phenotypic readouts. Additionally, cell sorting can be used to open up possibilities like RNA-sequencing. Donors with high proportions of serial degranulating NK cells can be reproducibly identified by our method. Loss of CD16 was associated with the number of degranulation events, whereas the upregulation of CD69 correlated with the timing of degranulation. Our method will be an important tool to identify NK cell populations with large proportions of serial killers and to potentially identify phenotypic markers specific for serial killing NK cells.

A novel CD5-based adoptive cell transfer therapy for systemic fungal infection

María Velasco-de Andrés[1], Cristina Català[1], Laura Carrillo-Serradell[1], Violeta Planells-Romeo[1], Marta Español-Rego[2], Lorena Pérez-Amill[3], Pedro Puerta-Alcalde[4], Carolina Garcia-Vidal[4], Beatriz Martín-Antonio[5], Francisco Lozano[1;2;6]
[1]Institut d'InvestigacionsBiomèdiques August Pi I Sunyer (IDIBAPS), Barcelona, Spain; *[2]Immunology department, Hospital Clinic of Barcelona, Barcelona, Spain*; *[3]Fundació Clinic per a la Recerca Biomèdique, Barcelona, Spain*; *[4]Infectious Disease Department, Hospital Clinic of Barcelona, Barcelona, Spain*; *[5]5Department of Experimental Hematology, Instituto de Investigación Sanitaria-Fundación Jiménez Diaz (IIS-FJD), UniversityAutonomous of Madrid (UAM), Madrid, Spain*; *[6]Departament de Biomedicina, Facultat de Medicina, Universitat de Barcelona, Barcelona, Spain*

Invasive fungal infections have become a global concern, driven primarily by the widespread use of aggressive immunosuppressive and surgical interventions, and the emergence of antimicrobial-resistant (AMR) strains. The paucity of the antifungal pipeline and the important side effects reported for the available ones, place the need of developing alternative strategies. Immunotherapeutic approaches involving adoptive transfer of immune cells engineered with chimeric antigen receptors (CARs) are gaining interest. Pre-clinical studies have already demonstrated the efficacy of human T cells redirected against fungi (e.g., *Aspergillus fumigatus* and *Cryptococcus neoformans*) and viruses (e.g., Human Immunodeficiency Virus, Hepatitis B Virus, Hepatitis C Virus, Human Cytomegalovirus, and Epstein-Barr Virus) through the expression of specific CARs. Our previous research highlighted CD5, a scavenger-like lymphocyte surface receptor, as a promising candidate for broad anti-fungal CAR designs due to its high binding affinity to β-glucans, a conserved constituent of fungal cell walls. Thus, a CD5-based second generation CAR has been expressed by lentiviral transduction on cord blood-derived human NK cells. Subsequent *in vitro* assessments revealed enhanced cytokine and chemokine production as well as surface activation markers up-regulation by CD5CARCBNK cells when co-cultured with a broad panel of fungal species. Moreover, under these co-culture conditions enhanced fungal killing and reduced fungal metabolic activity was also observed. Furthermore, *in vivo* experiments involving infusion of CD5CARCBNK cells into immunocompromised NSG mice undergoing systemic fungal infection induced by *Candida albicans* and *C. neoformans* demonstrated significantly higher survival rates and lower fungal load count compared to untreated controls. In summary, the antifungal properties exhibited by immune cells expressing our CD5-based CAR open new avenues for development of novel off-the-shelf adoptive cellular immunotherapies against invasive fungal infections. These approaches could be pursued independently or in combination with traditional antifungals, offering a promising strategy addressing the challenges posed by invasive fungal infections independently of their AMR status.

Dual modulation of cytotoxic and checkpoint receptors tunes the efficacy of Delta One T cells against colorectal cancer

Rafael Blanco Domínguez[1], Leandro Barros[1], Mariana Carreira[1], Sofia Mensurado[1], Bruno Silva-Santos[1]
[1]*Instituto de Medicina Molecular João Lobo Antunes, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal*

Colorectal cancer (CRC) remains a major unmet medical need. Notably, most microsatellite stable (MSS) advanced CRC tumors employ mechanisms to avoid neoantigen generation and/or HLA class I presentation, rendering them inconspicuous to αβ T cells. Thus, only around 10-15% of CRC with microsatellite instability (MSI), presenting high mutational burden due to deficient DNA mismatch repair, are responsive to current immunotherapies. In this context, Vδ1$^+$ γδ T cells, with their robust HLA-I-independent and neoantigen-independent cytotoxic functions, coupled with natural tropism for the gut and tumors, emerge as promising candidates for a broader CRC immunotherapy. We have recently developed a Vδ1$^+$ γδ T cell-based adoptive cell therapy, named Delta One T (DOT) cells, which has been translated to the clinic for hematological malignancies, but has never been applied in the challenging solid tumor space. Here we optimize and establish the pre-clinical proof-of-concept for using DOT cells for CRC treatment. First, we demonstrate the capacity of DOT cells to target a panel of both MSI and MSS CRC cell lines and patient-derived biopsies *in vitro*. Second, using an orthotopic (intercaecal) xenograft model of human CRC with MSS SW620 cells, we show that blood-infused DOT cells infiltrate the tumor lesions, controlling tumor growth *in vivo*. Importantly, tumor-infiltrating DOT cells exhibited a dysregulated balance of cytotoxic and inhibitory receptors, limiting their cytotoxic potential. We identified a dominant role of the innate receptor NKG2D in mediating CRC targeting, as blockade or knockout of this receptor in DOT cells impairs CRC killing. Enhancement of the NKG2D axis or inhibition of immune checkpoint receptors potentiated DOT-cell tumoricidal functions against CRC *in vitro* and *in vivo*. This study demonstrates the strong potential of DOT cells as a novel immunotherapy for CRC, while emphasizing avenues for improved efficacy through combinatorial approaches.

Engineering NK cell immunotherapy to optimise liver homing and T cell regulation

Mariana Diniz[1], Yiya Zhong[1], Stephanie Kucykowicz[1], Daniel Brown Romero[1], Jessica Davies[1], Joseph McDowell[1], John Counsell[1], Mala K Maini[1]
[1]*University College London, London, United Kingdom*

Purpose: NK cells are being developed for adoptive cell therapy of cancer with the advantages of intrinsic tumour-killing capacity, lack of MHC restriction and low toxicity. Cytokine activation (IL2/12/15/18) is widely used to promote memory-like NK cells with enhanced anti-tumour functionality. However, we recently showed that cytokine activation induces PD-L1 on human and murine NK cells, resulting in inhibition of hepatitis B (HBV)-specific T cells (*Diniz, SciTranslMed 2022*). Using monoclonal antibodies, we found that PD-L1-blockade reverted NK cell negative role and enhanced their capacity to help T cell responses. We hypothesised that targeting PD-L1-mediated regulation could generate more efficient NK cells for adoptive cell therapy in cancer.
Methods: The aims of this study were therefore to engineer primary NK cells to be retained within Hepatocellular carcinoma (HCC), exerting anti-tumour function without impeding the activity of neighbouring anti-tumour T cells through PD-L1. To do this, we transduced NK cells to express the chemokine receptor CXCR6 (which retains liver-resident NK cells) and to secrete anti-PD-L1 antibodies to counteract their checkpoint inhibition of T cells.
Results: Using VSV-G pseudotyped lentivirus we achieved transduction of primary human NK cells and confirmed induction of CXCR6 expression at similar levels of a reporter protein (GFP). Higher numbers of $CXCR6^{+}$NK-cells were recovered from matrigel containing CXCL16 or HepG2 supernatant compared to untransduced cytokine-activated NK-cells, indicating that the encoded CXCR6 receptor was functional. Production and secretion of anti-PD-L1 was confirmed by its capacity to block PD-L1 on NK or hepatoma cells *in vitro,* preventing staining of this ligand by flow cytometry. Their secretion of anti-PD-L1 antibodies converted cytokine-activated transduced NK cells into predominant 'helpers', able to boost $CD8^{+}$T cell responses to HBV peptide stimulation or hepatoma cells.
Conclusion: In summary, we genetically engineered cytokine-activated NK cells to have enhanced homing/retention within liver tumours and to mediate anti-tumour activity whilst releasing their helper function to boost antigen-specific T cells. This approach should promote the dual anti-tumour functionality of NK cells and T cells, to work in tandem rather than in opposition, against HCC.

Development of γδ T cell immunotherapy against Glioblastoma

Gabriel Marseres[1;2], Coline Gentil[2], Victor Bigot[2;3], Maxime Courant[3], Valerie Prouzet-Mauleon[4], Vincent Pitard[2;5], Atika Zouine[5], Sofia Mensurado[6], Claire Larrieu[7], Béatrice Turcq[4], Bruno Silva-Santos[6], Olivier Mollier[3], Julien Engelhardt[3], Lionel Couzi[2;3], Thomas Daubon[7], Julie Dechanet-Merville[2]
[1]Netherlands Cancer Institute, Amsterdam, Netherlands; *[2]ImmunoConcept UMR5164, Bordeaux, France*; *[3]Bordeaux University Hospital, Bordeaux, France*; *[4]University of Bordeaux INSERM UMS 3427 CRISPedit TBM Core, Bordeaux, France*; *[5]University of Bordeaux, INSERM UMS3427 TBM Core Facsility, Bordeaux, France*; *[6]Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal*; *[7]University of Bordeaux, CNRS, IBGC, UMR5095, Bordeaux, France*

Background: γδ T cells are unconventional T cells harboring features of innate and adaptive response. Indeed, they express both TCR receptors (although described interacting with their target in a mostly MHC independent manner) and NK receptors, conferring them cytotoxic characteristics. Actually, clinical scale *in-vitro* expanded γδ T cells (DOT cell procedure) are currently in clinical trial in Acute Myeloid Leukemia (AML). This sub-population is besides, specifically enriched in tissues and their number in tumors associates with better survival in different solid cancers. These characteristics make them of great interest to develop as therapeutic agent particularly in tumors with low mutational burden or low HLA-I expression, such as Glioblastomas (GBM).
GBM are the most frequent and aggressive primary brain malignancies, with very limited therapeutic options and a dismal prognosis. So far, immunotherapies evaluated in clinical trials have failed to provide significant clinical benefit for GBM patients, notably due to the high genetic heterogeneity and immunosuppressive environment of the tumor.
Here, we aimed at developing a new cell therapy strategy in GBM, using *in-vitro* expanded γδ T cells (DOT cells).
Results: Characterization of γδ T cells isolated from GBM patient samples highlighted Vδ1 and Vδ2 recruitment within tumors. In parallel, using commercially available GBM cell lines and patient-derived glioblastoma stem cells (GSCs), we showed that amplified γδ T cells, used in combination with interleukin (IL)-15, could efficiently recognize and kill GBM cells and spheroids *in-vitro*. Target cell killing relied on the granule exocytosis pathway and was impacted upon CRISPR-mediated knock-out of γδ TCR and NKG2D molecules suggesting their implication in GBM sensing by amplified γδ T cells. Finally, patient's γδ T cell amplification was also possible, and patient derived cells were still able to kill autologous and allogeneic targets. Altogether, our results are providing encouraging results to develop allogeneic use of γδ T cell therapies in GBM patients.
Perspectives: These data provide an *in vitro* proof of concept for off-the-shelf use of γδ T cells to target GBM and γδ T cell adoptive transfer is now being evaluated *in-vivo* in patient-derived xenograft mouse models.

Ethanol-treated human fibroblasts and their extracellular vesicles modulate TCD4+ lymphocytes

Daniella Figueiredo[1], Ariane Fidelis Busso-Lopes[1], Tatiane De Rossi[1], Rodrigo Gomes Bernardo Cruz[1], João Silva Vitor Ormonde[1], Jamile de Oliveira Sá[1], Larissa Tinô de Carvalho Silva[1], Adriana Franco Paes Leme[1]
[1]*Laboratório Nacional de Biociências - LNBio, Centro Nacional de Pesquisa em Energia e Materiais - CNPEM, Campinas, Brazil*

Purpose: The processes involved in carcinogenesis depend on changes in tumor cells and the dynamic communication in the microenvironment. Studies report smoking and alcohol consumption as risk factors for oral squamous cell carcinoma (OSCC). Still, the mechanism of alcohol on the OSCC initiation needs to be elucidated.
Methods: Peripheric blood mononuclear cells (PBMC) from healthy donor buffy coats were co-cultured with primary fibroblasts, previously treated with ethanol (EtOH), and their extracellular vesicles (EVs). T-cell activation was analyzed by CD25 and CD69 modulation at mRNA and protein expression using RT-qPCR (n=5) and flow cytometry (anti-CD25, n=8, and anti-CD69, n=5), respectively. To further explore the signaling effects, mass spectrometry-based proteomics of fibroblasts and their released EVs (n=6) was performed and biological processes were enriched by Panther tool.
Results: PBMC co-cultured for 72 hours with EtOH-treated fibroblasts or EVs showed lower mRNA expression of *CD25* and *CD69* (treated *vs.* control; $p \leq 0.05$; paired Student´s t-test) and a decrease in the percentage of $TCD3^+$ and $TCD4^+$ cells expressing CD25 (treated *vs.* control; $p \leq 0.05$; Wilcoxon test) and $TCD4^+$ cells expressing CD69 (treated *vs.* control; $p \leq 0.05$; paired Student´s t-test). Moreover, from 4,609 and 162 proteins identified and quantified in fibroblasts and their EVs, respectively, 236 proteins from fibroblasts and 10 from EVs were statistically modulated (treatment *vs.* control; $p \leq 0.05$; unpaired Student's t-test or proteins identified exclusively in one group). Proteins deregulated after ethanol treatment of fibroblasts were involved in cellular metabolism gene ontology (GO) processes such as cellular metabolic process, metabolic process, organic substance metabolic process, primary metabolic process, and proteasome-mediated ubiquitin-dependent protein catabolic process (FDR ≤ 0.05; Fisher exact test followed by FDR correction). Twenty-two out of the 236 EtOH-associated fibroblast proteins are mainly involved in cell metabolism, cell respiration, are part of the mitochondrial complexes I or IV, or have evidence of mitochondrial localization.
Conclusion: The results indicate that alcohol-treated fibroblasts negatively and indirectly modulate the activation of T cells, and this signaling may result from proteins involved in the cell metabolism.

Tolerogenic presentation of an alpha-synuclein antigen on a chimeric major histocampatibility complex class Ib molecule induces regulatory T cells and confers neuroprotection in an animal model for Parkinson's disease

Valentin Bruttel[1], Jingjing Wu[2], Fadhil Ahsan[1], Ann-Kathrin Karl[2], Shriya Mamatha Jayaram[1], Heike Wecklein[1], Maja Heubner[1], Daniela Brünnert[1], Rhonda McFleder[2], Jörg Wischhusen[1], Chi Wang Ip[2]

Purpose: In patients with Parkinson's disease (PD), alpha-synuclein (aSyn) specific autoreactive T cells become detectable long before neuronal pathology. Cohort studies have also shown immunosuppressants to prevent the onset of PD. However, due to the severe side effects, such treatments are unsuitable to treat patients with prodromal PD.
Methods: New model systems like our aSynA53T-AAV-driven mouse model of PD recapitulate involvement of T cells, behavioral symptoms, and histopathology with high face validity. This provides the opportunity to explore possible therapeutic modalities for this incurable disease. To inhibit neurodegeneration and prevent development PD in the absence of systemic immunosuppression, we have developed novel antigen-specific tolerance-inducing biomolecules that present peptide antigens on MHC class Ib-derived molecules. We have thus fused (i) the alpha3 domain of the T cell inhibitory human MHC class Ib molecule HLA-G to (ii) species-adapted MHC class I alpha1-alpha2 antigen-presenting domains, and covalently linked (iii) disease-related or unrelated antigenic peptides and (iv) beta2-microglobulin. We named the resulting single-chain proteins AutoImmunity Modifying Biologicals (AIM Bios).
Results: AIM Bios can polarize cognate $CD8^+$ T cells towards an antigen-specific $CD8^+CD122^+$ IL-10 secreting phenotype, and thereby induce antigen-specific tolerogenic $CD8^+$ T reg cells in human cells *in vitro* and in mice *in vivo*. Molecules built according to this pattern were tested for their ability to prevent tissue damage in the aSynA53T-AAV driven model for PD. While presentation of a virus-derived gp34 control antigen showed no effect, an AIM Bio molecule presenting a disease-associated aSyn $CD8^+$ epitope ameliorated mobility impairments in aSynA53T-AAV PD mice. *Post mortem* histopathological assessment confirmed the induction a favorable *in situ* immune cell composition and the rescue of dopaminergic neurons in the *substantia nigra*, and of dopaminergic termini in the *striatum*.
Conclusion: These molecules point towards a new treatment modality for patients with prodromal PD. Candidate molecules for use in humans are being developed.

Immune cell metabolism governs the outcome of immune responses and contributes to the development of autoimmunity by controlling lymphocyte pathogenic potential. In this study, we evaluated the metabolic profile of myelin-specific murine encephalitogenic T cells, to identify novel therapeutic targets for autoimmune neuroinflammation. By performing unbiased metabolomics analysis, we detected a potential break in the coenzyme A (CoA) synthesis pathway in actively-proliferating encephalitogenic T cells, compared to resting T cells. CoA fueling with the CoA precursor pantethine affected essential immune-related processes of autoreactive T cells, such as antigen-specific proliferation, cytokine production, and integrin-mediated cell adhesion, both *in vitro* and *in vivo*. Mechanistically, pantethine exerted its immunomodulatory effects in encephalitogenic T cells by linking metabolic reprogramming to alteration of intracellular signaling pathways. We then evaluated the impact of pantethine treatment on the development of experimental autoimmune encephalomyelitis (EAE), a mouse model of human multiple sclerosis (MS). Our data show that pre-clinical treatment with pantethine inhibited EAE development in two different mouse strains. Importantly, pantethine also significantly ameliorated the disease course when administered after disease onset in a therapeutic setting. Finally, pantethine limited pro-inflammatory cytokine production by human T helper 1 (Th1) and Th17 cells *in vitro*, as well as by T cells from MS patients, confirming its translational potential. In conclusion, we demonstrated that CoA fueling with pantethine in pro-inflammatory and autoreactive T cells may represent a novel therapeutic approach for the treatment of autoimmune neuroinflammation.

Role of the combination of serum Neurofilaments light chains and IgM bands in the prediction of progression in Multiple Sclerosis

José Luis Veiga[1], Enric Monreal[2], Alexander Rodero[2], Susana Sainz de la Maza[2], Mercedes Espiño[2], Raquel Sainz[2], Noelia Villarrubia[2], Juan Luis Chico[2], Fernando Rodríguez[2], Lucienne Costa-Frossard[2], Luisa María Villar[2]
[1]*Hospital Universitario Ramón y Cajal, Madrid*; [2]*Hospital Universitario Ramón y Cajal, Madrid, Spain*

Background: Multiple sclerosis (MS) is a chronic immune-mediated disease of the central nervous system. To find reliable prognostic biomarkers in MS is of the utmost clinical importance since it allows taking early accurate clinical decisions. In this line, high serum levels of neurofilament light chains (sNfL) have demonstrated to associate with a highly inflammatory MS and predict a higher probability of EDSS progression. On the other hand it has been widely proven that intrathecal IgM synthesis identified by the presence of oligoclonal IgM bands (OCMB) predicts an aggressive MS course. We explored the added value of OCMB to predict MS outcome.
Methods: This is a retrospective analysis performed in 366 patients with a clinically isolated syndrome suggestive of MS and positive oligoclonal IgG bands followed prospectively for five years, with available serum samples and OCMB data. We quantified serum light chain neurofilaments (sNfL) by a single molecule array (SIMOA) method using the NF-LIGHT™ Assay (Quanterix), and studied the prognostic value of OCMB, sNfL levels and the combination of both variables by quantifying time to didability progression measured using the Expanded Disability Status Scale (EDSS). Statistical analyses were performed using survival curves in Prism GraphPad version 10 software.
Results: We established the cut-off for sNfL values by exploring a cohort of 100 age and sex matched healthy controls. Values below 10 pg/ml were considered as normal. We the classified MS patients according bto showing high or normal sNfL values at disease onset. Having high sNfL values predicted an increased risk of disability progression (HR=1.82; 95% CI:1.12-3.11; p=0.016). Showing OCMB further increased the risk of progression in patients with high sNfL values (HR=2.33; 95% CI 1.148 to 4.730; p=0.034). Accordingly, the combination that more accurately predicted disability worsening was the combination of OCMB and high sNfL values. Patients with this condition showed a clearly higher risk of progression compared to the remaining ones (HR=2.28; 95% CI 1.23- 4.25; p=0.0024).
Conclusions: These results strongly suggest that the combination of sNfL and OCMB at disease onset may improve the ability of sNfL alone to early predict disease outcome in MS patients.

Size Matters; Particle size regulates the induction of anti-inflammatory responses and immune tolerance via αvβ3 mechano-sensor engagement

Roisin Lynch[1;2], Jorge Huete-Carrasco[2], Ed Lavelle[2]
[1]SFI Centre for Advanced Materials and BioEngineering Research, Trinity College Dublin, Dublin, Ireland; *[2]Trinity College Dublin adjuvant research lab, Dublin, Ireland*

The increased incidence of auto-immune and inflammatory diseases demands the identification of immune-therapies modulating tolerance and resolution without the risk of systemic immune-suppression. Here we propose the use of biodegradable micro-particles as adjuvants; with the propensity to drive anti-inflammatory responses and antigen-specific tolerance.

The Lavelle lab has focused on the importance of biomaterial-based adjuvant physico-chemical properties in the regulation of innate and adaptive immunity. Notably, particle size was found to be a critical factor that modulates dendritic cell activation and the subsequent activation and polarisation of T cell responses. We have identified that biodegradable poly (lactide-co-glycolide) (PLGA) particles within the narrow size window of 1-2 μm in diameter, drive potent secretion of IL1ra and IL-10 from key antigen presenting cells (APC's). Consequently, these anti-inflammatory APC's were proficient in priming and expanding a CD4+ regulatory T-cell (T-reg) population both in an *in-vitro* co-culture model and *in-vivo* studies.

Investigations into the mechanism by which these particles enhance anti-inflammatory responses revealed a key role for the integrin; αvβ3. Activation of this mechano-sensory integrin is hypothesised to be driven by changes in cell morphology and membrane tension induced by particles of the 1-2 μm range. Engagement of αvβ3 increased downstream anti-inflammatory signalling, initiating a positive feedback loop, promoting increased surface expression of αvβ3 and the TGFβ cell-membrane anchor; Glycoprotein A repetitions predominant (GARP).

These findings demonstrate the therapeutic potential of biodegradable micro-particles of this size as an adjuvant to promote immunological tolerance in a manner independent of biologic agents or potent immunosuppressants.

Furthermore these findings exhibit the importance of mechanical cues in driving immune responses, and how these can be harnessed in order to improve existing immune-therapies.

Single cell sequencing of antigen-specific autoreactive B cells in MuSK myasthenia gravis

Laurent Paardekooper[1], Jessica van Bokkum[1], Yvonne Fillié-Grijpma[1], Theresa Kissel[2], Susan Kloet[1], Martijn Tannemaat[1], Jan Verschuuren[1], Silvère van der Maarel[1], Maartje Huijbers[1]
[1]Leiden University Medical Center, Leiden, Netherlands; *[2]German Cancer Research Center, Heidelberg, Germany*

Recently a new group of autoimmune diseases hallmarked by predominant pathogenic IgG4 autoantibodies (IgG4-AID) was recognized. Why IgG4 predominates these disorders is unknown. Muscle-specific kinase (MuSK) myasthenia gravis (MG) is one of these IgG4-AIDs, in which autoantibodies block MuSK at the neuromuscular junction, causing fatigable muscle weakness. We hypothesize that targeted removal of $IgG4^+$ pathogenic B cells in these diseases could have therapeutic value. However, the unique phenotypical characteristics of both $IgG4^+$ B cells in general and autoreactive $IgG4^+$ B cells are poorly understood.
To characterize autoreactive ($IgG4^+$) B cells, we isolated PBMCs from MuSK MG patients and enrichment-sorted MuSK-reactive B cells using fluorescently-labeled, DNA-barcoded recombinant MuSK tetramers. As controls, we sorted equal numbers of IgM, IgG1-4 and IgA1-2 B cells from the non-MuSK-reactive population and from age-matched healthy donors. Next, libraries for 5' gene expression, B cell receptor (BCR) V(D)J mapping and CITE-seq scores were constructed on the 10x Genomics V2 platform. We recovered a median of 1.091 genes per cell and 80,6% of the cells had a complete V-J spanning pair. Subsequent quality control yielded 83% of all sequenced B cells suitable for further analysis.
Using CITE-seq scores, we identified 246 cells with >75 antigen tetramer binding events/cell. BCR sequences from several strongly MuSK binding cells were recombinantly produced to confirm reactivity in a MuSK ELISA. Unsupervised clustering shows highly MuSK-reactive patient B cells cluster separately from B cells of healthy controls with increased tetramer binding events, which likely arose from aspecific binding. The origin and clonality of the autoimmune response is currently being investigated by phylogeny reconstruction of BCR sequences. Potential therapeutic targets were selected from genes and associated pathways that are uniquely activated in MuSK-reactive $IgG4^+$ B cells. Furthermore, we identified generalized $IgG4^+$ B cell-specific differentially activated pathways by gene ontology analysis.
In conclusion, we successfully developed a multimodal labeling strategy to identify antigen-specific autoreactive B cells in single cell transcriptomics experiments. This modular strategy can be readily translated to any antigen. Autoreactivity- and isotype-specific gene expression profiles are currently being confirmed with *in vitro* experiments.

Microbiota-dependent T-cell response to α-synuclein-derived antigens triggers motor and non-motor symptoms associated to Parkinson's Disease

Rodrigo Pacheco[1;2], Zulmary Manjarres[1;3], Valentina Ugalde[1], Carolina Prado[1;2], Ornella Chovar[1;2], Margarita Calvo[3;4;5]
[1]Centro Científico y Tecnológico de Excelencia Ciencia & Vida, Fundación Ciencia & Vida, Santiago, Chile; *[2]Facultad de Medicina y Ciencia, Universidad San Sebastián, Santiago, Chile*; *[3]Facultad de Ciencias Biológicas, Pontificia Universidad Católica de Chile, Santiago, Chile*; *[4]Millennium Nucleus for the Study of Pain, Santiago, Chile*; *[5]División de Anestesiología, Escuela de Medicina, Pontificia Universidad Católica de Chile, Santiago, Chile*

Purpose: Previous evidence has shown that both the T-cell response and the microbiota are fundamental on the development of Parkinson's Disease (PD), which is characterized by the accumulation and post-translational modification of α-synuclein (αSyn). Modified αSyn constitutes a source of neo-antigens able to trigger an autoreactive T-cell response. Nevertheless, the relationship between the microbiota and the development of this autoreactive T-cell response in PD remains unexplored. Here we studied whether the dysbiosis of the gut microbiota and the T-cell response to αSyn-derived antigens associated to PD are functionally connected.
Methods: We used transgenic *SNCA* mice, which involve the overexpression of human αSyn (hαSyn). To deplete the microbiota, we used a wide-spectrum antibiotic cocktail. To deplete lymphocytes we generated *SNCA* mice deficient on recombination-activating gen 1 or deficient on membrane-bound IgM. Microbiome was analyzed by sequencing the variable V4 region of the 16S rRNA gene. Bioinformatics tools were used to analyse the sequence homology between bacteria and hαSyn.
Results: We observed that the depletion of either gut microbiota or T-cells abrogated the development of motor deficits, sensory threshold impairment, neuroinflammation and gut inflammation. Moreover, our results reveal the development of a T-cell response specific to neo-antigens derived from hαSyn in cervical and mesenteric lymph nodes. Of note, *SNCA* mice presented higher intestinal barrier permeability, which was associated with a significant gut inflammation. Furthermore, we found that particular bacterial components from intestinal microflora display some structures with sequence homology with hαSyn and significant potential binding to MHC molecules, thus suggesting molecular mimicry.
Conclusion: Our findings indicate that the development of both motor and non-motor manifestations as well as neuroinflammation in PD involves a T-cell mediated autoimmune response, which is triggered by changes in the gut microbiota that induce increased intestinal barrier permeability. Moreover, our findings suggest that dysbiosis in this PD model involves bacterial components with molecular mimicry with hαSyn.

Purpose: The lung is constantly exposed to airborne pathogens and particles that can cause alveolar damage and appropriate repair post-injury is essential for gas exchanges and life. Severe respiratory viral infections represent a global health issue and are typically associated with excessive inflammation and damage and abnormal tissue repair that can lead to acute respiratory distress syndrome, pneumonia and death, thus representing a serious unmet medical need. If the role on recruited blood monocytes and macrophages during the acute inflammatory phase is known to contribute to host innate defense mechanisms, the function of these cells in the induction of the lung functional repair remain underinvestigated. In this study, we deciphered the spatiotemporal trajectory and function of macrophages after virus-triggered lung injury.
Methods: By employing an *in vivo* model of influenza A virus-induced lung injury in combination with single-cell and spatial transcriptomic analyses, bone marrow chimeras, monocyte fate-mapping and gene targeting, we investigated the dynamic behavior and function of a distinct subset of monocyte-derived Ly6G-expressing macrophages ($Ly6G^+$ Macs).
Results: In the early recovery phase post-influenza A virus infection, $Ly6G^+$ Macs were transiently recruited in the alveolar spaces of lung perilesional areas. $Ly6G^+$ Macs exhibited a high metabolic potential, engulfed immune cells locally and clustered with alveolar type 2 (AT2) epithelial cells in zones of active epithelial regeneration. *In vivo* gene targeting and *ex vivo* wound healing assays showed that $Ly6G^+$ Macs were dependent on interleukin-4 receptor signaling and crucially contributed to euplastic alveolar regeneration by directly interacting with AT2 cells. Notably, similar macrophages were recruited in other models of injury and in the alveolar spaces of human injured lungs.
Conclusion: Our study identifies perilesional alveolar $Ly6G^+$ Macs as a spatially-restricted, short-lived macrophage subset engaging in a crosstalk with AT2 to promote epithelial regeneration and host recovery post-injury, thus representing an attractive therapeutic target.

Targeting neutrophil extracellular traps to reduce immunopathology in tuberculosis

Julia Kutschenreuter[1], Ramla Cusman[1], Keira Skolimowska[1], Jon S Friedland[1], Deborah L W Chong[1]
[1]*Institute for Infection and Immunity, St George's University of London, London, United Kingdom*

Purpose: *Mycobacterium tuberculosis (Mtb)*, the causative agent of Tuberculosis (TB), is responsible for 1.6 million deaths annually. Up to 94% of survivors suffer from clinically significant decreased lung function due to immunopathological changes. Neutrophils, key immune cells in the immune response to TB, can form extracellular traps (NETs) composed of DNA, citrullinated histone H3 (citH3) and myeloperoxidase (MPO) to encapsulate *Mtb*. They may regulate lung tissue remodelling by acting on fibroblasts, key cells in wound healing and fibrotic processes, which is in part regulated by secretion of matrix metalloproteinases (MMPs) and their inhibitors (TIMPs). We hypothesise, that NETs induced during *Mtb* infection drive lung immunopathology in TB.
Methods: Human peripheral neutrophils were infected with *Mtb* or stimulated with 100 µg/ml *Mtb*-antigen, ESAT-6, to induce NETs, which were quantified by PicoGreen dsDNA staining or an ELISA against citH3 and MPO. For confocal microscopy, NETs were stained for citH3, MPO and DNA. Primary human lung fibroblasts (PHLF) were stimulated with NETs or co-cultured with peripheral neutrophils and *Mtb* in a novel cellular model. PHLF gene expression and secreted mediators were measured by qRT-PCR and ELISA.
Results: Infection of neutrophils with *Mtb* at a multiplicity of infection of 10 induced NETs compared to resting neutrophils (238.9 vs. 112.7 ng/ml dsDNA, $p<0.001$; and OD_{450} 0.16 vs 0.07, $p=0.0197$, respectively). Confocal microscopy of ESAT-6 stimulated neutrophils confirmed co-localisation of extracellular citH3, MPO and DNA, key components of NETs. Stimulation of PHLF with exogenous NETs significantly increased secretion of the collagenase MMP-1 (2.2 vs 88.2 ng/ml $p<0.0001$), but not TIMP-1. In a neutrophil-PHLF co-culture system, *Mtb*-induced NETs lead to significantly increased MMP-1, MMP-3, IL-6, and IL-1β secretion and gene expression in PHLF. Pre-treatment with DNase, that degrades NETs, or with an inhibitor of NET formation, GSK484 significantly reversed the inflammatory response.
Conclusions: *Mtb* drives formation of NETs which act on lung fibroblasts to induce proinflammatory cytokine and MMP secretion which induce tissue remodelling in TB. Degrading NETs or preventing NET formation may represent a potential novel host-directed therapy to decrease fibroblast-dependent impaired lung function in TB patients.

Elevated matrix-metalloproteinase and pro-inflammatory cytokine activity due to helminth co-infection drives pulmonary tissue destruction in tuberculosis

Maria Cristina Loader[1;2], Sory Vasquez Alves[2;3], Manuela Verastegui[2], Robert H Gilman[2;4], Jon S Friedland[1]
[1]Institute for Infection and Immunity, St George's University of London, London, United Kingdom; *[2]Laboratorio de Investigación y Desarrollos, Universidad Peruana Cayetano Heredia, Lima, Peru*; *[3]PRISMA NGO, Lima, Peru*; *[4]Department of International Health, Johns Hopkins School of Public Health, Baltimore, United States*

Purpose: Tuberculosis (TB) and soil-transmitted helminth (STH) infections are widespread, infecting approximately 1.8 and 1.5 billion people respectively worldwide. TB-STH co-infected individuals appear to suffer increased lung damage compared to those with TB alone, however the mechanisms behind this remain unclear. We explored the impact of STH and TB infection on the innate human immune response, investigating pro-inflammatory cytokines and matrix metalloproteinases (MMPs), the drivers of lung tissue destruction.
Methods: We recruited adults with culture-confirmed pulmonary TB and healthy controls in Iquitos, a city in the Peruvian Amazon only accessible by boat or plane. Three stool samples were obtained for parasitological examination, sputum for TB confirmation, and blood for analysis of cytokines, MMPs and *Strongyloides* serology via ELISA or Luminex multiplex assay. CXRs performed as part of routine care were used to determine lung damage severity score.
Results: Forty out of 61 TB-positive participants (65.6%) had at least one STH diagnosed compared with 43.1% of TB-negative participants (P=0.02). The adjusted odds of TB-positivity in individuals with >=1 STH were 2.69 times higher than in STH uninfected (95%CI 1.14-6.59).
MMPs: Multivariable analysis showed STH infection was positively associated with MMP-1 (beta 1.3, P=0.025), MMP-9 (beta 1.5, P=0.022), MMP-10 (beta 1.3, P<0.001), and MMP-13 (beta 1.2, P<0.001). TB infection was also significantly positively associated with all MMPs measured. Furthermore, MMPs positively correlated with CXR severity score, with a significant association in MMP-1 (beta 2.06, P=0.03), MMP-8 (beta 1.83, P=0.01) and MMP-9 (beta 1.82, P=0.05).
Cytokines: Multivariable analysis found STH infection was positively associated with IL-1beta (beta 1.17, P=0.021), IL-6 (beta 1.3, P=0.029), IL-12 (beta 1.15, P=0.012) and IL-17 (beta 1.16, P=0.002). TB infection was also significantly positively associated with all cytokines measured.
Conclusion: STH infection was associated with an overall increase in matrix-metalloproteinase and pro-inflammatory cytokine activity. In addition, MMPs positively correlated with CXR severity score indicating increased lung damage in these individuals. TB co-infection with STHs may drive an increased type I immune response leading to increased pulmonary inflammation and tissue destruction. These data have future implications on screening and treatment of STHs in TB.

Plasmodium parasites cause malaria, a global health disease that is responsible for more than 200 million clinical cases and 600 000 deaths each year. Most deaths are caused by various complications, including malaria-associated acute respiratory distress syndrome (MA-ARDS). Despite the very rapid and efficient killing of parasites with antimalarial drugs, 15% of patients with complicated malaria succumb. This stresses the importance of investigating resolution mechanisms that are involved in the recovery from these complications once the parasite is killed. To study the resolution of MA-ARDS, *P. berghei* NK65-infected C57BL/6 mice were treated with antimalarial drugs after onset of symptoms, resulting in 80% survival. Micro-computed tomography revealed alterations of the lungs upon infection, with an increase in total and non-aerated lung volume due to edema. Whole body plethysmography confirmed a drastically altered lung ventilation, which was restored during resolution. Single-cell RNA sequencing indicated an increased inflammatory state in the lungs upon infection, which was accompanied by a drastic decrease in endothelial cells, consistent with CD8+ T cell-mediated killing. During resolution, anti-inflammatory pathways were upregulated and proliferation of endothelial cells was observed. MultiNicheNet interactome analysis identified important changes in the ligand-receptor interactions during disease resolution that warrant further exploration in order to develop new therapeutic strategies. In conclusion, our study provides insights in pro-resolving pathways that limit inflammation and promote endothelial cell proliferation in experimental MA-ARDS. This information may be useful for the design of adjunctive treatments to enhance resolution after *Plasmodium* parasite killing by antimalarial drugs.

Purpose: Sarcoidosis (SARC) is a multisystemic inflammatory and granulomatous disease that most commonly affects the lungs. Causes and mechanisms underlying granuloma formation and maintenance are still unknown, but SARC shares many similarities with tuberculosis (TB). We hypothesized that monocytes from patients with SARC and TB may retain a specific epigenetic signature that drives maladaptive innate immune training and disease.
Methods: To test this, we performed genome-wide epigenetic profiling of monocytes from newly diagnosed SARC or TB patients using CUT&Tag technology, and assessed the acetylation of lysine 27 of histone 3 (H3K27Ac) to identify enhancers of expressed genes. From this we identified super-enhancers (SE) and predicted the autoregulatory transcription factors (TF) that are part of the core regulatory circuitries (CRC) in each disease.
Results: Through differential analysis of genome-wide H3K27Ac profiles we identified genomic regions that specifically distinguished SARC patients from TB patients and from Healthy Controls (HC). There were 9 H3K27Ac enriched regions and 84 H3K27Ac depleted regions in SARC patients compared to HC. One region was specifically H3K27Ac depleted in SARC compared with TB (shrunken$\log_2$FC > | 0.1|, adj-p < 0.1). SE were identified in all samples and among SE-associated genes, we identified 8 auto-regulatory TF specific to SARC (i.e., TCF7, FOXJ2, PRDM1, FOXK1, FOXO3, USF1, ELF2, and NR4A1), 3 specific to TB (i.e., ZNF219, EGR3, IRF7) and 5 shared by both diseases (KLF11, MNT, E2F2, SREBF1, and IRF2). Functional analysis suggested a role played by type I interferon, glucose metabolism and apoptosis pathways. This confirmed our hypothesis with evidence of specific CRCs in either disease.
Conclusion: Our findings provide evidence that there are distinct monocyte epigenetic signatures associated with SARC and TB, and raise new and challenging perspectives on the role played by trained immunity in inflammatory diseases. Ongoing work will incorporate transcriptomic data in the identification of CRCs and integrate additional immune phenotyping and functional assays for a more comprehensive understanding of granulomatous diseases.

Rationale: COPD is a severe, progressive and heterogeneous condition with several clinical phenotypes. However, the composition of the local immune environment in COPD patients has rarely been investigated and may assist patient stratification.
Methods: Comprehensive immune cell and cytokine profiles were created from lung explants from end-stage COPD patients (n = 23 & 40) and healthy donor lungs (n = 20 & 31) following transplantation using computational flow cytometry and multiplex assays, respectively.
Results: COPD lungs presented with a distinct immune cell signature. Application of machine learning algorithms revealed an enrichment of lymphocytic populations (including cytotoxic and T helper cells) and decreased neutrophils in end-stage COPD patient lung compared with donor lungs. COPD patients presented with strongly divergent cytokine profiles in the lung and circulation, with cytokines being co-regulated or differentially regulated in between both compartments e.g. IL-6, CCL2 and CCL5. Plasma cytokines were most strongly affected by disease status, however, smoking history did not alter the circulating cytokine profile. In contrast lung cell counts correlated strongly with smoking pack years and decreased oxygenation, and decreased lung function correlated strongest with circulating proinflammatory cytokine levels. Sub-clustering the COPD cohort revealed the presence of severe adaptive-immune patient subtype.
Conclusions: End-stage COPD patients display unique inflammatory cellular and cytokine signatures that can be stratified in a novel, clinically meaningful, endotypes. Our approach may provide a future rationale for targeted personalized treatments.

The RNA-binding proteins TIA1 and TIAL1 control T-cell activation and germinal centre formation.

Trang-My Nguyen[1], Orlane Maloudi[1], Maïlys Mouysset[1], Ines Claire Osma-Garcia[1], Dunja Capitan-Sobrino[1], Yann Aubert[1], Manuel Diaz-Munoz[1]
[1]*Toulouse Institute for Infectious and Inflammatory Diseases (INFINITy), Inserm UMR1291, Toulouse, France*

Purpose: Effective germinal centre responses rely on the dynamic regulation of genetic programs for ample activation and production of immunomodulator molecules by T cells. Emerging evidence show the prevalence role of post-transcriptional mechanisms regulated by RNA-binding proteins (RBPs) in the control of T cell function. Our recent studies uncovered the RBPs T-cell antigen 1 (TIA1) and like 1 (TIAL1) as essential players for B-cell expansion and selection in germinal centres, but their roles in T cells remains unknown. Our hypothesis is that TIA1 and TIAL1 are part of a post-transcriptional regulatory program that shapes the transcriptome of T cells during activation for mounting effective immune responses.
Methods: We used conditional knock out (KO) mice to assess the intrinsic role of TIA1 and TIAL1 in T cells in different models of vaccination. To identify the molecular mechanisms regulated by TIA1 and TIAL1 in T cells, we performed individual crosslinking immunoprecipitation (iCLIP) and RNA sequencing in TCR-activated CD4 T cells.
Results: Phenotypical characterization of T cell subsets in different experimental models revealed an important role for TIA1 and TIAL1 in T cell activation both in-vivo and in-vitro. TIA1 and TIAL1 deletion in T cells impaired both acute and chronic germinal centre responses. TIA1 and TIAL1 were found associated mainly with introns and 3'UTR of thousands of mRNA targets. Molecular characterization of TIA1 and TIAL1 double KO CD4 T cells showed that these RBPs shaped quantitatively and qualitatively the transcriptome of T cells by controlling the expression of essential transcription factors like Myc required for T-cell metabolic reprograming and proliferation upon TCR activation.
Conclusion: TIA1 and TIAL1 are essential components of a post-transcriptional network that control antigen-mediated T cell activation of T lymphocytes. Understanding the functions of TIA1 and TIAL1 in T cells will uncover novel post-transcriptional mechanisms controlling immunity which could be exploited in the development of innovative immunotherapies against disease.

CD4-Lck signalling activates CDK1 to enhance nuclear transport in T cells

Dejan Mesner[1], Matt Whelan[1], Maitreyi Shivkumar[1;2], Clare Jolly[1]
[1]Division of Infection & Immunity, University College London, London, United Kingdom; [2]Leicester School of Pharmacy, De Montfort University, Leicester, United Kingdom

Engaging the TCR at the immune synapse of CD4 T cells activates Lck that is complexed with CD4 to initiate downstream signalling. Here, we sought to examine CD4-Lck signalling in isolation from the canonical pMHC-TCR pathway. We first turned to a naturally occurring example of such antigen-independent CD4 engagement that occurs when HIV-1 envelope protein (Env) binds to CD4 on T cells to initiate viral infection. In this assay, the HIV-1 Env expressed on a virus-infected T cell binds CD4 on the surface of an uninfected cell, forming a so-called virological synapse that we and others have shown shares similarity with the immune synapse. Using resting primary CD4 T cells we found that Env-CD4 engagement resulted in a rapid and transient increase in phosphorylation of Lck, Zap70, Erk, p38 and Akt, which was similar in kinetics, but smaller in amplitude compared to CD3-crosslinking. We confirmed that CD4 engagement alone was sufficient for this signalling using 5 μm beads coupled with anti-CD4 antibody and observed that this reductionist approach similarly phosphorylated Lck and other downstream kinases. Next, we investigated the functional consequences of this CD4-Lck signalling. Measuring classical activation markers, we found no evidence for cell activation or cell cycle progression. Instead, we observed an increased rate of nuclear transport in CD4-stimulated T cells that was evident for both karyopherin-independent transport of HIV-1 capsid through the nuclear pore complex, and more globally for karyopherin-dependent transport measured by increased nuclear localisation of importin β1. Strikingly, this correlated with altered localisation of nuclear pore proteins Nup62 and TPR, suggesting that CD4-Lck signalling triggers nuclear pore remodelling to facilitate increased nuclear transport kinetics. Consistent with these changes, we found that CD4-Lck signalling activated CDK1 which is known to phosphorylate nuclear pore proteins. Moreover, inhibitors of Lck or CDK1 abolished the changes in nuclear transport kinetics and nuclear pore architecture initiated by CD4-Lck signalling. We conclude that CD4-Lck signalling at the synapse activates changes in nuclear pore architecture and transport dynamics, revealing a role for CDK1 beyond cell cycle progression and providing new insights in signalling propagation in T cells.

NRK1-dependent cytoplasmic NAD/H synthesis determines CD4+ T cell inflammatory function and survival

Myah Ali[1], Victoria Stavrou[1], Nancy Gudgeon[1], Emma Bishop[1], Taylor Fulton-Ward[1], Bethany Turley[1], Silke Heising[1], Sally Mohamed[1], Sofia Hain[1], Lorna George[1], Bryan Marzullo[1], Minghao Deng[2], Daniel Tennant[1], Craig Doig[2], Gareth Lavery[2], Rebecca Drummond[1], Sarah Dimeloe[1]
[1]University of Birmingham, Birmingham, United Kingdom; *[2]Nottingham Trent University, Nottingham, United Kingdom*

$CD4^+$ T cell function is underpinned by metabolic reprogramming upon activation. Increased glycolysis provides biosynthetic precursors for clonal expansion and promotes cytokine expression. In parallel, elevated mitochondrial oxidative phosphorylation (OXPHOS) generates heightened ATP and reactive oxygen species (ROS). ROS disseminate and signal, promoting T cell differentiation, but must be mitigated to prevent oxidative damage. Nicotinamide adenine dinucleotide (NAD/H) is an essential redox cofactor for glycolysis and mitochondrial OXPHOS. It is also phosphorylated to NADP/H, which regulates ROS levels. NAD/H abundance increases in line with $CD4^+$ T cell metabolism upon activation, but synthetic pathways are not fully characterised.
In this study, we interrogated expression and activity of nicotinamide riboside kinase 1 (NRK1) in $CD4^+$ T cells, which phosphorylates nicotinamide riboside (NR), directing it into the NAD salvage pathway. We identified this increases upon cell stimulation, driven by TCR and CD28 signalling. NRK1 non-redundantly contributes to NAD/H abundance in these cells but suppresses their activation and function. Consistently, NRK1-deficient $CD4^+$ T cells have a hyper-inflammatory phenotype, expressing high levels of effector cytokines, which occurs alongside impaired viability.
Mechanistically, this is linked to NRK1 redistribution to the cytoplasm upon $CD4^+$ T cell activation, where it locally elevates NAD/H levels. This supports glycolysis, but more profoundly impacts cytoplasmic NADP/H generation, thereby determining ROS abundance and nuclear NFAT translocation. During invasive fungal infection, NRK1 activity critically maintains effector $CD4^+$ T cell frequencies within affected tissues, confirming that regulation of immune cell metabolism at the subcellular level determines whole organism immune responses.

Extracellular ATP Induces Aging-Associated Traits in CD4 T Cells

Sonja Rittchen[1], Anja Zdouc[1], Stefano Angiari[1], Johannes Fessler[1]
[1]*Division of Immunology, Otto Loewi Research Center, Medical University of Graz, Graz, Austria*

Purpose: The cellular aging process leads to immune function alterations, rendering aged individuals more vulnerable to various diseases. $CD4^+$ T cells, vital in adaptive immunity, undergo functional changes with age, including senescence-induced dysregulation. Beyond cellular changes, aging also affects cellular metabolism, including nucleotide metabolism. Additionally, tissue damage provoked by for example inflammaging can boost the release of nucleotides, such as adenosine-tri-phosphate (ATP). This study aims to explore the impact of extracellular ATP (eATP) on $CD4^+$ T cell characteristics reminiscent of aged immune systems, shedding light on potential mechanisms underlying immune aging.
Methods: Peripheral blood mononuclear cells (PBMCs) from young (<30 years) and aged (>55 years) donors were isolated, and T cell subsets were characterized using flow cytometry. A comprehensive panel assessed T cell activation markers, calcium signaling, proliferation, migration, mitochondrial activity, ROS production, and cytokine/granzyme B secretion upon extracellular ATP (eATP) stimulation. Additionally, subset-specific expression of ATP-binding P2Y receptors was evaluated.
Results: ATP-binding P2Y receptors, particularly P2Y2 and P2Y11, were significantly elevated in $CD4^+$ T cells from aged individuals, especially in memory subsets. Senescent T cell populations lost receptor expression, potentially rendering those cells insensitive to eATP. While eATP minimally affected calcium flux directly, it potentiated ionomycin-induced responses in young donors but not in aged counterparts. Conversely, $CD4^+$ T cells from aged donors exhibited heightened ionomycin responsiveness but reduced sensitivity to ATP. $CD4^+$ T cells from aged donors also showed minor amplification of mitochondrial potential after 24h activation with anti-CD3/CD28 in presence of eATP, with minimal effects on mitochondrial and cellular ROS. ATP-primed $CD4^+$ T cells from both, young and aged donors, displayed increased migration and significantly elevated granzyme B expression and secretion, along with enhanced production of IL-17A, IL-4, perforin, and granulysin.
Conclusion: These findings highlight age-related alterations in $CD4^+$ T cell responses to eATP, suggesting a potential role for purinergic signaling in immune aging. Elevated P2Y receptor expression in aged $CD4^+$ T cells may contribute to dysregulated immune metabolism and compromised functions.

Spatial and functional association of CD69 leukocyte activation receptor with Peroxiredoxin-1

María Jiménez-Fernández[1;2], Diego Calzada-Fraile[1;2], Danay Cibrián[1;2;3], Hortensia De la Fuente[1;3], Francisco Sanchez-Madrid[1;2;3]
[1]Department of Immunology, Instituto de Investigación Sanitaria Hospital Universitario de La Princesa (IIS-Princesa), Universidad Autónoma de Madrid (UAM), Madrid, Spain; *[2]Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, Spain*; *[3]Centro de Investigación Biomédica en Red de Enfermedades Cardiovasculares (CIBERCV). Instituto de Salud Carlos III, Madrid, Spain*

The early leukocyte marker CD69 is an immunoregulatory molecule that controls T cell activation, retention and differentiation. Recently, we have identified that the binding of oxLDL to CD69 induces the expression of PD-1 through the activation of NFAT. To decipher the molecular mechanisms of CD69-driven T cell regulation, we have carried out a "peroxidase-catalyzed proximity labeling" strategy. We have generated a fusion protein of CD69 with the ascorbate peroxidase APEX2 and stably over-expressed this construct in a CD69 knock-out (KO) T cell line of Jurkat previously generated by CRISPR-Cas9 technology. Among a number of CD69-spatially neighboring proteins, there was an unexpected enrichment in peroxiredoxins (PRDXs) such as PRDX2, PRDX4 and especially PRDX1. PRDXs are antioxidant enzymes that prevent cell damage caused by reactive oxygen species (ROS). In addition, PRDX1 acts as a molecular chaperone under oxidative stress conditions, enhances natural killer cell cytotoxicity, suppresses oncogenic proteins and it is a key regulator of lipid peroxidation. The association of CD69 with PRDX1 was validated by a pull-down assay in activated naïve CD4+ T lymphocytes obtained from wild-type mice compared to CD69-deficient mice. We have also evaluated the lipid peroxidation content in Jurkat and primary T lymphocytes by flow cytometry. Activation with anti-CD3/CD28 enhanced lipid peroxidation specifically in CD69+ T cells, since both KO Jurkat and mouse CD4+ T cells CD69-deficient showed less lipid peroxidation. Moreover, Jurkat overexpressing CD69 have increased lipid peroxidation that activated wild-type cells. These results may indicate a novel role for CD69 controlling the regulation of lipid peroxidation through its association with PRDX1, thereby modulating the activation and cellular fate.

A novel interaction between E-cadherin and PD-1 leads to inhibition of T cell function

Puja Kumari[1], Dibyendu Samanta[1], Gayatri Mukherjee[2]
[1]Department of Bioscience and Biotechnology, Indian Institute of Technology, Kharagpur, India; *[2]School of Medical Science and Technology, Indian Institute of Technology, Kharagpur, India*

Purpose: E-cadherin is a member of the cadherin superfamily widely known to participate in cell-cell adhesion processes. Interestingly, studies have demonstrated its ability to modulate functional responses of NK cells and T cells by interacting with the inhibitory receptor KLRG1. Like KLRG1, PD-1 is also an inhibitory receptor expressed on T cells that regulates T cell activation and promotes immune tolerance. Since E-cadherin is extensively expressed on the surface of epithelial cells, it is important to investigate its interaction with PD-1 and its role in peripheral tolerance.
Methods: The N-terminal ectodomains of E-cadherin and PD-1 were expressed and purified followed by interaction analysis using Surface Plasmon Resonance. Fluorophore-conjugated E-cadherin tetramers were used to check for interaction with PD-1 expressed on T cells via flow cytometry. The effect of E-cadherin on T cell activation and differentiation was investigated to understand the functional role of the interaction. The available structures of PD-1 and E-cadherin were analyzed followed by molecular docking and mutagenesis studies to map their binding interface.
Results: Biophysical studies with either mouse or human E-cadherin and PD-1 showed a concentration-dependent increase in response indicating an interaction between the two proteins. Moreover, E-cadherin was able to bind to PD-1-expressing T cells independently of KLRG1 expression and proportionate to the level of PD-1 expression, confirming the interaction between E-cadherin and PD-1 on T cells. The engagement of PD-1 by E-cadherin inhibited T cell activation, proliferation, and cytokine production, demonstrating the inhibitory effect of this novel interaction. The effect of E-cadherin mutants on T cells showed that the canonical homodimeric interface of E-cadherin participates in its interaction with PD-1.
Conclusion: E-cadherin and PD-1 can interact through their N-terminal ectodomains resulting in T cell inhibition. Given the expression of E-cadherin in the peripheral tissue, it is important to investigate the biological implication of the novel PD-1: E-cadherin interaction in maintaining peripheral tolerance. Also, the role of this interaction in immune-evasion strategies by tumor cells needs to be studied in-depth which may lead to the identification of novel therapeutic targets.

Blood Brain Barrier transmigration triggers inflammasome activation in Th lymphocytes during neuroinflammation

Gayel Duran[1;2], Lisa Schuetz[1;2;3], Janne Verreycken[1;2], Paulien Baeten[1;2], Baharak Hosseinkhani[1;2;4], Sam Duwe[5], Jelle Hendrix[5], Ilse Dewachter[6], Niels Hellings[1;2], Bieke Broux[1;2]
[1]University MS Center, Diepenbeek, Belgium; *[2]Neuro-Immune Connections and Repair Lab, Department of Immunology and Infection, Biomedical Research Institute, UHasselt, Diepenbeek, Belgium*; *[3]Internal Medicine, Maastricht University, Maastricht, Netherlands*; *[4]Laboratory of Angiogenesis and Vascular Metabolism, Center for Cancer Biology (CCB), VIB and Department of Oncology, Leuven Cancer Institute (LKI), KU Leuven, Leuven, Belgium*; *[5]Dynamic Bioimaging Lab, Advanced Optical Microscopy Centre and Biomedical Research Institute, Hasselt University, Diepenbeek, Belgium*; *[6]Biomedical ResearchInstitute Hasselt University, Diepenbeek, Belgium*

Rationale: Multiple Sclerosis (MS) is a chronic autoimmune disease of the central nervous system (CNS), characterized by infiltration of immune cells into the brain. The disease is initiated when self-reactive T cells are activated in the periphery, after which they travel to the CNS through the blood brain barrier (BBB). Once inside, an inflammatory cascade is triggered, causing damage to neuronal tissue, which results in neurological disabilities. Up to now, the role of the inflammasome herein was mostly studied in innate immune cells. However, recently it was shown that inflammasome activation in adaptive immune cells plays a role in other autoimmune diseases. Here, we aim to identify whether inflammasome activation in T helper cells is increased in MS patients, and whether it contributes to disease pathogenesis and progression.
Methods/Results: RNA analysis of ex vivo samples of MS patients and healthy controls reveals that inflammasome related markers are upregulated in CD4 T cells of MS patients. To visualize inflammasome activation in vivo, we used a preclinical mouse model, experimental autoimmune encephalomyelitis (EAE), in ASC-reporter mice. Herein, we identified an increase in inflammasome activation in the CD4 T cell subsets Th17, Th17.1 and Tregs, over time **exclusively** in the CNS. Lightsheet microscopy of whole brains of healthy and EAE induced ASC-reporter mice show a clear increase in immune cells containing inflammasome activation during disease. In NLRP3 knock out mice, EAE induction resulted in significantly lower disease scores compared to WT mice. Importantly, this coincided with a decreased CNS infiltration of Th1 and Th17 subsets. Finally, using human in vitro BBB migration assays, we found that only Th cells show increased inflammasome activation after BBB transmigration. Also, inflammasome activation in Th cells increased their migration rate, linking the inflammasome to the propensity of Th cells to migrate across the BBB.
Conclusion: These results indicate that inflammasome activation in Th cells is crucially involved in autoimmune neuroinflammation. Importantly, it appears to be linked to BBB transmigration, which is an initiating player in EAE and MS. Therefore, inhibition of inflammasome activation specifically in Th cells could be a possible therapeutic modality to treat MS patients.

CD29hi CD99hi T cells are upregulated in primary Sjögren's syndrome

Ayibaoyta Bahabayi[1], Zhonghui Zhang[1], Yiming Gao[1], Danni Liu[2], Pingzhang Wang[3;4], chen liu[1]
[1]*Department of Clinical Laboratory, Peking University People's Hospital, Beijing, China*; [2]*School of Basic Medical Sciences, Peking University Health Science Center, Beijing, China*; [3]*Department of Immunology, NHC Key Laboratory of Medical Immunology (Peking University), Medicine Innovation Center for Fundamental Research on Major Immunology-related Diseases, School of Basic Medical Sciences, Peking University Health Science Center, Beijing, China*; [4]*Peking University Center for Human Disease Genomics, Peking University Health Science Center, Beijing, China*

Purpose: Primary Sjögren's syndrome (pSS) is an autoimmune disease that is triggered by environmental factors in genetically susceptible individuals, resulting in a dysregulated immune response that leads to chronic inflammation and autoimmunity. This study aimed to explore the roles of CD29 and CD99 in human T lymphocytes and to clarify their significance in pSS.
Methods: Single-cell RNA-Seq data were employed to examine the expression of CD29 and CD99 in peripheral blood mononuclear cells. Flow cytometry was used to detect the expression of CD29 and CD99 in peripheral blood T lymphocytes of 24 pSS patients and 20 age- and gender-matched healthy controls. Based on RNA-Seq predictions, the expression of cytotoxic and activation-related molecules was analysed in both the CD29hi CD99hi and CD29int CD99int subsets. T lymphocytes were stimulated with anti-CD29 and anti-CD99 antibodies to elucidate the role of CD29 and CD99. CD29 and CD99 related cell subsets of pSS patients were detected, and their clinical effectiveness in diagnosing pSS was determined through Receiver Operating Characteristic (ROC) curves.
Results: Single-cell RNA-Seq data revealed a robust positive correlation between CD29 and CD99 in both CD4+T and CD8+T cells. Flow cytometry validated their co-expression, classifying T cells into CD29int CD99int and CD29hi CD99hi subsets. CD29hi CD99hi T cells demonstrated high expression of cytotoxic molecules and exhibited activation markers, with elevated levels of Ki-67, PD-1 and CD25. Stimulation with anti-CD99 and anti-CD29 antibodies increased granzyme B levels in CD29hi CD99hi CD8+T cells. CD29hi CD99hi CD8+T cells were significantly increased in pSS, indicating their potential for pSS diagnosis, as demonstrated by high AUC values in ROC analysis.
Conclusion: CD29 and CD99 showed significant co-expression in peripheral T cells, while CD29hi CD99hi T cells displayed characteristics of cytotoxic T lymphocytes and activated T cells. The changes in CD29hi CD99hi T cell subsets among pSS patients contribute to the early diagnosis of pSS.

SARS-CoV-2-specific antibody and T-cell responses after COVID-19 BA.1 bivalent boosting

Barbara Kronsteiner-Dobramysl[1], Melissa Govender[1], Chang Liu[1], Eleanor Barnes[1], Thushan de Silva[2], Christopher Duncan[3], Victoria Hall[4], Susan Hopkins[4], Katie Jeffery[5], Rebecca Payne[3], Alex Richter[6], Gavin Screaton[1], Lance Turtle[7], Paul Klenerman[1], Miles Carroll[1], Susanna Dunachie[1], on behalf of the PITCH Consortium+[8]
[1]*University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom*; [2]*University of Sheffield, Department of Infection, Immunity and Cardiovascular Disease., Sheffield, United Kingdom*; [3]*Newcastle University, Translational and Clinical Research Institute, Newcastle, United Kingdom*; [4]*UK Health Security Agency, Salisbury, United Kingdom*; [5]*University of Oxford, Radcliffe Department of Medicine, Oxford, United Kingdom*; [6]*University of Birmingham, Institute for Immunology and Immunotherapy, College of Medical and Dental Science, Birmingham, United Kingdom*; [7]*University of Liverpool, Institute of Infection, Veterinary and Ecological Sciences, Liverpool, United Kingdom*; [8]*Multiple, Multiple, United Kingdom*

SARS-CoV-2 variants of concern (VOCs) are a major issue for ongoing protection following COVID-19 vaccination and infection. In a longitudinal observational study of healthcare workers, we previously showed that T-cell responses to vaccination are well-maintained over time, and against VOCs, while antibody responses wane rapidly and are lost to emerging VOCs.
Here, we assessed the impact of the bivalent BA.1 COVID-19 vaccine (fourth dose=V4 received in autumn 2022) on T-cell and antibody responses using a multi-centre cohort, Protective Immunity from T-cells to COVID-19 in Healthcare workers (PITCH). This study uniquely compares responses in people who've received a bivalent vaccine dose with those having a parallel vaccination history, but did not receive the bivalent vaccine.
Peripheral blood mononuclear cells, plasma, serum, and nasal mucosal strips were collected at pre-V4 (V3+6 and 12 months) and post-V4 timepoints (V4+1 and 6 months). Individuals with no V4 were included at V3+18 months, equivalent to the V4+6-month timepoint. T-cell IFN-γ responses (ELISpot), circulating and nasal binding antibodies (MSD), and neutralizing antibodies to SARS-CoV-2 and relevant VOCs were measured.
Circulating IgG to spike and nucleocapsid were boosted by natural infection at pre-V4 timepoints (2022 UK summer/autumn). IgG levels were further increased by the bivalent booster, rapidly waning by V4+6 months. T-cell responses were well-maintained over time, with a slight boosting effect in spike and M+NP responses at V4+6 months, when circulating IgG and T-cell responses were similar in V4-boosted and non-V4-boosted individuals.
Neutralizing antibodies were boosted by V4, and a transient broadening of neutralizing capacity to VOCs BA.1, BA.2, XBB1.5 and BA.2.86 was noted one-month post-bivalent booster. Responses rapidly waned at V4+6 months, remaining slightly higher than the non-V4-boosted (V3+18) group.
Nasal IgG and IgA antibodies are being measured to give valuable insights into the boosting/broadening of mucosal antibody upon bivalent vaccination.
Our data demonstrate a transient broadening of neutralizing antibody responses due to the bivalent booster vaccine which might increase protection from new circulating VOCs during a narrow timeframe. We also highlight that the dynamics of T-cell and antibody responses to SARS-CoV-2 are now driven by a combination of natural infection events and vaccination.

SIMON says: Using machine learning to understand correlates of protection for SARS-CoV-2 vaccines in non-human primate challenge studies.

Caolann Brady[1;2], Tom Tipton[1;2], Oliver Carnell[3], Stephanie Longet[1;2;4], Karen Gooch[3], Yper Hall[3], Francisco J Salguero[3], Adriana Tomic[5;6;7], Miles Carroll[1;2]
[1]Centre for Human Genetics, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom; *[2]Pandemic Sciences Institute, University of Oxford, Oxford, United Kingdom*; *[3]UK Health Security Agency, Porton Down, Salisbury, United Kingdom*; *[4]International Center for Infectiology Research (CIRI), Team GIMAP, Claude Bernard Lyon 1 University, Saint Etienne, France*; *[5]National Emerging Infectious Diseases Laboratories, Boston University, Boston, United States*; *[6]Department of Virology, Immunology & Microbiology, Boston University Medical School, Boston, United States*; *[7]Biomedical Engineering, Boston University, College of Engineering, Boston, United States*

An automated machine learning platform, SIMON, can identify algorithms that model pathology and upper and lower respiratory tract viral control outcomes post-SARS-CoV-2 challenge. We have applied this platform to analyse the immune responses of ninety rhesus and cynomolgus macaques from various SARS-CoV-2 vaccine and re-challenge studies, to identify immune predictors of viral and pathological protection.
The immune predictors of protection identified include Spike binding and neutralising antibody, in support of the use of ELISA and MNA assays in human SARS-CoV-2 vaccine immunogenicity trials. The SIMON analysis has also extracted novel candidate CoPs in the adaptive cellular compartment including peripheral T cell subset frequencies. The frequency of the $CD14^{hi}CD16^{hi}$ monocyte population in the periphery, proposed to be associated with severe human COVID19 cases, has been demonstrated via SIMON to negatively impact pathology and viral load outcomes when present at high frequencies in the weeks following vaccination or primary challenge in NHPs.
SIMON has also been applied to identify early immune signatures that predict the emergence of high or low Spike binding titres. The $CD14^{hi}CD16^{hi}$ monocyte signature, identified to predict pathology, also predicted low Spike IgG titres. This points to restriction of the GC reaction when this monocyte population is in abundance, as has been reported in the context of co-infections. High baseline humoral immunity to human coronaviruses (HCoVs) was also identified as a predictor of low Spike IgG titres, providing an additional example of original antigenic sin. A systems immunology approach and the application of SIMON were vital to uncovering these findings, as the frequency of this monocyte population in the blood and the incidence of HCoV humoral immunity in macaques are both relatively low.
We have also applied SIMON to identify novel relationships between functional antibody, antibody isotype and antibody glycosylation in macaques, and the role of these compartments in providing clinical protection and mediating viral control upon challenge.
These findings encompass the longstanding value of a robust animal model in immunology and vaccinology research. The combination of this rich NHP dataset and the computational aptitude of SIMON has provided strong evidence for SARS-CoV-2 CoPs.

Local skin enrichment of chemical-specific T cells as strategy for causative allergen identification

Caterina Curato[1], Uwe Paasch[2], Sonja Molin[3;4], Andreas Luch[1], Ines Schreiver[1], Katherina Siewert[1]
[1]*German Federal Institute of Risk Assessment (BfR), Berlin, Germany*; [2]*University of Liepzig, Leipzig, Germany*; [3]*Ludwig-Maximilian-University Munich, Munich, Algeria*; [4]*Queen's University Kingston, Kingston, Canada*

Tattoos may initiate allergic reactions. Metals, e.g. nickel, contained in inks have been suspected as causative allergens to activate T cells responsible for clinical symptoms. Since a positive nickel patch test result does not necessarily indicate nickel as causative allergen, we here analyzed local skin T cell receptor (TCR) repertoires to confirm or exclude nickel as culprit in eczematous allergic skin reactions to tattoo.
Ni^{2+}-specific T cells detected by CD154 (CD40L)-based activation-induced marker (AIM) T cell assay using peripheral blood mononuclear cells and 200 µM $NiSO_4$ were sorted. Sequenced TCRs of activated T cells were quantified and compared to sequenced TCRs of matching blood randomly sorted T cells and healthy and inflamed skin biopsies of 3 patients with chronic tattoo allergic reactions and 1 nickel patch-tested patient.
We detected increased frequencies of Ni^{2+}-specific CD154+CD4+ T cells in positive nickel patch tested patient (1.3% allergic vs. 0.1% non-allergic) and tracked their TCRs in the skin repertoire. In the skin from the positive nickel patch test reaction, 28% and 45% and of Ni2+-specific TCRα and -β chains >2-fold enriched than in blood, respectively. Skin biopsies from allergic tattoo reactions lacked Ni2+-specific TCR enrichment, thus excluding Ni2+ as causative allergen. TCRs of unrelated antigen, e.g. tetanus toxoid, also lacked enrichment. In line with previous results, we observed an increased occurrence of the TRAV9-2 segment and histidine-containing complementary determining regions (CDR) 3 in both CD4+ memory T cell and inflamed skin TCR repertoires of the nickel allergic patient.
The local enrichment of Ni^{2+}-specific T cells in a small biopsy can identify or exclude nickel as culprit allergen *in situ* complementing patch test. This strategy combining AIM T cell assay and TCR sequencing can quantify chemical-specific T cell frequencies in blood and skin. Our approach may be transferred to other chemical sensitizers.

Single-cell sequencing reveals disrupted skin tissue resident memory T cell dynamics in allogeneic hematopoietic stem cell transfer and acute graft-versus-host disease

Laura Marie Gail[1;2], Florian Deckert[2;3], Luisa Unterluggauer[2], Ruth Dingelmaier-Hovorka[2], Johanna Strobl[2], Lisa Kleissl[1;2], Bärbel Reininger[2], Anna Redl[2], Lisa Ellen Shaw[2], Matthias Farlik[2], Werner Rabitsch[3], Georg Stary[1;2]
[1]CeMM Research Center for Molecular Medicine, Austrian Academy of Sciences, Vienna, Austria; *[2]Department of Dermatology, MedUni Vienna, Vienna, Austria*; *[3]Department of Medicine I, MedUni Vienna, Vienna, Austria*

Skin tissue-resident memory T cells (TRM) are important regulators of tissue homeostasis, but also implicated in inflammatory processes, including graft-versus-host disease (GVHD) that can occur after hematopoietic stem cell transplantation (HSCT). To date, there is lack of adequate human models to study tissue-instructed T cell reprogramming and TRM involvement in tissue-specific disease mechanisms. To investigate the role of TRM in GVHD pathology, we study patients undergoing allogeneic HSCT and with acute (a)GVHD. While most host immune cells are eliminated before HSCT by myeloablative conditioning, host skin TRM can survive this treatment and coexist in the skin next to transplanted donor T cells. In these patients with skin T cell chimerism, cells of host and donor can be distinguished by genetic differences.
We hypothesize that comparison of pre-existing host and developing donor TRM after transplantation under steady state und inflammation will unravel new pathways involved in regulating tissue residency and pathogenic signaling. Furthermore, we believe that interactions with structural skin cells and other immune cells are crucial in this regulation.
Here, we collected longitudinal blood and skin samples of HSCT patients and untreated aGVHD patients. We performed single-cell RNA/TCR sequencing to define host/donor genotype by SNP-based demultiplexing, investigate transcriptional changes in immune and non-immune cells, predict cell-cell interactions in the skin and assess dynamics of T cell clonality.
Among skin T cells, we found few donor cells in the skin by day 14, whereas they dominated during aGVHD. Shared donor T cell clones in skin and blood on day 100 displayed a TRM gene expression profile enriched in skin. However, specific subsets of the TRM pool found in healthy skin at steady state were declining after transplantation and in GVHD. This disrupted TRM homeostasis in aGVHD was accompanied by profound transcriptional changes in non-hematopoietic skin cells, including decreased expression of genes regulating extracellular matrix organization and upregulation of chemotaxis and antigen presentation pathways.
Conclusively, our study suggests a selective loss of certain TRM subsets after transplantation and has the potential to uncover new principles of tissue-instructed regulation of TRM development, maintenance, and pathogenicity under homeostatic conditions and in cutaneous inflammation.

Purpose: In this study we performed an in-depth investigation into the myeloid cellular landscape in the synovium of Rheumatoid Arthritis (RA) patients, 'individuals-at-risk' of RA (IAR) and healthy controls to examine the largely unexplored nature and contribution of synovial-tissue macrophage subsets in the pathogenesis of RA.
Methods: Single-cell synovial-tissue suspensions from RA (n=41), IAR (n=5) patients and healthy controls (n=11) were obtained through arthroscopy. Synovial tissue macrophage subsets were examined by advanced multiparameter flow cytometric analysis, single-cell and bulk RNA-sequencing, metabolic and functional assays.
Results: Flow-cytometric analysis demonstrated for the first time, the presence of a CD40-expressing CD206+CD163+ macrophage population dominating the inflamed RA synovium, associated with disease-activity and treatment response. In depth RNAseq and metabolic analysis demonstrated that this macrophage population is transcriptionally distinct, displaying unique inflammatory, and tissue-resident gene signatures, has a stable bioenergetic profile, and regulates stromal cell responses. Single cell transcriptomic profiling of synovial tissue cells from RA patients and healthy individuals was also performed to give a unique myeloid atlas from health to disease. scRNAseq profiling of 67908 RA and healthy synovial-tissue cells identified nine transcriptionally distinct macrophage clusters, further classified into four subpopulations; TREM2high, TREM2low, FOLR2high, IL-1Bhigh. Two clusters: IL-1B+CCL20+ and SPP1+MT2A+ were identified as pro-inflammatory macrophage populations. Interestingly both these clusters are enriched in RA compared to healthy synovial tissue, display heightened CD40 gene expression, are capable of shaping stromal cell responses, and importantly are enriched pre-disease onset in IAR. Functionally, RA synovial tissue myeloid cells are potent producers of pro-inflammatory mediators (reversed by CD40-signalling inhibition), significantly correlate with disease activity and treatment response and are capable of inducing an invasive phenotype in healthy synovial-fibroblasts. Crucially inflammatory myeloid signatures present in active RA synovium identified in phenotypic and single cell transcriptomic analysis, are an early phenomenon, occurring prior to clinical manifestation of disease in individuals 'at-risk' of RA (positive for ACPA) while inflammatory macrophage subsets identified in scRNAseq are also enriched early in disease.
Conclusion: Combined, these findings identify the presence of early pathogenic myeloid signatures that shapes the RA joint microenvironment and represents a unique opportunity for early diagnosis and therapeutic intervention.

Long-lasting protection against listeriosis and peritonitis by trained immunity

Charly Gilbert[1], Tiia Snäkä[1], Maelick Brochut[1], Didier Le Roy[1], Thierry Roger[1]
[1]*Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland*

Objective: We demonstrated that trained immunity, the memory-like property of the innate immune system, protects from a large panel of infections. Moreover, protection from listeriosis was maintained 9 weeks after the induction of training. Our objective was to determine whether trained immunity confers significantly longer protection from bacterial infections.
Methods: Mice were trained by intraperitoneal injection of β-glucan and challenged up to 7 months later, a considerable period in terms of mouse lifespan, with *Escherichia coli* intraperitoneally or *Listeria monocytogenes* intravenously. Peritoneal fluid, blood, bone marrow and spleen were collected to quantify bone marrow long-term and short-term hematopoietic stem cells (HSCs), multipotent progenitors (MPPs), leukocyte sub-populations and bacteria, to measure the antimicrobial activity of leukocytes, and to perform RNA seq on neutrophils.
Results: The induction of trained immunity induced an accumulation in the peritoneal cavity of small peritoneal macrophages that persisted 3 months, and a less pronounced recruitment of PMNs. Trained immunity increased bone marrow long-term-HSCs and myeloid-biased progenitor MPP3 as well as blood monocytes and neutrophils. Cell numbers returned to control levels after 7 months. Blood collected 3 months after training controlled better the growth of *Listeria monocytogenes* and produced more pro-inflammatory cytokines, including IIL-1β, IFNγ and TNF ($P<0.05$-0.01), in response to lipopolysaccharide than control blood. Peritoneal cells collected 7 months after training produced more IL-6 in response to lipopolysaccharide, CpG oligonucleotide and heat-killed bacteria than control cells ($P<0.01$). The transcriptome of bone marrow neutrophils trained for 6 months was enriched in gene pathways associated with wound healing and homeostatic processes. In the model of *Escherichia coli* peritonitis, mice trained 7 months prior to infection showed reduced bacteremia ($P=0.04$) and increased survival ($P=0.056$). In the model of systemic listeriosis, mice trained 3 and 7 months before infection showed decreased bacteremia ($P<0.05$) and increased survival (3 and 7 months: $P=0.002$ and $P=0.08$).
Conclusions:. Training has long-term effects on the number and reactivity of innate immune cells and provides long-lasting protection against lethal peritonitis and listeriosis. The underlying mechanisms of long-term imprinting are currently being investigated.

Rheumatoid arthritis and psoriatic arthritis circulatory monocytes display metabolic changes, with dysfunctional circadian rhythm and mitochondrial dynamics

Alyssa Gilmore[1], Success Amaechi[1], Megan Hanlon[1], Dumitru Anton[1], Carl Orr[2], Viviana Marzaioli[1], Douglas Veale[2], Ursula Fearon[1]
[1]Trinity College Dublin, Dublin, Ireland; *[2]St Vincents University Hospital, Dublin, Ireland*

Purpose: Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA) are distinct in clinical presentation and molecular profile. As crucial innate effector cells, we investigate the role of circulating RA and PsA monocytes in metabolic reprogramming, immune activation, circadian rhythm and mitochondrial dynamics.
Methods: PBMCs and CD14 monocytes were isolated from RA, PsA and healthy controls (HC). Frequency and immune/metabolism markers (PDL-1, HIF1a, pS6, pAKT, Glut1, BTLA) on monocyte subsets were assessed by flow cytometry. Metabolic analysis was performed on basal and LPS stimulated monocytes by RT-PCR and Seahorse-XFe-technology. In parallel, genes involved in circadian rhythm (CLOCK, BMAL1, PER1, PER2, NFIL3) and mitochondrial fission and fusion (DRP1, MFN1) were assessed by RT-PCR.
Results: Baseline ECAR following LPS stimulation was induced, with minimal effect on OCR, resulting in a significant shift of RA and PsA monocytes towards glycolysis ($p< 0.05$). Differential expression of PDL-1, pS6 and HIF1α were observed between RA and PsA monocytes, with higher expression in PSA than RA in classical monocytes. LPS induced metabolic genes, with fumarase induction significant in PSA ($p< 0.05$) and HIF1α more significant in RA ($p< 0.001$). RA monocytes also demonstrated increased endogenous NDufB5 expression ($p< 0.05$). Supporting mitochondrial dysfunction in RA, endogenous MFN2 was significantly increased in RA ($p< 0.05$), with induction of mitochondrial fission regulator DRP1 upon LPS stimulation. Endogenous circadian rhythm genes CLOCK, BMAL1 and PER2 were increased in RA (ns) and PSA ($p< 0.05$) over HC, with LPS-stimulation reducing expression to that of HC. Finally, downstream effector NFIL3 was induced with LPS in RA monocytes ($p< 0.05$), with no effect observed for PsA.
Conclusion: RA and PsA CD14+ monocytes display a shift towards a glycolytic phenotype. Differential metabolic marker expression is observed between monocyte subsets. Altered regulation of genes involved in circadian rhythm suggest differences in the cellular clock, with endogenous levels increased in RA and PsA. This was paralleled by altered mitochondrial dynamics, with significant induction of mitochondrial fission regulator DRP1 in RA monocytes. Taken together, this data supports differential metabolic dysregulation of RA and PsA monocytes, effects that may involve changes in the cellular clock, inducing monocyte pathogenic mechanisms.

Macrophage reprogramming in chronic organ disease – a lesson from the liver

Felix Heymann[1], Moritz Peiseler[1], Yuting Wang[1], Paul Horn[1], Leon Haas[1], Tianjiao Zhang[1]
[1]*Clinic for Hepatology and Gastroenterology, CVK, Charité, Berlin*

Purpose: Kupffer cells are a specialized population of tissue-resident macrophages with high phagocytic activity, acting as sentinels in the hepatic sinusoids to detect and remove bacteria, dead or dying cells, and aged platelets from the circulation. Furthermore, they are involved in antigen presentation and immune tolerance to protect from immunity against food-, gut- or commensal bacteria-derived antigens. On liver injury, Kupffer cell numbers decrease and get replaced by monocyte-derived macrophages, however the long-term consequences of these changes remain largely obscure. Therefore, we aimed to phenotypically and functionally characterize changes of the liver myeloid compartment in response to acute and chronic liver injury.
Methods: We leveraged intravital immunostaining and multi-color spectral laser scanning microscopy to study cell-cell interactions and macrophage scavenging function in mouse models of acute and chronic liver damage. Multiplex spectral flow cytometry was used for in-depth immunophenotyping of the myeloid and lymphoid compartment. T cell activity was assessed by assessment of proliferation, cell phenotyping and measuring antigen specific cytotoxic T cell responses.
Results: Intravital microscopy revealed stark alterations in liver macrophage cellular crosstalk with neutrophils and CD4+ T cells as well as impaired macrophage scavenging function. We could link these alterations with pronounced changes in macrophage phenotype showing reduced expression of scavenging markers Tim4, CD68, CRIg, CD163, CLEC2 and CD206. Functional and activation profiling of the T cell response showed a significant increase in T cell immunity following acute liver damage. Surprisingly, in chronic liver injury, we found a clear suppression of both CD4 and CD8 T cell activity, which was only partly dependent on antigen presentation during liver injury. Mice with chronic liver injury were more susceptible to sepsis and showed higher mortality following bacterial challenge, underpinning the biological and clinical relevance of our findings.
Conclusion: Acute and chronic liver injury induce distinct alterations in macrophage spatiotemporal cell-cell interactions. Furthermore, in response to injury, liver macrophages lose their scavenging function, and this translates into increased susceptibility to infection. Changes in macrophage function were also associated with altered T cell immunity, which highlights the importance of liver macrophages as central hubs of the hepatic immune response.

Functional heterogeneity of tissue resident macrophages of distinct origin during polymicrobial sepsis

Stephan Culemann[1;2], Stavroula Litsiou[1], Claudia Waskow[1;2;3]
[1]Immunology of Aging, Leibniz Institute on Aging - Fritz Lipmann Institute (FLI), Jena, Germany; *[2]Institute of Biochemistry and Biophysics, Faculty of Biological Sciences, Friedrich-Schiller University, Jena, Germany*; *[3]Cluster of Excellence Balance of the Microverse, Jena, Germany*

Life-threatening sepsis is characterized by a dysregulated systemic immune response and multi-organ failure upon infection. Mechanisms regulating the immune system's competence to fight the systemic infection without harming the host are still poorly understood. Especially the role of tissue-resident macrophages (TRM) as key players in the defense against invading pathogens and source of immune modulatory cytokines need further investigation. In recent years it has been shown that TRM are either of embryonic or adult hematopoietic stem cell (HSC)-derived origin. However, the functional impact of ontogeny of TRM in polymicrobial sepsis is largely unknown.
Conditional depletion and repopulation studies using Clodronate-Liposomes reveal that – in contrast to embryo-derived TRM - HSC-derived macrophages are a heterogenous population with varying expression of immune modulating receptors like Tim-4 and VSIG4, and a distinct ability to clear bacteria via phagocytosis. The exchange of embryo-derived TRM by adult HSC-derived macrophages is associated with higher mortality in the peritoneal contamination and infection (PCI) sepsis model demonstrating a protective role of embryo-derived TRM.
These findings imply that the ontogeny of tissue-resident macrophages determines their function and that homeostasis of macrophages of embryonic origin is key for shaping the immune response and survival of sepsis.

Immunological tools for the prediction of poor outcome in Oligoarthritis

Federica Raggi[1], Simone Pelassa[1], Chiara Rossi[1], Francesca Antonini[2], Martina Bartolucci[2], Chiara Artale[1], Federica Briasco[1], Silvia Maria Orsi[1], Marco Gattorno[1], Angelo Ravelli[3], Alessandro Consolaro[1], Maria Carla Bosco[1]
[1]Unit of Rheumatology and Autoinflammatory Diseases, Pediatric Science Department IRCCS Istituto Giannina Gaslini, Genova, Italy; *[2]Core Facilities, Clinical Proteomics and Metabolomics, IRCCS Istituto Giannina Gaslini, Genova, Italy*; *[3]Scientific Direction, IRCCS Istituto Giannina Gaslini, Genova, Italy*

Purpose: Oligoarthritis is the most common form of Juvenile Idiopathic Arthritis. The disease course and outcome within two years from diagnosis is vary variable, with most patients exhibiting an oligoarticular course, more benign and likely to achieve remission, and a significant proportion (30-40%) developing a polyarticular course (pcJIA), which is more severe and requires more aggressive treatment. New biomarkers are demanded for early discrimination of patients at risk of developing pcJIA. Cells causing inflammation and tissue-destructive effects in the joints of Oligoarthritis patients release extracellular vesicles (EV) both in plasma (PL) and synovial fluid (SF). A better characterization of inflammatory cells combined with that of EV content at disease onset may be valuable for the identification of early biomarkers predictive of pcJIA.
Methods: We utilized a strategy that combines classical approaches for the study of inflammatory cells in liquid biopsies and system biology–driven omic methods (miRNomic/proteomic) for the analysis of EV released by these cells. 97 treatment-naïve Oligoarthritis patients were enrolled in the study at onset and followed up for 24 months after diagnosis. EV-miRNA (EV-miR) and EV-protein (EV-Prot) expression profiling was carried out in PL and SF collected at disease onset. PL from 25 age-matched healthy children was used as control. Monocytes/Macrophages and T cell subsets were phenotypically characterized in peripheral blood (PB) samples from 26 patients and compared between those undergoing different clinical course.
Results: Omic approaches identified a signature of 7 EV-miR and 112 proteins expressed both at a systemic and local level able to discriminate new-onset patients from controls with a high potential diagnostic value. Supervised machine learning method and WGCNA analysis demonstrated the power of EV-miR 29a,-miR 223 and of 16 protein clusters in the stratification of patients undergoing different disease course. Cytoflurimetric analysis showed different proportions of activated CD4/CD8, effector memory CD8, T regulatory cells and M1/M2 monocyte/macrophages expressing the inflammatory hypoxic receptor TREM1 between the outcome groups, both in SF and PB samples
Conclusion: Our data provide new immunological indicators of pcJIA in new-onset Oligoarthritis patients that include, EV-miRs and EV-Prots and specific cell subsets.

Exploring the impact of CD300e in colorectal cancer: insights from obesity-related murine models

Stefania Vassallo[1], Annica Barizza[1], Sofia Giacometti[1], Sara Coletta[1], Marina de Bernard[1], Gaia Codolo[1]
[1]*Department of Biology, University of Padova, Padova, Italy*

The etiology of colorectal cancer (CRC) is multifaceted and intricately linked with lifestyle factors, particularly diet and obesity. High-fat diet (HFD)-induced obesity entails a persistent low-grade inflammation and dyslipidemia, fostering insulin resistance, steatosis, and lipotoxicity, thereby activating proliferation pathways in colonic epithelial cells. Recent research underscores a significant correlation between CD300e activation and impaired macrophages' antigen presentation. Interestingly, the greater part of tumor-associated macrophages in CRC patients display CD300e^{high}/MHC-II^{low} expression pattern, suggesting that CD300e may act as an immune checkpoint. Though categorized as an orphan receptor, sphingolipids emerge as potential ligands for both mouse and human CD300e, prompting the investigation of how CD300e affects CRC in the presence of obesity-associated metabolic dysregulation. Thus, we employed a murine model of obesity-related CRC in CD300e knock-out (KO) mice. Unexpectedly, HFD-fed mice exhibited no significant genotype-based disparities, in contrast to the standard diet (STD)-fed control groups, where KO mice displayed a remarkable reduction in tumor burden and an enrichment in IFN-γ-producing CD8$^+$ T cells in local lymph nodes, indicative of a boosted anti-tumor response compared to wild-type (WT) controls. Additionally, systemic immune profiling revealed a higher neutrophils-to-lymphocytes ratio in WT mice, a recognized adverse prognostic marker in CRC patients. Given the constrained size of tumors, immune cell infiltration was assessed in a subcutaneous model of CRC, confirming an enhanced anti-tumor immune response in KO mice characterized by pronounced MHC-II expression on macrophage surfaces, coupled with elevated IFN-γ-producing CD4$^+$ and CD8$^+$ T lymphocytes infiltration.
The absence of discernible variation in a HFD setting finds corroboration in an ongoing study highlighting a protective effect of CD300e in obesity, proposing that CD300e binding sphingolipids foster their scavenging, thus reducing the accumulation and the subsequent detrimental effects. Supporting this hypothesis, liver histology from HFD-fed KO mice revealed signs of lipotoxicity and pronounced immune cell infiltration, with a milder phenotype observed in WT mice.
In summary, these findings emphasize the pivotal role of CD300e in shaping a pro-tumor microenvironment, positioning it as a promising target for immunotherapy. Nonetheless, it is crucial to account for potential divergent effects of the receptor in the presence of comorbidities.

Type 2 innate lymphoid cells fuel breast cancer development by inhibiting anti-cancer immunity

Pascal Naef[1], Jacob I. Rodriguez[1;2], Hannah Savage[2], Isam Adam[2], Armando S. Villalta[2], Devon A. Lawson[2], Kai Kessenbrock[1]
[1]Department of Biological Chemistry, University of California, Irvine, Irvine, United States; *[2]Department of Physiology and Biophysics, University of California, Irvine, Irvine, United States*

The tumor microenvironment (TME) is an important regulator of breast cancer (BC) development. It is composed of acellular and cellular factors, among others immune cells like type 2 innate lymphoid cells (ILC2s). It has been shown that ILC2s are enriched in the TME of BC patients compared to healthy individuals, and in the 4T1 BC mouse model, ILC2s inhibited the immune response against the tumor cells at both the primary and the metastatic tumor site. However, the exact molecular mechanisms of how ILC2s regulate BC immunity remain largely unknown.
To reveal the phenotype of ILC2s in BC, we used the polyoma middle T antigen transgenic mouse model, mimicking luminal BC development. Single-cell (sc)RNA sequencing and flow cytometry experiments showed that ILC2s (expressing *Gata3*, *Rora*, *Il2ra*, and *Il7ra*) accumulated in the mammary fat pad (MFP) during BC development. Furthermore, the MFP ILC2s phenotypically changed during tumor development by increasing PD-1, c-KIT, and Neuropilin-1, while downregulating KLRG1 and Sca-1 expression. Both, healthy MFP and tumor ILC2s, expressed interleukin-5 and -13 after PMA/Ionomycin restimulation. We detected the same ILC2 phenotype in the tumors of $BRCA1^{mut}p53^{-/-}$ mice, which mimic the basal BC subtype. Next, we tested if ILC2s directly regulate cancer cell growth *in vitro*. Co-culturing the BC cell line 'VO' with healthy MFP or tumor ILC2s for 48 hours increased the number of viable VO cells. To assess the functional relevance of ILC2s in BC *in vivo*, we co-injected ILC2s and VO cells orthotopically into FVB mice and measured the tumor growth. While 85% of the mice that were co-injected with VO cells and ILC2s developed a tumor, 50% of the VO-only recipients rejected the tumor cells. ILC2-co-injection induced an increased infiltration of $Gr\text{-}1^{+}CD11b^{+}$ neutrophils, which could potentially inhibit anti-cancer immunity.
In summary, we showed that ILC2s accumulate, phenotypically change, and promote an immune-inhibitory environment during BC development. Additionally, ILC2s can directly promote BC cell growth *in vitro*. Further experiments will provide knowledge about ILC2s as an important player in the BC TME and identify novel molecular mechanisms that can be used to develop new therapeutic strategies to treat BC patients.

IL4I1 expression in macrophages leads to their pro-tumor profile and T-cell exhaustion in the course of tumor progression.

Malvina Seradj[1], Saniya Kari[2], Anna Llebaria-Fabrias[1], Renée Lengagne[1], Armelle Blondel[1]
[1]*Institut Cochin, Paris, France*; [2]*INFINITy (Institut Toulousain des Maladies Infectieuses et Inflammatoires), Toulouse, France*

Purpose: Deciphering how IL4I1 promotes pro-tumor properties of melanoma-associated macrophages.
Methods: Spectral flow-cytometry, imaging, co-culture, *in vivo* neutralization
Results:
1. Tumor-associated macrophages (Mφ) overexpress IL4I1 during melanoma progression
We established the pro-tumoral role of the phenylalanine oxydase IL-4 induced gene 1 (IL4I1) in mice transgenic for the human RET oncogen developing a spontaneous metastatic melanoma. Here we show an upregulation of IL4I1 expression in a fraction of Mφ in the course of RET melanoma progression.
2. Mechanism of IL4I1 induction in melanoma
To decipher the mechanism involved in IL4I1 expression in the tumor microenvironment, Mφ were cultured in presence of soluble factors derived from RET primary tumor. Among those, only recombinant TNF-α strongly induced IL4I1 in Mφ *in vitro*. Furthermore, TNF-α neutralization *in vivo* decreased IL4I1 expression by melanoma-associated Mφ in RET mice. Taken together, our data revealed a role of TNF-α in driving IL4I1 expression.
3. Mφ-specific deletion of IL4I1 delays melanoma growth
Next, we set-up conditional mice in which IL4I1 is specifically inactivated in Mφ. After transplantation with B16 melanoma cells, IL4I1$^{M\varphi KO}$ mice exhibited a reduced tumor growth compared to littermates. The incidence of both primary melanoma and cutaneous metastasis was also significantly delayed in RET-IL4I1$^{M\varphi KO}$ mice compared to RET control mice, highlighting the pro-tumoral properties of IL4I1^{+} Mφ.
4. IL4I1 deficiency favors anti-tumor properties of tumor-infiltrating T cells and reprograms Mφ toward an anti-tumoral phenotype.
The delay of tumor development in RET-IL4I1$^{M\varphi KO}$ mice is associated with reduced expression of exhaustion markers by tumor-infiltrating CD8^{+} T cells. Moreover, the genetic inactivation of *il4i1* in Mφ strongly decreased pro-tumoral markers expressed by Mφ themselves, but also permits to these Mφ to acquire anti-tumoral properties.
Conclusion: Our data reveal the key role of IL4I1^{+} tumor-associated Mφ in tumor aggressiveness through altered anti-tumoral functions of Mφ and CD8^{+} T cells. As IL4I1 is expressed by Mφ in most of human solid tumors, this study paves the way for targeting specific Mφ subsets to improve anti-cancer immunotherapies.

[*]Co-first authors

Foxp3+ regulatory T cells (Tregs) are immunosuppressive cells that inhibit tumor immunity. Their mechanism of action is complex and only partially understood. Here, we show that expression of the tumor necrosis factor (TNF) receptor type 2 (TNFR2) by Tregs is essential for limiting anti-tumor immunity. Genetic and inducible ablation of TNFR2 in Tregs leads to a reduction in tumor growth within a few days, which is associated with a rapid and by-stander effect on tumor-infiltrating T cells and myeloid cells. This anti-tumor effect has been confirmed in different mouse models. Mechanistically, Tregs and conventional T cells produce more TNF and IFNg, while monocytes, macrophages and neutrophils are more activated and produce increased levels of iNOS. Experiments using effector or blocking reagents show a direct anti-tumor effect of TNF and iNOS, which was confirmed by scRNAseq analyses. In conclusion, our work surprisingly shows that one of the main mechanisms of suppression of anti-tumor immunity mediated by Tregs depends on their expression of TNFR2. Tregs expressing TNFR2 limit tumor rejection by inhibiting TNF and iNOS production.

A Second Tumor Escape System mediated by HHLA2: Biological and Therapeutic Implications on effector cells.

Raphaëlle Leau[1], Mélanie Néel[1], Veronique Daguin[1], Fabienne Haspot[1]
[1]*Center for Research in Transplantation and Translational Immunology, Nantes, France*

Purpose: HHLA2, a newly discovered B7 family's member has emerged as a promising target in cancer immunotherapy. Its upregulation in many cancers, and notably in PD-L1 negative tumoral cells suggests a potential role in tumour evasion through its inhibitory receptor KIR3DL3. But KIR3DL3 is tough to highlight at mRNA and protein levels. HHLA2 also binds CD28H activating receptor on NK and T cells, although CD28H and KIR3DL3 have non-identical fixation sites on HHLA2. We investigated a new HHLA2 potential tumour immune escape mechanism based on the downmodulation of CD28H activating receptor.
Methods: We developed cell lines (K562 and HEK-T cells) expressing either the full length HHLA2 or HHLA2-IgV1's portion. Both cell lines expressing HHLA2 were able to bind CD28H- and KIR3DL3-recombinant molecules, while the one expressing HHLA2-V1 only binds CD28H-recombinant protein but not KIR3DL3.
Results: We found that HHLA2 expression results in a rapid loss of membrane CD28H on NK and T cells further followed by its loss intracellularly in both cell types. This was shown to be dependant of the HHLA2-CD28H contact and to correlate with the amount of HHLA2 expressed by the cell lines. However, cells expressing only the HHLA2-V1 portion have no impact on CD28H expression even if they were able to bind CD28H. Monensin highlighted the involvement of specific protein transport for CD28H loss in T cell and to a lesser extend in NK cells, while Brefeldin A and Bafilomycin A1 are ineffective for both. Other inhibitors are currently tested to decipher the mechanism underlying CD28H loss. We also recently confirmed these observations with cells naturally expressing HHLA2, i.e. ccRCC cell lines injected subcutaneously into immunodeficient mice, since they only express HHLA2 *in vivo*. A-498 freshly excised tumours showed mRNA expression of HHLA2 and extracted cells bound the recombinant proteins CD28H-Fc and KIR3DL3-Fc. Importantly, co-culture of this cells with T and NK cells also led to downmodulation of CD28H.
Conclusion: Based on these results, we hypothesise that overexpression of HHLA2 by tumour cells would result in the downmodulation of CD28H. We expect our findings to lead to treatment strategies that would preserve the HHLA2-CD28H activating interaction.

Investigating the Immunomodulatory Role of Epithelial YAP/TAZ in Gastric Metaplasia

Jacqueline Sung[1], Zhaoping Ju[1], Alex Gregorieff[1], Samantha Gruenheid[1]
[1]*McGill University, Montreal, Canada*

Purpose: Gastric cancer is one of the leading causes of cancer-related deaths and its prevalence has been associated with infection by *Helicobacter pylori*. *H. pylori* persistence leads to chronic inflammation which can lead to the development of preneoplastic conditions such as gastric metaplasia. This results in the elimination of parietal cells and the appearance of spasmolytic polypeptide/trefoil factor 2-expressing metaplasia (SPEM) cells at the base of the gastric glands which have been linked to tumour development. Initiation and progression of SPEM is immune-driven, with dependence on the activation of key players of type 2 inflammation such as innate lymphoid cells 2 (ILC2) and M2 macrophages. However, processes driving epithelial cell fate and immune status during regeneration of the gastric epithelium remain unclear.
Methods: The transcriptional effectors yes-associated protein 1 (YAP) and transcription coactivator with PDZ-binding motif (TAZ) of the Hippo pathway were conditionally deleted in the gastric epithelium using YAPfl/fl;TAZfl/fl;PGC-CreERT mice (YAP/TAZ KO). YAP/TAZ KO and littermate controls were subjected to high-dose tamoxifen (HDT) treatment to induce tissue damage as well as YAP/TAZ deletion. At various time-points following treatment, stomachs were collected and processed for histological analyses, cytokine multiplex, and immune profiling of the lamina propria using spectral flow cytometry.
Results: We show that epithelial YAP/TAZ play an essential role in controlling cell fate during gastric tissue regeneration in this chemical injury model. Loss of YAP/TAZ in the stomach epithelium resulted in persistence of gastric metaplasia upon tissue injury as well as chronic immune cell infiltration. Immunophenotyping experiments showed that unlike SPEM initiation and progression, tissue regeneration was independent of type 2 immunity. Instead, loss of YAP/TAZ resulted in a tissue destructive response associated with chronic recruitment of macrophages and B cells.
Conclusion:
These results suggest that epithelial YAP/TAZ may control cell fate decision as well as inflammation, highlighting the importance of immune-epithelial cell interactions in tissue regeneration and neoplasia development.

Roles and functions of the Foxk1 transcription factor to control T cell responses

Léa Baugé[1], Valentin Mellado[1], Alice Clément[1], Anne Gonzalez de Peredo[2], Sven Enerback[3], Bernard Malissen[1;4], Guillaume Voisinne[1], Romain Roncagalli[1]
[1]Centre d'Immunologie de Marseille-Luminy, Aix Marseille Université, INSERM, CNRS, 13288 Marseille, France, Marseille, France; *[2]Institut de Pharmacologie et de Biologie Structurale, Département Biologie Structurale Biophysique, Protéomique Génopole Toulouse Midi Pyrénées CNRS UMR 5089, 205 Route de Narbonne, 31077 Toulouse Cedex, France, Toulouse, France*; *[3]Department of Medical Biochemistry and Cell Biology, Institute of Biomedicine, University of Gothenburg, Gothenburg, Sweden, Gothenburg, Sweden*; *[4]Centre d'Immunophénomique, Aix Marseille Université, INSERM, CNRS UMR, 13288 Marseille, France, Marseille, France*

T lymphocytes play a key role in the immune response and their functions are intimately linked to metabolic programs. During immune responses, T cells undergo a metabolic reprogramming characterized by increased aerobic glycolysis, nutrient uptake and macromolecules synthesis. These processes are crucial for cell growth, differentiation, and acquisition of effector functions. In this regard, the AKT-mTOR signalling pathway has been shown to be an essential hub for regulating T cell metabolism and, consequently cell fate.
Using a quantitative phosphoproteomic approach, we have identified a new transcription factor called Foxk1 as being highly phosphorylated in T cells upon T Cell Receptor (TCR) engagement. Our results also indicate that Foxk1 phosphorylation and nuclear translocation is dependent of the AKT-mTOR kinase activities. Using T-cell specific Foxk1 deficient mice ($Foxk1^{-/-}$), we demonstrated that Foxk1 is required for full T cell activation. Foxk1-deficient T cells exhibited reduced proliferation and cytokine secretion following TCR stimulation. Furthermore, T cells from $Foxk1^{-/-}$ mice were less prone to acquire an effector like phenotype than wild-type cells when challenged in vivo.
Conversely, Foxk1 overexpression in T cells enhanced their effector functions in a TCR-dependent manner. In CD8+ T cells, this effect also results into enhanced cancer cell killing capacity *in vitro*, and improved tumor rejection *in vivo*.
Global proteomic analysis of TCR-stimulated CD4+ and CD8+ T cells from Foxk1 deficient mice revealed defective expression of critical proteins involved in metabolism, and in particular of effectors and enzymes of the glycolysis pathway. Accordingly, Foxk1 deficient T cells had reduced maximal mitochondrial respiratory capacity compared to wild-type and exhibited an impaired ability to enhance aerobic glycolysis upon TCR stimulation or glucose supplementation.
Altogether, these results indicated that Foxk1 is a major regulator of T cell metabolism and thus, of T cell effector functions. Its molecular targeting can be envisioned as a part of T-cell reprogramming to fight cancer or reduce auto-immune reactions.

Characterization of DNA Methylation dynamics during human thymic T lymphocyte development

Frederik Hamm[1;2], Marcel Finke[1], Emilie Coppin[3], Anne Schulze[1], Mingxing Yang[1], Abdulrahman Salhab[4], Gilles Gasparoni[4], Jörn Walter[4], Claudia Waskow[3], Julia K Polansky[1;2]
[1]Berlin Institute of Health Center for Regenerative Therapies, Berlin, Germany; *[2]German Rheumatism Research Centre, Berlin, Germany*; *[3]Leibniz Institute on Aging, Fritz Lipmann Institute, Jena, Germany*; *[4]University of Saarland, Saarbrücken, Germany*

The importance of DNA methylation (DNA-meth) for the regulation of the stability and plasticity of mature T cell subsets has been established in recent studies, such as the DNA-meth-regulated activity of the FOXP3-TSDR for the Treg phenotype or the progressive loss of DNA-meth in heterochromatic parts of the genome during differentiation and proliferation of peripheral CD4+ T cells. However, an in-depth understanding of the DNA-meth mediated control of T cell development in the thymus is so far lacking.
To address this lack of knowledge, we sorted 8 defined pediatric human thymic T cell progenitor subsets using a 19-color flow-cytometry panel and generated genome-wide DNA-meth profiles. Analysis of these datasets revealed that major DNA-meth remodeling occurs at two distinct developmental steps: from progenitors (DN1 and DN2) to the rearrangement populations (DN3, ISP4, early DP and late DP) and subsequently to mature T cells (SP4 or SP8). In addition, individual progenitor and mature T cell populations display distinct, cell-type specific DNA-meth signatures, indicating that DNA-meth mediated gene expression control is a driver of the ongoing developmental processes. In contrast, the DNA-meth landscape among rearrangement populations does not change significantly. To our surprise, the DNA-meth landscape in the heterochromatin remained stable throughout thymic differentiation of T cells, in contrast to what has been observed in mature peripheral T cells. Finally, we used our identified DNA-meth profiles of ex vivo isolated human thymocytes to verify the success of human T cell development in a humanized mouse model. We could show that populations from both systems cluster according to their common cellular phenotype, confirming that, in this model, the transplanted human hematopoietic stem cells (HSCs) undergo appropriate T cell development in the murine thymus. Still, big differences on the mean DNA-meth level could be observed, indicating substantial DNA-meth alterations during HSC-derived thymic precursor development.
Taken together, our data revealed a dynamic involvement of DNA-meth mediated mechanisms to the appropriate regulation of the complex T cell developmental cascade. Further, the generated reference DNA methylomes of thymic T cell subsets allow the validation of in vivo and in vitro model systems for human T cell development.

Not so TOP after all: cytokine 3'untranslated regions dictate responsiveness to mTOR-mediated translation in human T cells

Anouk Jurgens[1;2], Branka Popovic[1;2], Josephine Zwijnen[2], Floris Van Alphen[3], Arjan Hoogendijk[3], Aurelie Guislain[2], Monika Wolkers[1;2]
[1]Oncode Institute, Amsterdam, Netherlands; *[2]Department of Haematopoiesis, Sanquin Research, Landsteiner Laboratory, Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands*; *[3]Department of Molecular and Cellular Haemostasis, Sanquin Research, Amsterdam, Netherlands*

T cells are key contributors to clear our body from infected and malignant cells. When T cells respond to target cells, they undergo profound transcriptional and translational alterations. A key regulator of the protein turnover and degradation is the evolutionary highly conserved kinase mechanistic target of rapamycin (mTOR). mTOR signalling acts on T cell differentiation and homeostasis. It also supports T cell activation, and promotes the production of effector molecules, such as the key pro-inflammatory cytokines IFNγ, TNFα and IL-2. In this study, we uncovered a novel pathway that mTOR employs to regulate cytokine production in primary human T cells. Instead of the well-known 5' Untranslated region (5'UTR)-mediated mTOR regulation through TOP motifs, we found that mTOR inhibition reduces the expression of IFNγ, TNFα and IL-2 in a 3'UTR-dependent manner. Mutation studies revealed that, albeit the presence of non-classical TOP motifs in the cytokine 3'UTRs, mTOR-mediated regulation acts through AU rich elements (ARE). RNA binding protein (RBP) pulldown essays from activated T cells uncovered that LSM7 and DDX21 interact with the *IL2* 3'UTR in an ARE-dependent manner, and that this interaction is lost upon mTOR blockade with Torin. Concordantly, LSM7 or DDX21 deficiency in primary human T cells leads to amplified cytokine expression. Mechanistically, mTOR inhibition does not affect the stability of cytokine mRNA, but rather appears to induce alternative adenylation. In conclusion, we uncovered a novel mode of action of mTOR signalling modulating cytokine production through the 3'UTR.

A truncated LAT isoform lacking the 5 distal tyrosines still allows the development of gamma delta T cells

Mikel Arbulo-Echevarria[1], Luis M. Fernandez-Aguilar[1], Inmaculada Vico-Barranco[1], Isaac Narbona-Sanchez[1], Elke Kurz[2], Bernard Malissen[3], Michael L Dustin[2], Enrique Aguado[1]
[1]University of Cadiz, CADIZ, Spain; *[2]Kennedy Institute, University of Oxford, Oxford, United Kingdom*; *[3]Centre d'Immunologie Marseille-Luminy, Marseille, France*

Purpose: Previous results generated by our group showed that mutation of a negatively charged segment of LAT (Linker for the Activation of T cells) induced an increase of proximal intracellular signals, but downstream signals such as Ca^{2+} influx or MAPK pathways were partially inhibited. We therefore decided to generate the corresponding knockin strain of mice (LAT-NIL), in order to analyze the impact of these mutations on thymic development and T-cell functions.
Methods: LAT-NIL knockin mice were generated by means of a CRISPR/Cas9 nuclease approach for direct mutagenesis of Lat exon 7 sequence using an ssODN template harboring the desired mutations. The phenotype of homozygous and heterozygous mutant mice was analyzed by flow cytometry, using wild-type mice as controls.
Results: Homozygous LAT-NIL mice showed an almost total block of thymic development at the DN3 stage. RT-PCR performed with RNA obtained from thymocytes of LAT-NIL mice showed that the cDNA is shorter than WT-cDNA, and sequencing of this cDNA showed that exons 6 and 7 were deleted during the RNA maturation. This generated a frameshift introducing a premature STOP codon, which generated a shorter form of LAT adaptor (145 residues, with the last 39 coming from a frameshift) lacking the essential 5 distal tyrosines. Although we have not been able to detect the presence of this truncated LAT protein in LAT-NIL thymocytes, the analysis of spleens and lymph nodes from LAT-NIL mice always had a small population of gamma-delta CD3+CD8+ T cells, although they were not able to proliferate or activate.
Conclusion: Overall, our data reveal that the LAT adaptor is a crucial element in the TCR and pre-TCR signaling cassettes, and that a truncated form of LAT is not able to promote the development of alpha-beta T cells, although it does allow the development of a population of gamma delta, CD8 positive T cells.

ISG20L2 is a novel RNA-based regulator of T cell function

Ana Rodríguez Galán[1;2;3], Sara G Dosil[1;2], Lola Fernández-Messina[1;2;4], Francisco Sanchez-Madrid[1;5]
[1]Department of Immunology, Instituto de Investigación Sanitaria Hospital Universitario de La Princesa (IIS-Princesa), Universidad Autónoma de Madrid (UAM), Madrid, Spain; *[2]Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, Spain*; *[3]Department of Hematology, Hospital Universitario 12 de Octubre-Universidad Complutense, Instituto de Investigación Sanitaria Hospital 12 de Octubre (imas12), Madrid, Spain*; *[4]Faculty of Biology, Complutense University Madrid, Madrid, Spain*; *[5]Centro de Investigación Biomédica en Red de Enfermedades Cardiovasculares (CIBERCV), Instituto de Salud Carlos III, Madrid, Spain*

Purpose: We aim to understand the functional role of ISG20L2, a 3' to 5' exoribonuclease, in T cell function.
Methods: Pull down assay with biotinylated miRNAs, recombinant protein expression, miRNA degradation assays, primary human and mouse T cell isolation and culture, Jurkat T cell KO clones and ISG20L2-deficient T cell mouse models generated by CRISPR-Cas9, messenger and small RNAseq, qPCR, flow cytometry, western blot and confocal microscopy
Results: ISG20L2 appears to play a crucial role in CD4 T cell function by the degradation of a specific repertoire of RNAs. ISG20L2 expression is modulated by TCR engagement and IFN I stimulation and its silencing leads to increased basal expression of CD69 and IL2 secretion. However, its absence impairs several key processes during immune synapsis, including CD25 upregulation, CD3 synaptic accumulation, and MTOC translocation towards the antigen-presenting cell during immune synapsis. Additionally, ISG20L2 regulates the expression of multiple immunoregulatory molecules such as AHR, NKG2D, CTLA-4, CD137, TIM-3, PD-L1, and PD-1. Knockout of ISG20L2 results in increased levels of these molecules in Jurkat T cells, suggesting its role in immune regulation. This effect is further supported by the upregulation of CD137 and PD-1 on the cell surface of activated human primary cells lacking ISG20L2.
The essential physiological function of ISG20L2 is highlighted by the fact that global knockout of ISG20L2 in mice is not viable. Initial analysis of a mouse model with conditional knockout of ISG20L2 in CD4-positive cells confirms its involvement in modulating the expression of CD3 and the repertoire of immunoregulatory molecules. This suggests that ISG20L2 is crucial for orchestrating immune responses and maintaining immune homeostasis.
Conclusion: The dysregulation observed in key molecules for T cell responses supports a role for ISG20L2 as a novel RNA-based regulator of T cell function.

S1P-signaling inhibition suppresses Th1-like Treg generation by rewiring mitochondrial metabolism

Rachel Coulombeau[1], Claudia Selck[1], Nicolas Giang[1], Allison Maher[1], Richard Nicholas[2], Margarita Dominguez-Villar[1]
[1]*Imperial College London, London, United Kingdom*; [2]*Imperial College NHS Trust, London, United Kingdom*

Inflammatory environments are known to induce Treg plasticity, i.e., the generation of dysfunctional IFNγ+Tbet+ Th1-like Tregs. Th1-like Tregs show defective function and increased frequencies in autoimmune conditions including multiple sclerosis (MS). We previously identified the PI3K/Akt/FoxO pathway as a main regulator of Th1-like Treg plasticity, but the pathways restraining the generation of dysfunctional Th1-like Tregs are mostly unknown. Fingolimod is a functional agonist of sphingosine-1-phosphate (S1P) receptors, blocking lymphocyte egress from secondary lymph organs and used to treat MS. Data suggest that fingolimod affects immune cells beyond migratory properties, including increasing Treg proportion in treated MS patients. Preliminary data suggest that Th1-like Tregs upregulate several genes involved in S1P signaling. However, the effects of S1P signaling on Treg stability is unknown. Here we show that S1P signaling inhibition inhibits the generation of Th1-like Tregs and rescues their suppressive function. This is mediated by a decrease in mTOR and S6 phosphorylation and is reproduced by mTORC1 inhibition with rapamycin. Because mTOR plays an important role in immunometabolism, we investigated metabolic pathways in Tregs and Th1-like Tregs treated with fingolimod ex vivo and showed that Th1-like Tregs undergo mitochondrial uncoupling that is restored by S1P-signaling inhibition. The in vitro S1P-signaling inhibition results are validated in vivo, as Tregs from fingolimod-treated MS patients display decreased Th1-like Treg frequency, increased suppressive function, and restoration of mitochondrial metabolism.
These results highlight the involvement of mitochondrial metabolism in Treg plasticity and identify S1P-signaling inhibition as a target to suppress the generation of dysfunctional Th1-like Tregs.

Unraveling the Enigmatic Role of atypical ANCAs: A Novel Pathophysiological Mechanism in Ulcerative Colitis - Targeting Neutrophil Extracellular Traps

Erick Arturo Mendieta Escalante[1], Daniela Parada Venegas[1], Arno Bourgonje[1], Marcela Hermoso[1], Klaas Nico Faber[1], Gerard Dijkstra[1]
[1]*UMCG, Groningen, Netherlands*

Background and Aims: Ulcerative colitis (UC) is an inflammatory bowel disease characterized by chronic colon inflammation. Neutrophils and neutrophil extracellular traps (NETs) have been linked to UC. Atypical Anti-Neutrophil Cytoplasmatic Antibodies (a-ANCAs) are biomarkers for UC diagnosis, but after decades their target antigens are unknown. This study aims to investigate if these antibodies target NETs and their potential role in UC pathophysiology.
Methods: Serum samples and biopsies from UC patients and healthy volunteers were collected. Neutrophils from healthy controls were induced to form Lytic (PMA) and non-lytic (LPS-treated platelets) NETs. Indirect immunofluorescence (IIF) was used to detect a-ANCAs. Macrophage clearance were measured by IIF and real time live cell imaging and measured cytokine expression via Real-Time Quantitative PCR. Immunohistochemistry was employed to visualize NETs in colon tissue.
Results: a-ANCAs exclusively bound to ethanol-fixed neutrophils, with DNAse or trypsin treatment reducing binding. Binding was DNA-dependent and localized within DNA-protein complexes. Enhanced binding to non-lytic NETs was observed. In inflamed colon tissue, a-ANCAs recognized NETs linked to crypt abscesses. This antibodies impeded NET clearance and triggered pro-inflammatory responses in macrophages. Patients with this antibodies experienced worse UC future outcomes as resistance to treatment, presence of extraintestinal manifestations, or post-surgery activity.
Conclusion: A novel perspective through the discovery of a distinct antibody, Anti-NETs antibodies (ANETAs), which interact with NETs, forming immune complexes that inhibit NETs clearance by macrophages and induce pro-inflammatory responses, potentially contributing to UC pathophysiology. This "Proinflammatory Loop induced by ANETAs" (PLANETAs) mechanism could have implications for UC disease monitoring and therapy development.

EBV infection accumulates T-bet+ B cells that migrate to the CNS and cause MS-like lymphocyte infiltration in brain tissue of humanized mice

Fabienne Läderach[1], Ioannis Piteros[1], Elena Bremer[1], Lisa Rieble[1], Sandra Schmid[1], Christian Münz[1]
[1]*Institute of Experimental Immunology, University of Zürich, Zürich, Switzerland*

Epstein-Barr virus (EBV) is a common human γ-herpesvirus, which persistently infects more than 95% of the adult human population. There is strong epidemiological evidence that links EBV infection and its altered immune control to the autoimmune disease multiple sclerosis (MS). However, the mechanism by which EBV alters the immune system to increase MS risk remains largely unknown. Our aim is to study primary EBV infection in an *in-vivo* model to understand how alterations in the immune system during infection and migration of infected B cells might constitute a prerequisite for the development of MS. To that end we use HLA-DRB1*1501(HLA-DR15) and HLA-A*0201(HLA-A2) knock-in immunodeficient mice, carrying the main genetic risk factor of MS, HLA-DR15. Upon reconstitution with human immune system components from HLA-DR15 positive $CD34^+$ hematopoietic progenitor cells we can mimic symptomatic primary EBV infection in these animals.
Primary EBV infection leads to a significant increase of T-bet^+ $CXCR3^+$ atypical B cells (ABCs). This increase of ABC during infection positively corelates with viral burden in the animals. Furthermore, measurement of viral particles and *in-vitro* bioluminescence imaging revealed migration of EBV infected cells to the central nervous system (CNS) in highly infected animals. This migration of EBV infected cells is accompanied by the infiltration of ABCs and activated lymphocytes into the CNS. Single cell RNA sequencing indicated that a large population of the ABCs is a clonally expanded reservoir for EBV and shows upregulation of chemotaxis genes such as CCL3. Transfer of T-bet+ EBV transformed lymphoblastoid cell line into non-reconstituted mice confirmed that those cells can migrate into the CNS independently of other lymphocytes and are *ex-vivo* able to attract activated T cell.
These findings suggest that EBV infection drives the generation of a clonally expanded $CXCR3^+$ T-bet+ B cell population which can migrate into the CNS and might attract activated T cells. In certain predisposed individuals this could lead to the infiltration and local stimulation of cross-reactive and MS autoantigen specific T cells that potentially triggers MS pathology.

Human antiviral immunity is highly variable with significant consequences for disease susceptibility; yet the factors that contribute to such variation remain poorly understood. Here, we used samples and data from 1000 donors of the Milieu Interieur cohort to investigate factors associated with variation in the antiviral type-I interferon (IFN-I) response. We used ultrasensitive digital ELISAs (Simoa) to quantify IFNa and IFNb protein secretion in response to stimulation with agonists that activate antiviral TLRs including TLR3/MDA5 (polyIC), TLR7 (Gardiquimod), TLR7/8 (R848), TLR9 (ODN), as well as live influenza A virus (IAV) and Sendai virus. Using linear modelling controlling for age, we found that females produced more IFN-I in response to TLR7/8, IAV and Sendai virus, while males exhibited a stronger TLR3/IFIH1 response. We did not observe a sex difference in the TLR9 response. In response to all stimuli, we found that younger donors produced more IFNa and IFNb in response to stimulation compared with older donors. By testing 136 demographic variables we found strong environmental associations for the IAV IFN-I response including vaccine history, influenza antibody titre and serostatus. We also identified associations for smoking specifically with TLR7, but not TLR8, and between BMI, abdominal circumference and weight and the TLR3/IFIH1 IFNb response. To test for potential genetic associations we performed genome wide association studies of IFN-I responses, including age, sex, pDC and CD14+ monocyte counts as well as genetic PCs as covariates. We found that genetic variation in *IKZF1* is significantly associated with TLR7, TLR8 and TLR9 responses. The variants we identified in IKZF1 are associated with decreased IFN-I responses and are response quantitative trait loci for IKZF1 expression. Many of these variants have previously been associated with increased risk of autoimmune disease including systemic lupus erythematosus. We also found variants in *IRF7* that are associated with the response to TLR3/IFIH1, and in *SIGLEC14* and *LILRB2* that are associated with the TLR9 IFNa response. Ongoing work is focused on analysing sex hormone and sex chromosome effects, to understand what are the drivers of sex differences in IFN-I responses, and on performing fine mapping to identify causal variants in our analysis.

The T cell response against the EBV is shaped by HLA risk alleles in multiple sclerosis

Sanne Reijm[1;2], Jasper Rip[1;2], Jamie van Langelaar[1;2], Annet Wierenga-Wolf[1;2], Marie-Jose Melief[1;2], Harm de Wit[1], Yvonne Müller[1], Joost Smolders[2;3;4], Marvin van Luijn[1;2]
[1]Department of Immunology, Erasmus MC, Rotterdam, Netherlands; *[2]MS Center ErasMS, Erasmus MC, Rotterdam, Netherlands*; *[3]Department of Neurology, Erasmus MC, Rotterdam, Netherlands*; *[4]Neuroimmunology Research group, Netherlands Institute for Neuroscience, Amsterdam, Netherlands*

Purpose: Epstein-Barr virus (EBV) infection and the presence of HLA risk alleles are the major environmental and genetic risk factors for the development of multiple sclerosis (MS), respectively. We hypothesize that MS-related HLA (super)types present different EBV epitopes on EBV-infected B cells, resulting in an altered anti-EBV response by T cells. In this study, we aimed to link these environmental and genetic risk factors in MS by performing in depth characterization $CD8^+$ T cells in the context of risk and protective HLA alleles in MS.
Methods: For the characterization of EBV-specific $CD8^+$ T cells, 55 natalizumab-treated MS patients and 54 healthy controls were screened for presence of disease protective HLA-A*02 and risk HLA-B*07 allele using flow cytometry. MHC class I-coupled EBV and CMV peptides (n=10) were tetramerized with fluorochrome labeled streptavidins for separate detection of virus-specific T cells. The tetramers were included within an elaborate 38-color spectral flow cytometry panel including lymphocyte lineage markers, chemokine receptors, co-inhibitory and co-stimulatory receptors and brain-homing associated markers.
Results: HLA-A*02^+-restricted $CD8^+$ T cells were directed towards a wide variety of latent and lytic EBV peptides, while EBV-specific $CD8^+$ T cells restricted to HLA-B*07 were only found for the EBNA3A peptide. Using unsupervised clustering, EBV-specific $CD8^+$ T cells showed differential marker expression between HLA-A*02 and HLA-B*07 restricted cells. Interestingly, co-expression of co-inhibitory receptors TIGIT, CD160, KLRG1, PD1 and 2B4, was most pronounced on HLA-B*07-restricted EBV-specific $CD8^+$ T cells in MS patients, pointing towards a more exhausted phenotype. Additionally, brain homing and tissue residency-associated markers were found on these cells. CD20 was increased on EBV-specific T cells compared to other effector memory $CD8^+$ T cells and CCR5, similarly to the co-inhibitory receptors, was elevated especially on HLA-B*07-restricted EBV-specific $CD8^+$ T cells in MS patients.
Conclusion: Together, we show a link between HLA genetic risk and the T-cell response against EBV in MS. Our findings reveal a distinct phenotype of EBV-specific $CD8^+$ T cells, which is influenced by disease-related HLA alleles.

Integration of in silico analysis and in vitro functional analysis reveals Tissue Factor Pathway Inhibitor 2 (TFPI2) as a master transcriptional regulator and potential target to impede infliximab resistance in adult ulcerative colitis patients.

Hannah Fitzgerald[1], Flavia Genua[1], Ololade Lawal[1], Alexander Kel[2], Miriam Tosetto[3], Roisin Stack[3], Kieran Sheahan[3], Gregory Yochum[4], Glen Doherty[3], Sudipto Das[1]
[1]RCSI, Dublin, Ireland; *[2]geneXplain GmbH, Wolfenbüttel, Germany*; *[3]St Vincent's Hospital, UCD, Dublin, Ireland*; *[4]Pennsylvania State University, Pennsylvania, United States*

Purpose: Infliximab (IFX), an anti-TNF-α targeting agent, is used as the standard biological therapy for moderate-severe cases of ulcerative colitis (UC). However, approximately 40% of patients do not respond to IFX. While transcriptional alterations have been widely associated with non-response to IFX, the precise factors that regulate this remain poorly understood. The aim of this study was to perform a robust *in silico* analysis to identify master transcriptional regulators (MTRs) which regulate gene expression changes in IFX non-responsive UC patients, followed by their investigation in an *in vitro* model to establish their functional role in UC pathogenesis.
Methods: Differentially expressed genes (DEGs) identified from four independent public datasets were applied to the GeneXplain platform to identify transcription factors (TFs) enriched for the DEGs. This was followed by an upstream analysis to identify MTRs which regulate expression of these genes through the TFs. Finally, in a novel IBD-like *in vitro* system comprising of normal rectal epithelial cells treated with TNF-α, the role of these MTRs in driving an UC-associated phenotype was explored.
Results: Over 200 TFs were identified in both upregulated and downregulated genes in IFX non-responders across all data sets. RELA, NANOG, and FOSJUN were the top 3 TFs enriched for upregulated genes in three out of the four datasets. Using the TF data, the upstream analysis identified CXCL8, SELE, PTGS2, FCGR3, and TFPI2 as the top five MTRs. Furthermore, of the five MTRs, only TFPI2 was significantly upregulated in our IBD-like *in vitro* model. siRNA-mediated knockdown of TFPI2 in this model resulted in a significant decrease in genes including *TNFAIP6, TNFAIP3, FCGR3B, BIRC3* and *CXCL5*, all of which were predicted *in silico* to be upregulated by TFPI2. Intriguingly, downregulation of TFPI2 resulted in significant amelioration of pro-inflammatory cytokines including IL-1β, IL-10, IL-6 and IL-8.
Conclusion: This study for the first time identifies key MTRs, such as TFPI2, which act as master regulators of genes whose upregulation drives poor response to IFX. Therefore, these results indicate these MTRs, particularly TFPI2, as potential therapeutic targets whose perturbation in UC patients would likely result in improved response to IFX.

Maternal autoimmunity drives autoreactivity and potential neuropsychiatric sequelae in offspring independently of genetic factors

Sofie Fonager[1], Gudrun Winther[1], Yamira Weber[1], Thomas R. Wittenborn[1], Lisbeth Jensen[1], Lisbeth Ahm Hansen[1], Michael Carroll[2;3], Yonglun Luo[1;4;5], Lin Lin[1;4], Søren Egedal Degn[1]

Systemic lupus erythematosus (SLE) is a chronic autoimmune disease, targeting multiple organs, including the kidneys, skin, and lungs. However, up to 75% of patients experience neuropsychiatric manifestations ranging from headache to cognitive impairment and psychosis. This is proposed to be caused by cross-reactive autoantibodies targeting the cells of the CNS.
Particularly children of autoimmune mothers are at high risk of developing autism and learning disorders, since maternal transfer of autoantibodies, combined with genetic predisposition, can negatively impact the development and health of the offspring. Here, we used embryo transfers to examine the maternofoetal transfer of autoantibodies and immune activation in offspring, independently of genetic factors.
Healthy C57BL/6J embryos were implanted in either 564Igi females, a murine strain presenting with SLE-like disease due to an autoreactive B-cell receptor knock-in, or to healthy C57BL/6J females as controls.
Maternal transfer and endogenous production of both total and autoreactive antibodies were measured using solid-phase assays. Immune cell populations were analysed by flow cytometry, and the cortical microglia morphology along with astrocytic GFAP expression was visualized using immunohistochemistry and confocal microscopy and subsequently assessed via an image analysis pipeline.
Increased maternally transferred and endogenously produced (auto)antibody levels were detected in offspring born to autoimmune mothers, along with increased germinal center B cell populations in lymph nodes and spleen. However, no significant change in microglia morphology was observed between embryo transfer offspring, mothers, or controls.

Selective ablation of thymic and peripheral Foxp3+ regulatory T cell development

Dimitra Maria Zevla[1], Rikke Malmkvist[1], Carlos Alejandro Bello Rodríguez[1], Pablo Undurraga[1], Emre Kirgin[1], Marie Boernert[1], David Voehringer[2], Olivia Kershaw[3], Susan Schlenner[4], Karsten Kretschmer[1;5;6], Acelya Yilmazer[1]
[1]Center for Regenerative Therapies Dresden (CRTD), Dresden, Germany; *[2]Department of Infection Biology, Universitätsklinikum Erlangen and Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Ernlagen, Germany*; *[3]Department of Veterinary Medicine, Institute of Veterinary Pathology, Freie Universität, Berlin, Germany*; *[4]KU Leuven-University of Leuven, Department of Microbiology, Immunology and Transplantation, Leuven, Belgium*; *[5]Paul Langerhans Institute Dresden (PLID) of the Helmholtz Center Munich, University Hospital and Faculty of Medicine Carl Gustav Carus, Dresden, Germany*; *[6]German Center for Diabetes Research (DZD e.V.), Neuherberg, Germany*

Foxp3$^+$ regulatory T (Treg) cells of thymic (tTreg) and peripheral (pTreg) developmental origin are thought to synergistically act to ensure immune homeostasis, with self-reactive tTreg cells primarily constraining autoimmune responses. Here we exploited a Foxp3-dependent reporter with thymus-specific GFP/Cre activity to selectively ablate either tTreg (ΔtTreg) or pTreg (ΔpTreg) cell development, while sparing the respective sister populations. We found that, in contrast to the tTreg cell behavior in ΔpTreg mice, pTreg cells acquired a highly activated suppressor phenotype and replenished the Treg cell pool of ΔtTreg mice on a non-autoimmune C57BL/6 background. Despite the absence of tTreg cells, pTreg cells prevented early mortality and fatal autoimmunity commonly observed in Foxp3-deficient models of complete Treg cell deficiency, and largely maintained immune tolerance even as the ΔtTreg mice aged. However, only two generations of backcrossing to the autoimmune-prone non-obese diabetic (NOD) background were sufficient to cause severe disease lethality associated with different, partially overlapping patterns of organ-specific autoimmunity. This included a particularly severe form of autoimmune diabetes characterized by an early onset and abrogation of the sex bias usually observed in the NOD mouse model of human type 1 diabetes. Genetic association studies further allowed us to define a small set of autoimmune risk loci sufficient to promote β cell autoimmunity, including genes known to impinge on Treg cell biology. Overall, these studies show an unexpectedly high functional adaptability of pTreg cells, emphasizing their important role as mediators of bystander effects to ensure self-tolerance.

The activation and functional states of TIGIT+CD226+ Regulatory T cells (Tregs) and their role in autoimmunity

Meryl Attrill[1;2], Diana Shinko[1], Rosemarie Ford[1], Vicky Alexiou[2;3;4], Melissa Kartawinata[2;3], CHARMS study[2;3;4], JIAP study[2;3;5], Lucy R Wedderburn[2;3;5], Anne M Pesenacker[1]
[1]Institute of Immunity and Transplantation, UCL, London, United Kingdom; *[2]UCL Great Ormond Street Institute of Child Health, London, United Kingdom*; *[3]Centre for Adolescent Rheumatology Versus Arthritis at UCL UCLH and GOSH, London, United Kingdom*; *[4]Centre for Rheumatology, Division of Medicine, UCL, London, United Kingdom*; *[5]NIHR Biomedical Research Centre at GOSH, London, United Kingdom*

Foxp3+ regulatory T cells (Tregs) are crucial in maintaining immune tolerance and preventing autoimmunity, with TIGIT an important co-inhibitory receptor in Treg suppressive function. Sharing the same ligand (CD155/PVR), the effect of co-stimulatory CD226 expression on Tregs is less well defined. Furthermore, variable expression of TIGIT and CD226 on CD4+ T cells and Tregs have been linked to worsened disease activity in various inflammatory conditions, suggesting altered expression patterns impact regulatory maintenance.
Here we investigated the co-expression of TIGIT and CD226 on Tregs and effector T cells in autoimmunity, through spectral flow cytometry analysis of peripheral blood (PB), and synovial fluid (SF) of inflamed joints, from individuals with the childhood-onset condition Juvenile Idiopathic Arthritis (JIA). Synovial Tregs had increased co-expression compared to PB in JIA (mean %TIGIT+CD226+ of Foxp3+, SF 60.2% vs PB 19.4%, $p<0.0001$). Furthermore, a double positive Treg subset was detected in PB of individuals with clinically active JIA but was near absent in children who were clinically inactive. This suggests co-expression of these co-receptors could represent altered Treg response to certain inflammatory stimuli. Indeed, TIGIT+CD226+ Tregs from both SF and PB displayed a memory phenotype (>90% CD45RA-) with a heightened activation state, through increased expression of CD71, 4-1BB, PD-1 and CD39.
To further delineate the properties of TIGIT+CD226+ Tregs, we stimulated primary CD4+ T cells from healthy individuals *in vitro* with anti-CD3/CD28 beads or artificial antigen presenting cells and assessed Foxp3+ Treg phenotype. The percentage of TIGIT+CD226+ Tregs increased over time (mean 16.1% to 27.4% from day 1-4) with high expression of TNF superfamily receptors/ligands GITR, TNFR2, OX40, CD40L and 4-1BB found predominantly on CD226+ Tregs. Whilst TIGIT expression appeared key in maintaining CD25 and CD39 expression on CD226+ Tregs, TIGIT+CD226+ Tregs had reduced Foxp3 and Helios median fluorescence intensity (MFI) compared to TIGIT+CD226-, suggesting altered transcription factor-dependent profile.
We therefore propose TIGIT+CD226+ co-expression represents a highly activated Treg state in response to continuous inflammatory stimuli, such as in the inflamed joint. However, this state could represent altered functional stability of Tregs and could present as a possible target in monitoring or restoring tolerance in autoimmunity.

A binary Cre transgenic approach to study the differentiation and function of tissue-Treg cells

Philipp Stüve[1], Lisa Schmidleithner[1], Stefanie Brey[2], Thomas Winkler[2], Thomas Hehlgans[1], Markus Feuerer[1]
[1]LIT - Leibniz Institute for Immunotherapy, Regensburg, Germany; *[2]Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany*

Foxp3-expressing regulatory T cells (Treg) are critical for immune homeostasis by restraining excessive inflammation. Treg cells located in non-lymphoid tissues (tissue-Treg cells) possess not only immune regulatory but also tissue repair and regeneration functions, such as supporting insulin sensitivity in the adipose tissue and the regeneration of injured muscle or brain. To perform these functions, tissue-Treg cells need to undergo a tissue adaptation process and are characterized, e.g., by the expression of the interleukin 33 (IL-33) receptor (ST2) and killer cell lectin-like receptor subfamily G1 (KLRG1). We have recently characterized the differentiation process of tissue-Treg adaptation as a two-stage process starting in the secondary lymphoid organs and compared human and mouse tissue-Treg cell differentiation (Delacher et al. Immunity 2020; Delacher et al. Immunity 2021). Still, the final steps of tissue adaptation within tissues as well as pathways required for the maintenance of tissue-Treg cells remain largely unknown. Even though single-promoter-driven Cre systems provide a powerful tool to study the role of individual genes involved in differentiation and function, they are often not exclusive for cell types, lineage subtypes or differentiation stages. Therefore, current Cre drivers are not able to distinguish between lymphoid-Treg and tissue-localized Treg cells. To overcome this limitation, we developed a binary transgenic intein-mediated Split-Cre system using complementation-competent C-terminal-Cre and N-terminal-Cre domains, whose expression is driven by two separate promoters: Foxp3-N-Cre and Klrg1-C-Cre. This approach results in the reconstitution of a functional Cre recombinase specifically in tissue-Treg cells as demonstrated by reporter expression and specific gene deletion of floxed targeted genes. Overall, we developed a novel intersectional genetic method that allows specific targeting of tissue-Treg cells, which will help to gain a deeper understanding of Treg cell tissue adaptation and their function.

Aim: Regulatory T-cells (T_{regs}) are characterized by the expression of Foxp3, a master regulator involved in the development and function of T_{regs}. Foxp3 expression is dependent on activity of the Treg specific demethylated site (TSDR), which contains a CREB binding site. We aimed to find out how Foxp3 specific CREB deletion affects T_{reg} expression and function.
Materials and methods: T_{regs} from *Foxp3^{cre}CREB$^{fl/fl}$* mice and wildtype mice were analyzed by flow cytometry. Cytokine analysis was performed by flow cytometry, ELISA and RT-qPCR. Gene expression analysis was performed using Affymetrix HTA2 assays, ATAC-sequencing, and Methylation-assays. For functional relevance, a CD4 T cell mediated transfer colitis was performed.
Results and Discussion: *Foxp3^{cre}CREB$^{fl/fl}$* mice showed increased frequencies of T_{regs} (CD25+/Foxp3+) in thymus, spleen and peripheral lymph nodes and in non-lymphoid organs including lung and colon, but decreased Foxp3 expression at the single cell level. Despite decreased Foxp3 expression, enhanced expression of the IL-33 receptor (ST-2), IL-10, IL-13, and CREM was observed. CREB deficient T_{regs} were highly suppressive *in vitro* and prevented disease activity in a CD4 T cell mediated transfer colitis in an IL-10 dependent way. At steady state conditions, increased ST-2 expression was found in T_{regs} of spleen, thymus, mesenteric lymph node, lung and colon of *Foxp3^{cre}CREB$^{fl/fl}$ROSA^{RFP}* mice compared to WT mice. *In vitro* expansion of T_{regs} revealed that *Foxp3^{cre}CREB$^{fl/fl}$ROSA^{RFP}* T_{regs} have higher expansion capacity compared to wild type T_{regs}, but with lower proliferation. In non-expanded cells no differences were found between the WT and *Foxp3^{cre}CREB$^{fl/fl}$ROSA^{RFP}* T_{regs} with regard to cell proliferation and apoptosis. Mechanistically, in co-operation with CREM, CREB expression in T_{regs} alters chromatin accessibility to the ST-2 region and thereby influences T cell specific immune responses mediated by IL-10.

Tachykinin receptor 1 antagonism promotes the Foxp3+ regulatory CD4 T cells and controls gut inflammation and autoimmunity

Amrita Mishra[1], Surojit Karmakar[1], Namrita Halder[1], Mir Ahmad Habib[1], Dharmendra Kumar[2], Girdhari Lal[1]
[1]*National Centre for Cell Science, Pune, India*; [2]*Armed Forces Medical College, Pune, India*

Purpose: Neuroimmune communication at the gut-brain axis regulates gut inflammation and autoimmunity. Tachykinin receptors (TACRs) are known to express on neuronal and non-neuronal cells, and their expression is altered during inflammation. How TACRs signaling changes the phenotype and function of CD4 T cells and controls gut inflammation is not clearly understood.
Methods. Acute colitis was induced in naïve C57BL/6 mice by giving dextran sodium sulfate (DSS; 2% w/v) in drinking water. TACR expression on various tissues and immune cells was analyzed using quantitative RT-PCR, immunofluorescence staining, and multicolor spectral flow cytometry.
Results. Colonic biopsy samples of inflammatory bowel disease (IBD) and irritable bowel syndrome (IBS) patients showed increased TACR1 and TACR2 expression compared to control individuals. In DSS-induced colitis, treatment with TACR1 antagonist (CP96345) reduced the gut inflammation and colitis. TACR2 and TACR3 antagonists (Osanetant) did not affect the colitis. Mice with DSS-induced gut inflammation showed significantly increased TACR1 expression in the colon and secondary lymphoid tissues compared to control mice. Multicolor spectral flow cytometry analysis showed that antagonizing the TACRs significantly reduced the frequency of effector CD4 T cells ($CD4^+CD44^+ROR\gamma t^+$) and promoted regulatory CD4 T cells ($CD4^+Foxp3^+CD73^+CD62L^+LAP1^+$) in the Peyer's patch compared to control mice. Further, CD4 T cells expressed TACR1, and antagonizing TACR1 during *in vitro* differentiation promoted the $Foxp3^+$ Treg differentiation. Multicolor spectral flow cytometry and tSNE analysis showed that antagonizing TACR1 gives a unique cluster of suppressive $Foxp3^+$Tregs. Adoptive transfer of TACR1 antagonist-treated Tregs showed significantly more stable and suppressed effector CD4 T cell-induced experimental colitis in immunodeficient mice.
Conclusion. The present work showed that tachykinin antagonism promotes the differentiation of regulatory CD4 T cells. We provided a new mechanism of TACRs-based strategy to control gut inflammation and treat gut-associated inflammatory diseases in clinics.

Ontogeny and functions of peripheral regulatory CD4 T cells

Sonia Carvalho[1], Léa Giraud[1], Benjamin Saintpierre[1], Franck Letourneur[1], Aurélie Durand[1], Jacques Dutrieux[1], Bruno Lucas[1], Cédric Auffray[1]
[1]*Institut Cochin, Université de Paris Cité, CNRS UMR 8104, INSERM U1016, Paris, France*

Regulatory CD4 T (Treg) cells are key players in the prevention of autoimmune diseases. Treg cells include T Lymphocytes that are naturally produced in the thymus, called thymic Treg (tTreg) cells, and cells that have differentiated from naive CD4 T (CD4 T_N) cells in secondary lymphoid organs (SLOs) called peripheral Treg (pTreg) cells. Although they share a similar phenotype (characterized in particular by the expression of the transcription factor Foxp3), they are only partially redundant in inhibiting immune responses. Our aim is to gain a better understanding of the biology of pTreg cell subsets to obtain clues for manipulating their generation or their function in pathological contexts.
To explore pTreg cell generation, *in vitro* Treg cell polarisation assay were performed and the heterogeneity of the Treg cells obtained was assessed by scRNAseq. T-cell specific deficient mice were generated and characterized.
Our results demonstrate that pTreg cell generation is controlled by both the CNS1 enhancer in the Foxp3 gene and by 2 members of the Foxo transcription factor family. While in the absence of either of these elements, CD4 T_N cells are still able to differentiate into pTreg cells, their combined lack abolishes this ability suggesting that some Treg cells arise through Smad dependent mechanisms and others from Foxo dependent signaling. This heterogeneity has been confirmed in a scRNAseq experiment performed on Treg cells induced *in vitro* from WT, $CNS1^{KO}$ and $Foxo1/3^{KO}$ CD4 T_N cells. These results led us to generate $CNS1^{WT}$ and $CNS1^{KO}$ mice lacking Foxo1, Foxo3 or both. While deficiencies in Foxo1 or Foxo3 alone is not deleterious to the mice, the deletion of both leads to the development of a multi-organ autoimmune disease that is further exacerbated by an additional CNS1 deficiency. Consistently, Treg cell numbers in these various deficient mice are gradually reduced with deletions of Foxo1, Foxo3 and CNS1. Taken together, these results tend to demonstrate the existence of a heterogeneity, or even a dichotomy, of Treg cells induced from CD4 T_N cells.
This study reveals the complementary roles of the Foxo transcription factor and of the regulatory element CNS1 in pTreg cell ontogeny and heterogeneity.

Advancing CD8+ Treg cell therapy to the clinic for the treatment of kidney transplanted patients

Séverine Bézie[1], Mariane Lucazeau[1], Soraya Saiagh[2], Marie-Christine Leveque[2], Cecile Braudeau[1;3], Mina BENJELLOUN ZAHAR[2], Florence Vrignaud[2], Cecile Guillot Gueguen[4], Emmanuelle Papuchon[4], Béatrice Clemenceau[2;5], Regis Josien[1;3], Gilles Blancho[1;4], Diego Cantarovich[1;4], Ignacio Anegon[1], Carole Guillonneau[1]
[1]Nantes Université, CHU Nantes, INSERM, Center for Research in Transplantation and Translational Immunology, UMR 1064, Nantes, France; *[2]UTCG, CHU Nantes, Nantes, France*; *[3]CHU Nantes, Nantes Université, Laboratoire d'Immunologie, CIMNA, Nantes, France*; *[4]Institut de Transplantation Urologie Néphrologie (ITUN), Centre Hospitalo-Universitaire (CHU) Nantes, Nantes, France*; *[5]Nantes Université, Inserm UMR 1307, CNRS UMR 6075, Université d'Angers, CRCI2NA, Nantes, France*

Purpose: CD8+ Treg cell therapy is effective in preclinical models but has never been evaluated in a clinical trial. We designed a phase 1/2a clinical trial of cell therapy using GMP manufactured autologous polyclonal CD8+ Tregs to treat kidney transplanted patients from living donors.
Methods: CD8+ cells were isolated from peripheral blood by Clinimacs system, then CD8+CD4-CD45RClow/-CD56- cells were sorted by MACSQuant Tyto cell sorter. Cells were stimulated weekly with anti-CD3 and CD28 mAbs and cultured for 3 weeks in X vivo 15 supplemented with human serum, rapamycin, IL-2 and IL-15. Cytotoxicity was assessed by Annexin V/DAPI staining and suppressive ability was assessed in vitro and in vivo in NSG mice irradiated at 1.5 Gy and co-injected with human PBMCs.
Results: First, we set up a method for the isolation of CD8+Tregs from peripheral blood of healthy individuals using positive magnetic selection and flow cytometry in a safe closed system. We determined optimal clinical-grade culture conditions to preserve high proliferation rate, baseline phenotypic profile, and suppressive function in vitro and in vivo in a model of acute GVHD in NSG mice. We verified that they were resistant to classic maintenance immunosuppressive drugs, persistent and efficient in vivo but not cytotoxic. The method was validated on cells from patients with renal insufficiency, then transferred in the GMP facility with 3 validation runs demonstrating the phenotypic and functional stability of CD8+ Treg, meeting quality controls and release criteria.
The clinical study is a first-in-human, one-arm, open-label, prospective trial in patients with end-stage chronic renal failure requiring primary kidney transplantation, with 3 escalating doses of CD8+ Tregs administered the day before the transplantation without induction treatment and associated with classic maintenance immunosuppression. Patients are monitored for long-term safety, immunosuppression burden and occurrences of infections. Transcriptomic and proteomic analyses on blood, biopsy, and urine samples will inform on persistence and migration of Tregs to the graft. Recruitment will start mid-2024.
Conclusion: We designed a clinically compatible manufacturing process of CD8+Tregs and the first-in-human clinical trial evaluating the safety and hints of efficacy of CD8+Treg cell therapy in kidney transplant patients.

Use of nonengineered multiantigen specific Tissue-resident memory T cells for adoptive cellular therapy in gastrointestinal patients with liver metastases

Emilien Laloy[1], Jean Rene Pallandre[1], Syrine Abdeljaoued[2], Christophe Borg[2]
[1]Université de Franche-Comté, EFS, INSERM, UMR RIGHT, Besancon, France; *[2]CIC-1431, CHU Besançon, Department of oncology, EFS, INSERM, UMR RIGHT, Besancon, France*

Purpose: One of the major challenges for adoptive cell transfer (ACT) is the ability of T cells to infiltrate the tumor and to be able to persist for a long term. Tissue resident memory (T_{RM}) T cells are endowed with increased functionality and cytotoxicity compared to non-T_{RM} cells. Due to their efficacity and long-term persistence, the use of T_{RM} cells in ACT could be a useful approach.
Methods: Our team developed a reproducible, well-validated protocol for *in vitro* generation of multiantigen specific T_{RM} cells from patients' peripheral blood mononuclear cells (PBMCs). Monocyte-derived dendritic cells were loaded with CD4 and CD8 peptide mix and co-cultured with autologous PBMCs in the presence of T_{RM} cells polarizing cytokine cocktail. This **a**ntigen **s**pecific **T_{RM}** cells (AST_{RM}) generation protocol was tested on a cohort of patients presenting gastrointestinal cancers (cholangiocarcinoma, hepatocellular carcinoma, metastatic colorectal cancer, and stomach cancer).
Results: For the 15 tested patients, a CD4 and CD8 T_{RM} phenotype was observed ($CD69^+CD103^+$) and ($CD69^+CD103^-$). These two T_{RM} subsets highly expressed tissue homing biomarkers ($CXCR6^+CD101^+CD49a^+$). All generated T_{RM} cells highly expressed activation biomarkers and highly expressed PD1 which is a hallmark of T_{RM} cells and not associated with T cell exhaustion. However, no expression of LAG-3 nor TIGIT was observed. Seven of the tested patients (45%) presented TERT specific CD4 T_{RM} cells. NY-ESO1 and TERT specific CD8 T_{RM} cells were also observed. Remarkably, these *in vitro* generated T_{RM} cells were highly functional compared to antigen specific non T_{RM} cells. Over 50% of these generated CD4 and CD8 T_{RM} cells were polyfunctional as they co-produced IFNg, TNFa and IL-2. Interestingly, these T_{RM} cells were also highly cytotoxic as they were able to enact cancer cell lines eradication, mirrored by high expression of Annexin/7AAD.
Conclusion: On the light of these results, our team will be soon conducting a phase Ib proof-of-concept study "MERIT trial" that will allow the investigation for the first time of a novel therapeutic strategy using nonengineered multiantigen-specific T_{RM} cells combined to anti-PD-1 to treat patients with liver metastases.

Chasing Antigen-Specific T Cells with High Avidity (CATCH)

Kalliopi Zampeta[1;2], Larissa Henze[1;2], Andreas Thiel[1;2], Lucie Loyal[1;2]
[1]2Si-M / "Der Simulierte Mensch" a science framework of Technische Universität Berlin and Charité - Universitätsmedizin Berlin, Berlin, Germany, Berlin, Germany; *[2]Berlin Institute of Health at Charité - Universitätsmedizin Berlin, Berlin, Germany*

Cellular immunity to a specific antigen can be detected and characterized by the analysis of the quantity or functions of specific T cells either isolated *ex vivo* from blood or tissues or from *in vitro* systems. T cells express a highly variable set of specific immune receptors (T cell receptors, TCR) to recognize various peptides mostly in the context of HLA molecules. The strength and duration of the interaction of TCR with peptide-HLA complexes determine initial developmental steps of T cells, but are also decisively pivotal for the activation, following differentiation steps and the maintenance of functionally competent T cells that react efficiently in secondary challenges. For immediate productive immune reactions immune receptors with high affinity for their targets are indispensable, in particular for applications in malignant diseases. We here introduce the **CATCH** assay, the cytometric assessment of the CD3/TCR complex downregulation, as a novel technology to easily characterize functional avidities of T cell receptors directly in a precise and fast manner (Loyal et al., Science, 2021). By combining flow cytometric activation induced marker (AIM) assays with the analysis of CD3 downregulation we demonstrate efficient analysis and isolation of high avidity pathogen and tumor specific T cells within 4 hours covering a broad antigen concentration range. The method can be directly combined with functional analytics, but also be implemented for TCR engineering in human and mice. **CATCH** enables the high throughput *ex vivo* characterization of an individual's or a cohorts' T cell population quality. Integration of the **CATCH** assay into clinical studies and immune checkpoint inhibitor therapies harbors substantial potential for improving diagnosis and treatment success rates.

Optimized platform for the production of personalized T cells with transgenic TCRs for a chronic lymphocytic leukemia therapy development

Andrea Aran[1], Andrea Alonso[1], Roberto Martínez[1], Iván García-Loza[1], Berta Casanovas Albertí[1], Alejandro Ramírez-Chacón[1], E. Azucena González Navarro[2], Manel Juan Otero[2]
[1]Fundació de Recerca Clínic Barcelona - IDIBAPS, Barcelona, Spain; *[2]Servei Immunologia. Centre de Diagnòstic Biomèdic (CDB) - Hospital Clínic de Barcelona, Barcelona, Spain*

The adoptive transfer of autologous T cells genetically modified to express tumor-specific T cell receptors (TCRs) is a highly personalized therapy in development, facing significant challenges in the time required from identification, design, and manufacturing to patient administration. To address this, we propose to establish optimized methods for neoantigen-specific TCR identification and subsequent induction as transgenic TCRs in T cells. This will facilitate the development of a personalized advanced therapy focused on chronic lymphocytic leukemia (CLL), which is the most common leukemia in adults and has a high incidence in elderly individuals.
The project encompasses three main areas: (i) identification of candidate TCRs; (ii) lentiviral vector production and purification for efficient TCR delivery; and (iii) transgenic TCR transduction and validation. In the first part of the project, we have optimized processes for neoantigen affinity prediction for the HLA molecules and identification of neoantigen-reactive T cells.
Tumoral mutations in CLL patients were identified to determine neoantigens and bioinformatic predictions for both class I and class II HLA molecules were performed using NetMHCpan-4.1 and NetMHCIIpan-4.0, respectively. Additionally, for HLA-I peptides, we applied an immunogenicity prediction using the PRIME2.0 bioinformatic tool. Combining these two algorithms, between 2-5 peptides per patient (per HLA class) were chosen.
Candidate peptides were used to stimulate T cells. A 14-day activation protocol was established using T cells from healthy donors, with efforts to shorten it to 7-10 days and validated using T cells from patients. Direct peptide stimulation of peripheral blood mononuclear cells was compared with stimulation using monocyte-derived dendritic cells. CD154 and CD137 markers were chosen for assessing specific CD4+ and CD8+ T cell activation, respectively. Our results demonstrate successful optimization for identifying neoantigens from CLL tumors and selecting neoantigen-specific T cells.
Ultimately, this study seeks to develop a robust platform for personalized CLL therapy, extendable to other oncological diseases. The findings are expected to contribute to the advancement of cancer immunotherapy and personalized medicine.

This research project (PMPTA23/00027) is funded by the Instituto de Salud Carlos III within the framework of the *Plan de Recuperación, Transformación y Resiliencia* with financing from the European Regional Development Fund.

A folate receptor alpha specific, CD28/CD40-based chimeric costimulatory antigen receptor (CoStAR™), enhances anti-tumour activity of T cells and tumour infiltrating lymphocytes.

Milena Kalaitsidou[1], Owen Moon[1], Leyuan Bao[1], Mark Dudley[1], Robert Hawkins[1], Gray Kueberuwa[1], John Stephen Bridgeman[1]
[1]*Instil Bio, Dallas, United States*

Tumour infiltrating lymphocyte (TIL) therapy for treatment of refractory metastatic melanoma, has shown clinical efficacy in a number of clinical trials, and has recently received FDA approval. However, extending the clinical benefit to patients with other cancers has presented a challenge. Insufficient costimulation in the tumour microenvironment can lead to T cell anergy and exhaustion, leading to loss of anti-tumour activity. Here, we describe the construction and functional testing of a chimeric costimulatory antigen receptor (CoStAR) which enhances TCR signals in T cell and TILs upon antigen engagement. CoStAR comprises of a tumour associated antigen specific single chain antibody fragment (scFv) fused to the signalling domains of CD28 and CD40. Transfer of a FRα specific CoStAR to T cells augments T cell activity in a TCR-mediated signal 1 dependent manner. CoStAR also enhanced proliferation, even in the absence of exogenous IL-2. CoStAR activity was dependent on the engagement of surface anchored FRα and neither blocked nor activated by the soluble form, which can be found at high levels in patient serum. Peptide titration assays demonstrated that CoStAR mediated costimulation enhanced overall responses to peptide, but did not lower the activation threshold, a phenomenon shared with physiological costimulation. Using an *in vivo* tumour xenograft model, CoStAR enhanced control of tumour growth, and improved host survival. TIL from multiple cancer indications could be efficiently and reproducibly engineered to express CoStAR, resulting in augmented activity in response to target antigen expressing cell lines and autologous tumour digest. CoStAR represents a novel approach to enhancing TIL activity with synthetic costimulation, in turn increasing anti-tumour activity.

Adoptive PD1+ tumor-infiltrating lymphocyte therapy for metastatic TNBC: production results of the safety run-in phase of the TILS001 clinical trial

E. Azucena González Navarro[1], Marta Español-Rego[1], Laura Angelats[1], Marta Santiesteban[2], Cristina Saura[3], Eva Ciruelos[3], Luis Alvarez-Vallina[4], Juan Jose Lasarte[5], Alena Gros[3], Mafalda Olivera[3], Pablo Tolosa[6], Libertad Heredia[1], Daniel Jiménez[1], Catherina De Guzman[1], Fara Brasó-Maristany[1], Lorea Villanueva[6], Jordi Canes[6], Tomas Pascual[1], Manel Juan Otero[1], Aleix Prat[1]
[1]Hospital Clinic Barcelona, Barcelona; *[2]Universidad de Navarra, Navarra*; *[3]VHIO, Bar*; *[4]Hospital 12 Octubre, Madrid, Spain*; *[5]CIMA, Pamplona, Spain*; *[6]Grupo SOLTI, Barcelona, Spain*

Purpose: Compared to other breast cancer types, metastatic triple-negative breast cancer (mTNBC) carries a poor prognosis with rapid progression and lower survival rates. The TILS001 clinical trial (NCT05451784) evaluates the safety, tolerability, and effectiveness of infused PD1+ T-cells (NUMARZU-001). TILS001 is a single-arm, multicenter phase I/II study evaluating PD1+ TILs infusion as a treatment for advanced or mTNBC. The characterization of NUMARZU-001 in the first 3 infused patients is outlined below.
Methods: Three sequential phases before TILs infusion are done. Initially, a molecular prescreening phase is done to evaluate PD1 mRNA expression. Following this, in the prescreening phase, a preexpansion from a lesion is carrying out. Finally, after achieving full expansion of PD1+ TILs, patients undergo a non-myeloablative lymphodepleting chemotherapy regimen, followed by TILs infusion and subcutaneus IL-2 treatment.
Results: At data cut-off (September 2023), molecular prescreening was conducted on 51 pts, with 18 undergoing prescreening, and 3 received treatment. The median age was 49 years. One patient had received 4 prior treatment lines, while the other two had received 2 lines. Preexapnsion and full expansion were done in a centralized way without incidences. CD4+ T cells expansion and enrichment of Central Memory populations were observed.
Conclusion: Overall, our results show that clinical-grade production of TILs for advanced or mTNBC patients are feasible, and that the obtained products meet the current quality standards of the field. NUMARZU-001 has shown a manageable safety profile in the safety run-in phase. Recruitment is ongoing to increase number of treated patients and evaluate its efficacy further.

T follicular helper (Tfh) cells support the process of antibody affinity maturation within germinal centers (GCs), thereby facilitating the selection of protective high-affinity antibody variants. Recent studies demonstrate the presence of B cells and GC in various tumor types correlates strongly with better prognosis and response to immune checkpoint blockade (ICB), yet less is known about Tfh cells and their specificity in this context. Potential sites for Tfh-mediated tumor-specific affinity maturation include GCs within tumor-draining lymph nodes (tdLNs) and GC-like tertiary lymphoid structures (TLS) formed at the tumor site. Recently, our laboratory has identified and characterized MMP14-specific antibody-forming cells in ovarian cancer patients, which arise from T cell-driven antibody affinity maturation processes. These findings prompted us to investigate whether autoreactive T cells within the tumor microenvironment (TME) or tdLN could contribute to B cell selection. To address this, we developed a method to isolate and TCR-sequence self-reactive T cells *ex vivo* from ovarian cancer patients, using MMP14 as a model tumor-associated self-antigen. By performing single-cell genomics on matched tumor and tdLN samples, we can elucidate the nature and origin of the identified MMP14-specific T cells based on their TCR sequences. We found shared and unique cell population between the tdLNs and the TME. Most strikingly, CXCL13-expressing Tfh cells are found solely in the TME of ovarian cancer patients but not in the tdLN.
The identification of autoreactive Tfh cells in our study holds potential for understanding the adaptive immune response in ovarian cancer and the breakdown of tolerance within the TME. Furthermore, these findings may pave the way for novel therapeutic approaches for ovarian cancer patients by enhancing interactions between self-reactive T helper cells and B cells.

Probing tumour immune evasion via local immune profiling with fine needle aspirates in hepatocellular carcinoma (HCC)

Gloryanne Aidoo-Micah[1;2], Stephanie Kucykowicz[1], Vishnu Naidu[2], Nathalie Schmidt[1], Daniel Brown Romero[1], Rushabh Shah[2], Tate McKinnon-Snell[1], Yiya Zhong[1], Upkar Gill[3], Mariana Diniz[1], Laura J Pallett[1], Edward Green[2], Alexa Childs[1;2], Tim Meyer[1;2], Mala K Maini[1]
[1]University College London, London, United Kingdom; *[2]Royal Free Hospital, London, United Kingdom*; *[3]Queen Mary University, London, United Kingdom*

Purpose: Harnessing tissue-resident immunity for tumour clearance requires approaches that rescue local effector CD8+ T cells from intrinsic dysfunction, while overcoming extrinsic suppression by regulatory immune counterparts within the tumour niche. Thus, sampling immune cells sequestered in tumours is critical to the discovery of targetable regulatory pathways and subsets. In HCC, diagnostic biopsies often contain a mixture of immune cells from HCC and surrounding liver, and their invasive nature has restricted their application. We hypothesized that fine needle aspiration (FNA) of liver tumours would offer a minimally invasive method to monitor local tissue-compartmentalised immune responses to dissect primary and secondary immunotherapy resistance mechanisms.
Methods: Patients with advanced HCC were consented to provide matched blood, FNA and biopsy. Peripheral blood mononuclear cells (PBMC) from blood (n=25) and tumour infiltrating leukocytes (TIL) from FNA (n= 25) and biopsy (n=15) were isolated for *ex-vivo* spectral multi-parameter flow cytometric characterisation of effector and regulatory immune populations.
Results: FNA reproducibly yielded a broad range of viable immune subsets local to the tumour microenvironment (TME). Crucially, FNA were able to extract tissue-resident $CD8^+$ T cells ($T_{RM,}$ $CD69^+CD103^+CD8$) that could not be sampled in blood. The majority of tumour $CD8^+T_{RM}$ sampled before immunotherapy expressed immune checkpoints including PD-1, Tim-3 and 2B4, accounting for significantly higher expression of these therapeutic targets on the global $CD8^+$ T cells extracted from FNA or biopsies than from blood. Within the myeloid compartment, dendritic cells were reduced whereas granulocytic / polymorphonuclear myeloid derived suppressor cells (g-MDSC/PMN-MDSC) were significantly expanded in tumour FNA compared to blood, allowing characterisation of their dominant homing and immunoregulatory mechanisms to define novel therapeutic targets.
Conclusion: We show that minimally invasive FNAs are capable of comprehensively sampling the distinct immune landscape of HCC compartmentalised at the site of disease, including the expression of key immunotherapeutic targets (T-cell checkpoints and g-MDSC). The resulting data have allowed characterisation of immunotherapeutic targets for future personalised refinement of targeted immunotherapy to overcome tumour immune escape.

CX3CR1 loss by CD8 tumor infiltrating lymphocytes mediates immune evasion in colorectal cancer

Ugo Chartral[1;2], Eric Hervouet[1;3], Maxime Fredon[1], Nawfel Adib[1], Pauline Martin[4], Sylvain Simon[5], Paul Peixoto[1;3], Adeline Bouard[1;2], Syrine Abdeljaoued[1;2], Kathleen Ducoin[6], Nathalie Labarrière[6], Yann Godet[1], Angelique Viennot[1;7], Christophe Borg[1;2;7], Marie Kroemer[1;4], Romain Loyon[1]
[1]INSERM UMR RIGHT, Besancon, France; *[2]CHU de Besançon, Oncologie, Plateforme ITAC, Besancon, France*; *[3]Epigenexp Platform, Besancon, France*; *[4]Pharmacie, CHU de Besançon, Besancon, France*; *[5]Fred Hutchinson Cancer Research Center, Seattle, United States*; *[6]Nantes Université, Inserm, INCIT, Nantes, France*; *[7]CHU de Besançon, Oncologie, Besancon, France*

Purpose: This study aimed to investigate the regulation of CX3CR1 expression on CD8 T cells within the tumor microenvironment (TME) of colorectal cancer (mCRC) liver metastases and its implications for antitumor immunity. Furthermore, immune evasion mechanisms relying on the CX3CL1/CX3CR1 axis were investigated.
Methods: TGF-β-dependent pathways regulating CX3CR1 expression on CD8 T cells were explored in vitro and assessed by Flow Cytometry, RT-qPCR, and Chromatin Immunoprecipitation (ChIP). Peripheral blood mononuclear cells (PBMC) and tumor infiltrating lymphocytes (TILs) from mCRC patients were collected and their TCR diversity was analysed, as well as protein and transcriptomic CX3CR1 and miR-27a-5p expression. A Jurkat T cell-NALM6 in vitro immunological synapse model was developed to analyse mechanisms involving the CX3CL1/CX3CR1 axis in the regulation of T cell activation. **Results:** TGF-β was found to decrease CX3CR1 expression in CD8 T cells in a miR-27a-5p dependant manner independently of SMAD2/3. Our findings, based on mCRC patient-derived samples, underscored a significant variation in CX3CR1 expression between peripheral blood CD8 T cells and their associated TILs from CRC liver metastases. Moreover, cancer patients displayed heightened CX3CR1 expression in their antigen specific peripheral CD8 T cells. Transcriptomic analyses revealed a robust correlation between CX3CR1 expression and cytotoxic effector molecules such as perforin and granzyme. Furthermore, CX3CR1-CX3CL1 binding was found to increase TCR-induced signalling and to enhance effector functions of T cells.
Conclusion: Our results suggest the improvement of T cell activation following CX3CR1 engagement with its ligand CX3CL1. Thus, the loss of CX3CR1 within the TME, driven by TGF-β signalling in a miR-27a-5p dependant manner, should be considered as an immune evasion mechanism in cancer. Understanding the role of CX3CR1 in the modulation of the immunological synapse and its implications for antitumor immunity might lead to the development of new immunotherapeutic strategies.

IFN-γ predisposes acute myeloid leukemia to therapy resistance

Bianca E Silva[1], Alison Daubry[1], Charline Faville[1], Mégane Jassin[1], Frédéric Baron[1;2], Grégory Ehx[1]
[1]*Laboratory of Hematology, GIGA-I3, University of Liège, Liège, Belgium*; [2]*Department of Medicine, Division of Hematology, CHU de Liège, Liège, Belgium*

Acute myeloid leukemia (AML) patients frequently relapse following frontline therapies such as high-intensity chemotherapy and hypomethylating agents. Currently, the mechanisms underlying this therapy resistance remain elusive. We recently discovered that AML blasts present MHC peptides that are recognized by T cells at diagnosis, leading to their activation and subsequent secretion of cytokines. While such a response might help eradicate leukemia, we hypothesized that pro-inflammatory cytokines secreted by immune cells might also contribute to therapy resistance. Therefore, we performed large-scale transcriptomic analyses comparing blasts obtained at diagnosis from patients who either responded or did not respond to conventional cytarabine + anthracycline therapy. Our analyses revealed an upregulation of IFN-γ signaling signatures in patients resistant to therapy. Similar signatures were observed in patients resistant to the hypomethylating agent 5-azacytidine. Consequently, patients expressing high IFN-γ signaling scores at diagnosis had lower survival rates. Additionally, treating multiple AML cell lines with IFN-γ in vitro significantly decreased the cytotoxic activity of high doses of chemotherapeutic agents; treated cells exhibited faster proliferation rates following chemotherapy exposure than untreated cells, suggesting that IFN-γ signaling may accelerate relapse in patients. In conclusion, our findings suggest that inhibiting IFN-γ signaling might help overcome therapy resistance in AML.

This study is supported by funds from the Fonds de la Recherche Scientifique (FNRS) and Fondation Léon Fredericq.

Lack of TREM2 during anti-PD1 therapy reprograms intestinal macrophages and microbiota to enhance tumor rejection

Martina Molgora[1], Blanda Di Luccia[1], Darya Khantakova[1], Natalia Jaeger[1], Hao-Wei Chang[1], Rafael Czepielewski[1], Beth Helmink[1], Emily Onufer[1], Jose Fachi[1], Bishan Bhattarai[1], Tihana Trsan[1], Patrick Rodrigues[1], JinChao Hou[1], Jennifer Bando[1], Cristiane Secca da Silva[1], Marina Cella[1], Susan Gilfillan[1], Robert Schreiber[1], Jeffrey Gordon[1], Marco Colonna[1]

Immune checkpoint therapy (ICT) is successfully used to activate anti-tumor T cell responses in the treatment of several types of cancer. However, while many patients respond durably to ICT, a significant number remain unresponsive, prompting the investigation of complementary therapeutic avenues to improve ICT. Reprogramming tumor-associated macrophages (TAMs) by either blocking or deleting the macrophage receptor TREM2 attenuates tumor growth and promotes ICT. Another strategy to improve checkpoint therapy relies on the intestinal microbiota. Here, we found that the synergistic effect of TREM2 deficiency with anti–PD1 is dependent on the microbiota. Anti-PD1 combined with TREM2 deficiency induces proinflammatory programs in intestinal macrophages and a concomitant expansion of *Ruminococcus gnavus* (*R. gnavus*) in the gut microbiota. Gavage of wild-type mice with *R. gnavus* recapitulated enhancement of anti-PD1-mediated tumor elimination occurring in the absence of TREM2. The intestinal proinflammatory environment coincided with expansion, increased circulation, and migration of TNF-producing CD4+ T cells to the tumor bed. Thus, TREM2 remotely controls anti-PD1 checkpoint blockade through modulation of the intestinal immune environment and microbiota; *R. gnavus* is a potential probiotic agent for overcoming resistance to anti-PD1.

Liver metastases of colorectal carcinoma contain different subsets of tissue resident memory CD8 lymphocytes correlated with distinct risk of relapse following surgery and mediate immune checkpoint responses

Syrine Abdeljaoued[1], Emilien Laloy[2], Jean Rene Pallandre[2], Marie Kroemer[3], Laurie Spehner[4], Adeline Bouard[5], Virginie Mougey[5], Ugo Chartral[2], Angélique Vienot[6], Franck Monnien[7], Alexandre Doussot[8], Romain Loyon[2], Christophe Borg[1]
[1]Université de Franche-Comté, EFS, INSERM, UMR RIGHT,CHU Besançon, Department of Oncology, CIC-1431, Besançon, France; *[2]Université de Franche-Comté, EFS, INSERM, UMR RIGHT, Besançon, France*; *[3]CHU Besançon, Department of Pharmacy, UMR RIGHT, Besançon, France*; *[4]CHU Besançon, Department of Oncoglogy, CIC-1431, INSERM, UMR RIGHT, Besançon, France*; *[5]Université de Franche-Comté, EFS, INSERM, UMR RIGHT, ITAC Platform, Besançon, France*; *[6]CHU Besançon, Department of Oncoglogy, UMR RIGHT, Besançon, France*; *[7]CHU Besançon, Department of Pathology, UMR RIGHT, Besançon, France*; *[8]CHU Besançon, Department of Digestive and Oncologic Surgery, UMR RIGHT, Besançon, France*

Purpose: Tissue resident memory (T_{RM}) T cells have emerged as key players in cancer immunosurveillance, and their presence has been linked to a favorable clinical outcome in solid cancer patients. Liver metastases exhibit a highly immunosuppressive tumor microenvironment, however the role and clinical impact of T_{RM} cells infiltration in colorectal cancer remain elusive.
Methods: An exhaustive profiling using multiparametric flow cytometry was conducted on tumor infiltrating lymphocytes isolated from 27 patients' colorectal cancer liver metastases (CRC-LM) and compared to 16 peripheral blood samples of CRC-LM patients. Cytokine production was also evaluated in *in vitro* activated T_{RM} and non-T_{RM} cells. Prognostic value of T_{RM} cells was also assessed in a well-defined cohort of CRC-LM.
Results: Here we identified two subsets of T_{RM} cells expressing CD103 and/or CD69 showing significantly higher expression of tissue residency and activation biomarkers. $CD103^+CD69^+$ T_{RM} cells subset showed almost exclusive expression of tumor reactivity biomarkers PD-1 and CD39. Supporting this observation, $CD103^+CD69^+$ T_{RM} cells showed a more oligoclonal TCR repertoire. Both T_{RM} subsets presented higher cytotoxic and functional capacity compared to non-T_{RM} cells. Our study showed that only the presence of $CD103^+CD69^+$ T_{RM} cells was associated with longer recurrence free survival of colorectal cancer patients with liver metastases. Moreover, treatment with anti-PD-1 and anti-CTLA-4 therapy in CRC murine models resulted in expansion of this intratumoral T_{RM} population.
Conclusion: Taken together, our work demonstrates the existence of a phenotypic heterogeneity of T_{RM} cells in colorectal cancer liver metastases. In this study, we identified a population of $CD103^+CD69^+$ T_{RM} cells exhibiting the characteristics of tumor reactivity and correlated with better patients' prognosis, with potential implication in optimal therapeutic strategies determination.

Investigating the effects of targeting stromal cell sialylation on the tumour immune microenvironment in colorectal cancer

Aoise O'Neill[1], Hannah Egan[1], Norashikin Zakaria[1], Oliver Treacy[1], Sean Hynes[2], Aisling Hogan[3], Jenny Che[4], Li Peng[4], Aideen Ryan[1]
[1]Lambe Institute, University of Galway, Galway, Ireland; *[2]Discipline of Pathology, University of Galway, Galway, Ireland*; *[3]Department of colorectal surgery, university hospital galway, Galway, Ireland*; *[4]Palleon pharmaceuticals, Boston, United States*

Purpose: The tumour microenvironment (TME) of colorectal cancer (CRC) contains tumour cells, immune cells and stromal cells. The TME of CRC subtype CMS4 has been associated with poor prognosis, immunosuppression and more recently, sialylation. Sialylation is a post-translational process in which sialic acids (SA's) are added to cell surface glycoproteins forming sialoglycans. Sialoglyans bind immune cell inhibitory receptors called Siglecs, downregulating anti-tumour immunity. In our research, we are investigating the role of sialylation in stromal cell-mediated immunosuppression in CMS4 CRC.
Methods: We performed stromal-immune coculture assays in primary human ex vivo experiments including cancer and normal-associated fibroblasts (CAFs and NAFs) from CRC patients and NK cells. Cocultures included sialyltransferases inhibitor (SI) and sialidase (Sia) targeting of stromal cell sialylation. NK cell Siglec expression and NK cytotoxicity of HCT116 cancer cells were assessed via flow cytometry. We then conducted an in vivo study of stromal-rich CRC including SI and Sia targeting of stromal cells. Tumours, spleens and lymph nodes were analysed via flow cytometry including immune cell panels for T cells, NK cells, macrophages and dendritic cells. Analysis included Siglec expression and activational/functional marker expression in stromal-rich and SA-depleted stromal groups.
Results: Human ex vivo stromal-NK cocultures showed an induction of Siglec 9 on NK cells in the presence of CAFs, which is significantly reduced with targeting of SA on stromal cells. SA removal significantly increased NKG2D activation on NK cells. In vivo, growth of SA-targeted tumours was significantly lower than stromal-rich group. Flow cytometry analysis showed significantly higher numbers of CD49b+ NK cells and CD11b+ macrophages in SA-targeted groups. NK cells had significantly higher levels of granzyme B in tumours with stromal cell sialylation targeting. These effects were seen in the tumour but also systemically in the secondary lymphoid organs.
Conclusion: Together this data shows in multiple models of CRC that stromal cells can modulate the activity of immune cells including NK cells trough the Siglec/Sialic acid axis. Targeting stromal cell sialylation increased numbers and activation of NK cells and macrophages in vivo. Targeting stromal cell sialylation may be the key to reversing immunosuppression in stromal-rich CRC.

N-glycosylation shapes the thymic differentiation of gd T-cells

Rúben Pinheiro[1], Beatriz Santos-Pereira[2], Eduarda Leite-Gomes[2], Inês Alves[2], Salomé S Pinho[2], Bruno Silva-Santos[1]
[1]*Instituto de Medicina Molecular João Lobo Antunes, Lisboa, Portugal*; [2]*instituto de Investigação e Inovação em Saúde, Porto, Portugal*

Purpose: γδ T-cells differentiate in the thymus and play key roles in tissue homeostasis and in immune responses. Many of these properties are imprinted during their thymic maturation, and thus dissecting the underlying molecular mechanisms is essential to optimize the performance of γδ T-cells in immunotherapies. In this regard, glycosylation is a post-translational modification involved in multiple aspects of the immune system. However, its impact on γδ T-cell biology remains poorly defined, therefore we investigated the role of *N*-glycosylation in the development of γδ T-cells.
Methods: We used qRT-PCR and a lectin-based approach to investigate the regulation of *N*-glycosylation by γδ thymocytes, employing thymic organ cultures to address the role of metabolism in its modulation. Lastly, we used glycoengineered mouse models, lacking the early glycan-branching enzymes Gnt-I and Gnt-II in lymphocytes, to study the impact of this pathway on the differentiation of γδ T-cells along with *in vitro* TCR stimulation of immature γδ thymocytes to dissect its role in TCR activation levels.
Results: We show that γδ thymocytes committing to IFN-γ production (γδIFN) downregulate the *N*-glycosylation program, whereas IL-17-producing (γδ17) cells exhibit higher expression levels of critical enzymes of this pathway. As result, embryonic γδIFN thymocytes display a greater content in mannose *N*-glycans compared to their γδ17 cell counterparts. Importantly, we show that aerobic glycolysis blockade alters the *N*-glycome of developing γδ T-cells. Lastly, in glycoengineered mouse models, we observed a substantial impairment in γδ17 cell differentiation in the embryonic and adult thymus associated with defects in the regulation of their lineage transcriptional program. This was accompanied by an increase in the minimal threshold of TCR activation upon *N*-glycosylation inhibition in immature γδ thymocytes.
Conclusion: Globally, our results suggest that *N*-glycosylation program is upregulated in thymic γδ17 cells, being modulated by their metabolic profile and impacting their differentiation through the regulation of the γδ17 transcriptional program and the threshold levels required for TCR activation. In summary, our results shed new light on the biological role of *N*-glycosylation in thymic γδ T-cell development, which may condition their functional performance in immune responses.

Siglec-1/CD169+ macrophages orchestrate immune reaction and matrix deposition in pancreatic cancer

Ana Hennino[1], Kevin Thierry[1], Melissa Masmoudi[1], Zhichong Wu[2]
[1]Cancer Research Center Lyon, Lyon, France; [2]Research Institution of Pancreatic Disease, Shanghai, China

Purpose: Pancreatic cancer (PDAC) is set to be the 2nd deadliest cancer by 2030. PDAC is both a stromal and immune disease. With 80% of the tumor mass being stromal and most of the immune cells in the tumor microenvironment (TME) being macrophages. Several reports have revealed the importance of macrophage reprogramming in pancreatic cancer. Therefore, understanding the communication leading to pro- or and tumoral macrophages may be the key to unleash the potential of immunotherapy in PDAC.
Methods: Here we performed studies with primary cell lines issued from LSL-Kras$^{G12D/+}$; p16$^{fl/fl}$;Ptf1a-Cre; (KIC mice), stromal cells from LSL-Kras$^{G12D/+}$;Ptf1a-Cre (KC mice). The cells were orthotopically injected in CD169$^{DTR/DTR}$ recipients. We also performed single cell RNAseq analysis data on human PDAC single cell data set comprising of more than 70 patients. Mice were injected with diphtheria toxin in order to specifically deplete CD169 expressing cells. The pancreatic tumour growth and the changes in the local immune cells were analyzed by flow cytometry, immunohistochemistry and immunofluorescence.
Results: We found that CD169^{+} macrophages were highly abundant in pancreatic cancer in Humans and mice. We show here that stromal cells could polarize CD11b^{+}F4/80^{+} macrophages toward an immunosuppressive phenotype with expression of CD169. CD169^{+} macrophages could produce large amounts of stromal TGFBI that directly stimulated CXCL12 production by stromal cells, which attracted CD8^{+} T cells. Inhibition of CD169 by a DTR approach in an orthotopic pancreatic cancer model decreased matrix deposition and CD8^{+} T-cell infiltration within the tumor microenvironment.
Conclusion: These data suggest that CD169^{+} macrophages play a key role in sustaining the stromal reaction in pancreatic cancer and that specific targeting of this component might be beneficial to patients as an neoadjuvant therapy.

Glycosylation of γδT cells defines its activity and function associated with autoimmunity

Beatriz Santos-Pereira[1;2], Inês Alves[1], Manuel Vicente[1], Ana Campar[3], Carlos Vasconcelos[3], António Marinho[3], Salomé S Pinho[1]
[1]Institute for Research and Innovation in Health, Porto, Portugal; *[2]Faculty of Medicine from University of Porto, Porto, Portugal*; *[3]Clinical Immunology Unit, Porto University Hospital Centre, Porto, Portugal*

Purpose: *N*-glycosylation is a post-translational modification where glycans are added to proteins of essentially all cells. Evidence has shown the prominent role of glycans in T-cell biology. We demonstrated that human and murine thymocytes display different glycan structures that define developmental stages. Moreover, mannosylated *N*-glycans in thymocytes lead to defects in T-cell development, promoting the γδ-lineage, leading to increased susceptibility to inflammation and infection (Vicente M. et al., CellMolImmunol 2023). In addition, at the periphery, we observed that IL-17-producing γδT-cells recognize specific glycan structures associated with Systemic Lupus Erythematosus (SLE) disease (Alves I. et al., ScienceTransMed 2023). However, how altered glycans in γδT-cells could influence their response remains unknown. In this work, we explored the role of altered *N*-glycans expression on γδT-cell activity and function and its impacts on autoimmunity.
Methods: We started to analyze public RNA-seq data from healthy individuals and to characterize the glycosylation profile of γδT-cells from the peripheral blood of autoimmune patients. Moreover, to study the biological impact of altered glycans in γδT-cells´ function, we performed *in vitro* culture assays taking advantage of glycoengineered conditional KO mice developed in the group, in which selected glycogenes are deleted in lymphocytes. Finally, to disclose the impact of glycans on autoimmunity, we induced specific autoimmune diseases in the glycoengineered mice models.
Results: The public RNA-seq data from healthy individuals has revealed that peripheral γδT-cells exhibit a high dependency on the expression of glycogenes, namely those involved in the early *N*-glycan branching. Furthermore, the γδT-cells' glycosylation profile from the peripheral blood of autoimmune patients (including SLE) revealed a remarkable alteration in the *N*-glycosylation pathway. Moreover, *in vitro* culture assays with abnormal glycosylated γδT-cells revealed an association between the sequential *N*-glycosylation pathway and differential activation phenotypes of γδT-cells. Finally, using different glycoengineered mice, we demonstrated that truncation of complex *N*-glycan structures on γδT-cells defines its activity and cytokine production, contributing to an autoimmune-like disease in mice models.
Conclusion: In conclusion, we demonstrated the importance of glycans in regulating T-cell response and the impact on autoimmunity.

The interaction between TLR4 and sialic acid governs monocyte phenotype variations

Loise Råberg[1], Alexandra Stubelius[1]
[1]*Chalmers University of Technology, Gothenburg, Sweden*

Purpose: Osteoarthritis (OA) is a chronic, low-grade inflammatory joint disease characterized by pain, swelling, and reduced mobility. It affects up to 10% of the population, making it the leading cause of disability today. Despite its widespread impact, treatment options remain elusive due to the intricate and multifaceted nature of the disease. In OA, degenerated cartilage exhibits aberrant glycosylation, which can activate monocytes and T-cells, yet the mechanisms are unclear. We hypothesized that the monosaccharide Sialic acid (Sia) positioned at the outermost end of glycans on both cells and tissue proteins, could be involved in the disease pathogenesis, as it dictates immune regulation, including cellular communication, migration, and recruitment.
Methods: Using fluorescence-coupled metabolic labelling, we assessed Sia biosynthesis by flow cytometry in chondrocytes (Tc28a2) and monocytes (U-937) after different stimulations (LPS, IL1B/TNFa or TNFa alone). Subsequently, we assessed the removal of Sia on both human primary monocytes and porcine cartilage explants after treatment of the enzyme neuraminidase (Neu). The cellular effects of removing Sia on monocytes were compared to those induced by LPS and M-CSF in the presence or absence of the TLR4 inhibitor TAK-242. We evaluated the expression of Sialic acid immunoglobulin-like lectin (siglecs) 5, 9, and 15 by flow cytometry, ELISA, and confocal microscopy. For tissues, cartilage degeneration was assessed by measuring release of glycosaminoglycans using the DMMB assay.
Results: Metabolic labelling revealed that, in contrast to monocytes, chondrocytes increased their Sia biosynthesis only after IL1B/TNFa stimulation, not by LPS or TNFa alone. Removal of Sia by Neu generated comparable monocyte populations to LPS stimulation, characterized by a higher number of $CD16^{low}$ Siglec 15^{+} monocytes. Conversely, M-CSF-stimulation exhibited a greater abundance of $CD16^{high}$ Siglec 15^{high} monocytes. Blocking TLR4 resulted in Neu- and LPS-treated cells adopting a similar phenotype to that induced by M-CSF. DMMB results revealed a concentration-dependent release of glycosaminoglycans in explants treated with Neu.
Conclusion: Our study unveiled cell-specific molecular pathways linked to sialylation. Furthermore, a close association between Siglec 15 and TLR4 was observed. Neuraminidase demonstrated a concentration-dependent ability to degrade cartilage extracellular matrix, indicating its potential pathogenic mechanism in OA.

T cell glycosylation as a key player during colitis-associated carcinogenesis

Eduarda Leite-Gomes[1;2], Mariana Silva[2], Ana M Dias[2], Guilherme Faria[1;2], Ângela Fernandes[2], Rafaela Nogueira[2], Beatriz Santos-Pereira[2;3], Henrique Fernandes-Mendes[4], Mª Jesus Fernández-Aceñero[5], Carlos Taxonera[6], Paula Lago[4], Ricardo Marcos-Pinto[4], Salomé S. Pinho[1;2;3]
[1]ICBAS - Instituto de Ciências Biomédicas Abel Salazar da Universidade do Porto, Porto, Portugal; *[2]i3S - Institute for Research and Innovation in Health, Porto, Portugal*; *[3]FMUP – Faculty of Medicine of University of Porto, Porto, Portugal*; *[4]Department of Gastroenterology, Centro Hospitalar Universitário de Santo António, Porto, Portugal*; *[5]Department of Surgical Pathology, Hospital Clínico San Carlos, Madrid, Spain*; *[6]Department of Gastroenterology, Hospital Clínico San Carlos, Madrid, Spain*

Purpose: Inflammatory Bowel Disease (IBD)-associated carcinogenesis (CAC) is a major concern in the clinical management of patients with chronic IBD. Inflammation is a driving factor in IBD and cancer, but the mechanism underlying cancer progression remains poorly understood. Dysregulation of mucosal glycosylation has been described as a key regulatory mechanism associated with colon inflammation and colorectal cancer (CRC) development. Our group showed that colonic IBD $CD4^+$T cells glycosylation are deficient in β1,6-*N*-acetylglucosamine branched *N*-glycans, observed by a downregulation in *MGAT5* expression, associated with disease severity. On the other hand, aberrant expression of *MGAT5* in CRC was associated with immune escape.
Whether colitis and cancer differential glycosignatures constitute a new mechanism converting T cells from hyperactivated to an immunosuppressive phenotype in CAC, remains unknown.
Methods: We performed *in-silico* analysis of a publicly available human and mice dataset. A well-characterized cohort of 64 CAC patients at different stages of carcinogenesis (colitis, dysplasia and cancer) was assessed to evaluate colon immune cells' *N*-glycosylation profile. *In-vivo* studies (using AOM/DSS to induce CAC) were conducted in glycoengineered mice. The glycoprofile and immune profile of colon T cells was analyzed.
Results: *In-silico* analysis showed that the glycome profile switches in CAC towards more complex forms of *N*-glycans, emphasizing its importance in the CAC pathogenicity. Additionally, our cross-sectional study showed a distinct glycoprofile in the stroma, characterized by an increase of complex *N*-glycans in carcinoma compared to active colitis. Interestingly, higher complex *N*-glycans expression on the immune compartment of colitis samples was able to predict the progression in the carcinogenic cascade, with 87.9% specificity and 64.3% sensitivity.
Moreover, when glycosylation was remodeled, we observed a tumor development decrease in the CAC mouse model. Indeed, glycoengineered mice showed an increase in T cells infiltrate and pro-inflammatory cytokines. Interestingly, these colonic T cells on wild-type mice presented a switch on *N*-glycans composition along disease course.
Conclusion: We show for the first time that colonic T cells display a distinct glycosignature along the CAC cascade, impacting tumor development. This work reveals that complex *N*-glycans can be used as a biomarker to improve the clinical management of IBD patients.

In melanoma, lymphangiogenesis correlates with metastasis and poor prognosis and promotes immunosuppression. However, it also potentiates immunotherapy by supporting trafficking of immune cells. Lymphatic endothelial cells (LECs) are highly plastic cells that shape their phenotype according to distinct microenvironments, which likely define their functional properties, such as immunomodulation. Here, we show in a lymphangiogenic murine melanoma model that LECs upregulate the enzyme Ch25h, which catalyzes the formation of 25-hydroxycholesterol (25-HC) from cholesterol and plays important roles in regulating lipid metabolism, gene expression, and immune activation. LECs represent the main source of extracellular 25-HC in tumors, leading to the inhibition of PPAR-γ in intra-tumoral macrophages and monocytes. This prevents their immunosuppressive phenotype and instead promotes their conversion into proinflammatory myeloid cells that support effector T cell functions. We identify here in mechanistic detail a novel LEC function that supports anti-tumor immunity, which can be therapeutically exploited in combination with immunotherapy.

Profiling CRC liver metastasis immune microenvironment at steady state and after pre-surgical therapy

Cristina Faccani[1]
[1]*IRCCS San Raffaele Institute, Milan, Italy*

Purpose: Colorectal cancer (CRC) is the third most common cancer with more than 50% of patients developing metastases to the liver (CRC-LM), poorly responding to current therapies and leading to high risk of recurrence. This project undertakes a deep profiling of the immune landscape of CRC-LM from previously untreated or therapy treated patients, addressing the steady state immune contexture and the impact of pre-surgical therapy on its composition.
Material and methods: To dissect the CRC-LM microenvironment upon different therapeutic regimens, high dimensional 26-29 color flow cytometry panels were deployed to assess distinct immune cell subsets from tumor lesions, peritumoral tissue, distant normal liver and paired autologous whole blood obtained from patients.
Results: We showed a significant enrichment of intratumor $CD163^+$ $CD206^+$ HLA-$DR^{Low/Dim}$ M2-like cells, tissue resident $CD103^+CD69^+CD39^+CD8^+$ T cells co-expressing activation/exhaustion markers and activated $CD4^+$ Treg cells, encompassing both conventional and unconventional T cells.
Pre-surgical therapy and particularly the angiogenesis targeting regimens reshape both the T and the myeloid intratumor compartments, resulting in: i) the expansion of non-tissue resident and less exhausted LAG-$3^{high}CD39^{low}$ $CD8^+$ T cells at the expenses of large tissue resident exhausted LAG-$3^{neg}CD39^{high}$ populations; ii) the relief of local immunosuppression by reducing putative pro-tumor M2-like macrophages and Treg frequencies.
Conclusions: Our results define the immune landscape of CRC-LM and suggest pre-surgical therapy reshapes the immune composition, enforcing an immune-inflammatory response that may lead to reduced immunoregulation and increased anti-cancer T cell stimulation. Flow cytometry data are being integrated with genomics, bulk RNA-seq, spatially resolved multiplexing tissue analysis and correlated with clinical data. Finally, we are coupling at single cell level the mRNAseq, the surface phenotype and the clonal evolution of the main CD8 T cell subsets present at the steady state and reshaped by pre-surgical therapy.

Complement activation sustains tumor progression and invasiveness in human and mouse colorectal cancer - CRC

Elena Magrini[1], Kevin Berthenet[1], Monica Dambra[2], Luna Cordeiro Minute[2], Giovanni Pezone[1], Fabio Grizzi[1], Roberta Carriero[1], Fabio Pasqualini[2], Sarah Mapelli[1], Sebastien Jaillon[1;2], Alberto Mantovani[1;2;3], Cecilia Garlanda[1;2]
[1]IRCCS Humanitas Clinical and Research Center, Rozzano (Milan), Italy; *[2]Humanitas University, Pieve Emanuele (Milan), Italy*; *[3]The William Harvey Research Institute, Queen Mary University of London, London, United Kingdom*

The complement system emerges as a major player of tumor-promoting inflammation. Here, we investigated its contribution to colorectal cancer (CRC) development, where its role is still debated. Indeed, it has been reported that complement activation may exert pro or anti-tumoral function by regulating tumor cell functions or the tumor microenvironment (TME) through several mechanisms.
We investigated the role and mechanisms of complement in CRC by exploiting transplantable primary and metastatic MC38 CRC models in mice deficient of complement components. *C3*$^{-/-}$, *MBL1/2*$^{-/-}$ and *C4*$^{-/-}$ mice showed reduced susceptibility to primary tumor, as well as to CRC liver metastasis development, while C1q and factor B deficiency had no impact, indicating the importance of C3 and lectin pathway activation.
We investigated C3-downstream events and observed that the deficiency of complement 5a receptor 1 (C5aR1) in MC38 cancer cells reduced tumor growth *in vivo*, while its deficiency in mice did not, suggesting its relevance in tumor cell function but not in the TME in this context. In line with these results, *in vitro* experiments showed that MC38 cells express C5aR1 and respond to C5a in invasion assays.
Then, we explored the relevance of these results in human CRC. We observed a negative correlation between the expression of C5aR1, but not C3aR nor C5aR2, and survival of CRC patients from the human TCGA dataset. By analyzing C5aR1 expression on a cohort of CRC patient-derived tissues, we found that C5aR1 was mainly expressed by tumor cells and its expression was associated with lymph node metastasis, stage II to stage III transition and poor clinical outcome. In agreement with these results, C5aR1 expression by tumor cells and its association with tumor progression and poor prognosis have been also reported in lung, gastric and breast cancer.
Overall, these results confirm that the role and target of complement in CRC depends on the pathogenesis of the tumor, and highlight that complement and lectin pathway activation are components of CRC progression and metastatic process, suggesting C5AR1 as a potential therapeutic target in this disease.

Investigating the immune profile of early stage HER2+ breast cancer patients receiving chemotherapy and HER2-targeted therapies.

Denis M. Collins[1], Nicola Gaynor[1], Stephen Madden[2], Sinead Toomey[2], Ji Qiu[3], Jaine Blayney[4], Alfonso Blanco[5], Jean Fletcher[6], Barry Moran[6], Damien Kaukonen[2], Javier Sanchez Ramirez[2], Elaine Kay[7], Darran O'Connor[2], Ausra Teiserskiene[8], Alex Eustace[1], Richard Kennedy[4], Joshua LaBaer[3], William Gallagher[5], Bryan Hennessy[2;7], John Crown[1;9]
[1]Dublin City University, Dublin, Ireland; *[2]Royal College of Surgeons in Ireland, Dublin, Ireland*; *[3]Arizona State University, Arizona, United States*; *[4]Queen's University Belfast, Belfast, United Kingdom*; *[5]University College Dublin, Dublin, Ireland*; *[6]Trinity College Dublin, Dublin, Ireland*; *[7]Beaumont Hospital, Dublin, Ireland*; *[8]Cancer Trials Ireland, Dublin, Ireland*; *[9]Saint Vincent's University Hospital, Dublin, Ireland*

Purpose: Trastuzumab (T) was the first mAb therapy approved for the treatment (tx) of HER2+ breast cancer (BC). The HER2+ BC subtype makes up 15-20% of all BCs. T directly inhibits HER2 signalling activity and engages innate immune cells like natural killer (NK) cells through Fc receptor (FcR)-mediated antibody-dependent cell-mediated cytotoxicity (ADCC). Lapatinib (L) is a small molecule tyrosine kinase inhibitor (TKI) targeting HER2 and EGFR. T and L have been combined with chemotherapy in the clinic based on pre-clinical data reporting enhanced HER2 inhibition and augmented ADCC response. This is an overview of our comprehensive immune-based translational investigation of blood and tissue samples from the Irish Phase II ICORG/CTRIAL-IE 10-05 HER2+ BC neo-adjuvant (Neo-Adj) clinical trial.
Methods: ICORG/CTRIAL-IE 10-05 (NCT01485926) (n=88) compared T, L and TL in combination with chemotherapy (docetaxel/carboplatin). Serum, plasma, peripheral blood mononuclear cells (PBMCs) and formalin fixed paraffin embedded (FFPE) tumour biopsies were collected from patients. *Ex vivo* T-ADCC function of PBMCs was determined in co-culture assays (Guava flow cytometer). The phenotype of circulating PBMCs was determined (CytoFLEX platform). FcRs were genotyped (Agena MassArray technology). Serum tumour auto-antibodies (AAb) were detected (HD-NAPPA platform). Plasma chemokine profiles were assessed (Multiplex ELISA). RNA-Seq NK cell gene expression profiles were generated (CIBERSORT). Tumour infiltrating lymphocyte (TIL) data and clinico-pathological data were available. Data were assessed pre- *vs.* post-Neo-Adj tx, and by pathological complete response (pCR).
Results: Tumour NK gene cell signatures and peripheral immune cells (T cell/NK cell/monocyte, B cells) displayed significant alterations post-Neo-Adj therapy, primarily confined to the No pCR cohort. FcR genotype status did not associate with pCR. Neo-Adj tx attenuated *ex vivo* PBMC T-ADCC. Lower pre- and post-tx levels of the chemokine CCL17 were associated with the pCR cohort. AAbs targeting p53 were detected in patients with p53 tumour mutations. AAbs associated exclusively with pCR, partial response and non-responders were detected. No pCR patients with pembrolizumab-sensitive PBMCs emerged as a potential biomarker.
Conclusions: Translational studies from the ICORG/CTRIAL-IE 10-05 trial have identified distinct immune profiles associated with pCR, as well as potential biomarkers of response to HER2-targeted therapy/chemotherapy for exploration in larger datasets.

Flow cytometric analysis of TILs from different layers of human Glioblastoma samples revealed an enrichment of T cells expressing PD-1 and tissue-resident markers in the intermediate and marginal layers

Anna Vanni[1], Laura Maggi[1], Camilla Bonaudo[2], Francesca Matani[1], Giulia Lamacchia[1], Alessio Mazzoni[1], Lorenzo Salvati[1], Manuela Capone[1], Lucia Bartoli[1], Mirko Petti[2], Filippo Nozzoli[3], Lorenzo Cosmi[1], Francesco Liotta[2], Alessandro Della Puppa[1;2], Francesco Annunziato[1]
[1]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy; *[2]Neurosurgery, Department of NEUROFARBA, University of Florence, University Hospital of Careggi, Florence, Italy*; *[3]Section of Anatomic Pathology, Department of Health Sciences, University of Florence, Florence, Italy*

Purpose: Glioblastoma is the most common malignant brain tumor in adult population, for which immunotherapy show reduced efficacy. Current knowledge on immunotherapy failure is limited and detailed information about immune infiltrates in glioblastoma are urgently needed to personalized therapeutic strategy.
Methods: We enrolled 33 glioblastoma patients collecting peripheral blood (PB), total tumor resection or tumor samples from the central necrotic area, the intermediate and the marginal tissue through 5-aminolevulinic-acid (5-ALA) assisted surgery. T cells obtained from different samples were evaluated phenotypically, for immune-checkpoints and tissue-residency markers (Trm) expression, and functionally by assessing their cytokine production profile (TNF-α, IFN-γ, GMC-SF, IL-17, IL-10). Patients overall survival (OS) were retrospectively assessed and correlated with biological data.
Results: Flow-cytometric analysis showed a significantly higher frequency of T lymphocytes expressing PD-1, CD69 and CD103 in glioblastoma. In particular, we observed a preferential enrichment of CD8 expressing PD-1 and Trm markers (CD69 and CD103) in intermediate and marginal tumor areas, in which glioblastoma cells showed an active 5-ALA metabolism. T cells functionality was assessed by cytokine production, which results higher in glioblastoma compared to PB samples. In particular, the glioblastoma PD-1 positive T cells population maintained a good effector potential after restimulation ex-vivo. Interestingly, the higher frequency of IFN-γ-producing T cells was observed in the intermediate tumor layer. Notably, in the 5-ALA cohort a strong direct correlation between CD103 and OS in the necrotic layer, tipically not enriched in Trm effector cells, was observed. This result suggest an important role of Trm cells in tumor core, which however is apparently hardly infiltrated.
Conclusion: In this study we observed an enrichment in CD8+ Trm like T cells expressing PD-1, which retain a good effector potential, in the intermediate and marginal tumor areas compared to the necrotic core. Obtained results highlight the relevance of a comprehensive analysis of glioblastoma immune infiltrate to better understand the reasons for reduced efficacy of immunotherapy and to identify new biomarkers, prognostic factors and immunotherapy targets.

Understanding the mechanism of Cancer-associated fibroblast subpopulation reprograming-mediated immunomodulation in Colorectal cancer.

Lei Lei[1], Eileen Reidy[1], Niamh Leonard[1], Aoise O'Neill[1], Oliver Treacy[1], Louise Rabbitt[2], Catherine Timon[2], Merah AI-Busaidy[2], Aisling Hogan[3], Sean Hynes[4], Aideen Ryan[1]
[1]Discipline of Pharmacology and Therapeutics, School of Medicine, College of Medicine, Nursing and Health Sciences, University of Galway, galway, Ireland; *[2]Galway University Hospital, galway, Ireland*; *[3]Department of Colorectal Surgery, Galway University Hospital, galway, Ireland*; *[4]Division of Anatomical Pathology, Galway University Hospital, galway, Ireland*

Background: Consensus Molecular Subtype 4 (CMS4) of Colorectal cancer (CRC) has the worst patient outcome and significant therapy resistance in all of CRC. CMS4-CRC is characterised by an inflamed immunosuppressive tumour environment (iTME) and enriched with stromal cells. Cancer-associated fibroblasts (CAFs) which are the most abundant cells of the stromal cells in CRC are a heterogeneous population of cells, and their specific spatial-temporal functions are not well-defined. Two of the main CAF subgroups which are identified as myoCAFs and iCAFs are characterised by TNFα and TGFβ signatures, respectively. Understanding the mechanisms of CAF remodelling the iTME is crucial for the development of new therapies to target specific CAFs. We hypothesise that TNF-conditioned tumour secretome (TNF-TCS) and TGF-conditioned tumour secretome (TGF-TCS) model CAFs enhance their immunomodulation properties differentially and influence the NK cell functions in the CRC TME.
Methods: Using TCS and TNFTCS conditioning normal fibroblasts (NAFs), the RNA level screening was assessed by RNA sequencing. Using co-culture assays, we assessed the impact of the secretome from TNF-TCS and TGF-TCS conditioned MSCs on CMS4 CRC cell lines and primary NK cell activation and cytotoxicity of CRC cell lines by flow cytometry.
Results: We observed that both of TGF receptor and TNF receptor are highly expressed on CAFs. The expression of the chemokines is highly upregulated in TNF-TCS-conditioned NAFs. Following conditioning with TNF-TCS conditioned MSCs secretome, NK cell expression of the activation markers was significantly downregulated. The data from the cytotoxicity assay suggested that TNF-TCS conditioned MSC secretome impairs the NK function. TNF-TCS-conditioned MSC secretome also upregulated immune checkpoint markers, PD-L1 and PDL2, on both CMS4 tumour cells, suggesting two-way crosstalk that enhances immunosuppression in the CRC TME.
Conclusion: Subgroups of CAFs show the different functions and the potential for reprogramming in the iTME modification. TNF-TCS increase chemoattractant factors in NAFs. TNF-TCS-conditioned MSC secretome suppresses NK function and increases the immune checkpoint ligand expression on tumour cells. TGF-TCS may be involved in another mechanism to modify CAF immunomodulation function.
Using approaches to target CAF immunosuppressive signalling, we will define the role of targeting CAFs in developing novel immunotherapies.

Development of a soluble form of TIGIT with immune modulatory property

Namrata Ganguli[1], Dibyendu Samanta[1]
[1]*Department of Bioscience and Biotechnology,Indian Institute of Technology, Kharagpur, India*

Purpose: Tumor cells often express different ligands that interact with their corresponding receptors to inhibit T and NK cell function. Nectin-4, which is negligibly expressed in healthy adults is overexpressed in tumor cells in variety of malignant cancers and is widely considered as a cancer-specific biomarker. Nectin-4 preferentially interacts with an inhibitory receptor TIGIT that is highly expressed by both tumor-infiltrating T and NK cells. Nectin-4 is the only ligand that is not shared by both TIGIT and the activating receptor DNAM1 (also known as CD226), thus making it an important therapeutic target. Deciphering the molecular, structural, and functional basis of this interaction is, therefore, necessary to understand the tumor-immune cells crosstalk and design novel immunotherapeutic strategies.
Method: The ectodomain of TIGIT and nectin-4 were expressed and purified, followed by their interaction studies using surface plasmon resonance (SPR)-based biosensor. Structure-guided mutagenesis studies were done to map the nectin-4 binding interface on TIGIT. Based on the structural data, a novel TIGIT mutant exhibiting increased affinity toward nectin-4 was engineered.
Results: Our studies indicate that the membrane distal IgV domain of TIGIT and nectin-4 are sufficient to mediate the interaction between them and suggest a weak interaction as demonstrated by SPR-based analyses. Few residues of TIGIT that might play an important role in nectin-4 recognition were selected from the modeled complexes and mutated for mapping the binding interface. SPR-based studies reveal a decrease in binding response for all the TIGIT mutants in comparison to the wild type. Based on the biophysical data and structural analysis of the modeled complex, a novel TIGIT mutant has been engineered that shows higher affinity towards nectin-4 compared to wild-type TIGIT.
Conclusion: Targeting TIGIT:nectin-4 pathway is of prime importance for immunotherapy studies to design optimized therapeutics to treat cancer. Deciphering the molecular and structural basis of the TIGIT: nectin-4 interaction provided deeper insights into the structure-guided engineering of soluble TIGIT that preferentially interacts with nectin-4 expressed on cancer cells. The efficacy of the engineered high-affinity TIGIT in inducing NK and T cell cytotoxicity will be tested in cancer cell lines.

Targeting SUMOylation pathway triggers IFN-I-dependent activation of Natural Killer cells against Acute Myeloid Leukemias

Rawan Hallal[1], Denis Tempe[1], Marion De Toledo[1], Ludovic Gabellier[2], Guillaume Bossis[1]
[1]*CNRS UMR5535 Institut de Génétique Moléculaire de Montpellier, Montpellier, France*; [2]*Service d'Hématologie Clinique, CHU de Montpellier, Montpellier, France*

Natural Killer (NK) cells play a pivotal role in cancer immune surveillance. Patients with Acute Myeloid Leukemia (AML) presents a defective phenotype and function of NK cells facilitating AML immune escape. Enhancing NK cells activity in AML patients, either by activating endogenous NK cells or by adoptive transfer of ex vivo activated NKs, shows promising potentials for AML treatment. Several studies reported that SUMOylation, a protein posttranslational modification regulating the function and fate of thousands of proteins, plays critical roles in the control of anti-cancer immune responses. TAK-981, a first-in-class inhibitor of SUMOylation undergoing phase I/II clinical trials for cancer, is indeed emerging as an immunomodulatory drug.
In this study we demonstrate that targeting the SUMO pathway with TAK-981 activates primary NK cells from healthy donors and AML patients, increasing their cytotoxicity against AML cells and their ability to produce cytokines (IFN-γ, TNF-α, FasL). In addition, we show that TAK-981 increases *in vivo* the anti-leukemic activity of ex-vivo expanded human cord blood NK cells injected in AML mice models. At the molecular level, TAK-981 first induces *IFNB1* gene in NK cells, leading to the secretion of type I Interferon (IFN-I), which binds to the Interferon receptor IFNAR. This induces Interferon-Stimulated Genes (ISG) and activates NK cells *in vitro* and *in vivo*. Furthermore, inhibition of SUMOylation by TAK-981 stimulates IFN-I secretion by monocytes, contributing to NK cell activation in a paracrine manner.
Altogether, our results suggest that targeting SUMOylation with TAK-981 represents a promising strategy to reactivate AML patients' NK cells and enhance the efficiency of NK cells-based therapies NK for AML patients.

Using nanoparticles as artificial antigen presenting cells to activate human CD4 T cells for immunotherapy

Si-Sim Kang[1], Ariel Isser[2], Jonathan Schneck[1]
[1]*Johns Hopkins University, Baltimore, MD, United States*; [2]*Regeneron Pharmaceuticals, Inc., Tarrytown, NY, United States*

Introduction: CD4 T cell-based adoptive cell transfer (ACT) therapies have clinical success across multiple cancer types, including metastatic melanoma and epithelial cancer. One of the challenges of CD4 T cell-based ACT therapy is finding methods to expand tumor antigen-specific T cells. Therefore, engineering artificial platforms for antigen-specific T cell expansion is critical since it provides greater control over studying T cell biology and has significant translational relevance. We developed a nanoscale platform that expands murine and human antigen-specific T cells *in vitro*. This platform allows us to study the effector and helper function of CD4 T cells through precise tuning of material parameters, including shape, size, and ligand patterning.
Methods: Our lab utilizes artificial antigen-presenting presenting cells (aAPCs) – iron dextran particles conjugated with MHC class II and the co-stimulatory molecule to activate T cells. This aAPC platform provides T cells with two critical signals for T cell activation, which permits the activation of cognate antigen-specific CD4 T cells *ex vivo*. We isolate human CD4 T cells from PBMCs of healthy donors. We then stimulate CD4 T cells with HLA II aAPCs in media with inflammatory cytokine and assess the specificity, effector function, and memory profiles through tetramer staining, cytokine release assays, and peptide-pulsed lymphoblastoid cell line killing assays.
Results: Co-culturing Class II aAPCs and human CD4 T cells significantly increases the frequency of cognate antigen-specific CD4 T cells. Specifically, we successfully expanded tetanus toxoid (p30)-specific and herpes simplex virus (HSV)-specific HLA-DP4-positive CD4 T cells from healthy human PBMCs with aAPC. By the end of the 21-day expansion period, the antigen-specific cells showed substantial proliferation, escalating from under 1% to approximately 10% for HSV and exceeding 30% for p30. The resulting antigen-specific CD4 T cells display high levels of effector cytokine production, including TNF-a, IFN-g, IL-2, and granzyme B. Furthermore, these CD4 T cells demonstrated antigen-specific cytotoxic capabilities and are predominantly effector memory T cells.
Conclusion: These data show that aAPC platform can expand antigen-specific CD4 T cells from a rare precursor population. Therefore, this technology is beneficial in expanding rare neoantigen-specific cells for ACT for CD4 T cell-enriched cancers.

Potent CD8+ T cell effector functions induced by NaCl in cancer immunotherapy

Caterina Scirgolea[1], Rosa Sottile[1], Marco De Luca[1], Alberto Susana[1], Enrico Lugli[1]
[1]*IRCCS Humanitas Research Hospital, Rozzano, Milan, Italy*

CD8$^+$ T cells play a central role in anti-tumor immunity but inevitably become dysfunctional or "exhausted" in the tumor microenvironment. Ionic metabolism is emerging as a novel regulator of CD8$^+$ T cells in anti-tumor immunity. Here we show that sodium chloride (NaCl) counteracts T cell dysfunction to promote cancer regression. NaCl supplementation during CD8$^+$ T cell culture induced potent effector differentiation, IFN-γ production and cytotoxicity while maintaining gene networks responsible for stem-like plasticity. Accordingly, adoptive transfer of tumor-specific T cells resulted in enhanced persistence and superior anti-tumor immunity in humanized models. In mice, high salt diet (HSD) administration reduced growth of experimental tumors in a CD8$^+$ T cell-dependent manner, by inhibiting terminal differentiation, and by enhancing the effector potency of CD8$^+$ T cells. Mechanistically, NaCl enhanced glutamine consumption that was critical for cellular reprogramming. In humans, CD8$^+$ T cells undergoing antigen recognition in tumors and predicting favorable response to checkpoint blockade immunotherapy resembled those induced by NaCl. Collectively, we identified NaCl metabolism as a major regulator of CD8$^+$ T cell effector function, with potential translational use in cancer immunotherapy.

A novel combined treatment approach for pancreatic ductal adenocarcinoma enhances immune response and tumour reduction

Immacolata Maietta[1;2], Rosana Simón Vázquez[1;2], Africa González Fernández[1;2]
[1]CINBIO - Centro de Investigación en Nanomateriais e Biomedicina, Vigo, Spain; *[2]Instituto de Investigación Sanitaria Galicia Sur (IIS Galicia Sur), Vigo, Spain*

Purpose: Pancreatic ductal adenocarcinoma (PDAC) is aggressive and resistant to standard treatments. In our study, we aimed to enhance immune cell infiltration into tumors by combining therapies. This involved targeting the activation of the Hippo pathway, specifically YAP-1 and FOSL-1 genes, using lipoplexes carrying siRNA, alongside with conventional chemotherapy and epigenetic inhibitors. PDAC progression is influenced by immune cell invasion and genetic alterations. Our results show a significant increase in immune cell infiltration compared to the control group, where immune cells remained outside the tumor. This indicates that our strategy promotes immune cell penetration into the tumour microenvironment, enhancing the anti-tumoral response and offering hope for improved treatment outcomes.
Methods: We prepared lipoplexes carrying four siRNAs targeting YAP-1 and FOSL-1 genes using cationic liposomes made of DODAB and MO. This was combined with chemotherapy using Entinostat and low doses of Gemcitabine. We meticulously tested this treatment on human PDAC and mouse organoids and xenograft mouse models. Cell viability in organoids was assessed using immunofluorescence assays, while xenograft mice received lipoplexes targeting YAP-1/FOSL-1 followed by chemotherapy, with daily tumour growth monitoring. Subsequent histological analysis, RT-PCR, and Western blotting were performed on tumour and organoid samples to examine stromal changes, immune cell infiltration and confirmation of gene/protein silencing.
Results: Pre-treatment using liposomes aimed at YAP-1 and FOSL-1 led to a notable decrease in tumor size and collagen levels in the tumor's tissue, mainly due to changes in cancer-related fibroblasts (CAFs). Further treatment with Entinostat and Gemcitabine resulted in a significant reduction in tumor volume compared to using each therapy alone. These results were strongly supported by experiments conducted on models of PDAC, including xenografts and organoids. Additionally, histology and immunofluorescence tests indicated a rise in immune cells infiltrating the tumors. Our treatment notably increased the presence of immune cells within tumours, facilitating the success of subsequent immunotherapies.
Conclusion: Our study demonstrates the effectiveness of combining siRNA treatment, chemotherapy, and epigenetic inhibitors to enhance immune cell infiltration in PDAC tumours. This approach significantly reduces tumour size and collagen levels, indicating the potential for improved treatment outcomes through enhanced immune response and targeted therapy.

CD69-deficiency confers susceptibility to anti-PD1-induced myocarditis

Enrique Ortega-Sollero[1], Rosa Jiménez-Alejandre[1], Raquel Sánchez-Díaz[1], Pilar Martin[1]
[1]*CNIC, Madrid, Spain*

The advancement of immunotherapies has changed cancer treatment. Immune checkpoint inhibitors (ICIs) are monoclonal antibodies targeting PD-1 and PD-L1. ICIs stimulate the immune system, by inhibiting regulatory T cells, to attack cancer cells that evade the immune response. However, the mechanism of action of ICIs could lead to undesirable events (irAEs). During immunotherapy, autoimmune T cell are activated. Therefore, many systemic autoimmune diseases may arise, including myocarditis, which is the rarest, yet most fatal, with a mortality rate of 60%. There is a lack of animal models to study ICI-myocarditis, and specific biomarkers to predict this disease. Our group identified mmu-miR-721 as a biomarker for acute myocarditis in mouse and humans. The main objectives are to analyse and validate the *cd69*$^{-/-}$ mouse model for the study of the pathophysiology of ICI-myocarditis in tumor-bearing mice under immunotherapy, and to validate mmu-miR-721 as an early biomarker of this condition.
cd69$^{-/-}$ mice were used since our group has described how these animals develop exacerbated Th17 responses and consequently severe myocarditis. We analyzed the subsequent immune response in peripheral blood, lymph nodes and heart by flow cytometry, as well as the cardiac dysfunction by echocardiography.
We proposed an animal model of susceptibility to the development of myocarditis induced by effective antitumoral treatment with anti-PD1. ICI treatment in these animals induces cardiac inflammation followed by cardiac dysfunction, compared to WT animals that do not develop any heart disease after anti-PD1 treatment. Immune infiltrate is detected in the heart and mediastinal lymph nodes, with high Th17 responses. We demonstrate that mmu-miR-721 biomarker levels are significantly elevated in plasma 10 days after initiating anti-PD1 therapy in *cd69*$^{-/-}$ mice, along with classical biomarkers of cardiac damage, such as troponin.
Anti-PD1 treatment in *cd69*$^{-/-}$ mice generates cardiac inflammation due to a specific immune response towards the heart. Moreover, biomarker mmu-miR-721 levels are significantly elevated at day 10 of the treatment in plasma of *cd69*$^{-/-}$ mice. This finding has clinical relevance since the mmu-miR-721 could be the first specific and early biomarker of ICI-myocarditis susceptibility and development.

Developing bispecific antibody for sustained suppression of Influenza virus

Romila Moirangthem[1], Sapir Cordela[1], Dina khateeb[1], Ben shor[2], Ivan Kosik[3], Dina Schneidman Duhovny[2], Michal Mandelboim[4], Friederike Jönsson[5], Jonathan W Yewdell[3], Timothée Bruel[5], Yotam Bar-On[1]
[1]Technion - Israel Institute of Technology, Haifa, Israel; *[2]The Hebrew University of Jerusalem, Jerusalem, Israel*; *[3]National Institute of Allergy and Infectious Diseases, Maryland, United States*; *[4]Sheba Medical Center, Tel Hashomer, Israel*; *[5]Pasteur Institute, Paris, France*

Targeting multiple viral proteins is pivotal for sustained suppression of highly mutable viruses. In recent years, broadly neutralizing antibodies that target the influenza virus hemagglutinin and neuraminidase glycoproteins have been developed, and antibody monotherapy has been tested in preclinical and clinical studies to treat or prevent influenza virus infection. However, the impact of dual neutralization of the hemagglutinin and neuraminidase on the course of infection, as well as its therapeutic potential, has not been thoroughly tested. For this purpose, we generated a bispecific antibody that neutralizes both the hemagglutinin and the neuraminidase of influenza viruses. We demonstrated that this bispecific antibody has a dual antiviral activity as it blocks infection and prevents the release of progeny viruses from the infected cells. We show that dual neutralization of the hemagglutinin and the neuraminidase by a bispecific antibody is advantageous over monoclonal antibody combination as it results in an improved neutralization capacity and augmented the antibody effector functions. Notably, the bispecific antibody showed enhanced antiviral activity in influenza virus-infected mice, reduced mice mortality and limited the virus mutation profile upon antibody administration. Thus, dual neutralization of the hemagglutinin and neuraminidase could be effective in controlling influenza virus infection.

Myeloid-derived OLAH (oleoyl-ACP hydrolase) and its main catalytic products act as early biomarkers of life-threatening illness from diverse viral respiratory infections

Jeremy Chase Crawford[1], Xiaoxiao Jia[2], Robert C. Mettelman[1], Heather S. Smallwood[3], Amanda M. Green[4], Lee-Ann Van de Velde[1], Ryan S. Thwaites[5], Tanya Novak[6], Adrienne G. Randolph[6;7;8], Paul Thomas[1;8], Tim Flerlage[9], Zhongfang Wang[2;10], Brendon Y Chua[2], Katherine Kedzierska[2;8]
[1]Department of Host-Microbe Interactions, St. Jude Children's Research Hospital, Memphis, United States; *[2]Department of Microbiology and Immunology, The University of Melbourne, at the Peter Doherty Institute for Infection and Immunity, Melbourne, Australia*; *[3]Department of Pediatrics, The University of Tennessee Health Science Center, Memphis, United States*; *[4]Department of Infectious Diseases, St. Jude Children's Research Hospital, Memphis, United States*; *[5]National Heart and Lung Institute, Imperial College London, London, United Kingdom*; *[6]Department of Anesthesiology, Critical Care, and Pain Medicine, Boston Children's Hospital, Boston, United States*; *[7]Department of Anaesthesia, Harvard Medical School, Boston, United States*; *[8]Center for Influenza Disease and Emergence Response, (CIDER), United States*; *[9]Department of Pediatrics, Infectious Diseases, University of Rochester Medical Center, Rochester, United States*; *[10]State Key Laboratory of Respiratory Disease & National Clinical Research Center for Respiratory Disease, Guangzhou Institute of Respiratory Health, Guangzhou, China*

Purpose: Acute respiratory infections are characterized by varied disease severities and corresponding morbidity rates, and early identification of patients at risk for severe disease is integral to improving patient outcomes. We therefore set out to identify biomarkers of severe respiratory disease by studying cohorts with patients experiencing life-threatening respiratory symptoms due to acute viral infection.
Methods: Bulk and single-cell RNAseq and lipidomics were used to compare patients with life-threatening illness due to acute respiratory viral infections (including avian and seasonal influenza, SARS-CoV-2, and RSV) to healthy individuals or patients with less severe disease.
Results: Our anlayses identified *OLAH* (oleoyl-ACP hydrolase), a typically rarely expressed enzyme involved in fatty acid biosynthesis, as a biomarker of life-threatening disease across multiple viral infections. Among adults hospitalized with A(H7N9) influenza, those who succumbed to disease exhibited early elevations of peripheral *OLAH* transcription that persisted throughout the course of hospitalization. Likewise, single-cell analyses showed significant increases in *OLAH* among adults hospitalized with seasonal influenza compared to healthy subjects, particularly in peripheral monocytes and macrophages. *OLAH* was also identified as a biomarker for life-threatening disease outside of influenza infection; for instance, among children hospitalized with SARS-CoV-2, *OLAH* was the single-most differentially expressed gene increased in patients with life-threatening respiratory dysfunction compared to those with no-to-minimal respiratory dysfunction. Furthermore, lipidomics analysis of adults infected with SARS-CoV-2 showed significant upregulation of the main catalytic products of OLAH among hospitalized patients. Single-cell analyses of samples obtained from the lower respiratory tracts of children with acute lung failure due to seasonal influenza and/or RSV infection similarly showed upregulation of *OLAH* in monocytes, macrophages, and neutrophils, potentially implicating this peripheral biomarker in mechanisms underlying disease at the site of infection. Analyses of samples obtained from human challenge models of multiple respiratory infections consistently demonstrated that *OLAH* was not elevated during mild infections. Network analysis of the underlying datasets pointed to OLAH as a potential mediator of inflammation among specific myeloid subsets that traverse the respiratory tract and the periphery.
Conclusion: Upregulation of *OLAH* transcription during viral respiratory infection correlates with myeloid-mediated inflammation and provides an early biomarker of life-threatening illness.

Leptin is expressed in lung granulomas of Mycobacterium tuberculosis-infected DBA/2 mice and impairs anti-mycobacterial capacity of immune cells

Claudia La Rocca[1], Carla Palma[2], Maria Teresa Lepore[1], Carla Bromuro[2], Cristiana Barbati[2], Vincenzo Gigantino[1], Fortunata Carbone[1], Giuseppe Matarese[3]
[1]Laboratorio di Immunologia, Istituto per l'Endocrinologia e l'Oncologia Sperimentale, Consiglio Nazionale delle Ricerche (IEOS-CNR), Naples, Italy; *[2]Dipartimento Malattie Infettive, Istituto Superiore di Sanità, Rome, Italy*; *[3]Dipartimento di Medicina Molecolare e Biotecnologie Mediche, Università di Napoli "Federico II", Naples, Italy*

Purpose: Tuberculosis (TB) is one of the deadliest infectious diseases worldwide. In 2021, about 10.6 million people fell ill with TB and *M. tuberculosis* (MTB) infection caused 1.58 million deaths. Host-direct therapies are thought as novel strategies to defeat TB, including the multi-drug resistant TB. We investigated whether leptin, an adipocyte-derived hormone, playing a major role in the regulation of feeding and energy expenditure and linking nutritional status with neuroendocrine and immune functions, may be a host target for novel TB therapies. In humans, low levels of circulating leptin, likely associated with a decreased body fat, have been associated with pulmonary TB and leptin-deficient C5BL/6 mice are more susceptible than wild-type mice to MTB infection. However, a moderate caloric restriction reduces systemic levels of leptin and promotes an immunometabolic reprogramming leading to protection against pulmonary MTB infection in DBA/2 mice, a strain highly susceptible to MTB infection.
Methods: DBA/2 mice were infected *in vivo* with MTB, severity of pathology was studied evaluating bacterial load by CFU assay and lung pathology by histology. Leptin was analyzed in serum and in granuloma lesions. Spleen cells infected *in vitro* with MTB or recovered from MTB-infected mice were cultured in the presence or absence of leptin to measure the anti-mycobacterial capacity of immune cells. The effects of leptin on autophagy was analyzed by western blot and on the metabolic profile by Seahorse analysis.
Results: We found that leptin was expressed in granulomatous lesions of the lungs and spleens of MTB-infected DBA/2 mice, and its expression correlated with disease severity. Leptin was mainly found in lung area rich in foam cells, a distinct sign of TB progression and a secure niche for bacterium survival. Mechanistically, leptin reduced autophagy, increased cell survival and promoted foam cell formation, all mechanisms limiting macrophage ability to kill the pathogen. In addition, leptin reduced glycolysis and tended to promote mitochondrial respiration in spleen cells of BCG-infected mice cultured with Lipopolysaccharide, a potent innate immune stimulus.
Conclusion: Leptin, an adipocyte-derived hormone, is expressed in lung granulomas and could promote MTB infection by impairing anti-MTB capacity of immune cells.

Coronavirus disease 2019 (COVID-19) infections can lead to symptoms of chronic fatigue and exertion intolerance, persisting for months and even years post-infection. This is known as Post-Covid Syndrome (PCS) or Long-Covid. Today, about every 10th person develops PCS after acute SARS-CoV2 infection and no prescribable therapies exist. The clinical appearance is very heterogeneous, pointing towards different PCS etiologies. A subset of PCS patients develops myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) a severe postinfectious sequela of various infections. Clinical studies provided evidence for a role of autoantibodies in ME/CFS. Recent reports connect severe COVID-19 and PCS with an aberrant immune response. Some patients show dysregulations in the B cell compartment and formation of autoantibodies and therefore might benefit from immunoadsorption (IA) therapy, clearing immunoglobulins from the circulation. Clinical studies in ME/CFS show that about two thirds of patients benefit from IA. However, detailed understanding why some patients benefit from immunoglobulin removal is lacking.
To reveal leukocyte alterations indicative of IA-response, cytometry by time of flight (CyTOF) was used to profile leukocytes in blood samples from PCS patients meeting ME/CFS criteria pre- and post-treatment and age- and sex-matched controls. PCS-ME/CFS patients undergoing IA divided into responders (increase of physical function assessed by SF-36) and non-responders. IA-responsive patients' SF-36 improved after 1 month of treatment. We observed signs of dysregulated B cell maturation and increased B cell activation in PCS-ME/CFS patients compared to controls. Importantly, we detected these alterations only in pre-treatment samples of IA-responsive patients potentially enabling patient stratification in future clinical trials. Furthermore, dysregulations in the B cell compartment normalized at the end of treatment, suggesting a causal link.
This study demonstrates B cell alterations as a potential biomarker for PCS-ME/CFS patients and autoantibody-targeting treatment. Currently, we perform single-cell transcriptome and mechanistic *in vitro* analyses to understand which factors might drive the dysregulation of the B cell compartment and its contribution to PCS development. However, the study also highlights the complexity of PCS and the need to identify biomarkers predicting therapy response.

Study of Bdellovobrio bacteriovorus as a live antibiotic against Mycobacterium tuberculosis.

Archana Singh[1], Vidushi Sharma[1], Alisha Arora[1], Deepak Vats[1]
[1]*All India Institute of Medical Sciences, New Delhi, India*

Purpose: Ineffectiveness of anti-tubercular drugs and growing frequency of MDR and XDR TB warrants the use of novel ways to treat *Mycobacterium tuberculosis* infection. *Bdellovibrio bacteriovorus*, a Gram-negative bacterium known for its unique role as an obligatory predator within the periplasmic space of other Gram-negative bacteria, could be looked upon as a viable adjuvant to antibiotics, particularly in combating multidrug resistant pathogens like: *Mycobacterium tuberculosis.*
Method: Culture and Differentiation of THP-1 cells was done using PMA. Maintenance and culturing of bacteria (*Mycobacterium tuberculosis* H37Ra and *Bdellovibrio bacteriovorus*) was done for infection experiments. Determination of multiplicity of infection (MOI) was done via Calcein AM staining using Flow Cytometry. Spot clearance assay on H37Ra lawn was done to check for the direct killing capacity of *Bdellovibrio bacteriovorus*. THP-1 cells were treated with *Bdellovibrio bacteriovorus* before and after H37Ra infection with appropriate controls. Mtb clearance capacity was checked by colony forming units/assay (CFU). Intracellular cytokine and surface marker was assessed for macrophage phenotype profiling using Flow Cytometry followed by transmission electron microscopy study for bacterial colocalisation in macrophages.
Results: Our study is the first to explore the predatory potential of Bdellovibrio bacteriovorus against Mycobacterium tuberculosis. Bdellovibrio pretreatment showed Mtb clearance capacity in both extracellular and intracellular settings. Pretreatment of macrophages with *Bdellovibrio bacteriovorus* before H37Ra infection was found to significantly enhance intracellular mycobacterial clearance than the post treated and control groups as depicted by CFU counts. Bdellovibrio treatment also showed significant shift from necrosis to apoptosis and pyroptosis, which might be contributing towards the observed reduction in Mtb CFU count. However, we could not demonstrate any appreciable changes mediated by Bdellovibrio on immune environment within the macrophages. Furthermore, we found that *Bdellovibrio bacteriovorus* and H37Ra colocalize within macrophages as observed through Transmission Electron Microscopy, indicating the potential contribution of direct predation of H37Ra bacilli by *Bdellovibrio bacteriovorus* to the substantial reduction in CFU illustrated by the CFU assay.
Conclusion: These promising preliminary findings suggest an interesting interplay between *Bdellovibrio bacteriovorus* and macrophages, which could be further explored as a potential therapeutic agent against *Mycobacterium tuberculosis* using appropriate animal models.

Purpose: The role of resident lung immune cells against *Mycobacterium tuberculosis* (*Mtb*) still remains unclear. The aim of this study is to perform deep immunophenotyping in the lung parenchyma and vasculature and to investigate the differences in the response against *Mtb* depending on the organ and tissue of origin of the cells in a chronic TB mice model.
Methods: Female (n=13) and male (n=13) C57Bl/6 mice were infected by aerosolization (Inhalation Exposure System, Glas-Col) with *Mtb* H37Rv and sacrificed at 6 weeks post-infection. Mice were intravenously administered with anti-CD45 antibody prior to euthanasia to distinguish extravascular from intravascular fractions of the lung. Blood and lungs were extracted, and immune cells were obtained after erythrocyte lysis and Percoll density gradient centrifugation, respectively. Cells were stimulated overnight with PMA/Ionomycin, ESAT-6/CFP-10 (*Mtb*-specific), or PPD (mycobacteria-specific) and stained for surface and intracellular antigens with 33 antibodies related to local and central memory in T, B and NK cells. Samples were acquired using full spectrum Cytek Aurora 5-laser and analysed with FlowJo.
Results: We will focus for this abstract on the expression of inflammatory and memory markers on major cell subsets. For both specific stimuli, $CD4^+$ and $CD8^+$ T-cells expressed significantly higher levels of IL-17 and lower levels of IL-22 in blood than in the lung. Within the $CD4^+$ T-cells cells of the lung, there was a prevalence of pro-inflammatory cytokines IFN-γ and TNF, and a reduction of PD-1 in the vasculature region of the lung compared to its parenchymatic counterpart ($p<0.05$). Tissue-resident memory T-cells ($CD69^+CD101^+$ and $CD69^+CD103^+$[$p<0.05$], $KLRG1^-$[$p<0.01$]) were enriched in the parenchyma for both CD4 and CD8 lymphocytes. Additionally, we also observed that this tissue had lower levels of NK cells ($CD3^-NKp46^+$), with a predominantly immature phenotype ($CD27^+CD11b^{low}$;$p<0.05$), and a higher proportion of B cells with a regulatory phenotype ($CD3^-B220^+CD1d^+IL\text{-}10^+$;$p<0.01$), when compared to blood-originated immune cells.
Conclusions: Following *Mtb* infection, immune cells from lung parenchyma display specific tissue-residency and anti-inflammatory phenotypes in comparison to lung and peripheral vasculature, which express more canonical pro-inflammatory cytokines. The role of these and other immune populations will be further clarified by non-supervised multiparametric analyses.

Investigating long-term T cell memory responses to COVID-19 vaccines in people living with HIV

Maxine Höft[1;2], Roanne Keeton[1;2], Lee Fairlie[3], Penny Moore[4;5;6], Alex Sigal[7;8;9], Catherine Riou[1;2;10], Wendy Burgers[1;2;10]

South Africa has 7.5 million people with HIV (PWH), and an estimated 500 new infections every day; 67% of PWH are virally suppressed. Some vaccines elicit suboptimal responses in PWH. Ongoing systemic immunological dysfunction even in well-controlled HIV may influence COVID-19 vaccine responses. Few studies have characterised cellular immunity in PWH following COVID-19 vaccination.
The overall aim of the study is to monitor long-term immunological memory in PWH. This involves understanding the durability of T cell memory and identifying potential defects in cellular immunity in PWH.
Spike-specific T cell memory responses were examined longitudinally in PWH and compared to HIV-uninfected participants, in healthcare workers (n=90) from the Sisonke Ad26.COV2.S trial who received a homologous or heterologous (BNT162b2) vaccine boost. T cell responses were measured by flow cytometry.
The study participants were stratified into three groups based on their CD4:CD8 ratio, those within the normal range (≥ 0.9), and those exhibiting partial or poor immune reconstitution. Six months after boosting, spike-specific CD4 T cell frequencies decreased compared to baseline. However, there was a trend towards an increase in the proportion of CD8 T cell responders six months after booster vaccination, likely attributable to the vaccine response. Comparable T-cell profiles were observed in participants with both well and partially reconstituted CD4:CD8 T-cell ratios. However, participants with poor CD4:CD8 ratios had a lower proportion of CD4 and CD8 T-cell responders. Ongoing studies include the phenotyping of T cell memory subsets, T cell activation and exhaustion profiles as well as measuring durability and function (proliferative capacity, cytotoxic potential) of spike-specific T cells at 6 months versus 24 months post booster vaccination.
Participants living with HIV with well-reconstituted immune profiles exhibit robust T cell responses after booster vaccination, in the context of hybrid immunity. However, participants with poor immune reconstitution displayed deficiencies in both CD4 and CD8 T cell responses, both at baseline (reflecting the memory response post-primary vaccination) and post-booster vaccination. This study demonstrates the heterogeneity of SARS-CoV-2 T cell responses in people with HIV and highlights the importance of monitoring this population.

Purpose: Despite recent advances in vaccine development, gaps remains to understand the mechanisms driving long-term memory response to vaccines. The purpose of the work is to characterize the role of vaccine antigen persistence in generating durable immunity. Using the live-attenuated yellow fever (YF)-17D vaccine, one of the most efficient and durable vaccine, we explored molecular and cellular interactions in tissues of immunized non-human primates.
Methods: Two groups of cynomolgus macaques were either vaccinated with a commercial dose of live-attenuated vaccine or with the same dose of a β-propiolactone-inactivated vaccine adjuvanted with alum. Animals also received a 5-Iodo-2'-deoxyuridine (IdU) treatment to follow the mobilization and persistence of immune cells following immunization. Longitudinal systemic immune responses were characterized by mass cytometry, as well as viral load by qPCR, and neutralizing antibodies. At necropsy, different types of tissues were collected at several timepoints to follow antigen persistence by immunohistofluorescence (IHF) and *in situ* hybridisation; and to explore tissue immune responses by imaging mass cytometry (IMC). Results were compared to data obtained from tissues of macaques infected wild type Asibi strain.
Results: Low and transient viremia is observed in vaccinated animals (reaching 10^3 to 10^4 copies/mL) at approximately day 3 pi. Longitudinal analysis of immune responses by mass cytometry shows a high mobilization of innate and adaptive immune cells at early time-points. Adaptive T and B cells show persistent activation in the long term (up to 12 month pi) as demonstrated by the persistence of IdU^+ cells. Neutralizing antibodies were shown to persist for the live-attenuated vaccine whereas they decreased significantly around 3 months pi for the inactivated vaccine. By comparing these strategies, we identified differences in regulatory T cells and three types of circulating follicular helper cells ($CD127^+$ $PD\text{-}1^-$, $CD127^{mid}$ $PD\text{-}1^-$ $CD25^+$, and $CD127^{lo}$ $PD\text{-}1^+$) that could affect antibody persistence. In the tissues, YF antigens were detected at early timepoints mainly in the liver, although at lower rates than the infected animals, and in the spleen.
Conclusion: Our data enhance the understanding of the immunological mechanisms of YF-17D vaccination. Together, they highlight the relevance of specific immunological mechanisms that occur after vaccination.

Repeated SARS-CoV-2 mRNA vaccination results in decreased capacity of spike-specific serum antibodies to activate NK cells in older adults

Anne Gelderloos[1], Marije Verheul[1], Gaby Smits[1], Irene Middelhof[1], Rob van Binnendijk[1], Anne-Marie Buisman[1], Puck van Kasteren[1]
[1]*Dutch National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands*

To ensure prolonged protection against severe disease outcomes in the face of continued circulation of SARS-CoV-2 variants, many public health authorities have recommended a repeated booster vaccination regimen, especially in older adults. Previous research has shown that repeated vaccination results in a continued increase in post-vaccination antibody binding concentrations and neutralization titers. However, it has also been reported that repeated mRNA vaccination results in class-switching to IgG4. Importantly, little is known about the effect of repeated vaccination on the quality of the antibody response beyond neutralization, more specifically, the capacity of the induced antibodies to mediate Fc-dependent effector functions.
For the current analysis, we have assessed the capacity of serum antibodies to mediate SARS-CoV-2 spike-specific antibody dependent phagocytosis (ADCP), complement deposition (ADCD), and NK cell activation (ADNKA) in older adults (n=38, 65-77 years of age) at one month after completing the primary mRNA vaccination series, and at one month following the first and third mRNA booster dose. In addition, we measured SARS-CoV-2 spike-specific IgG binding concentrations, IgG avidity, and subclasses IgG1, IgG2, IgG3 and IgG4.
Although we observed a continued increase in the absolute functionality of the antibodies induced by repeated vaccination, we found that the capacity of the antibodies to mediate ADNKA and ADCD decreased after the third booster dose when corrected for IgG concentration. Repeated mRNA vaccinations also increased IgG4 responses over time in older adults. For ADNKA, the relative decrease in functionality associated with a decreased IgG3/IgG4 ratio.
Together, these data provide novel insights into the development of antibody quality upon repeated vaccination within a relatively short time period in the older adult population. Since increasing evidence suggests that Fc-mediated effector functions contribute to protection, these insights are important for the design of the most optimal (mRNA) vaccination policies in the event of repeated booster schedules.

This research was financially supported by the Dutch Ministry of Health, Welfare and Sport.

Mesoporous Silicon Microparticles (MSMPs) as a new adjuvant in a vaccine against the SARS-COV-2 virus

Ana López Gómez[1], Jana Ausió Cendra[1], Natalia Cuesta-Rubio[1], Alicia García-Culebras[1], Raúl José Martín-Palma[2], Eduardo Martínez-Naves[3], Manuel María Gómez del Moral[1]
[1]*Departamento de Biología Celular, Facultad de Medicina, Universidad Complutense de Madrid, Madrid, Spain*;
[2]*Departamento de Física aplicada, Facultad de Ciencias, Universidad Autónoma de Madrid, Madrid, Spain*;
[3]*Departamento de Inmunología, Oftalmología y ORL, Facultad de Medicina, Universidad Complutense de Madrid, Madrid, Spain*

Purpose: Our main purpose is to study the role of Mesoporous Silicon Microparticles (MSMPs) as a new adjuvant in a vaccine against SARS-CoV-2 based on the viral spike protein (S1). In this work we analyzed how MSMPs induce humoral and cellular response in wild type mice and protection against SARS-CoV-2 infection and COVID -19 dissease in K18-hACE2 transgenic mice. MSMPs immunoestimulatory effects were always compared with $Al(OH)_3$.
Methods: To achieve our objectives we immunized mice with MSMPs-S1 and studied humoral and cellular response, detecting IgG1, IgG2a and IgG by ELISA and IFNγ production by flow cytometry after stimulated splenocytes with Peptivator_S. Furthermore, we infected intranasally immunized K18-hACE2 mice with SARS-CoV-2 and studied viral replication in lungs and brain by qPCR. Disease development also was analyzed through clinical score, survival rates and weight variations during 15 days.
Results: Our findings indicate that MSMPs act as an adjuvant by enhancing humoral and cellular response, even better than $Al(OH)_3$ especially in the case of cellular response. In humoral response we detected higher levels IgG1, IgG2a and IgG antibodies than mice immunized with S1 and same leves of these antibodies as in mice immunized with $Al(OH)_3$-S1 except for IgG2a after boost. In this case we detected higher leves of IgG2a in the serum of mice immunized with MSMPs than in the serum of mice immunized with $Al(OH)_3$. In cellular response, mice immunized with MSMPs-S1 had higher level of IFNγ than mice immunized with $Al(OH)_3$-S1 and S1. After infection, we observed that mice immunized without adyuvants died within the first fives days. On the other hand, mice immunized with MSMPs-S1 or $Al(OH)_3$-S1 didn´t die, had less weight change and lower clinical score than those immunized with S1 protein. Finally, we analized the presence of SARS-CoV-2 in differents organs and detected higher viral load in non-immunized mice and mice immunized with S1 protein than in mice immunized with MSMPs-S1.
Conclusion: In conclusion our results demonstrate that MSMPs are a promising candidate as novel adyuvant in vaccine complex, enhancing both humoral and cellular response and providing protection against SARS-CoV-2 infection.

Vaccine-induced virus neutralizing antibody responses against seasonal Influenza virus H1N1 strains are not enhanced upon subsequent pandemic H1N1 infection.

Petra Mooij[1], Daniella Mortier[1], Aafke Aartse[1;2], Alexandre B. Murad[3;4], Ricardo Correia[3;4], António Roldão[3;4], Paula M. Alves[3;4], Zahra Fagrouch[1], Dirk Eggink[2;5], Norbert Stockhofe[6], Othmar G. Engelhardt[7], Ernst J. Verschoor[1], Marit J. van Gils[2;5], Willy M. Bogers[1], Manuel J.T. Carrondo[3], Edmond J. Remarque[1], Gerrit Koopman[1]

The first exposure to influenza is thought to shape the B cell antibody repertoire, leading to preferential enhancement of these initial responses upon subsequent exposures to viral variants. Here, we investigated whether this principle holds when there is a large genetic and antigenic difference between primary and secondary influenza virus antigens. Because humans have usually experienced a complex influenza virus exposure history, this was investigated in influenza-naive cynomolgus macaques. Two groups of six macaques were immunized four times with influenza virus-like particles (VLP) displaying either one (monovalent) or five (pentavalent) different hemagglutinin (HA) antigens derived from seasonal H1N1 (H1N1) strains. Four weeks after the final immunization, animals were challenged with pandemic H1N1 (H1N1pdm09). While immunization resulted in high virus neutralizing responses against all VLP-based vaccine strains, there was no cross neutralization against H1N1pdm09, and all animals became infected. No reduction in virus load in nose or throat in the monovalent or pentavalent vaccine group was detected. After infection, strong virus neutralizing responses were induced against H1N1pdm09. However, there was no increase in virus neutralizing titers against four of the five H1N1 vaccine strains and only a modest increase was seen against the influenza A/Texas/36/91 vaccine strain. After H1N1pdm09 infection, both the monovalent and pentavalent vaccine groups showed higher virus neutralizing titers against two H1N1 strains of antigenic intermediate distance between the H1N1 vaccine strains and H1N1pdm09 than the naive control group. Furthermore, both vaccine groups had higher HA-stem antibodies early after infection. In conclusion, immunization with VLPs displaying HA from antigenically distinct H1N1 variants resulted in increased breadth of the immune response upon subsequent H1N1pdm09 challenge, which however was limited to antigenic intermediate variants.

Adaptable live-attenuated SARS-CoV-2 OTS vaccines show preclinical safety and broad protection

Tuba Barut[1;2], Nadine Ebert[1;3], Bettina Salome Trüeb[1;3], Etori Aguiar Moreira[1;3], Péter Demeter Túrós[3;4;5], Llorenç Grau-Roma[5], Jacob Schön[6], Inês Berenguer Veiga[1;3], Annika Kratzel[1;3], Jenna N. Kelly[1;3;7], Melanie Brügger[1;3], Charaf Benarafa[1;3;7], Donata Hoffmann[6], Martin Beer[6;8], Volker Thiel[1;3;7]
[1]Institute of Virology and Immunology, Bern and Mittelhäusern, Bern, Switzerland; *[2]Department of Infectious Diseases and Pathobiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland*; *[3]Department of Infectious Diseases and Pathobiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland*; *[4]Graduate School for Cellular and Biomedical Sciences, University of Bern, Bern, Switzerland*; *[5]COMPATH, Institute of Animal Pathology, University of Bern, Bern, Switzerland*; *[6]Institute of Diagnostic Virology, Friedrich-Loeffler-Institut, Greifswald-Insel Riems, Germany*; *[7]Multidisciplinary Center for Infectious Diseases, University of Bern, Bern, Switzerland*; *[8]European Virus Bioinformatics Center, Jena, Germany*

Purpose: There is still a need for adaptable and highly efficacious vaccines that would protect against the wide spectrum of SARS-CoV-2 variants of concern (VOCs), as well as can be administered easily to provide both systemic and local mucosal immunity.
Methods: We developed live-attenuated vaccines (LAV) based on recoding the SARS-CoV-2 genome to enrich for "one-to-stop" (OTS) codons. Further, in order to increase the immunogenicity, we introduced additional mutations in the non-structural-protein-1 (nsp1), and the deleted the open reading frames (ORF) 6, 7ab and 8. Finally, by deleting the spike polybasic cleavage site (PCS), we aimed to reduce LAV replication in the lung and prevent vaccine shedding. The attenuation of the vaccine candidates as well as the protection they elicited were demonstrated in cell lines, nasal- and bronchial epithelial cells, in vivo K18-hACE2 mice and Syrian hamster models. Here we present the protection provided by the OTS-modified LAV in the lethal K18-hACE2 transgenic mice model.
Results: The adjustable OTS-modified LAV protected the K18-hACE2 mice efficiently against wild-type (WT) SARS-CoV-2 and other VOCs upon intranasal administration. Furthermore, LAV immunization resulted in faster virus clearance after SARS-CoV-2 challenge compared to mRNA vaccines, a block of transmission of WT SARS-CoV-2, and significantly reduced transmission of currently circulating variants.
Conclusion: To conclude, OTS-modified SARS-CoV-2 LAVs represent a new generation of live vaccines that are intranasal administered at the natural site of infection, provide efficient and innovative infection control, and conceptionally are readily applicable to many other emerging viruses.

Dissecting molecular drivers of NK cell dysfunction to enhance anti-tumor activity

Batel Sabag[1], Abhishek Puthenveetil[1], moria Levy[1], Noah Joseph[1], Fatima Awwad[1], Shahar Ashkenazi[1], Mira Barda-Saad[1]
[1]*Bar-Ilan University, Ramat Gan, Israel*

Purpose: Natural Killer (NK) cells are a critical arm of the innate immune response, serving as a powerful weapon against viral infections and cancer. However, approximately 13±6% of NK cells do not express classical inhibitory receptors during their education and are rendered naturally 'anergic,' exhibiting reduced effector functions. The molecular cascades regulating NK cell anergy remain mainly unknown. Furthermore, unlike T-cells, in which the dysfunctional immune cell state in tumors, known as 'exhaustion,' has been extensively studied, this state is not well characterized in NK cells. It is also unclear whether NK cell 'exhaustion' is completely distinct from 'anergy.' Our study aimed to unravel the molecular mechanisms and etiology that drive NK cell dysfunction, providing insights for manipulating these cell populations to enhance anti-tumor responses.
Methods involved RNA sequencing and protein-level analysis. This was followed by the utilization of 3D culture systems, in vivo pancreatic cancer models, and lipid-based nanoparticles (LNPs) to reprogram 'anergic' and 'exhausted' NK cells in their respective microenvironments. This was achieved by gene silencing the intrinsic regulators identified to govern this dysfunction, demonstrating the potential for reprogramming NK cells.
Results: Here, we profile the dysfunctional phenotypes and identify the transcription factor, Egr2, and diacylglycerol kinase, DGKα, as key intrinsic regulators of NK cell dysfunction. Egr2 silencing restored anergic NK cell cytotoxicity through the EGR2-DGKα-MAPK-pERK axis, potentially modulating SHP-1 activity and calcium levels. Utilizing a nanoparticle-based method, we reprogram dysfunctional NK cells in their native milieu, boosting their anti-tumor activity. Our data imply commonalities between the dysfunctional states 'anergy' and 'exhaustion.'
Conclusion: Targeting the transcription factor Egr2 represents a promising approach to rewiring the overall functional circuitry of NK cells, potentially overcoming dysfunction-associated transcriptional imprints, and augmenting the efficacy of immunotherapies. This research is pivotal in elucidating and restoring the anti-tumor activity of dysfunctional NK cells, offering crucial insights into their intricate biology within solid tumors and unlocking the full potential of NK-based therapies. Regulation of NK cell dysfunction at the molecular and transcriptional levels potentiates the development of next-generation immunotherapies for chronic infections and cancer.

Anti-CD20 mediated apoptosis in B-cell lymphoma impairs "don't-eat-me" CD47 signaling and boosts Fc receptor-mediated phagocytosis

Oanh Nguyen[1], Sandra Lara[1], Giovanni Ferro[1], Matthias Peipp[2], Sandra Kleinau[1]
[1]Department of Cell and Molecular Biology, Uppsala University, Uppsala, Sweden; *[2]Division of Antibody-Based Immunotherapy, University Hospital Schleswig-Holstein, Kiel, Germany*

The IgG1 anti-CD20 monoclonal antibody rituximab (RTX) is a well-established treatment for B-cell non-Hodgkin lymphomas (NHLs). However, not all B-cell NHLs respond to RTX treatment. Thus, there is an urgent need for new strategies to enhance RTX-mediated anti-tumor immune responses.
The efficacy of RTX depends crucially on the phagocytosis of antibody-opsonized tumor cells by monocytes/macrophages. The phagocytic process is regulated by the "don't-eat-me" CD47 molecule, which dampens the phagocytic activity. In this study, we demonstrate that by impairing CD47 signaling, we can significantly enhance RTX-induced phagocytosis of human $CD20^+$ B-cell lymphoma cells by human monocytes.
Our results reveal that an IgG2 isotype of RTX (RTX-IgG2) in combination with RTX-IgG1 or RTX-IgG3, can significantly induce enhanced phagocytosis of $CD20^+$ B-cell lymphoma cells in comparison with single use of RTX-IgG1 or RTX-IgG3. This effect was associated with CD20-dependent apoptosis by RTX-IgG2. Likewise, the apoptosis inducer staurosporine (STR) could enhance phagocytosis of lymphoma cells when combined with RTX-IgG1 or RTX-IgG3. Notably, we observed that apoptosis mediated by RTX-IgG2, as well as by STR, downregulated CD47 expression on the lymphoma cells. Indeed, microscopic analysis revealed that the expression of CD47 was decreased and scattered in patches on the cell membrane of RTX-IgG2 or STR-treated lymphoma cells. In contrast, RTX-IgG1 and RTX-IgG3 did not induce apoptosis and alteration of CD47 expression on the lymphoma cells. Aligned with this finding, we show that CD47-blocking antibodies, either with a functional or silenced Fc domain, on lymphoma B-cells enhance the phagocytic activity induced by RTX-IgG1 or RTX-IgG3 in monocytes.
Based on this principle, we further demonstrate that RTX-IgG2 can enhance the efficacy of other tumor-targeting antibodies, such as IgG1 anti-PD-L1, in stimulating phagocytosis of $CD20^+$ B-cell lymphoma cells.
In summary, our study demonstrates that RTX-IgG2 enhances Fc receptor-mediated phagocytosis of $CD20^+$ B-cell lymphoma cells through CD20-dependent apoptosis and downregulation of CD47. This finding emphasizes the potential of RTX-IgG2 as a valuable agonist in B-cell NHL treatment. Combining RTX-IgG2 with RTX-IgG1, or potentially any other tumor targeting antibody, offers an exclusive target-specific approach to boost the efficacy of $CD20^+$ B-cell lymphoma therapies.

Purpose: Tumor-associated macrophages (TAM) play a detrimental role in triple-negative breast cancer (TNBC). In-depth analysis of TAM characteristics and interactions with stromal cells, such as cancer-associated fibroblast (CAF), could provide important biological and therapeutic insights.
Methods and Results: Here we identify at the single-cell level a monocyte-derived STAB1+TREM2high lipid-associated macrophage (LAM) subpopulation with immune suppressive capacities that is expanded in patients resistant to immune checkpoint blockade (ICB). Genetic depletion of this LAM subset in mice suppressed TNBC tumor growth. Flow cytometry and bulk RNA sequencing data demonstrated that coculture with TNBC-derived CAFs led to reprogramming of blood monocytes towards immune suppressive STAB1+TREM2high LAMs, which inhibit T-cell activation and proliferation. Cell-to-cell interaction modeling and assays in vitro demonstrated the role of the inflammatory CXCL12-CXCR4 axis in CAF-myeloid cell cross-talk and recruitment of monocytes in tumor sites.
Conclusion: Altogether, these data suggest an inflammation model whereby monocytes recruited to the tumor via the CAF-driven CXCL12-CXCR4 axis acquire protumorigenic LAM capacities to support an immunosuppressive microenvironment.

Wiring the transcription factor network to prime natural killer anti-tumor immunity in triple-negative breast cancer

Veronica Manicardi[1], Gloria Manzotti[1], Elisa Salviato[1], Federica Torricelli[1], Elisa Gasparini[1], Alessia Ciarrocchi[1], Francesca Reggiani[1]
[1]*Azienda USL-IRCCS of Reggio Emilia, Reggio Emilia, Italy*

Background: Natural Killer (NK) are characterized by high transcriptional plasticity which is tightly connected with their effector functions. We and others demonstrated that some epigenetic drugs, such as BET inhibitors, drive an efficient immune response by modulating NK transcriptional programs and enhancing their overall anti-tumor response. This is particularly relevant in Triple-Negative Breast Cancer (TNBC) in which we demonstrated that NKs are the principal immune components that predict a divergent patient response to neoadjuvant chemotherapy. Thus, the stimulation of NK activation in tumor microenvironment may be a promising strategy to improve patient outcomes.
Purpose: In this work, we investigated how to prompt NK effector functions by modulating key Transcription Factors (TFs) to obtain transcriptional reprogrammed NKs with enhanced anti-tumor immunity.
Results: We explored the intracellular dynamics leading to NK activation elicited by BET inhibitors and applying RNA-Sequencing. Enrichment analysis of de-regulated genes (DEGs) revealed that immune-checkpoints (ICs) and other inhibitory receptors (KIRs) were the most down-regulated by the drugs. Top-scoring DEGs were integrated with data collected from our TNBC patients, as well as with established datasets of activated NKs. Gene promoters were in silico scanned with FIMO algorithm to predict upstream regulators. Our top-scoring TF was SMAD3, which we demonstrated to induce IC/KIR expression in NKs by the transcriptional cooperation with the epigenetic reader BRD4. Chromatin immunoprecipitation confirmed SMAD3/BRD4 enrichment on IC/KIR promoters and SMAD3/BRD4 inhibition was sufficient to reduce IC/KIR expression in NK92 and patient-derived NKs. Besides SMAD3, we identified other candidates TFs: VEZF1, RXRA, and MAZ. We further investigated these TF-dependent transcriptional programs merging our single-cell RNA-sequencing data with public datasets obtained from TNBC patients treated with IC inhibitors. We confirmed that the NK gene signature associated with our candidate TFs predicted a different immunotherapy response and NK activation is required to improve patient outcome.
Conclusions: Our results point out that the modulation of NK transcriptional programs can be a novel tool to potentiate NK effector functions toward TNBC. We identified several TFs that are putative master regulators of NK activation, opening novel opportunities to exploit them in the design of NK adoptive cell therapies in solid tumors.

PD-L1 ligation enhances NK cell anti-tumor function by inducing a metabolic shift

Katja Srpan[1], Kyle Lupo[1], Katharine Hsu[1]
[1]*Memorial Sloan Kettering Cancer Center, New York, United States*

Programmed death ligand 1 (PD-L1), abundantly expressed on tumor cells, is a pivotal target for immunotherapy investigations. PD-L1 blockade is efficacious in a broad range of malignancies, intriguingly, including PD-L1neg tumors. Natural killer (NK) cells are well understood to be a vital mediator of innate immunity against viral infection and malignancy and have recently been shown to express PD-L1 upon activation. Here, we elucidate the functional role of PD-L1 on circulating and tumor-infiltrating NK cells in patients with various hematologic and solid malignancies, as well as in murine tumor models. PD-L1+ NK cells can engage with therapeutic anti-PD-L1 antibody atezolizumab, soluble PD-1 or PD-1 expressed by T cells or tumor cells, and its ligation significantly enhances NK cell-mediated tumor clearance. Surprisingly, the increased anti-tumor immunity is not the result of increased NK cell degranulation, but due to improved migration into tumors via the CXCR3 chemokine pathway and cytoskeletal dynamics, enabling better synapse formation with tumor cells. Furthermore, PD-L1 ligation in NK cells induces a metabolic shift from glycolysis toward fatty acid oxidation with increased expression of CPT1A and fatty acids uptake. This metabolic shift was essential for the atezolizumab-mediated effect, as tumor-bearing mice with the NK cell-specific deletion of CPT1A failed to respond to treatment. This feature is specifically advantageous in glucose-deprived tumor microenvironments (TME) of highly glycolytic tumors, where T cell function is compromised, as we showed using the tumor model overexpressing the GLUT1 glucose receptor. Taken together, our work demonstrates that PD-L1 ligation not only enhances NK cell cytotoxic function but also increases tumor infiltration and helps overcome challenging TME conditions, resulting in a more effective anti-tumor function. These findings underscore the potential of targeting PD-L1 to augment NK cell-mediated anti-tumor responses. By enhancing NK cell function and infiltration, PD-L1-directed strategies offer promising avenues for improving cancer immunotherapy outcomes.

ERAP1 controls NK cell responses by regulating peptide-dependent interactions between HLA class I and NK cell inhibitory receptors in hematological malignancies

Kamila Król[1], Maria Troiano[1], Michela Falco[2], Marco Andreani[1], Doriana Fruci[1]
[1]*Bambino Gesù Children's Hospital, Rome, Italy*; [2]*Giannina Gaslini Institute, Genoa, Italy*

Background: Endoplasmic Reticulum Aminopeptidase 1 (ERAP1) plays a crucial role in trimming antigenic peptides for presentation by HLA class I molecules. It is highly expressed in many cancers, including leukemia and lymphoma. Inhibition of ERAP1, either genetically or pharmacologically, activates NK cells by disrupting the engagement of NK cell inhibitory receptors with their HLA ligands. Particularly sensitive to ERAP1 inhibition is the HLA-Bw4 B51:01 allele, which is recognized by KIR3DL1.
Purpose: This study aims to investigate whether inhibition of ERAP1 affects interactions with other HLA-NK inhibitory receptors pairs, potentially offering a novel approach for NK-cell-based cancer therapy.
Methods: A panel of leukemia and lymphoma cell lines, which express both ERAP1 and HLA-Bw4 alleles, was selected for ERAP1 silencing. Western blotting analysis confirmed the generation of ERAP1 knockout cell lines. The response of NK cells to ERAP1 depletion was assessed by functional killing and degranulation assays using primary NK cells (from 10 healthy donors) and established NK cell lines. The interaction between ERAP1-KO cells and NK cell inhibitory receptors was also examined through the binding capability of fusion proteins.
Results: ERAP1 depletion did not significantly alter the expression of HLA class I molecules on the cell surface. However, it led to increased killing and degranulation of NK cells. KIR^+ NK cells showed strong and consistent degranulation in response to ERAP1-KO targets in all healthy donors. Furthermore, the binding of NK inhibitory receptor-Fc fusion proteins to ERAP1-KO cells was weaker.
Conclusion: Inhibition of ERAP1 regulates interactions between NK cell inhibitory receptors and HLA class I molecules on target cells. This altered recognition between receptor and its ligand increases NK cell cytotoxicity reactions. Overall, these findings suggest that ERAP1 inhibition could be a promising therapeutic approach in hematological malignancies.

Developing intracellular antibodies that harness innate antiviral mechanisms to prevent HIV-1 infection

Florence Stel[1], Esther Zijlstra-Willems[1], Neeltje Kootstra[1], Teunis B.H. Geijtenbeek[1]
[1]*Amsterdam UMC, Amsterdam, Netherlands*

The innate immune system consists of various sensors and mechanisms to detect invading viruses. This includes intracellular receptors that recognize and degrade the incoming virus. TRIM21 is an intracellular antibody receptor involved in the intracellular immune response. The TRIM21 protein interacts with an antibody-coated virus and targets it for proteosomal degradation involving the E3 ubiquitin ligase complex. This highly specific antibody-TRIM21 technology holds great promise for the engineering of therapeutic antibodies to prevent viral infections via targeting of host or viral proteins. Here we investigated the potential of this TRIM21 technology in order to develop intracellular immunity against HIV-1 infection.
We designed nanobodies, based on llama antibodies, targeting the HIV-1 capsid protein p24, fused to the human IgG1 Fc domain. These p24 nanobody-Fc constructs were synthesized, and produced by a mammalian expression system. Next, they were characterized by flow cytometry and tested for their functionality to bind p24 through an ELISA-based binding assay. Lastly, the p24 nanobody-Fc constructs were stably expressed intracellularly in the U87-CD4-CCR5 cell line
Our data show that these Fc-modified nanobodies recognize intact HIV-1 capsid and have a functional Fc domain. Notably, HIV-1 p24 capsid was neither detected intracellularly nor extracellularly after HIV-1 exposure in the p24 nanobody-Fc expressing cell-line, even though HIV-1 had integrated in the genome at levels comparable to control cells. These data strongly suggest that the Fc-modified p24 nanobody degrades p24 and thereby prevents virus production.
To conclude, we have developed a novel p24 nanobody construct that efficiently prevents HIV-1 infection. Intracellular production of Fc-modified p24 nanobodies highly reduce p24 production levels in U87-CD4-CCR5 cells upon infection with HIV-1. This technology has a wide variety of potential applications in providing TRIM21-mediated intracellular immunity against virus infections.

ULBP2-expressing HCMV mutants affect NK cell function and activation

Greta Meyer[1;2], Anna R Simes[2;3], Jenny F Kuehne[1;2], Irina Bevzenko[1;2], Kerstin Beushausen[1], Jana Keil[1], Karen Wagner[3], Lars Steinbrück[3], Eva-Maria Borst[3], Martin Messerle[2;3], Christine Falk[1;2;4]
[1]Institute of Transplant Immunology, Hannover Medical School, Hannover; *[2]FOR 2830 Advanced Concepts in Cellular Immune Control of Cytomegalovirus, DFG, Würzburg, Germany*; *[3]Institute of Virology Hannover Medical School, Hannover*; *[4]German Center for Infection Research (DZIF), TTU-IICH (Immunocompromised host), Hannover/Braunschweig, Germany*

Purpose: HCMV infection elicits protective T and NK cell responses. Patients with inherited or acquired T/NK cell impairments, e.g., recipients of organ transplants under immunosuppression, are at high risk of HCMV infection. A protective HCMV vaccine – that is currently not available – would not only greatly reduce the risk for HCMV reactivation and disease in those patients, but also lower the incidence of graft rejection and is therefore of top priority. We hypothesize that a live-attenuated vaccine will elicit a broader and therefore more efficacious immune response. In this work, we aim to achieve immune cell activation as well as viral attenuation by generating HCMV strains expressing the NKG2D ligand ULBP2.
Methods: ULBP2-expressing HCMV mutants were constructed using either the TB40 (ΔUS2-US6) or theTB40R containing the immune-evasins US2-US6 and replace the UL16 region by ULBP2 which is expressed under a weak or strong promotor. Fibroblasts were infected with the respective virus mutants and analyzed by flow cytometry regarding ULBP2 and NK ligand expression. Cocultures of infected HFF with NK cells revealed immune cell activation and viral dissemination. Moreover, cytotoxic function of NK cells was analyzed by degranulation assays via CD107a expression.
Results: Fine-tuned, increased surface expression of ULBP2 was observed for the weak- and strong ULBP2-expressing mutants, but not in parental strains due to UL16-mediated retention. High amounts of soluble ULBP2 (sULBP2) were shed into supernatants also reflecting the promoter strength of ULBP2. However, sULPB2 did not affect NK cell cytotoxicity. In viral dissemination assays, trends became observable that NK cells exhibit improved control regarding virus transmission upon contact to ULBP2-expressing infected cells. Furthermore, ULBP2 expression in HCMV-infected HFF resulted in a fine-tuned NKG2D downregulation depending on ULBP2 cell surface expression levels, confirming graded interaction between NKG2D and ULBP2. Moreover, NK cells get activated by the ULBP2-expressing mutants as evidenced by the upregulation of CD69. Moreover, the expression of ULBP2 significantly enhanced NK cell cytotoxicity indicating a beneficial effect of ULBP2 expression regarding NK cell function.
Conclusion: Overall, expression of NKG2D ligands like ULBP2 to achieve NK cell attenuation represents a promising approach for a live-attenuated HCMV vaccine development.

Antiviral protective signature of Vδ2 T cells in pediatric patients after αβ/CD19-depleted hematopoietic stem cell transplantation

Veronica Bordoni[1], Federica Guarracino[1], Federica Galaverna[1], Valentina Bertaina[1], Giuseppina Li Pira[1], Marco Rosichini[1], Angela Pitisci[1], Enrico Velardi[1], Pietro Merli[1], Franco Locatelli[1], Chiara Agrati[1]
[1]*Department of Pediatric Hematology and Oncology - Bambino Gesù Children's Hospital, Rome, Italy*

Background: γδ T-cells represent key players in the immune-surveillance in the first months after TCRαβ/CD19-Depleted Haploidentical Stem Cell Transplantation (haplo-HSCT). Although encouraging data are available about the impact of Vδ2-targeting-therapy in improving haplo-HSCT clinical outcome, no data about the antimicrobial effectiveness of Vδ2 T-cells are still available.
Purpose: Aim of this study was to explore the potential direct and bystander antiviral activities of Vδ2 T cells after αβ- and B-cell depleted HSCT.
Methods: We performed a prospective study to compare overtime the phenotypic and functional signature of γδ T cells in patients experienced or not CMV reactivation (CMV-R and No-CMV respectively). The area under the curve (AUC) of the CMV-DNA was calculated for each patient. The immunological characterization of γδ T-cells was performed before (on the graft) and after haplo-HSCT pediatric patients (n=20) after 30, 60 and 120 days following HSCT by flow-cytometry. The antiviral activity of Vδ2 T-cells was tested on CMV-infected fibroblasts and the bystander effects on CMV-specific αβ T-cell immunity was analysed by flow-cytometry.
Results: Early after haplo-HSCT, the frequency of Vδ2 T-cells was significantly higher in No-CMV than in CMV-R patients, both at T30 and at T60. These cells were directly correlated with the plasmatic IL-15 and inversely correlated with the CMV-DNA AUC. Interestingly, this difference was already present in the grafts infused in No-CMV and CMV-R patients. The clustering analysis identified a key signature of protective Vδ2 T-cells, expressing CD16, CD45RA, NKG2D and CD107a. Stimulated Vδ2 T-cells from haplo-HSCT produced IFN-γ/TNF-α, increased CD86/HLA-DR expression on B cells and monocytes, and improved the αβ CMV-specific T-cell response. Finally, soluble factors released by activated Vδ2 T-cells inhibit CMV replication.
Summary/Conclusion: Altogether, these results identify an antiviral protective profile of Vδ2 T-cells early after haplo-HSCT and define their bystander activity on antigen presenting cell maturation and on αβ-specific T-cell immunity. These data open a new application of Vδ2-targeting immunotherapy after haplo-HSCT, adding the antiviral to the antitumor potential.

CD4+ T-cell tissue lymphopenia in human-papillomavirus-driven anal dysplasia in people living with human immunodeficiency virus

Rehana Hewavisenti[1], Zong-Hong Zhang[1], Cecilia Chang[2], Tony Wang[2], Priyanka Hastak[1], Fengyi Jin[1], Isobel M Poynten[1], Alexander Swarbrick[2], Andrew E Grulich[1], Anthony Kelleher[1;3], Sarah C Sasson[1]
[1]The Kirby Institute (University of New South Wales), Sydney, Australia; *[2]Garvan Institute of Medical Research (University of New South Wales), Sydney, Australia*; *[3]St Vincents Centre for Applied Medical Research, Sydney, Australia*

Purpose: People living with human immunodeficiency virus (HIV) face a significant risk of human papillomavirus (HPV)-driven malignancies including cervical cancer and anal cancer (AC), despite receiving antiretroviral therapy (ART). Men who have sex with men (MSM) display poor HPV clearance and frequently develop high-grade squamous intraepithelial lesions (HSILs), precursors to AC. AC incidence continues to rise among HIV+MSM, with a 19-fold increased risk despite reconstituted peripheral CD4+ T-cell counts. The immune mechanisms underlying HSIL transition to AC remain poorly understood. Here we quantified major tissue T-cell subsets according to HPV16 and HIV infection status. We then investigated the local immune transcriptome associated with 1) HSIL clearance (regression) and 2) HSIL persistence in HPV16+HIV+ MSM before malignant transformation.
Methods: T-cell proportions and infiltrative capacity were examined by multiplex-spectral microscopy on 66 anal biopsies from MSM. Using spatial transcriptomics, differences in signalling pathways between dysplastic and peri-lesion regions were assessed in regressive or non-regressive (persistent disease) biopsies from HPV16+HIV+MSM.
Results: Despite ART and reconstituted peripheral CD4+ T-cell counts, total CD4+ T-cell numbers in local tissue were significantly lower (P=0.0135) in HIV+MSM (~300 cells/mm2) compared to HIV-MSM (~700 cells/mm2), with the lowest numbers present in HIV+HPV16+ MSM. This trend was also evident within tissue-resident memory (CD103+T_{RM}) and peripheral (CD103-) CD4+ T-cell subsets. Similar CD8+ T-cell numbers were observed across groups. When assessing T-cell infiltration from the stroma:dysplastic border into dysplastic regions, CD4+ and CD8+ T-cells displayed significantly higher infiltration in HIV+MSM than HIV-MSM (P=0.0205). Spatial transcriptomics revealed divergent molecular signalling pathways. Non-regressive HSILs were characterized by MHC class I/II and positive immune regulation pathways, while regressive HSILs displayed homeostasis signals.
Conclusion: HIV+ MSM exhibit diminished anal mucosal CD4+ T-cell counts, despite heightened infiltration. CD4+ T-cell tissue lymphopenia may be linked to poor cytotoxic T-cell function, resulting in inadequate HPV clearance and AC progression. The transcriptomes of non-regressive HSILs are suggestive of ongoing HPV and/or HIV viral replication. Given current disease burdens in the ART era, understanding cellular and molecular mediators of HPV-related regression is crucial, and may lead to the development of host (e.g. checkpoint-inhibitor) or viral (e.g. siRNA) next-generation therapies.

Increased levels of intestinal CD103+ cells and plasma IgG/IgA ratio are associated to spontaneous HIV control

Joana Vitallé[1], Beatriz Domínguez-Molina[1], Sara Bachiller[1;2], Carmen Gasca-Capote[1], Cristina Moral-Turón[1], Isabel Gallego[1], Francisco José Ostos[1], Mohamed Rafii-El-Idrissi Benhnia[1;2], Jorge Carrillo[3], Julià Blanco[3], Luis Fernando López-Cortés[1], Ezequiel Ruiz-Mateos[1]
[1]Institute of Biomedicine of Seville - Virgen del Rocío University Hospital, Seville, Spain; *[2]University of Seville, Seville, Spain*; *[3]Institute of AIDS Research IrsiCaixa, Barcelona, Spain*

Purpose: Gut is an important tissue compartment of HIV reservoir and one of the main sources of the chronic inflammation found in people with HIV (PWH). HIV elite controllers (EC), are able to control HIV in the absence of antiretroviral therapy (ART). However, specific immune mechanisms associated with this spontaneous HIV control is not completely understood. Therefore, the purpose of the study was to elucidate which characteristics of cellular and humoral immunity are associated to spontaneous HIV control both in peripheral blood and gut.
Methods: Ileum and caecum biopsies and peripheral blood samples from EC (n=3), PWH on ART (ART; n=4) and HIV seronegative people (HD; n=4) were analyzed by multiparametric flow cytometry. Dendritic (DC), natural killer (NK) and T cell markers were measured, including gut homing markers (CD103, integrin β7 (β7+)). Plasma inflammatory markers as β2-microglobulin (β2M) and D-dimer levels were determined by immunoturbidimetric assay and an automated latex enhanced immunoassay, respectively. Lastly, total and HIV-specific IgG, IgA and IgM plasma levels were determined by ELISA in EC (n=20), ART (n=19) and HD (n=13).
Results: EC showed a higher frequency of CD103+ and CD103+β7+ myeloid DCs (mDCs), comparing with ART, in gut. We observed a higher CD103 expressing CD4+/CD8+ T cell ratio in EC, than in ART, in gut and blood. Taking to account all the participants, we found that different mDC subsets were directly correlated to CD4+ T and NK cell frequencies in gut. CD103+ mDCs were also associated to CD103+ CD4+/CD8+ T cell ratio in ileum. In addition, CD103+β7+ mDCs and T cells were inversely associated to plasma inflammatory markers (β2M and D-dimer) and monocyte frequencies in caecum and peripheral blood of EC and HD, but not in ART. Lastly, higher total and HIV-specific IgG/IgA ratio was observed in plasma of EC compared with ART; this ratio was correlated with the frequency of specific DC, NK cell and T cell subsets in gut and blood.
Conclusion: Increased frequencies of specific mDC and T cell subsets in gut, and higher plasma IgG/IgA ratio are associated to spontaneous HIV control and lower inflammatory status in EC.

CD4+T cells license Kupffer cells to revert the CD8+T cell dysfunction induced by hepatocellular priming

Valentina Venzin[1;2], Cristian Beccaria[1;2], Valeria Fumagalli[1;2], Federica Moalli[1;2], Chiara Perucchini[2], Chiara Laura[2], Pietro Delfino[2], Elisa Bono[2], Leonardo Giustini[2], Marta Grillo[1], Keigo Kawashima[2], Micol Ravà[2], Anna Celant[1], Pietro Di Lucia[2], Giorgia De Simone[1], Fulvia Vascotto[3], Luca G Guidotti[1;2], Matteo Iannacone[1;2]
[1]Vita-Salute San Raffaele University, Milan, Italy; *[2]San Raffaele Scientific Institute, Milan, Italy*; *[3]TRON gGmbH, Johannes Gutenberg University, Mainz, Germany*

Efficient priming of CD8$^+$T cell responses against non-cytolytic pathogens like HBV is believed to rely on CD4$^+$T cell help within secondary lymphoid organs, as the immunological dogma would dictate. This hypothesis is supported by an observation in experimentally infected chimpanzees, where CD4$^+$T cell depletion prior infection prevents CD8$^+$T cell priming and leads to persistent infection.
However, where when and how this issue occurs has never been described or mechanistically elucidated.
We took advantage of unique HBV transgenic mouse models, in which we have demonstrated that adoptive transferred HBV-specific CD8$^+$T cells that recognize hepatocellular viral antigens undergo activation and proliferation but fail to differentiate into antiviral effector cells. To understand the extent to which antigen-specific CD4$^+$T cells can help intrahepatic CD8$^+$T cell differentiation, we generated HBV-specific CD4$^+$ TCR transgenic mice (Env126), where all CD4$^+$T cells recognize an I-Ab-restricted T cell epitope of the HBV envelope protein.
Here, we show that the adoptive transfer of Th1-like Env126 effector CD4$^+$T cells in HBV-transgenic mice counteracts the CD8$^+$T cell dysfunction induced by hepatocellular priming, boost their proliferation and stimulate their production of IFN-γ, TNF-α, and Granzyme-B. This enhances CD8$^+$T cell-mediated liver immunopathology and suppresses HBV replication. Surprisingly, we found that dendritic cells are dispensable for the observed effect while on the contrary, Kupffer cells' (KCs) cross-presenting capacity is enhanced after adoptive transfer of Env126 effector CD4$^+$T cells. With multiphoton intravital microscopy we indeed revealed that HBV-specific CD4$^+$ and CD8$^+$ T cells simultaneously interact with individual KCs within the liver, and as such, the restorative process of Env126 T effector CD4$^+$T cells help is impeded upon KCs depletion. We finally identify CD40-CD40L signaling pathway engagement as the key for Env126 T cells-mediated KCs licensing and IL-27 as a potential novel mediator of dysfunctional CD8$^+$T cell rescue.
Our findings underscore the crucial role of antigen-specific CD4$^+$T cells in mitigating the CD8$^+$T cell dysfunction induced by intrahepatic priming through the extra-lymphoid licensing of KCs, revealing a hitherto unexplored dynamic. The described molecular and cellular mechanism behind this effect could lead to the development of innovative immunotherapeutic strategies to eradicate chronic hepatic infections and their life-threatening complications.

Tlr7 bi-allelism defines a functionally distinct B cell subset and drives systemic autoimmunity

Léa Ferrayé[1], Charles-Henry Miquel[1], Berenice Faz-Lopez[1], Magali Savignac[1], Jean-Charles Guéry[1]
[1]*INFINITY, Toulouse, France*

The incidence of autoimmune diseases, like Systemic Lupus Erythematosus (SLE) is markedly increased in women and in 47 XXY Klinefelter syndrome (KS) men, as compared to 46 XY men, possibly in relationship with differences in X chromosome dosage. While in women, one of the two X chromosomes is inactivated (XCI), some genes can escape XCI, leading to increased expression of these genes in female cells. *Tlr7* gene localized on the X chromosome encodes an endosomal TLR recognizing ssRNA from self and non-self, potentially leading to inflammation or autoimmunity. Indeed, expressed at double dose, *Tlr7* is sufficient to trigger systemic autoimmunity in mice. We have recently demonstrated that *TLR7* evades X silencing in an important proportion of immune cells from healthy women and KS men, resulting in enhanced TLR7 protein expression in female PBMCs. TLR7 bi-allelic B cells exhibited enhanced capacity for class switching into IgG+ B cells and plasmablasts in response to TLR7-specific ligands. This observation supports the notion that TLR7 overexpression through biallelism is a candidate contributor to the higher risk of SLE, in women and KS men. To address the causal relationship between *Tlr7* expression from the inactive X chromosome and the development of dysregulated immune responses involved in disease pathogenesis in SLE, we generated an original dual reporter mouse model in order to track *Tlr7* biallelic cells referred as BiA7 B cells in vivo. We will present evidence that BiA7 B cells represent a functionally distinct subset of B cells with enhanced capacity to differentiate into antibody secreting cells and PC. We also developed and validated a genetic model to restrict Tlr7-driven cellular mosaicism, thereby reducing considerably the frequency of B cells with Tlr7 bi-allelic potential and enforcing *Tlr7* mono-allelism in vivo. Using this model in a pristane-induced model of lupus in C57BL/6 background we provide evidence that lack of Tlr7 bi-allelism protects from systemic autoimmunity and the development of anti-Sm/RNP autoantibodies. The results may provide insights into the nature of the mechanism underlying the enhanced female susceptibility to systemic B cell autoimmunity.

Biological effect of cytokine specific auto-antibodies on immune responses in a healthy population

Florian Dubois[1;2], Jakob Hjorth Von Stemann[3], Violaine Saint-André[1;4], Vincent Bondet[1], Celine Posseme[1;2], Bruno Charbit[1;2], Lluis Quintana-Murci[5;6], Morten Bagge Hansen[3;7], Sisse Rye Ostrowski[3;7], Darragh Duffy[1;2]
[1]Translational Immunology Unit, Institut Pasteur, Paris, France; *[2]Cytometry and Biomarkers UTechS, Institut Pasteur, Paris, France*; *[3]Department of Clinical Immunology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark*; *[4]Institut Pasteur, Université Paris Cité, Bioinformatics and Biostatistics Hub, Paris, France*; *[5]Institut Pasteur, Université Paris Cité, CNRS UMR2000, Human Evolutionary Genetics Unit, Paris, France*; *[6]Chair of Human Genomics and Evolution, Collège de France, Paris, France*; *[7]Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark*

The presence and pathological effect of cytokine specific auto-antibodies (C-aAb) has been observed in autoimmune diseases (*Graudal et al., Ann Rheum Dis. 2002; Bradford et al., Cell Rep Med.2023*) and more recently in COVID-19 cases (*Bastard et al., Science 2020*). However, their presence in the plasma of healthy individuals raises questions about their biological effect and impact during different immune responses.
To address this question, we measured levels of c-aAb against IFNα, IFNg, CSF2, IL-1α, IL-6, and IL-10 in the plasma of 1,000 healthy donors of the Milieu Interieur (MI) cohort. Using TruCulture® whole blood stimulations, we observed a significant and strong association of IL-1α c-aAb with LPS induced IL-1α protein levels. LPS and *E. Coli* stimulation conditions showed differential gene expression associated with IL-6 c-aAb, while gene expression after Poly:IC stimulation was associated with CSF2, IFNa and IFNg c-aAb plasma titers. To further investigate the ability of healthy individuals' high-titer c-aAb to impact immune function, we conducted whole blood stimulations from 6 healthy donors in TruCulture tubes pre-loaded with LPS, PolyI:C, R848 as well as a Null control in the presence or absence of plasma containing high titer C-aAb against IFNα, IL-1α, IL-6, or IL-10. We observed widespread association of anti-IFNα and anti-IL-6 c-aAb with both baseline and induced gene expression. This experimental effect on c-aAb gene expressions was cross validated for certain genes in the MI cohort.
Our results demonstrate a biological effect of C-aAb on immune responses of healthy donors, at low concentrations previously thought to be non-neutralizing. Interestingly, their presence strongly impacted the regulation of immune gene expression even in the Null condition. Further investigation of the prevalence of C-aAb and their neutralizing activity in population-based cohorts will provide a better understanding of their role in shaping immune response variability between individuals.

Exploratory study of the utility of the detection of microRNAs in urine of patients with immune-mediated inflammatory diseases

Marisa Pardines Ortiz[1], Ana Triguero Martínez[1], Nuria Montes[1;2], Hortensia De la Fuente[3], Ana Romero Robles[4], Rosario García Vicuña[4], Amalia Lamana[5], Ana M. Ortiz[4], Rebeca Hernández Martínez[3;6], Mónica Marazuela[6], Isidoro González Álvaro[4]
[1]Biomedical Research Institute La Princesa Hospital (IIS-IP), Madrid, Spain; *[2]Methodology Unit, Biomedical Research Institute La Princesa Hospital (IIS-IP), Madrid, Spain*; *[3]Immunology Unit, Biomedical Research Institute La Princesa Hospital (IIS-IP) Madrid, Spain, Madrid, Spain*; *[4]Rheumatology Unit, La Princesa Hospital, Madrid, Spain*; *[5]Department Biology, Complutense University Madrid, Madrid, Spain*; *[6]Department of Endocrinology, La Princesa Hospital, Madrid, Spain*

Purpose: Micro-RNAs (miRNAs) are non-coding molecules (19-25 nucleotides) that regulate gene expression at the post-transcriptional level. They are detectable in serum, plasma and urine and proposed as diagnostic/prognostic biomarkers of diseases. We have described that miR-19b, miR-26b, miR-19a and miR-143 expression in serum from patients with immune-mediated inflammatory diseases (IMIDs) can be diagnostic or severity biomarkers. However, serial serum measurement is an invasive technique, thus we aim to determine whether it is possible to detect these miRNAs in urine.
Methods: Urine from healthy donors (HD) and urine and serum from patients with IMIDs (early arthritis [EA] and spondyloarthritis [SPA]) were collected. For RNA extraction, 250µl of urine was centrifuged and the supernatant was processed with the miRNeasy-Micro kit (Qiagen), a mixture of the controls UniSp2, UniSp4 and UniSp5 and the carrier MS2. We tested 2µl, 4µl and 6µl of extracted purified RNA for retrotranscription that was performed with miRCURY-LNA RT kit and UniSp6 as control (Qiagen). To determinate the optimal concentration of cDNA different dilutions (1:20, 1:30 and 1:40) were used for quantification of miRNA by qPCR, being performed in triplicate with the miRCURY-LNA-SYBR-Green PCR kit and primers UniSp2, UniSp5, UniSp6, hsa-miR-19a-3p, hsa-miR-19b-3p, hsa-miR-26b-5p and hsa-miR-143-3p. The CT values were analysed with the Bio-Rad CFX and normalised according to $2^{\Delta CT}$. Differences between groups was performed by Mann-Whitney test.
Results: No differences in the efficiency of retrotranscription of UniSp controls were observed with different concentrations, so the 2µl RNA extract was chosen. The cDNA dilution factor does not affect UniSp expression values, however, the 1:20 dilution was chosen trying to compensate the lower RNA extract. miRNA expression was 25-50 times higher in serum versus urine. However, miRNA expression in urine from IMIDs patients was higher than in HD. The expression of miR-19b, miR-19a and miR-26b was higher in EA and miR-19a and miR-143 in SPA compared to HD ($p<0.05$).
Conclusion: The presence of miR-19b, miR-26b, miR-19a and miR-143 has been detected in urine, indicating that their study as biomarkers in IMIDs is possible. This offers the advantage of using a non-invasive sample type for the screening/monitoring of IMIDs.

Presence and Characterization of Circulating Endothelial Cells in Individuals-at-Risk and patients with Rheumatoid Arthritis

Brianne Barker[1;2], Mary Canavan[1], Dumitru Anton[1;2], Aoife O'Rourke[1], Carl Orr[3], Douglas Veale[2], Ursula Fearon[1;2]
[1]Trinity College Dublin, Dublin, Ireland; *[2]ERC, St. Vincent's University Hospital, Dublin, Ireland*; *[3]St. Vincent's University Hospital, Dublin, Ireland*

Purpose: Rheumatoid Arthritis (RA) is known to be associated with an increased risk of cardiovascular comorbidity which is characterized by endothelial dysfunction resulting in circulating endothelial cells (CECs) within the vasculature. Though previous literature has identified the presence of CECs in RA circulation, little is known regarding their phenotypic profile and role in RA pathogenesis. We aim to identify and characterize CECs in the circulation in healthy controls (HC), RA, and in 'individuals-at-risk' (IAR) of developing RA.
Methods: Blood was obtained from HC, IAR, and RA patients and multiparametric flow-cytometry analysis (23-color panel) was performed. RA patients were further stratified between ACPA+ vs ACPA. CECs were identified as CD45-PDPN-CD146-CD31+ and subsequent analysis of phenotypic markers was quantified by flow-cytometry.
Results: CECs had a significantly higher frequency in RA patients compared to HC ($p<0.05$) with a similar increase observed in IAR, with no difference demonstrated between ACPA+ vs ACPA-. Expression of adhesion and cell-growth markers ICAM-1,-CD34, and-YAP had a trending increase in RA compared to HC. IAR demonstrated significantly higher expression of ICAM-1 compared to HC ($p<0.01$). A stepwise increase in expression of CD34 and YAP was observed from HC>IAR>RA. Stratification of RA patients demonstrated significantly higher frequency/expression of YAP in ACPA+ vs ACPA- ($p<0.05$). Frequency/expression of immunoregulatory markers CD55,-HLA-DR,-and CD200R1 were all higher in RA compared to HC ($p<0.05$ for CD200R1). A stepwise increase in these markers was seen from HC>IAR>RA ($p<0.05$ for CD200R1). Stratification of RA patients demonstrated increased frequency of CD55 ($p<0.05$),-HLA-DR,-and CD200R1 ($p<0.05$) in ACPA+ compared to ACPA-. These phenotypic changes were paralleled by a shift in the metabolic-profile of the CECs where the frequency of a key metabolic mediator pAKT was demonstrated from HC>IAR>RA ($p<0.05$) with pAKT expression increased in ACPA+ vs ACPA- ($p=0.06$). Interestingly, a significant stepwise decrease was observed for PDGFRa expression from HC>IAR>RA ($p<0.01$), with PDGFRa expression also lower in ACPA+ vs ACPA-.
Conclusions: CECs could act as a potential biomarker in IAR and RA patients of disease onset and progression but may also have implications for greater risk of developing a cardiovascular comorbidity, further contributing to disease pathogenesis.

Deciphering the impact of epigenetic imprinting for T cell differentiation in humans using an induced pluripotent stem cell (iPSC)-based in vitro model

Marcel Finke[1], Christopher Kressler[1;2], Frederik Hamm[1], Anne Schulze[1], Ramonique Lim[1], Harald Stachelscheid[3], Julia K Polansky[1;2]
[1]BIH Center for Regenerative Therapies (BCRT) at Charité – Universitätsmedizin Berlin, Berlin, Germany; *[2]German Rheumatism Research Centre (DRFZ), Berlin, Germany*; *[3]BIH Core Unit pluripotent Stem Cells and Organoids at Charité - Universitätsmedizin Berlin, Berlin, Germany*

Human induced pluripotent stem cells (hiPSCs) can be generated from any somatic cell, yielding a defined monoclonal cell line with limitless expansion capacity and the ability to be differentiated into any given cell type, including T lymphocytes. However, differentiation efficiency varies greatly among different hiPSC lines and there is no consensus how hiPSC differentiation capabilities are affected by retained genetic and epigenetic "imprinting" from their cellular origin.
In our research, we have successfully reprogrammed human pro-inflammatory CD4+ and CD8+ T cells into stable hiPSC lines (T-hiPSCs) and established a differentiation protocol that mimics thymic T cell development via an hematopoietic stem cell (HSC) intermediate step up to the CD4+CD8+ double positive (DP) stage. Using this differentiation assay, we observed a distinct phenotype when T-hiPSCs were used as starting material compared to other stem cells, such as the early expression of TCR/CD3 and the absence of unwanted "innate-like" CD8αα cells. To investigate the cause of this seemingly superior T cell differentiation potential, we analyze the epigenome of several hiPSC lines as well as sorted intermediary populations from the differentiation model and compare these profiles to the ones generated from their *ex vivo* isolated counterparts (e.g. HSCs from umbilical cord blood, various precursor subsets from human thymus samples). As one important contributing factor, we identified a heterogeneity among generated hiPSC-HSCs with a subset of HSCs displaying enhanced T cell differentiation potential, which was accompanied by a distinct epigenetic imprinting on the DNA methylation level.
Taken together, we generated a large epigenetic dataset, which allows to assess the impact of epi-/genetic imprinting on human T cell development in an hiPSC-based in vitro model. These insights will not only improve our understanding of successful T cell generation in humans, but will also be instrumental to progress towards the hiPSC-derived manufacturing of clinical T cell products for adoptive cellular therapies.

Interleukin-17-induced granulopoesis alters neuroautoimmune susceptibility in a mouse model of multiple sclerosis

Katlynn Carter[1], Rebecca Jasser[1], Michaela Blanfeld[1], Tommy Regen[1], Ari Waisman[1]
[1]*Universitätsmedizin at the Johannes Gutenberg Universität, Mainz, Germany*

Despite a 20-year known importance of interleukin-17 (IL-17)-mediated immunity in multiple sclerosis (MS), the decisive pathogenic mechanism of this cytokine remains elusive and under debate. Previous data from our lab suggests a peripheral role of IL-17 early in the disease course. This project investigates the effects of peripherally-mediated autoimmune mechanisms by IL-17 in a mouse model of MS, experimental autoimmune encephalomyelitis (EAE), using multidimensional flow cytometry. In the earliest stages of disease, priming of pathogenic T cells remains unaffected in mice lacking IL-17 (IL-17$^{-/-}$). Additionally, pathogenic functionality is not lost as IL-17$^{-/-}$ T cells initiate disease in wild-type mice using an adoptive transfer model of EAE. Just before disease onset, EAE immunized IL-17$^{-/-}$ mice show an expanded CD4+ T cell compartment in the spleen with increased production of pathogenic cytokines GM-CSF and IFNγ. To investigate whether CD4+ T cells were lacking in their migratory capacity, Rag1$^{-/-}$ mice, which lack functional T and B cells, were reconstituted with IL-17$^{-/-}$ and control CD4+ T cells and susceptibility towards EAE was analyzed. Mice receiving both groups of T cells developed disease, indicating a redundancy of IL-17$^{-/-}$ signaling for T cell migration. Though the IL-17$^{-/-}$ CD4+ T cell compartment mimics EAE-susceptible controls, the myeloid compartment of the spleen and dural meninges is significantly changed in IL-17$^{-/-}$ mice. Monocytes, macrophages, and dendritic cells are increased in the IL-17-deficient environment. Additionally, a shift in neutrophils towards more immature, anti-inflammatory signatures occurs in the IL-17$^{-/-}$ meninges, whereas a more mature, resident neutrophil population is observed in the spleen. Stromal cells have previously been recognized as a potential target of IL-17 signaling in the recruitment of inflammatory myeloid cells. Upon tamoxifen-induced deletion of the IL-17-specific receptor (IL-17RA) on PDGFRb+ stromal cells, EAE incidence and severity is significantly reduced. This phenotype was not observed upon deletion of IL-17RA on a wide range of immune cell subsets. This data suggests that IL-17 signaling promotes the recruitment and maturation of myeloid cells, potentially through stromal signaling, which is significantly alters the susceptibility towards development of EAE.

Both NK92 cells stably transfected with CD16 and expanded primary NK cells exert potent antibody-dependent cytotoxicity against multiple myeloma cells in vitro and in vivo

Evelyn Galano-Frutos[1;2], David Giraldos[1;2], Chantal Reina-Ortiz[1;2], Laura Cambronero[1;2], Isabel Marzo[1;2], Javier Naval[1;2], Alberto Anel[1;2]
[1]*University of Zaragoza, Zaragoza, Spain*; [2]*IIS-Aragón, Zaragoza, Spain*

NK92 cells were stably transfected with CD16 allowing for the exertion of antibody dependent cell mediated cytotoxicity (ADCC), hereupon labeled NK92-CD16 cells. Alongside, we also optimized a protocol to activate and expand NK cells obtained from PBMC of healthy human donors, generating expanded NK cells (eNK) with high cytotoxic potential. We tested both these effector cells against a panel of multiple myeloma (MM) human cell lines, alone and in combination with the anti-CD38 mAbs daratumumab or isatuximab, approved for MM treatment. We demonstrated a potent cytotoxic activity on the majority of the cell lines, especially when effector cells were combined with the therapeutic antibodies. The increase in ADCC activity was dependent on the level of CD38 expression in each MM cell line. No difference between daratumumab or isatuximab was detected when using NK92-CD16 cells. In specific eNK cells, the effect of isatuximab was more pronounced so we will study CD16 polymorphisms in these donors. Finally, we performed an in vivo experiment using MM1.S cells transfected with luciferase xenotransplanted in immunodeficient NSG mice. Once MM began to develop, these mice were treated with NK92-CD16 cells in the presence or absence of daratumumab. MM development was significantly inhibited by the combination of NK92-CD16 cells with the therapeutic antibody. These results indicate that the combination of highly cytotoxic NK cells with anti-CD38 antibodies is a plausible therapeutic approach for MM treatment.

Tolerogenic dendritic cells manifest strong cellular respiration as evidenced by oxygen consumption and lactate production

Antonia Peter[1], Tamara Traitteur[1], Sara Tekavec[1], Mats van Delen[1], Amber Dams[1], Morgane Vermeulen[1], Hans de Reu[1], Nathalie Cools[1;2]
[1]Laboratory of Experimental Hematology, VAXINFECTIO, Faculty of Medicine and Health Sciences, University of Antwerp, Antwerp, Belgium; *[2]Center for Cell Therapy and Regenerative Medicine, Antwerp University Hospital, Antwerp, Belgium*

A promising treatment approach for autoimmune diseases is to re-induce tolerance using tolerogenic dendritic cells (tolDCs). While the potential of tolDCs to downmodulate pro-inflammatory pathogenic responses in multiple sclerosis (MS) has been recognized, little is known about their mode of action and optimal culture conditions: Since metabolic pathways have been assigned a crucial role in shaping immune responses, we hypothesize that the immunoregulatory effect of tolDCs can be shaped by adjusting the microenvironment during the culture process. In doing so, we aim to increase the conversion rate of monocytes into tolDCs and optimize the manufacturing procedure.
Human conventional DCs (convDCs) and tolDCs are generated from monocytes in the presence of IL-4 and GM-CSF and stimulated by adding the pro-inflammatory cytokines IL-1-beta, TNF-alpha, and PGE2. The tolerogenic phenotype of tolDCs is induced by 1,25(OH)2 vitamin D3 and confirmed by allo-MLR and flow cytometry. Next, we monitor metabolically relevant parameters, including oxygen (O2) consumption and lactate production, and assess the effect of different culture conditions such as O2 deprivation and daily media change on the cells' characteristics.
Our data show that tolDCs generated in the presence of 1,25(OH)2 vitamin D3 demonstrate reduced expression of the maturation markers CD80, CD83, and CD86 as compared to convDCs, and induce T-cell hyporesponsiveness in an allo-MLR. Additionally, tolDCs manifest significantly increased lactate production and O2 consumption as compared with convDCs. Furthermore, hypoxic culture conditions significantly decrease the viability and conversion rate of the cells, elicit reduced expression of identity markers (CD209, HLA-DR) and maturation markers (CD83, CD80, CD86), and upregulate migration markers (CCR5, CCR7). Functional assays revealed a significantly enhanced migration capacity of tolDCs under hypoxia. Moreover, daily removal of acidic metabolites affects the semi-mature phenotype of tolDCs, but not their tolerogenic function.
Our observations may provide further insights into how tolDCs contribute to tolerance induction by metabolomic reprogramming. Furthermore, these findings might offer a deeper understanding of tolDC fate after patient administration, where O2 levels do not exceed 5%. In summary, a better understanding of tolDC metabolism could lead to new ways of optimizing tolDC-based vaccines by increasing their potential to fight autoimmune diseases.

Coculture with human umbilical cord-derived mesenchymal stromal cells facilitates ex vivo expansion of human regulatory T cell subpopulations

Qifeng Ou[1], Shirley Hanley[1], Rachael Power[1], Sarah Hontz[1], Sarah Cormican[1], Stephen J. Elliman[2], Janusz Krawczyk[3], Neema Negi[1], Matthew D. Griffin[1]
[1]Regenerative Medicine Institute (REMEDI) at CÚRAM SFI Centre for Research in Medical Devices, School of Medicine, University of Galway, Galway, Ireland; [2]Orbsen Therapeutics Ltd, Galway, Ireland; [3]Department of Haematology, Galway University Hospitals, Saolta University Healthcare Group, Galway, Ireland

Purpose: Ex vivo-expanded regulatory T cells (Treg) are a promising immunomodulatory therapy but challenges exist in identifying and efficiently manufacturing highly potent Treg for specific applications. Mesenchymal stromal cell (MSCs) are known to promote Treg survival and proliferation. In this study, the influence of co-culture with clinical–grade human umbilical cord-derived MSCs (hUC-MSCs) on yield and phenotype of three distinct Treg subpopulations was investigated.

Methods and Results: FACS-purified, $CD4^{+}/CD25^{hi}/CD127^{lo}$ total human Treg from n=7 healthy donor blood samples were expanded in 96-well plates with anti-CD3/anti-CD28 beads, IL-2 and rapamycin for 14-21 days with and without hUC-MSCs. Treg yield was 4.3±2.0 greater for hUC-MSC-co-cultured (MSC)-Treg than for control (CTRL)-Treg ($p<0.01$) while phenotypic marker expression (Foxp3/Helios/CD39/ICOS/CTLA-4/HLA-DR) and T effector cell (Teff) suppressive potency were similar. The $\%HLA\text{-}DR^{+ve}$ of expanded Treg correlated with %suppression of Teff proliferation. Therefore, three primary Treg subpopulations were FACS-purified from n=4 healthy donor blood samples: Treg-I($CD45RA^{+}/HLA\text{-}DR^{-}$), Treg-II($CD45RA^{-}/HLA\text{-}DR^{+}$), Treg-III($CD45RA^{-}/HLA\text{-}DR^{-}$) and each was culture-expanded in the presence or absence of hUC-MSCs. Under CTRL conditions, expansion was achieved for Treg-I(197.1±198.7-fold) and T-reg-III(26.8±29.6-fold) but not for Treg-II(0.7±0.6-fold). hUC-MSC co-culture resulted in significantly higher fold-expansion of all Treg subpopulations compared to CTRL, but the magnitude of the enhancing effect was substantially greater for Treg-II and Treg-III than for Treg-I. hUC-MSC co-culture also resulted in higher $\%HLA\text{-}DR^{+}$ for all Treg subpopulations, and in higher $\%FoxP3^{+}$ and $\%Helios^{+}$ for Treg-III. All three culture-expanded Treg subpopulations demonstrated potent suppression of $CD4^{+}$ and $CD8^{+}$ Teff proliferation and expression of other functionally-relevant surface markers (CD39/ICOS/CTLA-4) which were not modified by hUC-MSC co-culture.

Conclusion: Co-culture with clinical-grade hUC-MSCs substantially enhances the yields and preserves the potency of human Treg subpopulations in ex-vivo expansion cultures with greatest effect on non-naïve ($CD45RA^{-}$) subpopulations. This can facilitate the identification, functional characterisation and production of Treg subpopulations with distinct therapeutic benefits.

The effect of adoptive cellular immunotherapy on solid tumors of a novel human JBT19 UPS sarcoma cell line

Kateřina Krausová[1;2], Pavla Táborská[2], Dmitry Stakheev[2], Pavol Lukáč[1], Lenka Rajsiglová[1], Luca Vannucci[1], Daniel Smrž[1;2]
[1]*Laboratory of Immunotherapy. Institute of Microbiology of Czech Academy of Sciences, Praha 4, Czech Republic*;
[2]*Department of Immunology, Second Faculty of Medicine, Charles University and University Hospital Motol, Praha 5, Czech Republic*

Purpose: Adoptive cellular immunotherapy (ACI) is a promising modality of cancer treatment. However, it often fails in the treatment of solid tumors, primarily due to the inability of immune cells to infiltrate the tumor and effectively eliminate tumor cells. One example of such tumors with low immune infiltration is undifferentiated pleomorphic sarcoma (UPS), which is challenging to treat. This cell line is particularly useful for studying ACI's efficacy because it expresses PD-L1 and collagen. These are ligands for immune checkpoint receptors, PD-1 and LAIR-1, respectively. We have previously described a novel patient-derived UPS cell line, JBT-19. Therefore, we aimed to determine the effect of ACI on solid tumors of a novel human JBT19 UPS cell line.

Methods: We used nu/nu mice with xenografted JBT19 tumors and treated them with *ex vivo*-generated lymphocytes, whose reactivity and cytotoxicity to JBT-19 tumor cells were evaluated by flow cytometry analysis. The ACI efficacy was then evaluated by tumor growth. In addition, we modified the JBT-19 cell line to express GFP protein. Because UPS are highly metastatic tumors, we used GFP-expressing JBT19 cells and confocal microscopy to monitor the metastatic spread.

Results: Firstly, we compared different ways of ACI application and found out that whereas direct i.t. application of *ex vivo*-generated JBT19-reactive and -*in vitro* cytotoxic lymphocytes did not affect tumor growth, their i.v. application delayed tumor growth. However, none of these applications were sufficient to eradicate tumors at the applied dose. Furthermore, we found that JBT19 cells metastasized to lymph nodes independently on the ACI therapy.

Conclusions: Although ex vivo-generated lymphocytes were reactive to JBT-19 tumor cells and effectively killed them *in vitro*, their ability to kill JBT-19 tumor cells *in vivo* was negligible. And despite immunotherapy, the tumor metastasizes to lymph nodes. In conclusion, treating UPS with ex vivo-generated lymphocytes is a promising approach to affect tumor growth. However, the efficacy of this approach still requires optimization and/or additional therapeutic interventions.

Funding: The research was supported by funding from the Ministry of Health, Czech Republic—project NU23-08–00071.

Tertiary lymphoid structure-related immune infiltrates in NSCLC tumor lesions correlate with low tumor-reactivity of TIL products

Suzanne Castenmiller[1;2], Nandhini Kanagasabesan[1;2], Aurelie Guislain[1], Benoit Nicolet[1], Marleen van Loenen[1], Kim Monkhorst[3], Alexander Veenhof[3], Egbert Smit[3], Koen Hartemink[3], John Haanen[3], Rosa de Groot[1], Monika Wolkers[1;2]

Adoptive transfer of tumor infiltrating lymphocytes (TIL therapy) has proven highly effective for treating solid cancers, including non-small cell lung cancer (NSCLC). However, not all patients benefit from this therapy for yet unknown reasons. Defining markers that correlate with high tumor-reactivity of the autologous TIL products is thus key for achieving better tailored immunotherapies. We questioned whether the composition of immune cell infiltrates correlated with the tumor-reactivity of expanded TIL products. Unbiased flow cytometry analysis of immune cell infiltrates of NSCLC tumor lesions was used for correlations with the T cell differentiation and activation status, and with the expansion rate and anti-tumor response of generated TIL products. The composition of tumor immune infiltrates was highly variable between patients. Spearman's Rank Correlation revealed that high B cell infiltration negatively correlated with the tumor-reactivity of the patient's expanded TIL products, as defined by cytokine production upon exposure to autologous tumor digest. In-depth analysis revealed that tumor lesions with high B cell infiltrates contained tertiary lymphoid structure (TLS)-related immune infiltrates, including $BCL6^+$ antibody-secreting B cells, IgD^+BCL6^+ B cells and $CXCR5^+BLC6^+$ $CD4^+$ T cells, and higher percentages of naïve $CD8^+$ T cells. In conclusion, the composition of immune cell infiltrates in NSCLC tumors associates with the functionality of the expanded TIL product. Our findings may thus help improve patient selection for TIL therapy.

Exploring the Impact of Immune Reconstitution on Clinical Outcomes Following Allogeneic Stem Cell Transplantation and CAR-T Cell Therapy

Hayley Foy-Stones[1], Christopher Armstrong[2], Christopher Larry Bacon[2], Nina Orfali[2], Derek G. Doherty[3], Anthony McElligott[3], Tor Hervig[4], Aoife Kilgallon[3], Nicola Gardiner[1]
[1]Cryobiology Laboratory Stem Cell Facility, St. James's Hospital, Dublin, Ireland, Dublin, Ireland; *[2]National Adult Stem Cell Transplant Programme, Department of Haematology, St. James's, Dublin, Ireland*; *[3]Trinity Translational Medicine Institute, Trinity College, Dublin, Ireland, Dublin, Ireland*; *[4]Irish Blood Transfusion Service, Dublin, Ireland, Dublin, Ireland*

Introduction/Background: Immune therapies such as allogeneic stem cell transplantation (allo-SCT) and chimeric antigen receptor T (CAR-T) cell therapy are proven treatments for patients whose blood cancers have not responded to chemotherapy. However, up to 50% of patients relapse. The recovery of the patient's immune system, particularly T-cells, significantly influences survival rates.

Materials and Methods: In this longitudinal study, we biobanked peripheral blood mononuclear cells from twenty patients undergoing allo-SCT and from ten patients who received CAR-T cell therapy. We utilised multicolour flow cytometry to analyse $CD4^+$ T-cells, $CD8^+$ T-cells, mucosal-associated invariant T (MAIT) cells, invariant natural killer T (iNKT) cells, $CD56^+$ T-cells, NK cells, monocytes, and subsets of γδ T-cells. In the CAR-T cell therapy cohort, we assessed circulating CD19 CAR-T cells and their exhaustion marker phenotype. Statistical analysis was conducted using R Studio (V4.2.3) and GraphPad (V10.2.0).

Results: Preliminary findings in the allo-SCT group linked slower T-cell recovery and poor outcomes, particularly $CD56^+$ T-cells, known for their potent anti-tumour activities. In the CAR-T cell therapy group, patients achieving a complete response (CR) showed higher numbers of CAR-T cells compared to those with persistent disease (PD). Conversely, the persistent disease (PD) group exhibited higher levels of T-cell exhaustion markers.

Conclusion: Our preliminary findings suggest that tracking immune profiles following allogeneic stem cell transplant could serve as valuable predictors of clinical outcomes. In the CAR-T cell therapy cohort, we observed a potential correlation between sustained CD19 CAR-T cell persistence and favourable outcomes, while the presence of exhaustion markers may signify poor clinical prognoses.

Genome

Conor Lawlor[1], Michael Freeley[1], Monika Ziminska[2], Emma Carroll[2], Jordan Wilson[2], Helen McCarthy[3]
[1]School of Biotechnology, Dublin City University (DCU), Dublin, Ireland; *[2]pHion Therapeutics, Belfast, United Kingdom*; *[3]School of Pharmacy, Queen's University, Belfast, Belfast, United Kingdom*

Chimeric antigen receptor (CAR) T-cell therapy has revolutionised the treatment of leukaemia and lymphoma, but the requirement for viral vectors to deliver the gene encoding the CAR into T-cells results in complex manufacturing procedures, is costly, and raises safety issues due to the risk of insertional mutagenesis. Non-viral delivery methods are therefore being actively explored but need to overcome the challenging nature of T-cells as being *hard-to-transfect* due to numerous biological barriers that limit transgene delivery and expression. The cell-penetrating peptide (CPP) RALA is an amphipathic peptide comprising 30 amino acids that delivers nucleic acids including plasmid DNA (pDNA), mRNA or siRNA into mammalian cells. The positive charge associated with RALA promotes condensation with negatively charged nucleic acids into self-assembling nanoparticles of <200nm that facilitate delivery into cells *via* an endosomal-based mechanism. This project is exploring whether RALA can deliver nucleic acids, such as CAR-encoding genes, into human T-cells and has shown that RALA can deliver both pDNA and mRNA encoding eGFP into the Jurkat leukaemic T-cell line with similar transfection efficiencies (TEs)of approximately 15-30%. Further studies have optimised transfection and culture conditions to increase TEs and cell viabilities. Interestingly, this work also demonstrated 3.53-fold differences in RALA-mediated transgene expression between independent stocks of Jurkat T-cells sourced from the same supplier but cultured in different labs, which provides a novel opportunity to identify and characterise the biological barriers that limit transgene delivery and expression in this cell type. Proteomic analysis of each Jurkat T-cell stock has highlighted notable differences in expression of proteins that influence endosomal trafficking and nuclear import, which suggests that they may limit transgene delivery and expression. Several of these proteins are being characterised in further studies. It is hypothesised that manipulating human T-cells to surmount inherent biological barriers may increase the efficiency of non-viral delivery of nucleic acids, including CAR genes, into human T-cells for clinical purposes.

Background: Human cytomegalovirus (CMV) disease remains a major challenge in hematopoietic stem cell transplant recipients (HSCTR) and solid organ transplant recipients (SOTR), associated with recurrence (15-30%) and antiviral drug resistance (5%). Given the limited efficacy of available antiviral drugs, there is a growing interest in developing anti-CMV adoptive cell therapies. Both αβ and Vδ2^{neg} γδ T cells are key effectors of the anti-CMV immune response. Taking into account the limitations of αβ T cell therapies in CMV-seropositive HSCTR receiving a graft from a CMV-seronegative donor (D-R+ HSCTR), and in D+R- SOTR, our goal was to explore a complementary Vδ2^{neg} γδ T cell-based immunotherapy.

Results: Using a clinical-grade protocol, we obtained a robust Vδ2^{neg} γδ T cell (DOT cells) amplification *in-vitro*, from both CMV-seropositive and CMV-seronegative healthy donors. Regardless of CMV serostatus, amplified γδ T cells displayed an activated central memory phenotype, low exhaustion markers, and an overt cytotoxic phenotype. In response to CMV-infected cells, amplified DOT cells degranulated and secreted IFNγ, and altogether controlled viral dissemination *in-vitro*. At the mechanistic level, CMV-induced reactivity was observed independently of the γδTCR, but required the co-stimulatory receptor LFA-1. To evaluate *in-vivo* efficacy, we further derived a mouse γδ T cell expansion protocol from the human protocol, recapitulating the phenotypic features of amplified human γδ T cells. Adoptive transfer of amplified mouse γδ T cells was protective against mouse CMV infection. Finally, CMV-reactive γδ T cells could also be amplified from kidney transplant recipients undergoing a refractory CMV infection, paving the way for an autologous adoptive cell therapy. Amplified γδ T cell maintained their viability and functionality in the presence of immunosuppressive drugs currently used in SOTR such as tacrolimus, ciclosporin, or everolimus.

Perspectives: Altogether, these data provide a proof-of-concept for a future clinical trial of amplified γδ T cells in refractory or resistant CMV disease in SOTR.

Generating metabolically superior T cells as a novel immunotherapy to treat solid tumors.

Michael Berger[1], Yarden Engel[1], Amijai Saragovi[1], Zahala Baron[1], Dinorah Friedmann-Morvinski[2], Alina Brosque[2]
[1]Lautenberg center for Immunology and Cancer Research, The Hebrew University, Israel, Jerusalem, Israel; *[2]The George S. Wise Faculty of Life Sciences, Tel Aviv University, Israel, Tel Aviv, Israel*

Harnessing the natural ability of T cells to target and eliminate cancer, adoptive T cell transfer therapy (ACT) has shown promise in inducing clinical responses in a subset of patients. However, the effectiveness is notably hindered when tackling solid tumors, mainly due to the challenging tumor microenvironment (TME). This environment is characterized by a reduction in nutrients, particularly glucose, which limits the availability for T cell function.

Therefore, our objective was to address the metabolic competition within the TME by engineering "metabolically superior T cells" (MSTCs). These MSTCs are modified cytotoxic T lymphocytes capable of utilizing trehalose as a carbon source instead of glucose. Trehalose, a disaccharide utilized by insect cells but not naturally metabolized by human cells, offers an alternative energy substrate. By introducing genes encoding the trehalose transporter (Tret1) and the trehalose-hydrolyzing enzyme (Trehalase-Treh1) from Drosophila melanogaster into T cells, we initiated a new metabolic process. MSTCs thus gain uncompetitive carbon and potentially improve the efficacy of ACT therapy against solid tumors.

We successfully cloned Treh1 and Tret1 genes into a retroviral vector and transduced them into human primary CD8+ T cells. Trehalose metabolic tracing analysis confirmed that MSTCs can utilize trehalose and integrate trehalose-derived carbons into the exact same metabolic pathways as glucose. Furthermore, in glucose-deprived conditions supplemented with trehalose, MSTCs exhibited enhanced survival, proliferation, and cytokine secretion, indicative of sustained effector functions crucial for antitumor immunity. Preliminary in vivo findings reveal a significant improved efficacy in CAR-T cell therapy against glioblastoma, underscoring the potency of this technology.

These promising results suggest that MSTCs engineered to utilize trehalose offering new avenues for enhanced cancer therapy.

Exploring DARPins to detect MHC class I restricted antigen presentation

Sandra Schmid[1], Fabienne Läderach[1], Obinna Chijioke[1], Birgit Dreier[2], Andreas Plückthun[2], Christian Münz[1]
[1]Experimental Immunology - University of Zurich, Zürich, Switzerland; [2]Department of Biochemistry, University of Zurich, Zürich, Switzerland

The global prevalence of Epstein-Barr virus (EBV) exceeds 90%, with significant implications for public health given its association with various malignancies including infectious mononucleosis, contributing to approximately 1.8% of cancer-related deaths. Despite its discovery over 60 years ago, critical knowledge gaps persist regarding the cellular components initiating immune responses against EBV, essential for vaccine and treatment development.

Current methods for detecting EBV epitopes primarily rely on indirect approaches, such as T cell clones, which are laborious, time-consuming, and dependent on epitope immunogenicity. Although investigations into direct detection methods utilizing immunoglobulins like T cell receptor (TCR)-like antibodies are underway, achieving sufficient target specificity remains a challenge.

In this study, we propose employing designed ankyrin repeat proteins (DARPins), engineered proteins with target-specific binding capabilities, as an alternative to immunoglobulins for detecting specific EBV peptides presented on HLA-B35.

As proof-of-concept, we target intracellular EBV antigens via the MHC-complex using DARPins, circumventing the TCR and thus bypassing reliance on the TCR repertoire. We characterize the peptide specificity of selected DARPins through alanine scanning. Compared with T cells reacting to the same peptide, these DARPins display different binding angles. Furthermore, we enhance the epitope binding capacity in a physiologically relevant setting by associating these DARPins with cell membranes using chimeric antigen-like receptors (CARs). Ultimately, we assess the avidity and killing capacity of DARPin-CARs relative to T cell receptors.

In conclusion, we aim to establish DARPin technology as a novel approach for specific detection, diagnosis, and elimination of EBV-infected cells. In addition, our study offers novel insights into T cell and antigen-presenting cell interactions, furthering understanding of immune responses to EBV.

Background and Objectives: Ca-10 is a carbohydrate antigen expressed on the murine Ehrlich tumor and recognized by the monoclonal antibody A10, which exhibits reactivity against various human solid tumors. Our prior research demonstrated that mice vaccinated with Ca10 generated specific antibodies to this antigen, leading to growth inhibition of transplanted tumors. In this study, we describe the antigen Ca10 as a feasible target for CAR-T cell immunotherapy against solid tumors.
Methods: The CAR was engineered based on the A10 antibody sequence. The single-chain variable fragment (ScFv) chain was inserted into the pcDNA3.1 plasmid and synthesized in a soluble form using transfected HEK 293T cells. This was done to verify its proper expression and antigen recognition ability, assessed through ELISA and flow cytometry. Jurkat cells and primary CD3+ cells from healthy blood donors were then genetically modified with a second-generation Ca10ScFvCAR construct (Ca10-CAR) via lentiviral transduction. Subsequently, their capability to identify Ca10+ cells was assessed *in vitro*.
Results: The soluble ScFv fragment exhibited precise recognition of the target antigen, both when in a soluble state and when expressed on the surface of Ca10+ tumor cells. Jurkat cells were effectively transduced with the Ca10-CAR construct and demonstrated selective activation when co-cultured with Ca10+ cells, as evidenced by PLCγ phosphorylation and CD69 expression. In human primary T cells, a CAR transduction efficiency of up to 60% was obtained. When co-cultured with Ca10+ cells, Ca10-CAR expressing T cells exhibited specific IFN-γ production and efficiently lysed target cells.
Conclusion: Our results suggest that the antigen Ca10 may be a specific and effective target for the treatment of solid tumors by CAR-T cells.

Cytotoxicity of Vδ1 γδ T Cells Isolated from Healthy Donor PBMCs against Colorectal Cancer Cells.

Amy Walsh[1;2], Anthonia Ekperuoh[1;2], Rosemary O'Connor[3], Henry Paul Redmond[1;2], Cathriona Foley[1;2]
[1]Department of Surgery, School of Medicine, College of Medicine and Health, University College Cork, Cork, Ireland; *[2]Department of Surgery, Cork University Hospital, Cork, Ireland*; *[3]School of Biochemistry and Cell Biology, Biosciences Institute, University College Cork, Cork, Ireland*

Purpose: γδ T-cells are associated with favourable patient prognosis in several cancer types and promising cytotoxic lymphocytes for next-generation cancer immunotherapies. γδ T-cells are MHC unrestricted, excellent for allogeneic adoptive cell therapy, and targets of immune checkpoint blockade in MHC-I deficient tumours. Clinical-grade protocols have been developed to selectively expand Vδ1 γδ T-cells *in vitro*. PBMCs, a source of Vδ1 T-cells, provide ease of access and large numbers of cells. This work aimed to expand γδ T-cells from PBMCs and assess cytotoxic tumour killing towards colorectal cancer (CRC) cell lines.
Methods: γδ T-cells from PBMCs were expanded from eight healthy donors. αβ T-cell depletion was followed by anti-CD3 selection. Isolated cells were cultured with IL-15, anti-CD2, and anti-CD3 for 21±1 days, to drive preferential Vδ1 T-cell proliferation. Cells were phenotyped by flow cytometry and donors with >0.5% αβ T-cells at day 21 excluded. Tumour killing assays with expanded immune cells (n=5) and CRC cell lines (HT-29) were undertaken (Effector:Target (E:T) ratios 0:1, 5:1, 10:1, and 20:1). Immune cell products were grouped based on high (n=3) and low (n=2) Vδ1 T-cell proportions at day 21 and high (n=2) and low (n=3) cell number fold increases in total Vδ1 T-cells between days 0 and 21. Tumour cell cytotoxicity between groups was compared.
Results: Expanded cells from seven donors increased from $1x10^6$ to $5x10^6$ cells, of these Vδ1 T-cells increased from 7% to 32%, Vδ2 T-cells decreased from 23% to 10% and αβ T-cells remained <0.5% by day 21. There was more HT-29 cytotoxicity at an ET ratio of 5:1 (25%), 10:1 (33%) and significantly more at 20:1 (38%, p=0.03) compared to control (0%). There were no significant differences in cytotoxicity between groups with high and low proportions and cell number fold changes in Vδ1 T-cells.
Conclusion: γδ T-cells from PBMCs of healthy blood donors that were treated to preferentially expand Vδ1 T-cells demonstrated anti-tumour cytotoxicity. This was not dependent on the proportions of Vδ1 T-cells present or the extent of Vδ1 T-cells expansion of cell number fold change over time.

Regulatory T cells (Tregs) harbor an enormous therapeutic potential as their immuno-suppressive function may counteract overshooting immune responses in an antigen-specific manner. Adoptive transfer of Tregs is emerging as a promising therapeutic intervention to restore immune tolerance in situations of unwanted immune reactions such as autoimmune diseases, organ transplant rejection or graft-versus-host disease. To this end, patient-derived, *in vitro* expanded Tregs have been successfully tested in clinical trials. However, low Treg numbers in peripheral blood, limited expandability, lack of antigen-specific expansion protocols and loss of Treg lineage stability hamper their wide-spread application. Therefore, alternative cellular sources for immune-suppressive Tregs are of great interest.
The demethylated state of the Treg-specific demethylated region (TSDR) in the *FOXP3* gene is a key epigenetic switch to assure sustained expression of the Treg master transcription factor FOXP3. Our group has shown that activation of the TSDR by CRISPR-dCas9-based epigenetic editing induced physiological FOXP3 protein expression levels in human naïve and memory CD4+ T cells. However, this was not sufficient to convey a Treg phenotype. Here, we show that improved epigenetic editing using *in vitro* transcribed mRNA is highly efficient and that after prolonged culture, edited conventional T cells upregulate specific Treg markers and downregulate production of pro-inflammatory cytokines. Importantly, this is also the case in pro-inflammatory memory T cells, which were far believed to be resistant to FOXP3 induction and phenotype switching.
We here suggest mRNA-based epigenetic editing as a new viable tool for the targeted modification of T cell phenotypes, which might be also be exploited for clinical applications in the future.

In vitro targeting of non-hematological tumour cells by immortalized NK cells engineered with a CD6-based chimeric antigen receptor

Lucía Aragón-Serrano[1], Laura Carrillo-Serradell[1], Violeta Planells-Romeo[1], Cristina Català[1], Michael O'Dwyer[2], María Velasco-de Andrés[1], Francisco Lozano[1;3;4]
[1]Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain; *[2]University of Galway, Galway, Ireland*; *[3]Servei d'Immunologia, Centre de Diagnòstic Biomèdic, Hospital Clínic de Barcelona, Barcelona, Spain*; *[4]Departament de Biomedicina, Facultat de Medicina, Universitat de Barcelona, Barcelona, Spain*

Adoptive transfer of T cells engineered with chimeric antigen receptors (CARs) have shown good efficacy against haematological malignancies, but further developments and optimisations are still needed in the case of solid tumours. One challenge is the finding of the most suitable target, as tumour-specific antigens (TSA) may vary between patients and tumour-associated antigens (TAA) may lead to on-target off-tumour toxicities. CD6 is a lymphocyte receptor expressed by all T cells, and some B and NK cell subsets, whose reported ligands (CD166/ALCAM, CD318/CDCP-1) are overexpressed on malignant cells. Thus, we designed a CD6-CAR encompassing the whole extracellular region of CD6 and the cytoplasmic activation motifs of CD3zeta and CD137/41BB to target CD166-positive and/or CD318-positive tumour cells. In order to avoid some constraints imposed by autologous CAR-T cells (e.g., development of cytokine-release syndrome and immune-effector-cell-associated neurotoxicity syndrome), we explored the alternative use of allogeneic NK cells, which present milder toxicities. To that end, NK cell leukemia KHYG-1 cells were lentivirally transduced and selected for stable CD6-CAR expression. Co-culture assays with double CD166- and CD318-positive cells of ovary carcinoma (SKOV-3) or colon adenocarcinoma (DLD-1) origin showed superior cytotoxic effects for CD6-CAR KHYG-1 cells compared to untransduced (UT) KHYG-1 cells. The analysis of co-culture supernatants also showed higher secretion levels of INF-γ, CCL-4/MIP-1β and granzyme B for CD6-CAR KHYG-1 cells compared to UT ones. By contrast, when performing similar co-cultures with cells of lymphoblastoid (Raji, Daudi) and erythromyeloid (K562) origins, similar cytotoxicity levels were observed for both UT and CD6-CAR KHYG-1 cells. Interestingly, such leukemic cells differ from DLD-1 and SKOV-3 ones in that they show low/negative CD166 and CD318 expression levels as supported by transcriptomic data from the Human Protein Atlas platform. In conclusion, the results support the notion that CD6-CAR KHYG-1 cells will specifically target tumour cells expressing high CD166 and/or CD318 surface levels, which would represent a safety advantage when performing in vivo studies. Accordingly, preliminary cell transfer assays to immunodeficient NSG mice shows no toxic effects upon i.v. infusion with increasing amounts (1, 5 and 10 x10E6) of CD6-CAR KHYG-1 cells. Eosinophil counts in anti-CD19 CAR-T cell therapy. Could they predict efficacy and prognosis?

Cristina Arnaldos Pérez[1], Marta Español-Rego[1;2], Valentín Ortiz-Maldonado[2;3], Núria Martínez Cibrián[3], Susana Rives[4;5;6], Anna Alonso Saladrigues[4], Sergio Navarro Velázquez[1;2], Leticia Alserawan[1], Libertad Heredia[1], Daniel Jiménez[1], Catherina De Guzman[1], Mercedes Montoro Lorite[3], Álvaro Urbano Ispizua[2;3;7], Julio Delgado[2;3;7], Mariona Pascal[1;2], Manel Juan Otero[1;2;7], E. Azucena González Navarro[1;2]
[1]Department of Immunology, Centre Diagnòstic Biomèdic, Hospital Clínic, Barcelona, Spain; *[2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain*; *[3]Department of Haematology, Hospital Clínic, Barcelona, Spain*; *[4]Leukemia and Lymphoma Department, Pediatric Cancer Center Barcelona (PCCB), Hospital Sant Joan de Déu, Barcelona, Spain*; *[5]Institut de Recerca Sant Joan de Déu, Barcelona, Spain*; *[6]Instituto de Salud Carlos III, Centro de Investigación Biomédica en Red De Enfermedades Raras (CIBERER), Madrid, Spain*; *[7]University of Barcelona, Barcelona, Spain*

Purpose: Anti-CD19 CAR-T cell therapies have achieved complete response rates over 90% in B-cell acute lymphoblastic leukemia (B-ALL). However, one-third of these patients with an initial response, relapse within six months. Several studies have looked for a biomarker that can predict the efficacy of this therapy. Patients with non-Hodgkin lymphoma (NHL) with higher eosinophil counts before or after CAR-T cell infusion have shown better outcomes. However, its significance in B-ALL remains unknown. The aim of this study was to determine whether these findings were reproducible in our clinical trial cohort and to study their significance in ALL patients.
Methods: Thirty six patients in our phase I clinical trial (CART19-BE-01 NCT03144583) who received our own designed anti-CD19 academic CAR-T cell therapy (ARI-0001, varnimcabtagene autoleucel) were included (27 with B-ALL, 7 with NHL and 2 with chronic lymphocytic leukemia). All of them were resistant or refractory to treatment and had a prognosis of less than 2 years. We obtained clinical data of survival and determined eosinophil counts at baseline and one, two and three months after infusion.
Results: In our overall cohort, patients with eosinophil counts higher than the median (13/34) showed improved event-free survival (617.5 vs 349.5 days, p=0.03) and overall survival (783.8 vs 524.7 days, p=0.03). B-ALL patients event-free survival was higher in the group with basal eosinophil counts over the median (6/27) (694.5 vs 329.7 days, p=0.02). However, no differences in survival were observed between the NHL patients.
Conclusion: Eosinophil count could be a survival and prognostic biomarker in patients treated with anti-CD19 CAR-T cell therapy. However, further studies with larger cohorts are required.

Study on the effect of corticosteroids on lung development with the SSEA1+ stem/progenitor cells derived lung organoid model

Yan-Ru Cho[1], Bor-Luen Chiang[2]
[1]Graduate Institute of Immunology, College of Medicine, National Taiwan University, Taipei, Taiwan; *[2]Genome and Systems Biology Degree Program, College of Life Science, National Taiwan University, Taipei, Taiwan*

Purpose: The immaturity of the lung is a leading cause of mortality in preterm infants with severe pulmonary complications, such as respiratory distress syndrome (RDS). Antenatal corticosteroids are widely used as a treatment for women at risk of preterm delivery. However, there is only limited evidence showing the detailed mechanisms of antenatal corticosteroids on fetal lung maturation, and the impact of corticosteroids on lung stem cells has not been clarified. Thus, our study aimed to investigate the influence and mechanism of corticosteroids on lung organoid model generated from pulmonary-derived SSEA-1$^+$ stem/progenitor cells, hoping to explore the effect and mechanisms of antenatal corticosteroids on fetal lung development.

Methods: To explore the effects of corticosteroids in fetal lung development, the pulmonary SSEA1$^+$ stem cells were isolated from neonatal mice and embedded in 50% Matrigel. SSEA1$^+$ cells were cultured for 14 days to generate the lung organoids, providing sustained dexamethasone stimulation throughout the process. The effect of steroids on epithelium development was evaluated by qRT-PCR, immunofluorescence, ELISA, and western blot.

Results: The sustained stimulation with dexamethasone did not affect organoid generation but resulted in a slight increase in organoid irregularity. We found that the gene expression of type 1 and type 2 alveolar cell markers increased under the conditions of 100 nM and 1000 nM dexamethasone treatment. In contrast, dexamethasone reduced the expression of *MUC5AC*, the goblet cell marker. However, the expression of basal, club, and ciliated cell markers showed no significant difference between control and dexamethasone stimulation. We will also further clarify the molecular mechanisms involved.

Conclusion: These results demonstrated that corticosteroids promote the differentiation of SSEA1$^+$ stem cells into alveolar-like lung organoids, indicating the beneficial impact of corticosteroids on pulmonary maturation. Consistent with the well-known function of corticosteroids in anti-inflammation, our data also suggested the decrease of mucin production in lung organoids. Despite our initial understanding of corticosteroids in lung development, further researches are required to clarify the long-term and potential side effects of corticosteroids on fetal lung development and health.

Galectin-1-deficient Foxp3+ regulatory T cells show limited long-term protection in experimental inflammatory bowel disease

Raquel Fernández-Pérez[1], Rebeca Sánchez-Domínguez[1], Omaira Alberquilla[1], Miguel A. Martín[1], Juan Antonio Bueren[1], Marina Garin[1]
[1]*CIEMAT / IIS Fundación Jiménez Díaz / CIBER-ER, Madrid, Spain*

Cell therapy with regulatory T cells (Tregs) have been proposed in recent years thanks to their potential to maintain immune homeostasis and its capacity to control unwanted immune responses. Galectin-1 is a β-galactoside-binding protein lectin that exhibits broad anti-inflammatory and pro-resolving activities by targeting different subsets of immune cells. Our previous studies showed that galectin-1 is expressed by regulatory T cells and contributes to their immunosuppressive function. The aim of this study was to investigate the role that galectin-1 plays in the function Treg cells *in vivo*. Remarkably, while basal Treg cell properties and *in vitro* suppression capacity were similar, mice lacking galectin-1 showed enhanced inflammatory responses to DSS treatment compared to galectin-1 sufficient mice although the Tregs/T effector balance was increased in colitic *Lgals1*$^{-/-}$ mice. Additionally, cell therapy studies with Treg cells were conducted using an experimental model of chronic colitis induced by transfer of naïve CD4^{+} T cells in immunodeficient *Rag1*$^{-/-}$ mice. Our results demonstrate that galectin-1 is an effector molecule actively involved in the modulation of intestinal inflammatory responses mediated by effector T cells. Galectin-1 expression stabilizes the immunomodulatory phenotype of the Treg cells, as well as their persistence *in vivo* under inflammatory conditions thus improving the long-term efficacy of cell therapy with Treg cells. Taken together, these findings reveal that galectin-1 is critical for Foxp3^{+} Treg cell function and suggest that the endogenous expression of galectin-1 is required to prevent Treg cell plasticity toward a Th1-like Treg cell phenotype in experimental colitis. These evidences highlight that the expression of galectin-1 should be carefully evaluated in future cell therapy protocols with Treg cells in order to achieve efficient and stable long-term immunosuppression in patients with inflammatory bowel diseases.

Antibacterial activity of KHYG-1 cells stably expressing a lymphoid scavenger-like receptor-based chimeric antigen receptor

Violeta Planells-Romeo[1], Laura Carrillo-Serradell[1], Lucía Aragón-Serrano[1], Cristina Català[1], Michael O'Dwyer[2], María Velasco-de Andrés[1], Francisco Lozano[1;3;4]
[1]Instituto de Investigaciones Biomédicas August Pi i Sunyer (IDIBAPS), Barcelona, Spain; *[2]University of Galway, Galway, Ireland*; *[3]Servei d'Immunologia, Centre de Diagnòstic Biomèdic, Hospital Clínic de Barcelona, Barcelona, Spain*; *[4]Departament de Biomedicina, Facultat de Medicina, Universitat de Barcelona, Barcelona, Spain*

Bacterial infections can lead to severe life-threatening situations (septic shock) mainly as a result of immune-debilitating disorders (e.g. diabetes mellitus, cancer, AIDS), aggressive medical/surgical interventions (e.g., organ transplantation, prosthesis replacements, immunosuppressive drugs), emergence of antimicrobial resistant (AMR) strains, and shortage of new antibiotics in the pipeline of the pharma industry. In this context, there is an urgent need of new strategies for treating severe bacterial infections regardless of their AMR status. Adoptive transfer of either normal or engineered immune cells offers the possibility of potentiating the immune response against infectious diseases. To this end, we have taken advantage of the broad-spectrum microbicidal activity of natural killer (NK) cells and the broad-bacterial recognition properties of CD6 -a lymphoid scavenger-like receptor - to generate NK cells expressing a CD6-based chimeric antigen receptor (CD6CAR). Such CD6CAR encompasses the whole extracellular region of CD6, the transmembrane region of CD8α and the cytoplasmic activation motifs of 4-1BB/CD137 and CD3ζ. Lentiviral particles coding for the CD6-CAR were used to transduce KHYG-1 cells (an immortalised leukemic NK cell line), which were further selected for stable and high CD6-CAR expression by cell sorting. Co-culture assays of CD6CAR$^+$ KHYG-1 cells with Gram-positive (*Staphylococcus aureus and Listeria monocytogenes*) and Gram-negative (*Escherichia coli, Klebsiella pneumoniae, Acinetobacter baumanii and Pseudomonas aeruginosa*) bacterial strains for 2h demonstrated a superior cytotoxic activity with regard to untransduced (UT) KHYG-1 cells, as evidenced by reduced bacterial colony counts and bacterial metabolic activity (XTT assays). These results constitute the first evidence on the prospect of developing an adoptive CD6CAR NK cell transfer immunotherapy against bacterial infection and warrants further *in vitro* and *in vivo* assays to better characterize its efficacy and safety. Accordingly, preliminary cell transfer assays to immunodeficient NSG mice show no toxic effects upon i.v. infusion with increasing amounts (1, 5 and 10 x10E6) of CD6-CAR KHYG-1 cells.

Search and find: Regulatory T cells

Katja Leben Zupet[1], Kristina Manzoni[2], Jon Žnidarčič[3], Karen Butina Ogorelec[4], Andrea Šarac[3], Maša Čater[3], Simon Horvat[3], Anže Smole[1], Jelka Pohar[1]
[1]National Institute of Biology, Ljubljana, Slovenia; *[2]Faculty of Biotechnology and Drug Development, University of Rijeka, Rijeka, Croatia*; *[3]Biotechnical Faculty, University of Ljubljana, Ljubljana, Slovenia*; *[4]InnoRenew CoE, Wood , Izola, Slovenia*

Background and purpose of the study: Cellular immunotherapy with modified regulatory T cells (Tregs) represents a step towards an alternative therapeutic option for patients with autoimmune diseases that restores immune homeostasis and induces regeneration of damaged tissue. Tregs are a rare subset of CD4+ T cells with CD4+ CD25+ FoxP3+ phenotype. Optimization of the isolation and activation of Tregs for therapeutic purposes is required, especially in relevant animal models. Our work addresses the optimization of activation, expansion and phenotypic purity of ex-vivo Tregs.

Methods: Mouse spleens and lymph nodes were harvested from C57BL/6 mice. The Treg population was enriched from the total cells by magnetic separation. The cells were activated and expanded in diverse conditions and monitored. Cell expansion and immunophenotype were evaluated.
Results: The aim of this work was to determine the conditions that lead to a high number of viable cells, a high frequency of Treg cells and the most pronounced FoxP3+ CD25+ Treg phenotype.
Cell expansion peaked between day 4 and 8 and flow cytometry indicated successful Treg enrichment. The efficiency of Treg enrichment varied between conditions.

Conclusions: We have successfully established isolation and expansion protocols for murine CD25+ Foxp3+ regulatory T cells and comprehensive flow cytometry staining panels. During the expansion protocol, the proportion of Treg cells decreases while the proportion of contaminants increases. By comparing different cultivation conditions, we were able to find the condition that yields the highest percentage of Treg cells.

Novel A20 based therapeutic strategies to fight lung cancer

Monika Homolya[1], Max Schwab[1], Michael Machtinger[1], Emilio Casanova[1;2], Herwig Moll[1;2]
[1]*Medical University of Vienna, Vienna, Austria*; [2]*Comprehensive Cancer Center, Vienna, Austria*

Background: Lung cancer remains the leading cause of cancer-related mortality globally. Despite immune checkpoint blockade therapy emerging as the primary treatment for lung adenocarcinomas harboring non-targetable oncogenic KRAS mutations, patients still have poor prognosis. This underscores the urgency to enhance immunotherapy-based treatment approaches. Recently, we identified that the systemic downregulation of the anti-inflammatory protein A20, induces a tumor-suppressive microenvironment in mouse models of lung cancer. This identifies A20 as a promising target for immune modulation to improve the effectiveness of immune-based therapies.
Methods: Using mouse models of KRAS-driven lung tumorigenesis, we evaluated the response of the tumor immune microenvironment in response to partial systemic A20 downregulation. In vitro analyses of A20 heterozygous and wild type CD8+ T cells were carried out using flow cytometry and RT-qPCR. In vivo evaluations included survival assays, histological examinations, flow cytometry, and measurement of tumor size.
Results: Our findings revealed that systemic reduction in expression of the immune-modulatory enzyme A20, observed in A20 heterozygous mice, induced modifications in the tumor microenvironment. This led to the formation of an anti-tumorigenic milieu, promoting increased infiltration of $CD4^+$ and $CD8^+$ T lymphocytes, as well as antigen presenting cells. In our *in vitro* studies, we observed that decreased A20 expression in $CD8^+$ T cells enhanced their proliferation capacity and demonstrated greater anti-tumor activity in killing assays compared to wild-type $CD8^+$ T cells. Furthermore adoptive transfer of antigen-specific $CD8^+$ T cells resulted in a more significant reduction in tumor cell growth in A20 heterozygous recipients compared to wild-type recipients. This improved efficacy of T cell transfer can be attributed to the potent anti-tumorigenic microenvironment present in the A20 heterozygous mice.
Conclusion: Our preliminary results demonstrated that systemic downregulation of the anti-inflammatory protein A20 in immune cells of the stroma, enhances the anti-tumor capability of $CD8^+$ T cells and impedes tumor growth in mice. Additional experiments are required to investigate whether A20 heterozygosity in other immune cells boosts their anti-tumor potential. Additionally, we aim to investigate whether a combination therapy involving controlled A20 downregulation in immune cells alongside immune checkpoint blockade effectively limits tumor growth in KRAS-driven lung adenocarcinoma.

Quantitative transcriptome analysis of purified equine mast cells identifies a dominant mucosal mast cell population

Srinivas Akula[1;2], Miia Riihimaki[2], Ida Waern[2], Magnus Abrink[2], Amanda Raine[1], Lars Hellman[2], Sara Wernersson[2]
[1]*Uppsala University, Uppsala, Sweden*; [2]*Swedish University of Agricultural Sciences, Uppsala, Sweden*

Introduction: Equine asthma is a prevalent respiratory disease in horses, presenting challenges to animal welfare and performance. Mast cells (MCs) are implicated in asthma pathogenesis, yet their specific role in equine asthma remains unclear. This study aimed to characterize MCs in equine asthma through transcriptome analysis of bronchoalveolar lavage fluid (BALF) from asthmatic horses.
Methods: BALF samples were collected from three horses with varying degrees of asthma severity. The study used a unique MACS Tyto sorting process to separate MCs from bronchoalveolar lavage fluid (BALF). Expression profiles of MC-specific markers, proteases, surface receptors, enzymes, transcription factors, and immune-related genes were analyzed.
Results: MCs isolated from BALF predominantly exhibited a mucosal MC (MMC) phenotype, expressing high levels of tryptase but lacking chymase and carboxypeptidase A3. The high-affinity IgE receptor (FcεRI) alpha and gamma chains were expressed, while the beta chain expression was low. MCs showed low expression of stem cell factor receptor (CD117/c-kit) and interleukin-33 receptor (ST2). Notably, MCs expressed high levels of MHC class II genes, complement components, suggesting involvement in immune responses. Expression of histamine receptor 4 and leukemia inhibitory factor indicated potential inflammatory functions.
Discussion: Transcriptome analysis revealed a distinct MMC population in the airways of asthmatic horses, characterized by unique expression profiles compared to classical connective tissue MCs. The absence of chymase and low beta chain expression in FcεRI suggests atypical features of equine MCs. High expression of MHC class II genes and immune-related molecules indicates potential roles in antigen presentation and immune modulation. The findings suggest that BALF MCs may contribute to inflammatory responses in equine asthma, emphasizing the need for further research on MC subtypes and their functions in equine respiratory diseases. Overall, this study provides valuable insights into the phenotype and functions of MCs in equine asthma, laying the groundwork for future investigations on MC-mediated mechanisms and therapeutic targets in equine respiratory disease

Short Chain Fatty Acids and other microbiota metabolites in Lipid Transfer Proteins Allergy

Paula Álvarez Romero[1], Laura Carrero Chiquillo[1;2], Rocío Aguado Álvarez[1;2], Juan Molina Alcaide[1;2], Berta Ruiz León[1;2], Aurora Jurado Roger[1;2]

[1]Maimonides Biomedical Research Institute of Córdoba (IMIBIC)/ University of Córdoba, Córdoba, Spain; *[2]Reina Sofía University Hospital, Córdoba, Spain*

Purpose: Microbiota and their metabolites have been increasingly studied for their impact on human health. Short Chain Fatty Acids (SCFA) are small carboxylic acid molecules, with one to six carbon atoms, produced predominantly by gut microbiota, which have relevant biological activity. Furthermore, Ole e 7 and Pru p 3 are Lipid Transfer Proteins (LTP) from olive pollen (*Olea europaea*) and peach (*Prunus persica*), respectively. The prevalence of Pru p 3 allergy is extensively described in Europe and, likewise, Ole e 7 allergy is especially prevalent in Andalucía (Spain). The aim of this study was to elucidate the role of microbiota metabolites in the pathogenesis of allergy disease to LTPs.

Methods: A cohort of 92 allergic patient were recruited at Reina Sofía University Hospital (Córdoba, Andalucía, Spain) and classified into two groups: MONOLE or BISENSITISED, depending on whether they had positive specific IgE to Ole e 7 exclusively, or to both Ole e 7 and Pru p 3, respectively (ImmunoCAP 250; positivity threshold > 0.35 kU/L). Additionally, 31 non-allergic individuals were considered as negative controls. Faecal samples were collected and dehydrated to quantify microbiota metabolites (number of carbon atoms): acetate (C2), propionate (C3), butyrate (C4), valerate (C5), caprylate (C8), methionine (C5), formate (C1) and isobutyrate (C4), using proton nuclear magnetic resonance spectroscopy.

Results: No differences were found between groups regarding demographic variables (age, gender, body mass index, place of residence, pet cohabitation and adherence to Mediterranean diet). The analysis of microbiota metabolites revealed that caprylate was the only significantly different metabolite ($p<0.05$) when comparing the three groups independently, allergic versus non-allergic, and MONOLE versus BISENSITISED (caprylate: 0.0422 μmol/g (non-allergic controls) < 0.0673 μmol/g (MONOLE) < 0.1992 μmol/g (BISENSITISED)). Additionally, we found significant differences when we compared the three groups and allergic versus non-allergic, for both C2:C3 and C2:C4 ratios (C2:C3: 3.26 (non-allergic controls) > 2.65 (MONOLE) > 2.43 (BISENSITISED); C2:C4: 4.62 (non-allergic controls) > 3.18 MONOLE ≈ 3.07 (BISENSITISED)).

Conclusion: These results suggested that microbiota metabolites could be involved in the pathogenesis of LTP allergy, and could be associated with the direction of the allergic march, from non-allergic to bisensitised patients.

PLAUR alternative splice pattern analysis in patients with bronchial asthma and rheumatoid arthritis

Jiri Litzman[1;2], Petra Kuliskova[3], Lucie Ballonova[3;4], Peter Slanina[2], Marcela Vlkova[1;2], Petr Nemec[1;2], Jan Baros[1;2], Julie Stichova[1;2], Premysl Soucek[2;3], Tomas Freiberger[2;3]

[1]St Anne´s University Hospital, Brno, Czech Republic; *[2]Faculty of Medicine, Masaryk University, Brno, Czech Republic*; *[3]Centre for Cardiovascular Surgery and Transplantation, Brno, Czech Republic*; *[4]Faculty of Science, Masaryk University, Brno, Czech Republic*

Purpose: The *PLAUR* gene encodes uPAR (CD87), a multifunctional protein involved in fibrinolysis, blood coagulation, bradykinin production, and cell adhesion and migration regulation. *PLAUR* undergoes alternative splicing in exons 5 and 6, resulting in shortened uPAR variants. The impact of these splicing variants on immunopathology remains unexplored.

Aim: This study aimed to define *PLAUR* expression and splicing patterns in monocytes, M0 macrophages, and M1 macrophages from patients with bronchial asthma (BA) and rheumatoid arthritis (RA).

Methods: The study included:

- 39 healthy adult controls
- 30 RA patients: 15 with low disease activity (DAS28_CRP ≤ 3.2) and 15 with moderate and high disease activity (DAS28_CRP > 3.2)
- 31 BA patients: 16 with well-controlled asthma (BA-M) and 15 with poorly controlled asthma (BA-S)

Monocytes were isolated from peripheral blood by magnetic separation and activated with M-CSF and IFNγ to promote differentiation into M1 macrophages. RNA from these cells was reverse-transcribed to cDNA. RT-PCR quantified the total *PLAUR* transcripts, and fragment analysis of specific PCR amplicons covering the alternatively spliced exons determined the frequency of splicing isoforms.

Results: Compared to healthy volunteers, patients with poorly controlled BA (BA-S) displayed a statistically significant increase in the ΔE6 T7b variant across all cell types (monocytes, M0, and M1 macrophages). Additionally, M0 and M1 macrophages from BA-S patients showed a significant increase in the ΔE5 T7a variant frequency compared to healthy controls. Significant changes in ΔE6 T7b and ΔE5 T7a splice variant frequencies were observed between BA-M and BA-S M0 macrophages. Both BA-M and BA-S groups exhibited changes in transcript frequency during macrophage differentiation.

In RA patients, significant changes in splice variant frequency were only observed during differentiation (M0 to M1) and not between disease activity groups.

Conclusion: Our findings suggest a role for alternative PLAUR splicing in macrophage differentiation. Additionally, the observed changes in BA patients point towards a potential role of uPAR variants in the pathogenesis of various immunopathological diseases.

Lymphocyte transformation test in assessing allergic causality and cross reactivities to glycopeptides and lipoglycopeptides in non-severe cutaneous adverse reactions

Daniela Aguilar[1], Laura Miguel Berenguel[1], Ricardo Cuesta Martin de la Camara[1], Elena Ramírez[1], Olga Rogozina[1], Miguel González Muñoz[1]

[1]*Hospital Universitario La Paz, Madrid, Spain*

Purpose: Lymphocyte transformation test (LTT) has been reported as a reliable tool to determine vancomycin sensitization in DRESS cases. Cross-reactivity between glycopeptides is controversial and has only been immunologically confirmed by in-vitro testing in a small subset of vancomycin-induced DRESS patients. Our objective is to evaluate the usefulness of LTT in identifying the specific drug causing the adverse drug reaction (ADR) in non-Severe Cutaneous Adverse Reactions and analyze glycopeptide cross-reactivity.

Methods: We performed a retrospective, cross-sectional, descriptive study in 20 patients with delayed adverse reactions in a tertiary hospital (La Paz University Hospital, Madrid, Spain) between 2015 and 2024. Clinical histories were reviewed to determine the results of allergy studies, including skin testing (prick and intradermal with delayed reading and/or patch tests). Skin testing was not performed in cases of organ-specific reactions. Probability scores were assigned using the Spanish pharmacovigilance system algorithm and the Roussel Uclaf causality assessment method (RUCAM) algorithm for the causality evaluation in cases of hepatitis.

Results: 45% of patients (9/20) were positive to glycopeptides or dalbavancin and 40% (8/20) to another drug; hence in 85% of patients an immune causality was proven by LTT.

Regarding patients with exanthematous reactions (10/20), 9 skin tests were made with only 1 positive result, while 50% of LTT were positive. Four patients were positive to glycopeptides or dalbavancin, and 4 patients to other drugs; so LTT allowed to demonstrate the immune causality in 80% of patients.

As for specific-organ reactions (7/10), immune causality was proven in 85.7% of patients (6/7): 3 to glycopeptides and/or dalbavancin and 3 to other drugs.

Cross-reactivity was defined as the positivity of the LTT to at least two drugs despite exposure to only one. Following this criteria, 4 cases were detected: 3 cross reactivities between vancomycin and teicoplanin, and 2 cross reactivities between vancomycin and dalbavancin.

Conclusions: LTT proved to be useful in identifying immune-mediated ADRs to glycopeptides. Cross-reactivity was observed, particularly between vancomycin and teicoplanin, and LTT allowed to identify them. LTT was a valuable instrument to guide physicians in uncertain cases, with unclear clinical manifestations or inconclusive tests.

Recombinant Blomia tropicalis allergens for precise differential diagnosis of allergic sensitization

Nishelle Dsouza[1], Milena Weber[1], Eszter Sarzsinszky[1], Gabrielle Pauli[2], Huey Jy Huang[1;3], Margarete Focke-Tejkl[1;3], Mikhail Tulaev[1], Walter Keller[4], Thomas Schlederer[1], Rudolf Valenta[1;3], Susanne Vrtala[1]

[1]Medical University of Vienna, Vienna, Austria; *[2]University of Strasbourg, Strasbourg, France*; *[3]Karl Landsteiner University of Health Sciences, Krems, Austria*; *[4]University of Graz, Graz, Austria*

Background: Around 30% of the general population is affected by house dust mite (HDM) allergy and *Blomia tropicalis* (Blo t) is an important HDM species in tropical and sub-tropical areas. Our goal was the isolation and characterization of allergens from this mite species and to use them for component resolved diagnosis, to distinguish between genuine IgE sensitization to Blo t and *Dermatophagoides pteronyssinus* (Der p).

Methods: We produced wild-type-like recombinant allergens (Blo t 1, Blo t 2, Blo t 5, Blo t 8, Blo t 10, Blo t 13, Blo t 21) by expression in *Escherichia coli* and characterized them by mass spectrometry, circular dichroism analysis and patients' IgE reactivity. Microarrays were produced containing these recombinant Blo t allergens as well as the most important Der p allergens. Sera from HDM allergic patients from the tropics (n=15) and from a temperate climate zone (n=33) were tested for IgE reactivity on the microarray chip.

Results: We found that Blo t 2, Blo t 5 and Blo t 21 were the most important allergens for Blo t sensitized patients. Patients from the temperate climate zone without exposure to Blo t showed strong IgE reactivity to Der p allergens and low IgE reactivity to Blo t allergens, which was inhibited by preincubation with Der p allergens. Patients from the tropics were identified as either Blo t monosensitized or Blo t/Der p cosensitized.

Conclusion: Our results demonstrate that microarrays containing a panel of the most important Blo t and Der p allergens are able to identify the disease-eliciting HDM species, which is a prerequisite for the selection of the allergen-specific forms of treatment for the patients.

Funding: Supported by a research grant from WORG Pharmaceuticals, Hangzhou and by a research grant (Danube Allergy Research Cluster) of the country of Lower Austria.

Impact of crosstalk between Th2 cells, ILC2s and cDC2s on lung eosinophilia in a mouse model of allergic bronchopulmonary aspergillosis.

Lisa-Marie Graf[1], Stefan Wirtz[2], David Voehringer[1]

[1]*Infektionsbiologische Abteilung, Universitätsklinikum Erlangen, Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany*; [2]*Medizinische Klinik 1, Universitätsklinikum Erlangen, Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany*

Allergic bronchopulmonary aspergillosis (ABPA), a severe form of eosinophilic, allergic asthma is caused by the airborne fungal mold *Aspergillus fumigatus* (*Af*). The predominant immune response to this disease is type 2 immunity-driven, especially T helper 2 (Th2) cells are crucial for the ABPA pathology. However, the contribution of other type 2 immune cells, like ILC2s and cDC2s remains to be investigated. We have established a mouse model that mimics ABPA, which is based on repeated intranasal treatment with a low dose of living *Af* conidia. This model revealed that type 2 innate lymphoid cells (ILC2s) and two distinct type 2 conventional dendritic cell (cDC2) populations are increased in an *Af*-challenged lung. ILC2s appeared to be critical for induction of lung eosinophilia but they were not sufficient because eosinophilia was blunted in Rag1$^{-/-}$ mice despite significant increase of ILC2s. Moreover, deletion of IL-4 and IL-13 from Th2 cells completely ablated lung eosinophilia while deletion of both cytokines in ILC2s had no effect. Unexpectedly, mice with selective deletion of cDC2s showed not only an impaired Th2 and eosinophil response but also reduced numbers of ILC2s in the ABPA lung. We conclude that cDC2s induce both Th2 cells as well as ILC2s, with both cell types being critical for the strong eosinophilia observed in ABPA.

Skin mast cells require integrin β1 for their perivascular alignment and induction of contact hypersensitivity

Aaron Hoffmann[1], Katsoulis-Dimitriou Konstantinos[1], Dudeck Jan[1], Anne Dudeck[1]

[1]*Otto von Guericke University Magdeburg, Magdeburg, Germany*

Purpose: Allergic contact dermatitis (ACD) is a T-cell mediated chronic inflammatory skin disease affecting 20% of Europe's population over their lifetime. As crucial sentinel cells, mast cells (MCs) have critical pro-inflammatory functions in innate and adaptive immune responses due to the immediate release of active mediators, including TNF and histamine. Notably, perivascular MCs exhibit essential functionality for the onset and kinetics of inflammation by the directional release of mediators into the bloodstream. However, the mechanism underlying MC attachment to vessel walls, a prerequisite for the intraluminal degranulation, remains to be fully elucidated.

Methods: Here, we studied the role of the adhesion molecule integrin β1 (Itgb1) on perivascular MC vessel attachment and intravascular degranulation *in vivo*, using a mouse model of conditional Itgb1 deletion in connective tissue-type MCs (CTMCs). Utilizing advanced quantitative high-throughput image analysis techniques to fluorescence microscopy images, we investigated MC morphology and distribution in the ear skin. Furthermore, using the contact hypersensitivity (CHS) mouse model for ACD, we examined the functional significance of Itgb1 in MCs in the context of skin inflammation.

Results: Fluorescence microscopy of Itgb1-deficient mice ($MC^{\Delta Itgb1}$) revealed that Itgb1 is crucial for the spatial distribution of MCs in the ear skin. In detail, the spindle-like morphology, homogeneous distribution, and perivascular alignment of MCs in the perivascular niche along the blood vessels is impaired in $MC^{\Delta Itgb1}$ mice, particularly at arterioles. Moreover, we observed a reduced capacity to degranulate into the blood vessels. Upon CHS, $MC^{\Delta Itgb1}$ mice showed a drastically diminished ear swelling, accompanied by a significant reduction of leukocyte infiltration. In particular, the challenged ear skin exhibited a reduction in the number of neutrophils, macrophages and $CD8^+$ T cells. Furthermore, the lack of Itgb1 in MCs resulted in an impaired degranulation efficiency *in vitro*.

Conclusion: Our findings reveal the pivotal role of Itgb1 in MC distribution, morphology, and perivascular alignment along the dermal blood vessels. Additionally, we highlight its significance in MC degranulation capacity and pro-inflammatory functions in CHS responses.

Characterisation of Furin deletion in myeloid cells during allergic inflammation.

Martín I. González-Rodríguez[1], Tanja Salomaa[1], Marko Pesu[1], Ilkka S. Junttila[1;2;3]

[1]Tampere University, Tampere, Finland; *[2]Oulu University, Oulu, Finland*; *[3]Nordlab Finland Laboratories, Oulu, Finland*

Furin is an important member of the proprotein convertases enzymes family, which modulate the activation of several immune mediators such as TNF, TGF-β and IL-1β. Studies in mice have revealed the importance of Furin in T cell tolerance and homeostasis. Furthermore, it has been reported that mice with Furin deficiency in myeloid cells (LysMCre-fur) have important biological differences in macrophages function during inflammatory responses. Nonetheless, little is understood regarding the implications of Furin deletion within allergic contexts. Therefore, we utilize the LysMCre-Fur mice to induce papain-dependent allergic inflammation characterized by elevated IgE titers. Through comprehensive flow cytometry analysis, we aim to identify the cellular pathways within the myeloid and lymphoid cell compartments in this setting. Finally, using *in vivo* and *ex vivo* functional assays we further characterize myeloid cells in their metabolism, phagocytosis, and migration capabilities. Due to its role in immune modulatory processes, the identification of cellular pathways associated with Furin deficiency in myeloid cells might unravel new therapeutic targets in inflammatory diseases, including allergies and severe cases of viral infections.

Effect of diesel exhaust particles on immune response of primary human nasal epithelial cells in HDM-allergic rhinitis patients

Nahyun Kim[1], Moo Kyun Park[2], Doo Hee Han[2]

[1]Center for Medical Innovation, Biomedical Research Institute, Seoul National University Hospital, Seoul, South Korea; [2]Department of Otorhinolaryngology-Head and Neck Surgery, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, South Korea

Purpose: House dust mite (HDM) has been known as an allergenic stimulant that affects the skin, upper and lower airways, and the eyes, causing atopic sensitization and allergic symptoms in HDM-allergic patients. The purpose of this study was to investigate whether the immune function was disrupted by diesel exhaust particles (DEPs) in primary nasal epithelial cells from HDM-allergic rhinitis patients.

Methods: PHNE cells from individual subjects with HDM allergy (HDM+) or without HDM allergy (HDM-) were cultured at an air–liquid interface (ALI) to create a fully differentiated, in vivo-like model of the epithelium. Subsequently, they were exposed to DEPs and/or HDM at the apical side of the PHNE during ALI days 10 to 14. The formation and integrity of tight junctions were monitored by measuring transepithelial electric resistance (TEER). The levels of tight junction proteins and epithelial immune molecules were assessed through confocal microscopy and biochemical assays.

Results: When the PHNE were exposed to DEPs and/or HDM at the apical side on ALI day 10 for 24h, 48h, 72h, and 96h, TEER significantly decreased in PHNE of HDM+ subjects after 96h. A similar trend was observed in PHNE of HDM- subjects; however, there was no statistical significance. No difference in pattern was observed between HDM- and HDM+ PHNE in cell viability when the cells were exposed to 50 μg cm^{-2} DEPs and/or 30 μg ml^{-1} HDM for 24h, 48h, 72h, and 96h, although cell viability significantly decreased in response to DEPs but not HDM exposure for 48h, 72h, and 96h in both groups. The expression levels of cytokines expressed in PHNE, such as IL-8, IL-25 and IL-17RC, were significantly changed by exposure to DEPs or HDM for 96h in both HDM- and HDM+ PHNE on ALI day 10, but the pattern of differentially expressed immune molecules differed between HDM- and HDM+ PHNE.

Conclusion: The sensitivity of immune molecules expressed in PHNE in response to DEPs or HDM differed between the HDM- and HDM+ groups. This difference may induce barrier and immune dysfunction of PHNE against environmental pollutants such as DEPs and HDM in HDM+ rhinitis, resulting in nasal symptoms.

Specific immunoglobulin E binding patterns to wheat salt-soluble proteins in Thai patients with wheat-induced anaphylaxis

Pisit Ubonsri[1]

[1]*Mahidol University, Nakhonpathom, Thailand*

Purpose: Wheat is recognized as one of the primary eight allergens, contributing to a substantial public health concern worldwide, particularly in Thailand. Symptoms associated with wheat allergy can vary widely, ranging from mild to severe manifestations, including anaphylaxis. Cases of wheat-induced anaphylaxis (WA) have been documented in Thai patients. However, while several studies have linked salt-insoluble proteins, such as gluten, to anaphylaxis, fewer investigations have examined the role of salt-soluble (SS) proteins in this regard. Therefore, the identification of wheat SS allergens could greatly enhance the diagnostic capabilities for WA among sensitized patients in Thailand. Here, we examined the binding patterns of SS proteins in sera from WA patients and performed allergenic determination using immunoblotting and basophil degranulation assays.

Methods: Patient sera were collected from 10 individuals diagnosed with WA, and levels of wheat-specific IgE (sIgE) were quantified using ImmunoCap. SS proteins were extracted from durum wheat flour using a buffer containing salt. Immunoblotting was performed using the patient sera to determine the binding pattern of sIgE to wheat SS protein extract. Major SS proteins were purified using the electro-elution method before allergenic determination by immunoblotting and basophil degranulation assays.

Results: The ImmunoCap results revealed varying levels of sIgE ranging from 3 to 486 kUA/L in the patients. Analysis of the sIgE profiles of wheat SS proteins demonstrated IgE binding to a 40 kDa SS protein in 9 out of 10 profiles, while 8 out of 10 profiles exhibited IgE binding to either a 45 kDa or 38 kDa SS protein. Additionally, the 38 kDa SS protein (SS38) induced more than 60% degranulation of IgE-primed basophils at a concentration of 1 ng/ml.

Conclusion: The wheat SS protein involved in Thai WA patients is localized at 38 kDa (SS38) and is capable of inducing basophil degranulation, indicating an allergic reaction. SS38 may serve as a significant marker for WA in Thai patients, although further experimentation with a larger population of WA patients is necessary to confirm this observation. Further characterization of the SS38 is also warranted for future studies.

GM-CSF-primed eosinophils enhance mast cell activation

Xue-Ying Luo[1;2], Sherezade Moñino-Romero[1;2], Francesca Levi-Schaffer[1;2;3], Marcus Maurer[1;2], Stefan Frischbutter[1;2]

[1]Institute of Allergology, Charité – Universitätsmedizin Berlin, Berlin, Germany; *[2]Fraunhofer Institute for Translational Medicine and Pharmacology ITMP, Immunology and Allergology, Berlin, Germany*; *[3]Pharmacology and Experimental Therapeutics Unit, School of Pharmacy, Institute for Drug Research, Faculty of Medicine, the Hebrew University of Jerusalem, Jerusalem, Israel*

Purpose: The Allergic Effector Unit (AEU), consisting of mast cells (MCs) and eosinophils (Eos), has been shown to contribute to chronic allergic inflammation. However, the detailed mechanisms underlying the cellular interaction have not been fully elucidated. In this study, we investigated whether soluble mediators derived from MCs or Eos or physical cell contact can activate them and thus affect their effector status, which may help to understand diseases besides allergies in which both effector cells are involved.

Methods: MCs isolated from human breast skin were activated with anti-IgE or cortistatin-14. MC activation was assessed by β-hexosaminidase and histamine release as well as CD63 expression. MCs or their culture supernatants were added to Eos from peripheral blood of healthy volunteers and Eos activation was assessed by expression of CD69 using flow cytometry. Cytokine-blocking antibodies were used to assess the contribution of MC cytokines to Eos activation. To simulate Eos infiltration into the skin, Eos from peripheral blood of healthy individuals or chronic spontaneous urticaria (CSU) patients were injected into skin explants from healthy donors. Histamine levels were analyzed in the interstitial fluid extracted with hollow microneedles.

Results: Supernatants from MCs activated by anti-IgE or cortistatin significantly upregulated CD69 on Eos. Blocking of GM-CSF significantly reduced CD69, while IL-5 or IL-3 blockade had no effect. MCs treated with GM-CSF-activated Eos supernatants, showed significantly enhanced degranulation, particularly at low anti-IgE stimulation strength. Peripheral Eos from chronic spontaneous urticaria patients significantly enhanced MC degranulation *in vitro* and after injection in *ex vivo* skin resulting in higher histamine release compared to healthy Eos.

Conclusions: Our findings suggest that the bidirectional interaction between MCs and Eos (AEU) could lead to a reciprocal activation cycle driven by physical contact and the release of GM-CSF by MCs. This promotes chronic activation of these two cell types and contributes to disease pathology. Therefore, disruption of the AEU, e.g., by targeting GM-CSF or its receptor, could be a valuable approach for the treatment of chronic allergic inflammation.

Global associations of macronutrient supply and asthma disease burden

Duan Ni[1], Alistair Senior[1], David Raubenheimer[1], Stephen Simpson[1], Laurence Macia[1], Ralph Nanan[1]

[1]*The University of Sydney, Sydney, Australia*

Objectives: Global age-standardized prevalence of asthma has decreased over time, in parallel with which, the gross domestic product (GDP) per capita and nutritional landscapes also changed at a global level. Both socioeconomic status and nutritional factors are critical confounder for asthma, but most studies so far neglected to interrogate their correlations and interactions comprehensively. Hence, we aim to systematically investigate the relationship between nutrient supply, a good proxy of food environment, socioeconomic status and asthma disease burden at a global level over time.

Methods: Asthma disease burden, macronutrient (protein, carbohydrate and fat) supply and GDP data covering more than 150 countries around the globe from 1990 to 2018 was collated. Various multi-response generalized additive mixed models (GAMMs) were used to analyze the effects of macronutrient supplies and GDP over time on asthma disease burden.

Results: A model considering the interactions between macronutrient supplies and GDP, with an additive effect of time was favoured. Modelling results showed that carbohydrate supply was most strongly associated with increase of asthma disease burden, while fat supply had an opposite effect, and protein supply conferred less influences.

Conclusions: Globally, carbohydrate supply seems to play a driving role for asthma disease burden while fat supply might be the opposite. This is supported by previous studies about the amelioration of established asthma by ketogenic diet and might be linked to the diet quality. Further in-depth studies are warranted, which will be critical for future clinical research and practice and public health intervention.

How nutritional landscapes impact food allergy

Duan Ni[1], Alistair Senior[1], Jian Tan[1], Laurence Macia[1], Ralph Nanan[1]

[1]*The University of Sydney, Camperdown, Australia*

Food allergy is an emerging public health concern and characterizing the propensity towards food allergy is one of the "holy grails" in allergy research. Foods, nutrient environments and host biology are critical determinants for food allergy development. Previous studies mainly focused on the macroenvironments (hygiene hypothesis), the hosts' biological characteristics and specific allergenic proteins. Some important aspects like the intrinsic properties of common trigger foods and their extrinsic interactions with other foods, nutrients and the dietary environments have been neglected.

Leveraging unprecedented epidemiological and nutritional data, we concentrated the overall dietary environment of common food allergens and their intrinsic nutrient compositions. We found that dietary environments, reflected in the supplies of allergenic foods and the general macronutrients, minimally influenced food allergy. Interestingly, lower protein and glycine contents in trigger foods were correlated with reduced allergy.

This work represents the first report to our knowledge to comprehensively investigate nutritional factors impacting food allergies based on the epidemiological and nutritional landscapes. We believe that our findings are of interests to allergists and immunologists. It will inform future allergy studies and clinical management for food allergy and might influence public health dietary recommendations.

Peanut-allergic young children after 1 year of oral immunotherapy show changes in their gut microbiota composition and functional potential

Isabella Badolati[1], Ymke de Jong[1], Carina Uhl[2;3], Marleen Joustra[1], Caroline Nilsson[2;3], Anna Asarnoj[2;4], Eva Sverremark Ekstrom[1]

[1]Stockholm University, Stockholm, Sweden; *[2]Karolinska Insitutet, Stockholm, Sweden*; *[3]Sachs' Children and Youth Hospital, Södersjukhuset, Stockholm, Sweden*; *[4]Astrid Lindgren Children's Hospital, Karolinska University Hospital, Stockholm, Sweden*

Background: In recent years, oral immunotherapy (OIT) has shown promising results in the treatment of peanut allergy, especially in young children. However, which mechanisms are involved in the OIT and how tolerance is promoted remain unclear.

Purpose: In this study, our aim was to assess whether OIT, already after 1 year, affects the gut microbiota of peanut-allergic young children, and if differences are observed compared to similarly aged children that continue to avoid peanut.

Methods: Fecal samples were collected from 30 peanut-allergic children (1-3 years old), 15 of which received peanut OIT while 15 avoided peanut for a period of 1 year, as part of our larger study named SmaChO (Small Children OIT). Microbial DNA was isolated from fecal samples, and 16S rRNA sequencing was performed using the Illumina NextSeq P1 platform. Fecal water was also extracted and used to stimulate healthy PBMCs, from which the cytokine production was measured by ELISA. For all of the analyses, comparisons at 1 year follow-up between the two groups of children, as well as between baseline and 1 year, within each group, were performed.

Results: After 1 year, the children treated with OIT showed a distinct gut microbiota profile as compared to their untreated counterpart, with an increased richness and more abundant Clostridia bacteria, including *Faecalibacterium* and *Lachnoclostridium*. The trajectory of numerous microbial taxa over time also differed between the two groups, and in general, less changes from baseline were observed in case of no treatment. Furthermore, fecal water from children undergoing OIT prompted a type 1/regulatory cytokine secretion from healthy PBMCs, while fecal water from the peanut avoidance group elicited a type 2 cytokine skew.

Conclusion: One year of OIT in young peanut-allergic children has an impact on their gut microbiota, both in terms of composition and potential function. These observed alterations may be linked with the development of peanut tolerance, while the untreated children continue the path of allergy development.

Comparison of two multiplex arrays for in vitro allergy diagnosis with the reference singleplex method

Adrian Marynowski[1], Melissa E. Liriano-Alba[1], Fabio Román-Balderrama[1], Alberto Martínez-Cano[1], Aitana Alberdi Callejo[2], María Catalá[2], José González-Fernández[1], Celia González-Agudo[1], Reyes Tejedor-Lázaro[1], Fátima González-Chantal[1], Carlos Blanco-Guerra[2], Arantzazu Alfranca[1]

[1]Immunology Department, Hospital Universitario La Princesa, Madrid, Spain; *[2]Allergy Department, Hospital Universitario La Princesa, Madrid, Spain*

Purpose: The aim of this study was to evaluate the analytical performance of the recently commercialized ALEX$^{2®}$ microarray (MacroArray Diagnostics, 117 extracts and 183 molecular components) for *in vitro* allergy diagnosis, to compare it with ISAC® (ThermoFisher, 112 molecular components), the most commonly used array, and with the reference singleplex ImmunoCAP® (ThermoFisher).

Methods: Serum samples of 40 patients from La Princesa Hospital Allergy Unit (Madrid, Spain) with previous ISAC® analysis were tested with ALEX$^{2®}$. Cohen´s kappa (κ), positive percentage agreement (PPA) and negative percentage agreement (NPA) of ALEX$^{2®}$ results compared to ISAC® (as a non-reference standard) were calculated for the 102 common molecular allergens. In 29 of these samples ImmunoCAP® specific IgE (sIgE) results for allergen extracts and components were also available and were compared to ALEX$^{2®}$ in a similar manner. Clinical records and skin prick tests (SPT) data were used to evaluate the in vitro sensitization results.

Results: An overall agreement (OA) of 98% (κ=0,88) was observed between ALEX$^{2®}$ and ISAC®, with 91% PPA and 99% NPA. Similar agreements were found when ALEX$^{2®}$ and ISAC® molecular components were compared with ImmunoCAP® (OA: 95% (κ=0,89), PPA: 94%, NPA: 95% and OA:96% (κ=0,92), PPA: 95%, NPA: 97% respectively). However, OA for extracts between ALEX® and ImmunoCAP® was barely 51% (κ=0,21) with 33% PPA and 100% NPA. The discrepancies were due to plant-food and pollen extracts. All cases had positive SPT and ImmunoCAP® results, together with clinical records suggestive of an allergic reaction. The possibility of cross-reactive carbohydrate determinants (CCD) was considered with only 2 out of 11 discrepant sera (18%) showing a positive CCD result using ISAC®.

Conclusion: Our results show a substantial agreement for molecular components between ALEX$^{2®}$ and ISAC® and between both microarrays and the singleplex ImmunoCAP®. However, a low concordance was found for extracts when ALEX$^{2®}$ and ImmunoCAP® were compared, mainly plant-food and pollen extracts. These findings highlight the need for further evaluation of ALEX$^{2®}$ extracts performance before using this multiplex platform on a routine basis.

Oral tolerance to walnut and peanut evaluated through basophil degranulation

Laura Carrero Chiquillo[1;2], Ana Navas[1;2], Juan Molina Alcaide[1;2], Raquel Bernardo[1;2], Javier Torres[2], Aurora Jurado Roger[1;2]

[1]Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Córdoba, Spain; *[2]Hospital Universitario Reina Sofía, Córdoba, Spain*

Purpose: The utility of basophil activation test (BAT) has been proved in the diagnosis of allergic diseases. Furthermore, it has been demonstrated to be useful distinguishing between sensitization and true allergy to peanut and also transient desensitization to sustained unresponsiveness. The aim of this study was to evaluate the predictive capacity of BAT in achieving oral tolerance to walnut and/or peanut.

Methods: In this descriptive prospective study, a total of 14 paediatric patients were included. All of them exhibited allergy symptoms to walnut and/or peanut and underwent oral tolerance between 2021 and 2023. BAT using walnut and/or peanut extracts (ALK Abelló y LETI Prick-Test) at different concentrations (0.1-1,000 ng/mL) was performed, together with serum sIgE to whole extract and the molecular available components (Jug r 1, Jug r 3, Ara h 1, Ara h 2, Ara h 3, Ara h 6, Ara h 8, y Ara h 9; ImmunoCAP250) quantification. All measures were performed before starting immunotherapy and one year later.

Results: Among all, 14/14 (100%) patients exhibited cutaneous symptoms, 2/14 (14.3%) respiratory symptoms and 1/14 (7.1%) digestive symptoms and 2/14 (14.3%) needed adrenaline implementation. Mean age was 10.5±3.3. The 78.6% were men. Of all, 42.9% exhibited allergy to peanut, whereas 64.3% to walnut. sIgE to Ara h 9 increased after one year of immunotherapy (1.8±4.4 kU/L vs. 5.3±12.4 kU/L; p = 0.068), whereas BAT against peanut at all analysed concentrations decreased, but only when using 1 ng/mL of whole extract, it followed a statistical tendency (71.7% vs. 52.4%; p = 0.075). Regarding walnut allergy, these tendencies were not observed. Currently, all patients tolerate nuts.

Conclusions: BAT could be a candidate biomarker predictor of tolerance to peanut, even though more studies with larger cohorts are needed to confirm this hypothesis and extrapolate it to other food allergies.

Development of atopic diseases among offspring of mothers belonging to gestational diabetes mellitus (GDM) risk group

Anu Bärenson[1;2], Aili Tagoma[1], Heili Varendi[2], Raivo Uibo[1]

[1]University of Tartu, Department of Immunology, Institute of Bio- and Translational Medicine, Tartu, Estonia; *[2]Tartu University Hospital Childrens´ Clinic, Tartu, Estonia*

Objectives: The main aim was to evaluate if the diagnoses of atopic dermatitis, asthma and allergic rhinitis at 1-, 2- and 5- years of age in children were related to maternal GDM. The second aim was to analyse the impact of maternal health characteristics on the development of the abovementioned skin or respiratory disorders in the offspring.

Study design: The follow- up study group of Gestational Diabetes Study (GDS) conducted at Tartu University Hospital, Estonia, between 2014-2020 comprised of 223 mother- children diads. All women taking part in the GDS had at least one risk factor for developing GDM. Information about the diagnoses of atopic dermatitis, asthma, and allergic rhinitis in children at 1-, 2-, and 5- years of age was obtained from Electronic Health Records.

Results: Our results show that maternal pre-pregnancy obesity (BMI> 30) and pathological weight gain during pregnancy play an important role in the development of atopic dermatitis, asthma and allergic rhinitis among the offspring of women belonging to the GDM risk group. Only children of women with GDM needing antidiabetic medications were more prone to the development of respiratory disorders at 2 years of age.

Conclusion: Among pregnant women at risk for GDM, regardless of the GDM diagnosis itself, maternal weight related factors have a significant impact on the development of offspring's atopic diseases. Therefore, besides GDM mothers, greater attention must be paid to women at risk, but not developing GDM- their children seem to be even more at risk of atopic diseases as these women do not receive necessary interventions during pregnancy.

Aknowledgements: The study was supported by EC Horizon 2020 HEDIMED grant no. 874864 and Estonian Research Council grant no. PRG712.

Interleukin-1β signaling is critical to urban particulate matter-induced exacerbation of airway allergic inflammation.

Tien-Hsuan Chen[1], Bor-Luen Chiang[1]

[1]*Graduate Institute of Clinical Medicine, National Taiwan University, Taipei, Taiwan*

Purpose: Warnings on health impacts of air pollutants had been reported in clinical surveys worldwide. Past researches showed that the aerosol particles induced aggravation of allergic airway inflammation through exerting type 2 helper T cells (Th2)-biased response and accumulation of oxidative stress. However, underlying mechanisms between lowering the threshold of disease initiation and immunomodulation are not fully understood. In this study, we investigated the particulate matter 2.5 ($PM_{2.5}$)-induced effect on IL-1β and inflammasome-related pathway in asthma setting due to their established role sensing the environmental cues.

Methods: We set up a $PM_{2.5}$ exposure model in addition to murine model of ovalbumin (OVA)-induced allergic airway inflammation without Alum adjuvant. The OVA model included a sensitization phase with subcutaneously OVA injection and a challenge phase through intranasal route. According to grouping, the pollutant particles (collected in March 2019, Kaohsiung, Taiwan) were given weekly during the sensitization phase. Blockade of IL-1β pathway were conducted by neutralizing antibody in both phases. Further *ex vivo* experiments were done to track the cellular source of IL-1β in activated immune cells.

Results: In disease setting, exposure to the particles enhanced lung infiltrations and resulted in more severe eosinophilic inflammation and induction of neutrophilic inflammation. In the circulation, the particles suppressed OVA-specific IgG2a and generated a Th2-biased microenvironment. However, the particles alone had no significant effect on the airway function and histopathology in naive mice. Neutralizing of IL-1β in the OVA model would decrease the lung infiltrations and suppress OVA-specific IgG1 and IgE. Following the results, neutrophils were identified as the potential source of $PM_{2.5}$-enhanced IL-1β in both inflammasome-dependent and independent manner.

Conclusion: Collectively, these data suggested the contribution of IL-1β pathway in $PM_{2.5}$-induced adjuvant effect on airway allergic inflammation. The $PM_{2.5}$-enhaced IL-1β could be secreted by the infiltrating neutrophils in both inflammasome-dependent and independent manner. Blockade of the pathway by neutralizing antibody partially ameliorate the particle-induced impact. Thus, providing a novel coping strategy on pollutant control and further understanding on etiology of asthma.

Purpose: Trained immunity (TI) describes a phenomenon by which innate immune cells such as macrophages, acquire an immunological memory resulting in a heightened response following exposure to a non-specific secondary pathogenic stimulus. Triggered by metabolic changes and subsequent chromatin remodeling, TI leads to elevated levels of pro-inflammatory cytokines. TI may be harmful in the context of asthma as the surge in cytokine production could further drive exacerbations in patients. Recent literature shows that increased expression of the pro-inflammatory cytokine, macrophage migration inhibitory factor (MIF) enhances this trained response in macrophages from mice containing the high expressing human MIF polymorphism, in response to the allergen house dust mite (HDM). This study is the first to investigate the molecular mechanisms behind why high human MIF expression leads to an enhanced trained response in HDM-mediated trained immunity *in vitro*.

Methods: Naive bone marrow-derived macrophages (BMDMs) from novel humanized MIF mice with either the low-expressing MIF promoter polymorphism ($CATT_5$) or the high-expressing MIF promoter polymorphism ($CATT_7$) or wild type (WT) litter mate controls, were trained with HDM *in vitro*, prior to being exposed to a secondary heterologous stimulus on day 7. The MIF inhibitor SCD-19 was used to show a MIF-specific role, MTA and HAT inhibitors show epigenetic remodeling occurs, Seahorse extracellular flux analysis shows an altered metabolic phenotype. To translate these findings to a clinical setting, monocyte derived macrophages (MDMs) isolated from serum from both healthy and severe asthma patients were investigated for trained immunity.

Results: HDM-trained $CATT_7$ BMDMs show significantly enhanced production of proinflammatory cytokines such as IL-6, IL1β and TNFα in response to secondary insults with LPS in comparison to both $CATT_5$ and WT BMDMs. Similar results were seen in patient samples, with increased MIF expression correlating to amplified trained responses. As well as having increased pro-inflammatory cytokine production, trained macrophages have an altered metabolic phenotype post HDM-stimulation.

Conclusion: High human MIF expression correlates to an enhanced HDM-induced trained response which may drive further exacerbations in asthmatic patients.

Development of monoclonal antibodies against cat allergen Fel d 3 and their application for the analysis of cat allergen extracts

Vytautas Rudokas[1], Aurelija Zvirbliene[1]

[1]*Institute of Biotechnology, Life Sciences Center, Vilnius University, Vilnius, Lithuania*

Cats rank among the most popularly owned companions globally. They are a major source of allergens and their continuous exposure to allergic individuals leads to the development of allergic rhinitis and asthma. Presently, allergen extracts of low precision, consisting of naturally occurring mixed allergen components and other biomolecules, remain commonly employed for diagnosing allergy and administering immunotherapy. The principal challenges associated with these extracts include inconsistencies in composition between different manufacturers and even production lots, and a deficiency in standardization. The quantification of specific allergen components within these extracts could be achieved through immunoassays utilizing allergen-specific monoclonal antibodies (MAbs). Such thorough examination of allergen extracts could serve as a foundation for standardization and subsequent enhancement of the product.

In response to the growing demand for the standardization of allergen extracts, cat allergen Fel d 3 fused with maltose-binding protein (MBP) was synthesized in *E. coli*. The allergen was purified using affinity chromatography of MBP-passenger proteins. Then the hydrolysis reaction was optimized to detach MBP and recombinant Fel d 3 was purified using two-step affinity Ni-NTA and ion exchange chromatography. The antigenic similarity of recombinant Fel d 3 with a native allergen was confirmed by its reactivity with the IgE from blood serum specimens of patients with diagnosed cat allergy by indirect ELISA. Then Fel d 3-specific murine MAbs were generated by hybridoma technology. They were purified by protein A affinity chromatography, characterized by immunochemical methods and a highly specific sandwich ELISA for the quantification of Fel d 3 was developed. Lastly, sandwich ELISA was used to measure the precise concentration of Fel d 3 in cat allergen extracts from different manufacturers and source materials – epithelium, hair and dander. The lowest content of Fel d 3 was in the extracts from epithelium material. Our study demonstrates the significant differences between allergen extracts from different manufacturers or source materials and demonstrates the MAbs being an applicable tool for the analysis of allergen extracts which leads to better standardization opportunities.

Macropinocytosis is the principal uptake mechanism of antigen-presenting cells for allergen-specific virus-like nanoparticles

Armin Kraus[1], Bernhard Kratzer[1], Al Nasar Ahmed Sehgal[1], Doris Trapin[1], Matarr Khan[1], Nicole Boucheron[1], Winfried Pickl[1;2]

[1]Medical University of Vienna, Center for Pathophysiology, Infectiology and Immunology, Institute of Immunology, Vienna, Austria; [2]Karl Landsteiner University of Health Sciences, Krems, Austria

Purpose: Virus-like nanoparticles (VNP) are regarded as efficient vaccination platforms and have proven to be useful for the non-anaphylactogenic delivery of allergen-specific immunotherapy in preclinical models. In fact, we previously showed that *Moloney* murine leukemia virus-derived VNP, containing a shielded version of the major mugwort pollen allergen, were hypoallergenic and induced immunotolerance. The ability of antigen-presenting cells (APCs) to take up VNP has been a curiosity of substantial practical significance, however, the physiological principles governing particle uptake remained elusive as of yet.

Methods: Herein we sought to determine the mode of VNP uptake by APCs. Accordingly, we screened a collection of substances known to inhibit different uptake pathways by APCs. The human leukemia monocytic cell line THP-1 and the murine dendritic cell line DC 2.4 were examined for the uptake of fluorescently labelled VNP in the presence or absence of inhibitors. The inhibitory effect of candidate substances that blocked VNP uptake in APC lines was subsequently evaluated in studies with primary APCs present in splenocyte and lung cell homogenates *in vitro*, and their impact on allergen-specific T-cell activation was investigated upon intratracheal application of VNP *in vivo*.

Results: Uptake of allergen-specific VNP *in vitro* and *in vivo* was mainly observed by macrophages and $CD103^+$ dendritic cells and was sensitive to inhibitors that block macropinocytosis, such as hyperosmolarity induced by sucrose or the polyphenol compound Rottlerin at low micromolar concentrations, but not by other inhibitors. Also, T-cell proliferation induced by allergen-specific VNP was significantly reduced by both substances. In contrast, substances that stimulate macropinocytosis, such as Heparin and phorbol myristate acetate (PMA), increased VNP-uptake and may thus help modulate allergen-specific T-cell responses.

Conclusion: We have identified macropinocytosis as the principal uptake mechanism of APCs for allergen-specific VNP *in vitro* and *in vivo*, paving the way for further improvement of VNP-based therapies, especially those that can be used for tolerance induction in allergy in the future.

TCR- and HLA-transgenic humanized mouse model for birch pollen allergy

Mirjam Schaar[1], Bernhard Kratzer[1], Al Nasar Ahmed Sehgal[1], Doris Trapin[1], Barbara Bohle[2], Alina Neunkirchner[1], Ursula Wiedermann[3], Rudolf Valenta[2;4], Winfried Pickl[1;4]

[1]Medical University of Vienna, Center for Pathophysiology, Infectiology and Immunology, Institute of Immunology, Vienna, Austria; *[2]Medical University of Vienna, Center for Pathophysiology, Infectiology and Immunology, Department of Pathophysiology and Allergy Research, Vienna, Austria*; *[3]Medical University of Vienna, Center for Pathophysiology, Infectiology and Immunology, Institute of Specific Prophylaxis and Tropical Medicine, Vienna, Austria*; *[4]Karl Landsteiner University, Krems, Austria*

Purpose: Sensitization to birch (*Betula verrucosa*) pollen is one of the main causes of pollinosis in the Northern hemisphere. Bet v 1 represents the major birch pollen allergen, to which over 95% of birch pollen allergic patients are sensitized. Bet v $1_{142\text{-}153}$ had been previously identified as the immunodominant T-cell epitope in birch pollen allergic individuals and its contribution to cross-reactivities with other PR-10 proteins was elucidated.

Methods: A transgenic mouse model expressing a human Bet v $1_{142\text{-}153}$-specific T cell receptor (TCR), human CD4, as co-receptor, and the associated human leukocyte antigen (HLA)-DR7 was generated, to investigate the processes of allergic sensitization and specific organ manifestations upon natural allergen exposure *via* the airways. Primary and secondary lymphoid organs of hCD4-TCR-HLA-DR7 transgenic mice were analyzed by multiparameter flow cytometry and compared with wildtype C57BL/6 mice. Functionality of T cells derived from spleens of allergen-naïve hCD4-TCR-HLA-DR7 transgenic mice was evaluated in splenocyte proliferation assays and specific cytokine secretion was studied.

Results: Of the $CD3^+CD4^+$ T cells 90.1±8.4% co-expressed hCD4, and 61.6±9.8% of those $CD3^+mCD4^+hCD4^+$ cells co-expressed the human Bet v $1_{142\text{-}153}$-specific TCR. Of $CD19^+$ B cells 60.1±8.0% co-expressed HLA-DR7. *In vitro*, specific T cell proliferation to Bet v 1 or Bet v $1_{142\text{-}153}$ peptide but not to Art v 1 or Art v $1_{23\text{-}36}$ peptide (representing the unrelated major allergen/immunodominant T cell peptide of mugwort pollen) could be induced. Bet v 1-specific T cells secreted both Th1 and Th2 cytokines into cell culture supernatants. Results of *in vivo* experiments upon exposure of allergy mice to birch pollen extract will be presented.

Conclusion: This is the first preclinical TCR- and HLA-transgenic humanized mouse model for birch pollen allergy which is responsive to the immunodominant Bet v $1_{142\text{-}153}$ peptide recognized by allergic patients. This model will be useful to investigate mechanisms of birch pollen allergy and to develop preventive and therapeutic strategies.

Clinical relevance of molecular diagnosis in patients sensitized to olive tree (Olea europaea) pollen in a cohort of patients from the province of Cádiz

Javier Galán Picón[1], Alberto Gallardo García[1], Jorge Mannelli[1], Raquel De la Varga-Martínez[1]

[1]*Hospital Universitario Puerta del Mar, Cádiz, Spain*

Purpose: Olive tree (Olea europaea) pollen is one of the most important causes of pollinosis in the Mediterranean basin. Twelve allergens (Ole e 1 to Ole e 12) have been purified and characterized from it, and patients can be sensitized to many different combinations of them. The aim of this study is to describe the sensitization profile to olive tree pollen and to assess molecular diagnosis to predict the efficacy of allergen-specific immunotherapy (AIT).

Methods: A cohort of 823 patients from the province of Cádiz was selected based on pneumoallergen screening performed during 2023. In this study, levels of total immunoglobulin E (tIgE) and specific immunoglobulin E (sIgE) against the complete extract (CE) of olive tree pollen and against specific components (SC) -major allergen Ole e 1 and minor allergens Ole e 7 (LTP) & Ole e 9- were analyzed. The ratio 1 (sIgE-CE/tIgE) and ratio 2 (sIgE-SC/sIgE-CE) of these components was determined.

Results: 73.4% (604) of patients with positive pneumoallergen screening were sensitized to the CE of olive tree pollen. 98% (592) of sensitized patients tested positive for Ole e 1, with a mean of 20 kU/L (Q1-Q3: 1.7-24.1); 28.3% (171) tested positive for Ole e 7, with a mean of 24.4 kU/L (Q1-Q3: 0.6-38.3); and 23.5% (142) tested positive for Ole e 9, with a mean of 31.8 kU/L (Q1-Q3: 2.2-54.1). 6.5% of patients sensitized to the CE of olive tree pollen presented sIgE levels lower than 0.35 IU/L against the studied components.

35.6% patients (61) were sensitized to Ole e 7 as the major allergen according to ratio 2.

Conclusion: In our population, the allergen Ole e 1 behaves as the major allergen of olive tree pollen, while allergens Ole e 7 and Ole e 9 behave as minor allergens. Patients monosensitized to Ole e 7 (9) along with patients who, according to ratio 2, exhibited predominant sensitization to Ole e 7 (61), might have less effective immunotherapy since Ole e 7 is not quantified in most commercial extracts. Therefore, the use of ratio 2 could be clinically useful in predicting the efficacy of immunotherapy.

More severe symptoms are associated to specific IgE detection of a higher number of LTPs using microarray technology.

Juan López Pérez[1], María Pilar Osácar Puyoles[2], Sergio Zuheros Serrano[2], Carlos Colás Sanz[1;2], Luis Martinez-Lostao[1;2]

[1]*Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain*; [2]*Universidad de Zaragoza, Zaragoza, Spain*

Purpose: The diagnosis of polysensitised patients in allergology presents challenges due to multiple reactions and difficulty in identifying triggers. In this regard, molecular diagnosis by microarrays has shown promise in identifying the allergens involved and cross-reactivity relationships. This study analysed the detection of specific IgE in patients sensitised to multiple allergens, using two microarray techniques (ImmunoCAP ISAC and ALEX). Specific IgE profiles, concordance of results and their relationship with symptomatology were analysed to determine whether there is an association between LTP-specific IgE levels and allergic symptoms.

Methods: A prospective longitudinal observational study was conducted in a cohort of 39 polysensitised allergic patients in whom symptoms were studied after fruit ingestion and specific IgE was analysed using two microarray techniques. For statistical analysis, nine allergenic components of the LTP families were selected, non-parametric tests were used and a significance level of $p<0.05$ was established.

Results: More than 80% of the patients tested positive for six or more allergens, and the LTP families had a high detection rate of positive allergen components. With a Pearson correlation value of 0.81, the ISAC and ALEX approaches showed a high degree of correlation for LTPs sensitization values. Additionally, sensitivity to more LTPs was found to be correlated with severe symptoms when compared to no symptoms ($p=0.008$ for ISAC and $p=0.028$ for ALEX). High average values of these positive LTPs were likewise found to be associated with severe symptoms ($p=0.046$ for ISAC and $p=0.027$ for ALEX). Severe symptoms were also linked to sensitization to higher numbers of LTPs and high average values of positive LTPs when diverse groups of LTP allergens were created, based on the sequence homology of LTP proteins, the route of allergen entrance, or their prevalence in our cohort.

Conclusion: The detection of specific IgE using microarray methods is useful for the diagnosis and treatment of polysensitised patients. Patients who are sensitised to more LTPs and who have higher values of specific IgE against LTP allergens are more prone to experience severe symptoms.

Performance characteristics of a novel, fully automated immunoassay microarray for the qualitative serological detection of specific IgE directed against Bet v 1

Yasemin Ataman-Önal[1], Brian Steele[1], Gerber Gomez[1], Rocio Pasion-Galvan[1], Jose Santiago[1], Michael Hausmann[1], Christian Fischer[1]

[1]*AliveDx Suisse SA, Eysins, Switzerland*

Purpose: Bet v 1 (main allergen from the Birch tree pollen) is an important contributor to IgE-mediated allergic disorders. We report the performance characteristics of a novel, single-use, microarray immunoassay (MosaiQ Allergy Bet v 1, AliveDx, Eysins, Switzerland) (Bet-v-1-Microarray) when used with the fully automated MosaiQ® system, for the qualitative detection of specific IgE (sIgE) directed against Bet v 1, compared with ImmunoCAP™ Specific IgE (Phadia AB). The assay's reproducibility and repeatability were also assessed.

Methods: Bet-v-1-Microarrays, sized 40 mm x 10 mm x 8 mm, were prepared by printing Bet v 1 allergens onto functionalized glass chips and assembled into magazines for automatic processing on the MosaiQ 125 instrument. 163 anonymized, residual serum samples, characterized by the comparator method as reactive (n=63) or as non-reactive (n=100) were tested with the investigational device. Magazine lot reproducibility was assessed over five days, on three magazine lots, across two instruments; instrument reproducibility was evaluated over five days, on one magazine lot, across three instruments; repeatability was assessed on one instrument and one magazine lot, two runs per day, over five days. Reproducibility panels were composed of three samples (non-reactive, low-reactive, high-reactive).

Results: In the method comparison evaluation, after the exclusion of 1 reactive sample as per protocol, the investigational device identified as reactive 60 out of 62 characterized reactive samples by the comparator and all 100 non-reactive samples; for a positive, negative and overall agreement of 96.8% (95%CI: 88.8%, 99.6%), 100% (95%CI: 96.4%, 100%) and 98.8% (95%CI: 95.6%, 99.9%), respectively. Agreement of the investigational device with expected results in the evaluations of reproducibility by lot (869 data points) and by instrument (435 data points) as well as in the assessment of repeatability across days and runs (291 data points) were all 100%.

Conclusion: Bet-v-1-Microarray showed high concordance with the compared device for the qualitative detection of Bet v 1 sIgE. Additionally, Bet-v-1-Microarray demonstrated a high degree of precision in the reproducibility and repeatability evaluations. This device/platform has the potential to multiplex and contribute to the comprehensive assessment of allergic disorders. Further ongoing steps include the addition of other allergens to the microarray.

Purpose: Basophils are among the most important effector cells in allergy. In the context of allergy to drugs, like antibiotics, the infectious context may have some role in basophil-related allergic response that should be considered in *in-vitro* tests. We investigated whether the addition of TLR ligands (TLR-L) that emulate interactions with infectious components, could increase basophil activation and degranulation.

Methods: Twenty-nine amoxicillin (AX)-confirmed allergic and 20 tolerant exposed subjects were analysed by basophil activation test (BAT), using AX alone or in combination with TLR-L 1–8, using CD63 or CD203c basophil activation markers.

Results: Among all TLR-L tested, LPS in combination with AX gave the maximum effect, increasing CD63 expression in 51.7% of AX-allergic compared to 41.4% in the absence of LPS, without compromising specificity. Importantly, using LPS+AX we were able to detect 47% of patients who would have been otherwise reported as negative by conventional BAT (using AX alone). Additionally, combining strategies based on LPS+AX and different activation markers, an increased sensitivity (54.8%) and a specificity of 100% were achieved compared to conventional BAT.

Conclusion: There are differences between upregulation of CD63 and CD203c basophil-activation markers in response to pathogen receptor stimulation. The inclusion of LPS in BAT could be a diagnostic-wise strategy for beta lactam allergies.

The crucial role of lipid receptors on pathogenic T helper cells during house dust mite allergic airway inflammation

Anna Krone[1], Simon Schreiber[1], Tobias Franz[1], Negele Jonas[1], Johanna Kotrba[1], Marc Roder[1], Anja Sammt[1], Camilla Merten[1], Nouria Jantz-Naeem[1], Robert Geffers[2], Christoph Garbers[3], Anne Dudeck[1], Andreas Müller[1], Burkhart Schraven[1], Sascha Kahlfuß[1]

[1]Institute for molecular and clinical immunology, University Hospital, Magdeburg, Germany; *[2]Genome Analytics Research Group, Helmholtz Centre for Infection Research, Braunschweig, Germany*; *[3]Institut for clinical biochemestry, Hannover Medical School, Hannover, Germany*

Purpose: Asthma is a an inflammatory airway disorder that affects millions worldwide, with increasing incidence also attributed to climatic changes. CD4+ T helper type 2 (Th2) cells are pivotal in orchestrating the inflammation within the lung tissue. Recent studies have highlighted the involvement of lipid receptors on T cells as key regulators of immune responses in asthmatic lungs, which show an altered lipid composition compared to healthy lungs. Elucidating the mechanisms underlying lipid receptor-mediated T cell differentiation and communication with the airway epithelial barrier promises novel immunotherapeutic avenues.

Methods: To investigate the role of lipid receptors on CD4+ T cells in vivo, we applied acute and chronic house dust mite (HDM)-induced allergic airway inflammation models in wildtype and CD4-specific lipid receptor knockout mice. We examined lungs, mediastinal lymph nodes, and serum of the mice by flow cytometry, ELISA, histological stains, and single-cell RNA sequencing

Results: Significant differences in HDM-specific serum IgE levels and cytokine profiles were observed in acute and chronic asthma models (unpaired Student's t test). Our data further showed that lipid receptors are crucial for the generation T follicular helper cells, which are known as precursors of T helper 2 cells, and are in particular important for the generation of tissue resident memory CD4+ T cells that maintain allergen-specific immunity in the asthmatic lung.

Conclusion: The results underline, that lipid signaling plays an essential role in the pathogenesis of asthma by regulating the immune response and contributing to airway inflammation. Further research is mandatory to find a promising strategy for asthma treatment.

Interactions of metal allergens with T cell receptors

Franziska Riedel[1], Caterina Curato[1], Marina Aparicio Soto[1], Leonie Maibaum[1], Wiebke K. Peitsch[2], Katherina Siewert[1]

[1]German Federal Institute for Risk Assessment, Department of Chemical and Product Safety, Berlin, Germany;
[2]Vivantes Klinikum im Friedrichshain, Department of Dermatology and Phlebology, Berlin, Germany

Metal allergens are the most prevalent chemical sensitizers. Upon diagnostic patch testing, 11%, 3% and 2% of the general population react to nickel, cobalt or chromium, respectively. Sensitization may lead to allergic contact dermatitis, a T cell mediated disease, or implant failure. Despite these real-live data, it is currently unknown how metal ions interact with T cells and activate them. Available regulatory tests predict only a moderate potency for metal allergens, possibly because T cell assessment is lacking.

To include T cells in a test system, we applied a CD154 (CD40L)-based activation-induced marker (AIM) assay. Peripheral blood mononuclear cells were incubated with $NiSO_4$, $CoCl_2$, $PdCl_2$ or $CrCl_3$ in the presence of a CD40 blocking antibody, enabling CD154 surface staining. Cells were analyzed by flow cytometry and reactive CD154+CD4+ memory T cells were sorted for RNA- and unique molecular identifier-based full-length αβ T cell receptor (TCR) sequencing.

Using buffy coats and fresh blood donations (allergic and non-allergic individuals), we identified high frequencies of reactive T cells peaking at ~400 µM before toxic effects became dominant. Most frequent were Pd^{2+}-reactive cells (mean 3.0%, n = 17), followed by Cr^{3+}-, $Co^{2+}$and Ni^{2+}-specific cells (0.64%, n = 6; 0.51%, n = 10 and 0.27%, n = 10).

Among TCR repertoires, individual gene segments were overrepresented for certain metal-specific TCRs, e.g., TRAV9-2 for Ni^{2+}-specific TCRs (28% of TCRs vs. 6% of random TCRs) or the TRBV4 family for Pd^{2+}-specific TCRs (21% of TCRs vs. 6% of random TCRs). As a second, independent feature, Ni^{2+}-, Co^{2+}- and Pd^{2+}- but not Cr^{3+}-specific TCR showed an increased use of the amino acid histidine in the a- and b-chain complementarity determining region 3 (CDR3).

In conclusion, we provide direct quantitative data on metal-specific T cells and identify metal ion binding points to the TCR. The engagement of TCRs via conserved features is reminiscent of superantigens and the strong T cell reactivity may contribute to the high prevalence of metal allergies.

A novel alveolar macrophage depletion mouse model identifies IRF4 as a master regulator of alveolar macrophage effector function during type 2 lung inflammation

Stijn Verwaerde[1;2], Jean-François Hastir[1;2], Sjoerd Schetters[1;2], Ursula Smole[1;2], Leen Seys[1], Karel Van Damme[1;2], Martijn Schuijs[1;2], Sofie De Prijck[1;2], Kim Deswarte[1;2], Laura Bub[3], Tim Willinger[3], Martin Guilliams[1;2], Bart Lambrecht[1;2]

Background: Alveolar macrophages (AMs) represent the predominant immune cell population within healthy pulmonary tissue and have been implicated in exerting an immunoregulatory function within the lung milieu. However, their precise involvement in allergic conditions has been subject to extensive debate, primarily due to the limited availability of techniques capable of selectively depleting AMs and distinguishing between the functional contribution of resident embryonic-derived AMs versus recruited bone marrow-derived counterparts.

Methods and Results: Intranasal administration of interleukin 33 (IL33) and house dust mite (HDM) extract, established *in vivo* models of allergic asthma, result in an early recruitment of eosinophils, neutrophils, and type 2 innate lymphoid cells (ILC2s) into the bronchoalveolar lavage fluid (BALF). To elucidate the underlying mechanisms orchestrating inflammatory cell influx in the BALF, single-cell RNA profiling of IL33-treated animals was conducted, revealing substantial transcriptional alterations within resident AMs, concomitant with the synthesis of type 2-associated chemokines, notably CCL17 and CCL24. Subsequent ATAC sequencing unveiled an enrichment of IRF4 motifs in resident AMs following IL33 exposure, accompanied by an upregulation of IRF4 expression with intracellular staining. To test the impact of resident AMs on BALF cellular influx *in vivo,* we engineered a novel transgenic mouse model (Specific AM Deleter mice – or SPAM deleter) enabling selective depletion of AMs through diphtheria toxin administration. Leveraging this system, intratracheal adoptive transfer of IRF4-deficient resident AMs into SPAM deleter mice post-AM depletion revealed a reduction in cellular infiltrate within the BALF, albeit not in the pulmonary parenchyma, upon exposure to IL33 or a model of HDM-induced asthma. This reduction correlated with diminished levels of BALF eotaxin (CCL11, CCL24) and CCL17. Additionally, we demonstrated the dependence of IRF4 expression on ILC2-derived IL13, rather than IL33, through adoptive transfers involving *Il4ra*-/- and *Il1rl1*-/- AMs in SPAM deleter animals and utilizing ILC2-deficient transgenic mice.

Conclusion: We generated a novel mouse model allowing for specific depletion of AMs and found that resident AMs promote cellular influx in the BALF but not in the lung parenchyma during models of experimental asthma. Mechanistically, ILC2-derived IL13 drives IRF4 upregulation in AMs, thereby inducing the expression of type 2-associated chemokines.

Introduction: Atopic dermatitis (AD) is a chronic inflammatory skin disease characterized by the interplay of genetic, environmental, and immunological factors, frequently associated with food allergies (FA). Both AD and FA are associated with penetration of allergens and microorganisms through the disrupted skin or gut barriers. In this study, we search for serum biomarkers associated with barrier integrity (TSLP) and immune response to bacteria (CD14 and lipopolysaccharide binding protein (LBP)) in patients with AD and FA to milk, eggs or its combination.

Methods: We collected blood serum from 165 infants or toddlers (aged 3-12 months) with manifested forms of AD. Part of these patients had AD associated with FA (mainly to cow milk and egg). Serum levels of TSLP, CD14 and LBP markers were measured by ELISA and comparative analysis for each marker was performed in patients with and without FA to milk; patients with and without FA to eggs; and patients with and without combined milk and eggs FA.

Results: We found significantly lower levels of serum TSLP in AD patients with FA to milk ($p=0.036$), and with combined milk and eggs FA ($p=0.038$), but not with FA to eggs only ($p=0.084$) in comparison to AD patients without FA. The serum levels of CD14 were also significantly lower in patients with AD and FA to milk ($p=0.0089$), and to milk and eggs ($p=0.023$), but not to eggs only ($p=0.077$). The serum levels of LBP weren't significantly different in all groups tested compared to AD patients without FA

Conclusions: Biomarkers related to barrier integrity and immune response to bacteria are lower in patients with AD and FA to milk or milk and eggs in combination. Further, we will link these data with the results of the microbiota analysis and identify the combination of markers that could predict the onset and progression of the disease in AD and FA patients.

Molecular insights into shrimp allergy

Dhouha Krir[1;2], Ines Ben Sghaier[1], Yosra Nasri[1], Mariem Marrak[1;2], Imen Zamali[1;2], Ahlem Ben Hmid[1;2], Hayet Kbaier[1], Mouldi Hidri[1], Walid Hamdi[1], Yousr Galai[1;2], Melika Ben Ahmed[1;2], Samar Samoud[1;2]

[1]*Pasteur Institute of Tunis, Department of Clinical Immunology, Tunis, Tunisia*; [2]*Faculty of Medicine of Tunis, University of Tunis El Manar, Tunis, Tunisia*

Background: Crustacean allergy, particularly to shrimp, is one of the eight major food allergens that account for approximately 90% of severe allergic reactions. Given its typical association with a type I hypersensitivity reaction, quantitative determination of specific IgE stands as the most reliable diagnostic approach.

Purpose: Our aim was to assess the seroprevalence of specific IgE antibodies, specifically targeting molecular recombinant Tropomyosin rPen a1, in individuals exhibiting clinical symptoms suggestive of shrimp allergy.

Methods: We conducted a retrospective study spanning a 39-month period (01/01/2021-01/04/2024). Sera from 25 patients were analyzed for shrimp specific IgE (F24) and/or their major molecular recombinants (F351) (Tropomyosin rPen a1) using a fluoro-enzyme immunoassay (FEIA).

Results: Among the 25 samples analyzed from individuals with clinical symptoms suggestive of shrimp allergy, 14 (56%) tested positive for shrimp specific IgE. The mean age of the participants was 19.5 years. Five out of the 14 (35,7%) patients who tested positive for f24 experienced a severe allergic reaction in the form of Quincke's edema while 6 (42.8%) manifested urticaria. Out of the participants, only 9 (64.3%) sought additional testing for Tropomyosin rPen a1. In 77.7% of these cases, the results were positive, indicating a true allergy to shrimp. Cross-reactivity was detected in 11 of the 14 f24-positive patients, which represents 78.6% of the group. Among them, 27,2% had food allergy and 36,3% had respiratory allergy.

Conclusion: The high prevalence of shrimp allergy in our series, along with the notable risk of anaphylaxis associated with Tropomyosin rPen a1, highlights the importance of molecular antigens in evaluating prognosis and improving the management of allergic patients. A larger cohort study is needed to confirm these findings.

Component-resolved allergy diagnostics in Honeybee venom allergy

Georgi Nikolov[1], Radoslava Emilova[1], Yana Todorova[1], Maria Nikolova[1], Bogdan Petrunov[1]

[1]*National Reference Laboratory of Immunology, National Centre of Infectious and Parasitic Diseases, Sofia, Bulgaria*

The purpose of our study is to perform component resolved diagnosis (CRD) of honeybee venom allergy (HBV) using specific recombinant allergen molecules.

Patients and Methods: 30 patients (21 male and 9 females, aged 11-69 years) were included in this study. The included criteria were history of the systemic allergic reaction after bee stings and positive reaction after allergy skin test with allergen extract of bee venom (papule size > 3 mm, erythema > 3 mm). The following molecules were used to perform CRD: rApi m1 (Phospholipase A2) (i208); rApi m2 (Hyaluronidase) (i214) and major allergen of HBV - Api m 10 (Icarapin) (i217).

The serum concentration of specific IgE (sIgE) against natural bee venom extract (i1) as well as against recombinant allergen molecules of bee venom were measured by FEIA and values ≥0.35 kU/l were considered positive.

Results: The elevated >0.35 kU/l serum sIgE levels against natural bee venom extract (i1) was observed in all participants (100%). The results of positive sIgE against recombinant allergen molecules were as follows: 43% Api m 10 (Icarapin), 70% rApi m1 Phospholipase A2 (i208) and 60% rApi m2 Hyaluronidase (i214). Noteworthy, in 7 (23%) of the participants we observed positive sIgE levels against all three specific recombinant allergen molecules.

Conclusion: Api m1, Api m2 and Api m10 are suitable for identifying specific sensitization to HBV. Taking into consideration that CRD is particularly important for the elucidation of double sensitization, the commercial availability of a panel of marker allergens can be considered highly valuable for adequate diagnostics.

Purpose: The hallmark of obese asthma is the infiltration of neutrophils and Th17 cells to the lungs. This asthma phenotype confers more resistance to corticosteroid treatment. Endothelial glycocalyx (EG) is a network of proteoglycans and glycoproteins that regulates leukocyte-endothelium interaction. EG shedding induced by heparanase increases leukocyte migration. We hypothesized that obesity-induced gut dysbiosis promotes EG shedding and increase pulmonary neutrophil and Th17 cell influx, resulting in asthma exacerbation.

Methods: Female C57BL/6 mice were fed with high-fat diet (HFD) for 12 weeks following exposure to ovalbumin (OVA) for the induction of experimental asthma. Bronchoalveolar lavage fluid (BALF) and lungs were collected to evaluate pulmonary inflammation by flow cytometry and histopathologic analyze. Airway resistance was measured by FlexVent. Lung EG integrity was evaluated by electron microscopy. EG shedding was evaluated in serum samples from asthmatic with obesity and lean asthmatic subjects by ELISA. Intestinal permeability was measured by FITC-dextran assay. Gut microbiota was characterized by 16S RNA sequencing. Lungs and spleen homogenates were incubated under aerobic or anaerobic conditions to evaluate bacterial translocation.

Results: Mice with obesity exposed to allergen (HFD+OVA) showed increased neutrophils in the BALF, Th17 cells and mucus production in the lungs compared to lean mice exposed to OVA (LFD+OVA). HFD+OVA also exhibited increased airway resistance compared to LFD+OVA. We observed reduction in lung EG thickness in HFD+OVA compared to HFD and LFD+OVA groups. Asthmatic patients with obesity exhibited increase of serum heparanase compared to lean asthmatic subjects. HFD+OVA exhibited an increase of *Romboutsia* and reduction of *Parabacteroides* in the feces compared to LFD+OVA. These bacteria are related to endothelial function and heparanase inhibition, respectively. HFD+OVA displayed an increase of intestinal permeability and consequent bacterial translocation to spleen. In the lungs of HFD group, aerobic bacteria were predominant with loss of anaerobic bacteria growth observed in LFD mice, independent of OVA exposure.

Conclusion: Obesity promotes bacterial translocation that is probably inducing EG shedding after the allergen exposure. EG shedding increases neutrophil and Th17 cell influx to the lungs and exacerbates asthma. EG might represent therapeutic target to reduce pulmonary inflammation during the comorbidity obesity and asthma.

Lung Microbiota analysis of asthmatics reveals pathogenic microbial blooms corresponding to lung inflammation and reduced microbial diversity

John Mac Sharry[1], Laura Walsh[1], Desmond Murphy[2]

[1]*University College Cork, Cork, Ireland*; [2]*Cork University Hospital, Cork, Ireland*

Background: The existence of the lung microbiota has in recent years become to be appreciated. The lung microbiome by the nature of the lung function and mucociliary clearance is believed to be dynamic but diversified. We sought to characterise the lung microbiota in severe and non-severe asthmatics and investigate if the microbiota provided an insight into the pathology of severe asthma.

Methods: Bronchoalveolar lavage (BAL) samples from 44 patients with a known diagnosis of asthma were collected. BAL cell counts and cytokine levels in both the lavage sample and matched serum samples were analyzed. Following DNA extraction, the microbial community of the BAL was analyzed using whole genome sequencing followed by analysis using the OneCodex platform and confirmation by qPCR.

Results: The lung microbiome is dynamic but does have consistent microbial species such as Micromonospora and Prevotella (90 % of all samples) with an average Shannon diversity of 3.5. Severe asthmatics who smoke and have reduced FEV-1 displayed less abundance of *Prevotella pallens* and those with a Body mass Index (BMI) > 30 had reduced presence of Micromonospora species. Several samples displayed the presence of reduced microbial diversity and pathogenic blooms of *Haemophilus influenzae*, *H. parainflunezae*, *Staphylococcus sp. HMSC057B0* and *Streptococcus pneumoniae*. These blooms correlated with increased BAL neutrophils, lymphocytes and raised BAL IL1b, IL-8, IL-17 and TNFa and serum neutrophils.

Conclusion: The lung microbiota is reflective of asthmatic severity and screening for decreased microbial diversity and microbial blooms could provide a useful tool for asthma stratification but also targeted therapeutics during episodes of exacerbation.

Airway and systemic immunoglobulin profiling and immune response in adult asthma

John Mac Sharry[1], Laura Walsh[1], Desmond Murphy[2]

[1]*University College Cork, Cork, Ireland*; [2]*Cork University Hospital, Cork, Ireland*

Introduction: Immunoglobulins play a vital role in host immune response and in the pathogenesis of conditions like asthma. Therapeutic agents such as monoclonal antibodies target specific elements of the asthmatic inflammatory cascade. Decisions to utilize these medications are often based on systemic inflammatory profiling without direct insight into the airway inflammatory profile. We sought to investigate the relationship between immunoglobulin and cytokine profiles in the airway and systemic immune compartments of adult asthmatics.

Methods: Blood sampling and bronchoscopy with bronchoalveolar lavage (BAL) were performed in 76 well-defined adult asthmatics. Antibody and cytokine profiles were measured in both BAL and serum using ELISA and quantibody arrays.

Results: There was no relationship between BAL and serum levels of IgE which is of significance in an asthma population. Significant correlations were found between BAL and serum levels for IgM (P<0.0001), IgA (P<0.001), IgG2 (P<0.02) and IgG4 (P<0.0001) and also BAL and plasma levels of IL-10, IL-13, IL-4, TNF-α (P <0.0001), IL-1β (P=0.04), IL-5 (P=0.001) and IL-6 (P =0.002).

Conclusions: This study highlights the importance of sample site when investigating the roles of immunoglobulins and cytokines in disease pathogenesis and suggests that both localized and systemic immune responses are at play. The prescription of asthma monoclonal therapy is generally based on systemic evaluation of cytokine and immunoglobulin levels. Our research suggests that this approach may not fully reflect the pathophysiology of the disease and may provide insight into why some patients respond to these targeted therapies while others do not.

Antigen presenting cells in melanoma – role in tumor regression

Teodora Monica Neagu [1;2;3], Carolina Constantin[1;2], Carmen Dumitru [2], Sabina Zurac [2;4]

[1]Victor Babeș National Institute of Pathology, Bucuresti, Romania; *[2]Colentina Hospital, Bucharest, Romania*; *[3]Faculty of Biology, Bucharest, Romania*; *[4]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*

Purpose: We aimed to evaluate the presence of antigen presenting cells (APC) in various areas of cutaneous melanoma, with regression and non-regression features in order to correlate with the local immune response.

Methods: 102 parrafin embeded cutaneous melanoma samples (Ethical Commitee approval and individual informed consent) were investigated for the presence of Langerhans cells (LCs) and other immune cells that infiltrate the regressed and non-regressed areas. 62 superficial spreading melanoma (SSM), 31 nodular melanoma (NM) and 9 acral-lentiginous melanoma (ALM) were investigated. Immunohistochemistry: S-100, HLA-DR, LCA, CD-1, Langerin (CD207), CD4, CD5, CD8, CD 14, CD 16, CD22. Melanoma regression was established according to the pathology guidelines.

Results: Out of the 102 samples, reggresion was identified in 39 SSM and 7 ALM, statistically significant in stage I melanomas localized on the trunk. Within the regressed areas LCs were found frequently with a nodular distribution. Regression is associated with statistically significant presence of tumor infiltrating lymphocytes (TIL), in almost all stage I melanoma cases (84.3%). TIL has mainly Th cells, reduced number of B cells and macrophages; CD4: CD8 ratio is 4:1 with a large interval from 1.3 to 19. TILs were found in thin and superficial melanomas with a high density in deep dermis. Dendritic cells (DC) S-100+ were identified in deep dermis in all samples at a density of 55±6/mm2, more frequent in *in situ* melanomas as compared to profound and invasive melanomas. LC:DC S-100 + ratio was identified in the 5.5 to 15.5 interval. LC residing in the melanoma epidermis have a lower proportion of S100+ expression in the majority of melanomas (80%) in comparison to the normal adjacent epidermis ($p < 0.0005$), while around 50% of the samples had a significant reduction of LC CD1+ in the tumor epidermis compared to the normal epidermis ($p<0.0005$).

Conclusion: The presence of APCs in the regressed areas of cutaneous melanomas brings new information on the active immune response within the tumor.

The presented study was financed through grants PN-III-P4-PCE-2021-0549 (PCE9/2022), NASR, [PN 23.16.01.03] and authors acknowledge also COST Action CA21108 - European Network for Skin Engineering and Modeling (NetSkinModels).

Targeting the unconventional

Michele Mishto[1]

[1]*Crick Institute, London, United Kingdom*

Since 2004 we know that proteasomes can ligate peptide fragments through a process called peptide splicing and few examples of their immunogenicity in the context of cancer have been published. We developed several pipelines to identify and predict these unconventional epitopes and tested their immunogenicity and potential for therapeutical applications mediated by CD8+ T cell cytotoxic activity.

The immunological relevance of proteasome-generated spliced epitopes is still unclear and their identification requires specific know-how and tools, which have been developed by my lab and collaborators, putting us at the cutting edge of this research field. The potential role of these targets for the next generation immunotherapies still needs to be defined, for example using these tools.

Celiac disease defined by over-sensitivity to gliadin activation and superior antigen presentation of dendritic cells

Michael Hudec[1], Kamila Riegerová[2], Jan Pala[3], Viera Kútna[4], Marie Černá[1], Valerie Bríd O´Leary[1]

[1]Department of Medical Genetics, Third Faculty of Medicine, Charles University, Prague, Czech Republic; *[2]Department of Immunology and Clinical Biochemistry, Prague, Czech Republic*; *[3]Department of Pathophysiology, Third Faculty of Medicine, Charles University, Prague, Czech Republic*; *[4]Department of Experimental Neurobiology, National Institute of Mental Health, Klecany, Czech Republic*

The autoimmune condition, Celiac Disease (CeD), displays broad clinical symptoms due to gluten exposure. Its genetic association with DQ variants in the human leukocyte antigen (HLA system has been recognised. Monocyte-derived mature dendritic cells (MoDCs) present gluten peptides through HLA-DQ and co-stimulatory molecules to T lymphocytes, eliciting a cytokine-rich microenvironment. Having access to CeD associated families prevalent in the Czech Republic, this study utilised an in vitro model to investigate their differential monocyte profile. The higher monocyte yields isolated from PBMCs of CeD patients versus control individuals also reflected the greater proportion of dendritic cells derived from these sources following lipopolysaccharide (LPS)/ peptictryptic-gliadin (PTG) fragment stimulation. Cell surface markers of CeD monocytes and MoDCs were subsequently profiled. This foremost study identified a novel bio-profile characterised by elevated CD64 and reduced CD33 levels, unique to CD14++ monocytes of CeD patients. Normalisation to LPS stimulation revealed the increased sensitivity of CeD-MoDCs to PTG, as shown by CD86 and HLA-DQ flow cytometric readouts. Enhanced CD86 and HLA-DQ expression in CeD-MoDCs were revealed by confocal microscopy. Analysis highlighted their dominance at the CeD-MoDC membrane in comparison to controls, reflective of superior antigen presentation ability. In conclusion, this investigative study deciphered the monocytes and MoDCs of CeD patients with the identification of a novel bio-profile marker of potential diagnostic value for clinical interpretation. Herein, the characterisation of CD86 and HLA-DQ as activators to stimulants, along with robust membrane assembly reflective of efficient antigen presentation, offers CeD targeted therapeutic avenues worth further exploration.

Screening and Application of hepatocellular carcinoma-related Antigen AFP Specific T cell Epitope Spectrum

Suyue Zhu[1], Yi Wu[1], Yu Zhao[1], Yandan Wu[1], Fangping Yue[1], Chuanlai Shen[1]

[1]*Department of Microbiology and Immunology, Medical School of Southeast University, Nanjing, China*

Purpose: To identify the predominant T cell epitope spectrum of AFP presented by 45 predominant HLA-A/B/ C molecules in Chinese and East Asian populations, and to establish a broad-spectrum T cell epitope peptide library that not only conforms to the HLA polymorphism of the vast majority of populations in this region, but also fully reflects the richness of T cell epitopes in HCC antigen. Combined with ELISpot technology, a multi-level universal detection system for HCC patient-specific T cell immune function was established.

Methods: We used multiple databases to predict and screen the candidate epitopes of AFP, and then used two experimental methods to verify the immunogenicity of the candidate epitopes. First, we collectc PBMCs from peripheral blood of HCC patients and confirm HLA genotyping .then we utilized the matching HLA-A/B/C molecular candidate epitope and PBMCs co-culture for 6 hours, and the activation frequency of $CD8^+$T/INF-γ+ was detected by ICS with FCM. Second, the competitive binding experiment was performed between the candidate epitopes and HMy2. CIR cell lines which expressing different HLA molecules.

Results: 68 candidate epitopes could be cross-represented by different HLA-A/B/C molecules, and aslo could induce strong AFP-specific $CD8^+$T responses in vitro by Elispot experiment with PBMCs of HCC patients.Compared to the negative group the activation frequency of $CD8^+$T/INF-γ+ increase by more than 5 multiple.

Conclusion: 68 AFP epitopes are AFP specific $CD8^+$T cell epitopes, which can be used for the universal detection system of specific T cell immune function in HCC patients and the study of tumor vaccine.

Exploring the role of T cell epitopes in the development of non-specific Lipid Transfer Proteins Allergy

Paula Álvarez Romero[1], Juan Molina Alcaide[1;2], Rocío Aguado Álvarez[1;2], Ana Navas[1;2], Bárbara Manzanares Martín[3], Aurora Jurado Roger[1;2]

[1]Maimonides Biomedical Research Institute of Córdoba (IMIBIC)/ University of Córdoba, Córdoba, Spain; *[2]Reina Sofía University Hospital, Córdoba, Spain*; *[3]Transfusion, Tissues and Cells Centre (CTTC), Córdoba, Spain*

Purpose: Type I hypersensitivity is mediated by specific immunoglobulin E (sIgE), produced by B cells. T cells are less studied, although important, due to Human Leukocyte Antigen (HLA) class II-mediated peptide presentation by dendritic cells. Allergen-specific responses of CD4+ T-cells contribute to sensitisation and promotes their differentiation towards Th2. The purpose of this study was to elucidate the role of HLA-class II in the development of allergy to non-specific Lipid Transfer Proteins (nsLTPs), specifically to Pru p 3, the peach nsLTP, and to Ole e 7, the olive pollen nsLTP.

Methods: Allergic patients to Ole e 7 and/or Pru p 3 were selected at the Reina Sofía University Hospital (Córdoba, Spain) according to sIgE levels (ImmunoCAP 250; positivity threshold>0.35 kUI/L) and classified into three groups: MONOLE (Ole e 7-monosensitised; n=14), MONPRU (Pru p 3-monosensitised; n=15) or BI (bisensitised; n=13). Their HLA class II (HLA-DRB1, -DQB1, -DPB1) was sequenced using Luminex® xMAP® technology. Prediction of T-cell epitopes was conducted by Immune Epitope Database Analysis Resource, using Uniprot code Q9LED1 for Pru p 3 and Ole e 7 sequence from literature.

Results: MONOLE patients mainly exhibited rhinoconjuntivitis (92.9%) and asthma (85.7%), but not oral-allergy symptoms, in contrast to MONPRU patients, who described Rosaceae symptoms (73.3%), and less often, respiratory symptoms (60.0% rhinoconjuntivitis and 26.7% asthma). Additionally, BI patients manifested oral-allergy and respiratory symptoms. HLA-class II frequency analysis in all patients showed the prevalence of HLA-DRB1*04, –DQB1*03, including serologic DQ7, DQ8 and DQ9, and DPB1*04 (23.8%, 42.9%, and 50%, respectively). Statistical analysis revealed significant differences in DR11-DQ7 frequency between the three groups (MONOLE=0/14; MONPRU=10/15; BI=4/13; for DR11 and MONOLE=1/14; MONPRU=12/15; BI=4/13; for DQ7; $p<0.05$) and a tendency for DR4 (MONOLE=10/14; MONPRU=5/15; BI=4/13; $p=0.054$). Furthermore, T-cell epitope analysis predicted a high binding capacity between Pru p 3 epitopes and DR11, and also, between Ole e 7 epitopes and DR4. DQ3 epitope binding showed good scores with both nsLTPs.

Conclusion: Certain HLA class II alleles could promote presentation of specific nsLTPs epitopes to T-cells. The difference in the binding ability among epitopes and HLA molecules could underlie the predisposition of some individuals to nsLTPs allergy.

A new look on the antigens involved in multiple sclerosis: using immunopeptidomics to identify naturally processed myelin epitopes

Eline Mertens[1;2], Judith Derdelinckx[1;3], Karin Schildermans[2;4], Mats van Delen[1;2], Geert Baggerman[2;4], Inge Mertens[2;4], Nathalie Cools[1;5]

[1]Laboratory of Experimental Hematology, VAXINFECTIO, University of Antwerp, Antwerp, Belgium; *[2]Health Unit, Flemish Institute for Technological Research (VITO), Mol, Belgium*; *[3]Department of Neurology, Antwerp University Hospital, Antwerp, Belgium*; *[4]Centre for Proteomics, University of Antwerp, Antwerp, Belgium*; *[5]Centre for Cell Therapy and Regenerative Medicine, Antwerp University Hospital, Antwerp, Belgium*

Purpose: Multiple Sclerosis (MS) is a chronic disease affecting 2,8 million people worldwide. Current treatment options include immunosuppressive agents. However, these therapies heighten the risk of opportunistic infections and malignancies. Therefore, antigen-specific therapies are being developed. Crucial to the development of these therapies is the knowledge of which epitopes are involved in MS. In this project, we have made use of a mass spectrometric-based approach called immunopeptidomics to identify epitopes that have been processed from myelin proteins by dendritic cells (DCs).
Methods: Mature, stimulatory DCs (mDCs) and tolerance-inducing DCs (tolDCs) were differentiated from monocytes. mDCs and tolDCs were electroporated with myelin oligodendrocyte glycoprotein (MOG) and myelin basic protein (MBP) mRNA. Tolerogenicity of tolDCs was determined before and after electroporation by making use of allogeneic mixed lymphocyte reaction and immunophenotyping. The expression of MOG protein in electroporated tolDCs was studied with intracellular staining. Antigen presentation in electroporated mDCs was assessed by measuring the activation of MBP-specific T cells in a DC-T cell coculture with interferon (IFN)-γ ELISA. Immunopeptidomic analysis was performed on electroporated mDCs and tolDCs to identify the presented myelin-derived antigens.
Results: Electroporation did not change the tolerogenic phenotype of tolDCs as evidenced by reduced expression of the costimulatory markers CD80/CD83/CD86 and a reduced T cell-stimulatory activity compared to mDCs. MOG protein expression was detected after mRNA electroporation. mRNA-electroporated mDCs were able to activate T cells in an antigen-specific manner as seen in the higher secretion of IFN-γ in the cocultures with mRNA-electroporated mDCs compared to those with non-electroporated mDCs. MOG- and MBP-derived epitopes were detected on mRNA-electroporated mDCs and tolDCs by immunopeptidomic analysis.
Conclusion: We have shown here that immunopeptidomic analysis on DCs loaded with myelin proteins by electroporation can be used to identify naturally processed myelin epitopes. Interestingly, one of the identified epitopes had not yet been described in literature. Furthermore, we were able to show that electroporation was able to induce antigen presentation to T cells. In further experiments, we will also perform immunopeptidomics on DCs loaded with myelin lysate by phagocytosis. This further approaches the in vivo processes involved in antigen presentation.

Closer Peptide Repertoire Similarity of HLA-B14:03 and HLA-B27:05 Sheds Light on Ankylosing Spondylitis Susceptibility

Laura Cobos-Figueroa[1], Javier Robles-Parrado[1], Carmen Mir[1], Ana Pintor-Poveda[1], Pilar Lauzurica[1], Elena Lorente[1]

[1]*National Center for Microbiology, Madrid, Spain*

The human major histocompatibility complex class I (HLA-I) gene HLA-B*27 is the main risk factor for the rheumatic disease ankylosing spondylitis (AS) through an unknown mechanism. However, in African populations, where B*27 is rare, the B*14:03 allotype is strongly associated with AS, while B*14:02, which only differs from B*14:03 at one residue (L156R), is not associated with the disease. Here, we have used large-scale mass spectrometry-based peptide sequencing to analyze the peptidomes of HLA-B*14:03, HLA-B*14:02, and HLA-B*27:05, obtaining more than 2000 peptide ligands for each molecule. Remarkably, we found 1011 ligands shared by the AS-associated HLA-B*27:05 and -B*14:03 alleles and not by the non-AS-associated B*14:02 allele. Surprisingly, although B*14:03 and B*27:05 differ by 15 amino acids in their peptide binding domain, they show a large overlap of their ligands (64 and 43% respectively), while B*14:03 and B*14:02, which differ by only one residue, show a lower degree of overlap (33-35%). Furthermore, the B*14:03 peptide repertoire most resembles that of B*27:05 at the P1, P2, and P5 positions of the peptides, and differs most at the C-terminal position, where B*14:03 is more restrictive than B*27:05. We have modeled how the change at residue 156 of the two B*14 alleles could have a long-range indirect effect on residues P1, P2, and P5 of the peptide ligands, explaining the different amino acid distribution observed between the two B*14 subtypes at those positions. Most of the 1011 specific ligands of B*14:03 and B*27:05 presented R/K/A/G at P1, R at P2, and L/F at the C-terminal position. Furthermore, we found that 10 of these 1011 peptides are common with the specific ligands of the most frequent HLA B*27 alleles associated with AS and have not been identified in the ligandomes of the B27 subtypes not associated with the disease, and may act as arthritogenic self-peptides.

In summary, our results show that the two AS-associated allotypes B*14:03 and B*27:05, but not the non-AS-associated allotype B*14:02, share very similar peptide repertoires and binding characteristics, supporting specific common peptide ligands of HLA-B*27:05 and B*14:03 as a mechanism to explain the development of ankylosing spondylitis.

Unlocking HLA diversity: innovative CRISPR strategies for peptide repertoire analysis

Laura Cobos-Figueroa[1], Carmen Mir[1], Ana Pintor-Poveda[1], Pilar Lauzurica[1], Elena Lorente[1]

[1]*National Center for Microbiology, Madrid, Spain*

The human leukocyte antigen (HLA) system plays a crucial role presenting peptides to T lymphocytes during infectious, tumoral and autoimmune processes. However, identifying these peptides poses challenges due to the high polymorphism, polygeny, and limited availability of specific antibodies for most HLA alleles. Traditionally, transfection methods have been used to express HLA molecules of interest, but these techniques have significant limitations in terms of expression regulation and availability of suitable cell types.

To address these limitations, we propose an innovative strategy employing CRISPR technology to selectively eliminate undesired class I HLA molecules, followed by an analysis of the peptide repertoire via immunoprecipitation with a pan-specific HLA antibody. In JY cells expressing HLA-A*02:01, B*07:02, and C*07:01, we deleted HLA-B and -C molecules and examined the peptide repertoire of the HLA-A*02:01 molecule using mass spectrometry. Subsequently, we immunoprecipitated HLA molecules with PA2.1 and the pan-specific antibody W6/32 in both wild-type (WT) clones and clones lacking HLA-B and -C ($BC^{-/-}$). To validate our approach, we compared our methodology with the use of a specific antibody (PA2.1).

Notably, the overlap observed between the peptides identified in $BC^{-/-}$ clones using the pan-specific W6/32 antibody and those identified using the HLA-A*02-specific PA2.1 antibody was comparable to the overlap observed between the peptides identified using pan-specific W6/32 from $BC^{-/-}$ clones and those identified using HLA-A*02-specific PA2.1 from WT clones. On average, our analysis revealed approximately 2000 peptides presented by HLA-A*02:01 in both settings. These results support the feasibility of our methodology for identifying the peptide repertoire of other HLA molecules of interest for which specific antibodies do not exist.

Furthermore, we deleted HLA-A*02:01 in the BC-/- clones to explore the ligands presented by non-classical class I HLA molecules. Following immunoprecipitation with W6/32, we identified over three hundred peptides presented in the absence of HLA-A, -B, and -C by mass spectrometry.

These findings highlight the potential of our approach in delineating the peptide repertoires of other HLA molecules lacking specific antibodies, thus opening new avenues for investigating antigen presentation mechanisms in various pathophysiological contexts.

Optimization of dendritic cell activation via HIV-1 infection under xeno-free conditions

Paul Schweighofer[1], Wilfried Posch[1], Doris Wilflingseder[1;2]

[1]Institute of Hygiene and Medical Microbiology / Medical University of Innsbruck, Innsbruck, Austria; [2]Dept. of Pathobiology, Infectiology Unit, Veterinary University of Vienna, Vienna, Austria

Human platelet lysate (hPL) as a medium constituent for immune cells has been investigated and improved over decades and with the rising qualities in its production, the replacement of fetal calf serum (FCS) for various cell lines gains feasibility and urgency. To achieve this, specific qualitative criteria need to be met in order to identify successful replacement, namely benchmarks such as viability, differentiation, activation and functionality of the immune cells.

In this study, the quality and quantity of human monocyte-derived dendritic cells (DCs), cultured in (hPL)-based or (FCS)-containing media when infected with HIV-1 or stimulated with lipopolysaccharide (LPS), were monitored. The DC phenotype of immature, mature and HIV-infected DCs as well as cell viability, DC differentiation and maturation status and infection levels were studied in detail using multi-parameter flow cytometry. Confocal microscopy was applied as a qualitative and quantitative tool for virus particles measurements and DC phenotype and productive infection of DCs was quantified by ELISA against the viral p24 protein.

Confocal imaging and p24 ELISA as quantification tool for infection levels illustrated dendritic cells cultured in FCS superior compared to hPL-cultured DCs. Unspecific activation was higher in FCS-grown immature DCs. Calculations based on the viability of dendritic cells throughout the procedure relative to the seeded amount and the differentiation and maturation rates showed elevated yields of LPS-matured cells grown in hPL, while HIV-C infection led to significantly higher yields of matured cells in the FCS setting.

So far, we found that hPL presents as a viable substituent for the differentiation and activation of dendritic cells through LPS application. Since for HIV-infection as well as in immune-competent *in vitro* models, an immature DC phenotype is essential, to date FCS cannot be replaced from the differentiation protocol so far and thus, this process needs further optimization.

The project was funded by the Austrian Sciene Fund (FWF-project P33510-B13 to Professor Doris Wilflingseder) and supported by the intramural funding program of the Medical University Innsbruck Ph.D. Research Training Groups, Project 2022-1-2 “CONNECT”

The hidden power of anti-inflammatory macrophages: unveiling their role as cross-presenters in the activation of cytotoxic T cells

Alexine de Wit[1], Geert Van. den. Bogaart[1], Frans Bianchi[1]

[1]*University of Groningen, Groningen, Netherlands*

Cross-presentation is the process by which antigen-presenting cells (APC) present antigens derived from extracellular sources on their major histocompatibility complex class I (MHC-I) molecules. Cross-priming is the process by which APCs activate naïve CD8+ T cells via cross-presentation in secondary lymphoid organs. Consequently, cross-presentation and cross-priming are essential for the elimination of infected or malignantly transformed cells.

Traditionally, dendritic cells have been recognized as the primary cell type responsible for cross-priming, with other APCs like macrophages often considered incapable of this process. However, this view has recently been challenged. Using mRNA transfection of autologous cytolytic T cells and newly engineered antigen specific T-cell lines, we were able to contrast the cross-presenting and cross-priming capabilities of pro-inflammatory and anti-inflammatory macrophages and also link these with their effector phenotypes.

Contrary to our initial expectations, we discovered that anti-inflammatory macrophages are very good cross-presenters. Moreover, we found that, although they are poor activators of naïve CD8+ T cells, they are highly capable of reactivating memory CD8+ T cells. These findings suggest a significant role for anti-inflammatory macrophages in combating recurring infections.

Our research expands the already versatile roles of macrophages, as it suggests that they are not only involved in tissue homeostasis, wound healing, and acute and chronic innate immune responses, but also in battling infections by the reactivating cytotoxic T lymphocytes from the adaptive immune system.

Increasing contribution of mitochondria-derived peptides to the HLA-DR immunopeptidome on different T1D stages

Manel Garcia[1], Yago Arribas[2], Saioa Auzmendi[1], Mercè Rubió[1], Dolores Jaraquemada[1], Carme Roura-Mir[1]

[1]*Institut de Biotecnologia i Biomedicina, Universitat Autònoma de Barcelona, Barcelona, Spain*; [2]*Inserm U932, Immunity and Cancer Unit, Curie Institute, Paris, France*

The trigger behind b-cell destruction in human Type 1 Diabetes (T1D) is unknown. Changes in their protein content are sure to alter the MHC-peptide repertoire of APCs and have an impact in autoreactive T-cell activation. Thus, the analysis of these variations might help identifying key processes behind T1D initiation or maintenance.

To assess the changes in pancreas proteome along T1D progression, human pancreas tissue homogenates from Pre-diabetic, Early and Long term T1D patients were digested with trypsin and analysed by mass spectrometry. Nearly 6000 proteins were identified in all samples, with quantitative and qualitative differences between disease stages. Roughly 100 proteins were differentially expressed across samples and interestingly each of them contained at least 200 unique proteins. The loss of insulin and the reduction of hallmark endocrine proteins confirmed the expected characteristics across samples. The same homogenates were used for pulsing moDCs expressing the T1D-related HLA-DR4 allele. MHC-II-peptide complexes were immunoprecipitated and the eluted peptides analysed by mass spectrometry. The identifications met the characteristics of MHC-II-presented peptides, and a large percentage of their parental proteins reflected the differences across their corresponding proteomes. Peptides derived from potentially relevant parental proteins were detected across samples including the EEF1A1, an autoantibody target in T1D patients, and Reg1A and Reg1B, described T-cell autoantigens in NOD mice. Furthermore, our previous data demonstrated that 25% of these parental proteins were identified in lysosomal fractions from a human b-cell line, including 10 of the parental proteins deemed relevant and 50 mitochondrial proteins. Noteworthy, the mitochondrial proteins showed a progressive decrease in overlapping peptides from Pre-diabetic to T1D stages. Interestingly, both diabetic stages tended to present longer peptides which harboured a higher number of HLA-DR4-binding cores. This could represent a greater number of stable MHC-peptide complexes, widening the array of peptides potentially recognized by the immune system.

These results point at changes in protein content in the pancreas throughout diabetes development and highlight their effect in APCs' MHC-peptide repertoire. The changes in peptide characteristics and the presence of their parental proteins in b-cell lysosomes may indicate a doorway for these proteins into the APCs processing and presentation machinery.

Genetic and Immunological Analysis of PfEBA175 Gene and Antibody Responses in Malaria Patients from Different Transmission Settings in Ghana

Linford Otoo[1], Festus Acquah[1], Linda Amoah[1]

[1]*University of Ghana, Accra, Ghana*

Malaria remains a significant public health challenge in Ghana, with varying transmission intensities across different regions. Understanding the genetic diversity of malaria parasites and host immune responses is crucial for developing effective control strategies. In this study, we investigated the genetic and immunological characteristics of the *Pf*EBA175 gene and antibody responses in malaria patients from various transmission settings in Ghana.

Dried blood spot samples (n=125) were collected from individuals residing in areas with very high (VH), high (H), low/medium (L/M), and very low (VL) malaria transmission settings. *P. falciparum* DNA and serum were extracted using the Chelex extraction method. Serum samples were analyzed using ELISA to assess natural antibody immune responses against EBA175 and the gametocyte stage antigen Pfs230. *P. falciparum* DNA was amplified using PCR, followed by gel electrophoresis and sequencing using the Illumina platform. Multiple sequence alignment and maximum likelihood tree construction were performed to assess genetic relatedness.

Our results revealed no significant differences in immune responses against EBA175 and Pfs230 across different transmission settings and age groups. Moreover, despite the identification of variations in *Pf*EBA175 gene sequences compared to the reference strain *P. falciparum* 3D7, phylogenetic analysis did not identify a clear genetic distinction between parasites from the different transmission settings. This finding suggests potential gene flow or genetic exchange between parasites across different transmission zones, challenging the notion of geographical isolation in malaria parasite populations.

These findings provide insights into the genetic diversity of malaria parasites and host immune responses in diverse transmission settings in Ghana, which is essential for informing malaria control interventions and vaccine development efforts.

Proteomes of gut commensal bacterial extracellular vesicles: search for conserved surface epitopes

Roselydiah Makunja[1], Arina Maltseva[1], Tiina Pessa-Morikawa[1], Masuma Khatun[1;2], Mikael Niku[1]

[1]Veterinary Biosciences, University of Helsinki, University of Helsinki, Finland; *[2]Department of Obstetrics and Gynecology, University of Helsinki, University of Helsinki, Finland*

Purpose: Gut microbiota produces extracellular vesicles (EVs) loaded with proteins, polysaccharides, nucleic acids and metabolites, which modulate intestinal host-microbe interactions and systemic immunity. Recent studies imply that maternal microbial EVs may also be transferred to the fetus. Targeted studies of microbial EVs in host tissues is challenging due to lack of specific reagents distinguishing host and microbial EVs. We analyzed proteomes of mammalian gut commensal EVs, in order to generate antibodies against widely conserved surface epitopes.

Methods: We cultured 15 common bacterial species of the mammalian intestinal microbiota, broadly representing the known phylogenetic diversity, extracted EVs using ultracentrifugation and size exclusion chromatography, characterized the EVs using nanoparticle tracking and electron microscopy, and analyzed the EV proteomes by LC-MS/MS. In addition, we retrieved previously published commensal microbiota EV proteomics datasets. We characterize functional protein groups using the EggNOG mapper and UniProt, and search for optimal immunogenic surface epitopes using the EpitoCore pipeline.

Results and conclusion: The EV proteomic profiles of gram-positive and gram-negative bacteria were expectedly different. The observed proteomes varied in terms of both composition and richness. The most abundant EV proteins tended to be associated with cell surface (such as ABC transporters and porins) but were usually different between bacterial species. The most widely distributed proteins were generally slow-evolving ones with cytosolic localization (such as ribosomal proteins, translation initiation factors and chaperones).

Selection of high affinity recombinant antibodies against human complement protein C3

Ginka Cholakova[1], Rada Poryazova[1], Alexandra Kapogianni[1], Ivanka Tsacheva[1]

[1]*Faculty of Biology - Sofia University, Sofia, Bulgaria*

Introduction: C3 is the key protein in the activation of the Complement system and it is a contributor for the maintenance of an effectively functioning immune system. C3 also appears to be a target for autoantibodies during the development of autoimmune diseases such as Systemic Lupus Erythematosus (SLE). In order to study the molecular aspects of C3 autoantigenicity we aimed to select a high affinity anti-C3 antibodies from the "Griffin 1" phage display library expressing human scFv antibodies.

Materials and methods: We screened the "Griffin 1" phage library in four rounds of selection for anti-human C3 scFv antibodies. We applied a new approach with decreasing the amount of antigen twice in every successive round which resulted in selection of high-affinity recombinant antibodies. The selected anti-C3 phages were used to transfect a non-suppressor *E.coli* HB2151 cells followed by induction and expression of soluble monoclonal anti-C3 scFv antibodies. A quantitative analysis by ELISA was used to assess the scFv clones as low or high affinity ones. A qualitative analysis by immunoblot determined the epitope specificity of the selected clones against C3 and its smaller fragments C3b, C3c and C3d.

Results: Four rounds of phage selection yielded a phage suspension with a titer of 2.76 x 10^4 pfu/ml. Forty clones of recombinant antibodies recognized C3 molecule and five clones, designated B11, F8, F9, F10 and F11, were found to have the highest binding affinity to the tested antigen. Four clones B11, F8, F10 and F11 recognized C3, C3b and C3c, but not C3d.

Conclusion: Antibody phage display is a successful approach to overcome the low immunogenicity of evolutionary conservative proteins like C3. Additionally, the selection approach with decreasing amounts of antigen resulted in four high affinity monoclonal anti-C3 scFv antibodies with established epitope specificity within C3c, suitable for further experimental work.

Uncovering untapped potential: noncanonical neoepitopes and T-cell metabolism in paediatric acute lymphoblastic leukaemia

Nicole Acuti[1;2], Julia Stachowiak[3], Hanna P. Roetschke[1;3;4], Yehor Horokhovskyi[3], Henning Urlaub[5;6], Juliane Liepe[3], Michele Mishto[1;4], Anna Schurich[2]

[1]The Francis Crick Institute, London, United Kingdom; *[2]School of Immunology and Microbial Sciences, Department of Infectious Diseases, King's College London, London, United Kingdom*; *[3]Quantitative and Systems Biology, Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany*; *[4]School of Immunology and Microbial Sciences, Peter Gorer Department of Immunobiology, King's College London, London, United Kingdom*; *[5]Bioanalytical Mass Spectrometry, Max Planck Institute for Multidisciplinary Sciences, Göttingen, Germany*; *[6]Institute for Clinical Chemistry, University Medical Center Göttingen, Göttingen, Germany*

Tumour-specific antigens, also termed neoepitopes, are ideal targets for cancer precision therapies due to their exclusive presence on cancerous cells and frequent implication in the malignant transformation process, rendering them not easily repressible by the tumour via antigen loss. Nevertheless, presentation of neoantigens is often limited by their capability to efficiently undergo the human leukocyte antigen class I presenting pathway due to possible sequence restrictions. To overcome this, our project harnesses noncanonical neoepitopes, consequently obtaining more potentially antigenic and immunogenic neoepitope sequences. Due to the high prevalence of tumour-specific fusion proteins in paediatric acute lymphoblastic leukaemia, noncanonical neoepitopes could be a promising target for immunotherapy. Using our *in vitro-in silico* pipeline we have already identified potential neoepitopes, which we are currently validating via distinct *ex vivo* approaches, including exploring their ability to induce anti-cancer T-cell responses. However, to ultimately harness the most promising targets for immunotherapy, it is crucial to gain a better understanding of the functional profile of patients' T-cells, including differentiation, effector functions and exhaustion levels. The latter are inherently linked to the T-cells' metabolic profile, an area that still lacks comprehensive exploration in children and will be a primary focus of our project. In conclusion, our study aims to improve adoptive cell therapies through identification of novel immunogenic cancer-specific neoantigens and the strengthening of T-cell responses tailored to our patients.

Potential cross-reactivity between tisular transglutaminase neo-epitope antibodies and Helicobacter pylori antibodies in coeliac disease diagnosis

Marc Perez-Guzman[1], Juliana Ochoa Grullon[1], Silvia Sanchez Ramon[1], Miguel Fernandez Arquero[1], María Guzmán-Fulgencio[1], Alejandro Pereiro Rodríguez[1], Maria Palacios Ortega[1], Angela Villegas Mendiola[1], Teresa Guerra Galan[1], Kauzar Mohamed Mohamed[1], Maria Dolores Mansilla Ruiz[1], Maria del Carmen Rodriguez[1], María Ruiz[1]

[1]*Hospital Clínico San Carlos, Madrid, Spain*

The processing of gliadin peptide by the tissue transglutaminase (tTG) produces deamidation and cross-linking reactions resulting in deamidated gliadin peptide (DGP) and tTG-neo epitope complexes that become immunogenic and may lead in coeliac disease (CD) in genetically predisposed indivduals. Detection of tTG neo-epitope antibodies is increasingly used for CD screening due to its high sensitivity because of the conformational epitope recognition. However, some patients show high titers of tTG neo-epitope that not correlates with levels of IgA and IgG against tTG, DGP or IgG against endomysium. Once known this, we observed that some of these patients were positive for *H. pylori* IgG antibody suggesting a possible cross-reactivity between *H. pylori* antibodies and tTG neo-epitope antibodies. To look into this phenomenon, we analyzed the *H. pylori* IgG antibody levels from the sera of 33 patients with tTG neo-epitope positive test for IgA and IgG antibodies using ELISA. Results show that 11 patients (30%) tested positive for *H. pylori* IgG, and only 2 of them were tested and resulted positive for *H. pylori* through endoscopic examination, suggesting that antibodies against *H. pylori* might cross-react with neoepitope assays of tTG, potentially interfering in CD screening. Moreover, given the possible cross-reaction with other antibodies, intestinal diseases and other infections should be considered in cases where tTG neo-epitopes antibodies are positive and result negative for *H. pylori*. Further studies are needed to clarify the clinical significance of this potential cross-reactivity.

Expansion of CD8 T-cells recognizing tumor-shared antigens is correlated to the clinical outcomes of hepatocellular carcinoma patients treated with atezolizumab and bevacizumab

Laurie Spehner[1;2;3], Adeline Bouard[4;5], Christophe BORG[1;2;6], Angélique VIENOT[1;6]

[1]UMR-Right, BESANCON, France; *[2]CIC 1431, BESANCON, France*; *[3]CHRU de Besançon, Besançon, France*; *[4]ITAC platform, Besançon, France*; *[5]University of Franche-Comté, Besançon, France*; *[6]Department of Medical Oncology, CHRU de Besançon, Besançon, France*

Purpose: Hepatocellular carcinoma (HCC) is the most common type of liver cancer detected late and therefore associated with poor prognosis. Development of immunotherapy allowed improvement of survival in advanced HCC. However, objective responses occur only in a third of patients and the identification of biomarkers to predict therapeutic efficacy or patient relapse remains a major health issue.

Methods: CD8 specific immune responses of various antigens (telomerase, survivin, NY-ESO-1, mage (A1 and A3) and glypican) were evaluated by IFN_{γ} ELISpot assays in 10 healthy volunteers (HD) and 20 patients with advanced HCC treated by atezolizumab and bevacizumab in first-line setting included in ITHER study (NCT02840058). Peripheral blood mononuclear cells were analyzed before and after 3 months of atezolizumab and bevacizumab. The correlation between biological and clinicopathological parameters were analyzed.

Results: The frequencies of mage-A1, mage-A3 and glypican specific CD8 T-cell responses were higher in HCC patients than HD (5/19 vs 1/10 for mage-A1, 3/19 vs 1/10 for mage-A3 and 5/18 vs 1/10 for glypican). In addition, the frequency of telomerase specific CD8 T-cell responses were higher in responder HCC patients before and after treatment than non-responder HCC patients. Interestingly, the survivin and NY-ESO-1 specific CD8 T-cell responses were only observed in responder HCC patients at baseline; and after immunotherapy, the frequency of these specific responses were lower in non-responders compared to responders HCC patients in particular for survivn (1/9 vs 5/10). Moreover, mage and glypican specific CD8 T-cell responses were only observed in responder HCC patients after atezolizumab and bevacizumab treatment. At baseline, responder HCC patients had a higher frequency of mage-A1 specific CD8 T-cell responses than non-responder (4/10 vs 1/8).

Conclusion: These results validated the immunogenicity of these antigens derived peptides in advanced HCC patients treated by immunotherapy. Moreover, HCC patients with no survivin and NY-ESO-1 specific CD8 T-cell responses at baseline, and no mage and glypican specific CD8 T-cell responses after treatment had a poor prognosis. Thus, our results suggest a correlation of specific CD8 T-cell responses signature with atezolizumab and bevacizumab-mediated clinical outcomes. Our results also provide the rational for the immune-monitoring of HCC patients.

A SARS-CoV-2 nucleocapsid protein-derived peptide influences primary and memory cellular responses by affecting the signal 1 and 2 during T cell activation

Davide Proietto[1], Elena Torreggiani[1], Beatrice Dallan[1], Martina De Laurentis[1], Eleonora Gallerani[1], Valentina Albanese[2], Victor Appay[3], Lacey Sian Llewellyn[4], Salvatore Pacifico[1], David A. Price[4;5], Antonella Caputo[1], Riccardo Gavioli[1], Francesco Nicoli[1]

Purpose: Cytotoxic $CD8^+$ T cells play an important role in vaccination and protection against SARS-CoV-2. In the attempt of identifying SARS-CoV-2 antigen-derived epitopes, we observed that an HLA-A2-restricted peptide from the nucleocapsid protein ($N_{219-227}$, LALLLLDRL, herein referred to as "LAL") possesses the ability to hinder $CD8^+$ T cell responses specific for other SARS-CoV-2 portions. Consequently, the aim of the present study was to determine the effects of the LAL peptide on epitope-specific naive and memory T cells. Moreover, we sought to explore the underlying molecular mechanisms involving both innate and adaptive immunity.

Methods:

PBMCs from Healthy donors with any history of melanoma and of SARS-CoV-2 infection or vaccination were used to investigate the impact of the LAL peptide on the priming naive $CD8^+$ T cells specific for the melanoma-derived EV10 through an *in vitro* approach. Subsequently, we examined the effect of this peptide on memory antigen-specific responses (elicited by a pool of commonly recognized viral epitopes) and upon general TCR stimulation (via aCD3 and aCD28) by Intracellular Cytokine Staining and by assessing proliferation as well as the expression of other functional markers. Concurrently, we measured the influence of the LAL peptide on the expression and presentation of MHC class I (on T2 and LCL cell lines) and on innate immune cell numbers and functionality.

Results: The LAL peptide negatively affected primary responses decreasing the expansion of primed naive $CD8^+$ T cells specific to EV10. Furthermore, it caused a significant reduction in cytokine production upon stimulation with a pool of memory viral peptide epitopes and upon general TCR ligation via aCD3 and aCD28 in $CD8^+$ T cells. These effects were connected with a reduction of the expression of MHC class I and of the co-stimulatory molecule CD86.

Conclusion: The LAL peptide hampered both the signals 1 (MHC class I expression) and 2 (co-stimulatory molecule) required for T cell activation. This accounted for a reduction in primary and memory epitope specific $CD8^+$ T cell responses, suggesting that this nucleocapsid-derived sequence could exert immunoevasion mechanisms during SARS-CoV-2 infection and indicating the importance of its targeting for vaccine rational design.

Chimeric virus-like particles as an efficient carrier for generating monoclonal antibodies against conserved epitopes of SARS-CoV-2 spike protein

Agne Rimkute[1], Milda Norkiene[1], Danguole Ziogiene[1], Kerstin Wernike[2], Aurelija Zvirbliene[1], Indre Kucinskaite-Kodze[1]

[1]Institute of Biotechnology, Life Sciences Center, Vilnius University, Vilnius, Lithuania; *[2]Institute of Diagnostic Virology, Friedrich Loeffler Institute, Greifswald-Insel Riems, Germany*

Diagnostics and prevention of the coronavirus disease 2019 (COVID-19) caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) are essential for controlling the virus spread and reducing ongoing mortality rates. Even though the developed vaccines helped to control the pandemic and prevented severe cases of the disease, the virus still circulates with novel variants constantly emerging, hence SARS-CoV-2 molecular tests are still relevant. Given that the SARS-CoV-2 spike (S) protein is susceptible to mutations, the conserved spike epitopes hold great promise for future virus research.

Yeast-expressed chimeric virus-like particles (VLPs) formed by major capsid protein VP1 of hamster polyomavirus, exposing the target sequences on its surface are successfully applied as an effective immunogen. In this study, eleven 10-11 aa-long S protein peptides (at positions 129-137, 247-256, 278-287, 364-373, 420-430, 457-467, 491-500, 554-564, 815-825, 863-873 aa of ancestor S protein and 491-500 aa of Omicron S protein) were chosen based on the conservative aa sequence, surface localization and interaction with ACE2 receptor and were used for the generation of monoclonal antibodies (MAbs) by hybridoma technology. The results of the indirect ELISA proved that only five peptides were highly immunogenic. Overall, thirteen hybridoma cell lines secreting high affinity and specificity mouse IgG MAbs against six different SARS-CoV-2 S protein epitopes including positions 247-256, 591-500, 554-564, 815-825, 863-873 aa of ancestor and 491-500 aa of Omicron S protein were developed. Purified MAbs recognized recombinant S proteins by ELISA and Western blot. In addition, all of the generated MAbs were reactive with recombinant S proteins of different SARS-CoV-2 variants, such as B.1.1.7, B.1.351, B.1.617.1, B.1.617.2 and B.1.1529 which confirm that recognized epitopes are likely to be conservative. To analyze the ability of the MAbs to recognize natural SARS-CoV-2, indirect immunofluorescence analysis was used, which showed that six generated MAbs clones reacted with S protein in coronavirus-infected cells. The obtained results demonstrate that recombinant chimeric VPLs harboring target epitopes are specialized tools for development of targeted MAbs. The generated MAbs could be used for further research of the antigenic structure of SARS-CoV-2, also for developing MAbs-based immunoassays.

Identification of the novel HLA-C*01:65:02 allele

Juan López Pérez[1], Mercedes Inda Landaluce[1], Luis Martinez-Lostao[1;2]

[1]Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain; *[2]Instituto de Investigación Sanitaria de Aragón, Zaragoza, Spain*

Purpose: A novel HLA-C allele was identified in a liver transplant donor during our routine HLA typing analysis using nextgeneration sequencing (NGS).

Methods: Genomic DNA was isolated from splenic lymphocytes using Maxwell 16 Blood purification kit (Promega), HLA loci were sequenced on on an Illumina based GenDx NGSgo-MX6-1 platform (GenDx, Netherlands) and analyzed with NGSengine v2.31 (GenDx). Informed consent was obtained to perform genetic study.

Results: During HLA-C sequence analysis, a novel allele was shown as result, now named HLA-C*01:65:02. Subsequent analysis indicated that our sequence was identical to HLA-C*01:65:01 except for the codon 174, in exon 3. This change consists in a single nucleotide change from AAT in C*01:65:01 to AAC in C*01:65:02, which is a synonymous substitution for the amino acid asparagine. The amino acid sequence of C*01:65:01 is identical to HLA-C*01:02:01, except for the codon 197 in exon 2. This change consists in a single amino acid substitution from GAG of C*01:02:01 to AAG in C*01:65:01, which leads to a change in the amino acid sequence from glutamic acid to lysine. The full HLA typing of the individual expressing this novel allele was found to be HLA-A*02:01:01, -; -B*18:01:01, 56:01:01; -C*01:65:02, 05:01:01; -DRB1*03:01:01, 11:01:01; -DQB1*02:01:01, 03:01:01; -DPB1*04:01:01, 11:01:01.

Conclusion: The sequence was first submitted to GenBank and then to the IPD-IMGT/HLA Database. The name C*01:65:02 has been officially assigned by the WHO Nomenclature Committee for Factors of the HLA System in January 2024. This follows the agreed policy that, subject to the conditions stated in the most recent Nomenclature Report; names will be assigned to new sequences as they are identified.

Anti-MPO and anti-PR3 doble-positive: more is less

Lydia García Serrano[1], Sergi Cantenys Molina[1], Adrián García García[1], Jordi Bas Minguet[1], Francisco Morandeira Rego[1]

[1]*Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Spain*

Purpose: Anti-neutrophil cytoplasmic antibodies (ANCA) are mainly direct against myeloperoxidase (MPO) or proteinase-3 (PR3). Anti-MPO or anti-PR3 single positivity are closely related to ANCA-mediated vasculitis (AAV), although they have also been associated less frequently with other autoimmune diseases such as inflammatory bowel disease (IBD). These autoantibodies are rarely found to be concurrently present in patients, but in clinical practice some patients present MPO+PR3+ double-positivity. Currently, few studies have characterized the clinical features of these patients. The aim of this study was to compare the characteristics of patients with double-positive ANCA versus single-positive.

Methods: Retrospective study of 105 serum samples MPO+PR3+ (DP), MPO+PR3- (MPO+) or MPO-PR3+ (PR3+) analyzed by CLIA. Clinical data of ANCA-associated vasculitis (AAV), non-AAV autoimmune disease, inflammatory bowel disease (IBD) and organ involvement were collected and compared between DP and MPO+ or PR3+ patients.

Results: DP patients show lower anti-MPO values than MPO+ (43 CU (IQR 30-96) vs 153 CU (IQR 62-434); p<0.001) and lower anti-PR3 values than PR3+ (52 CU (IQR 34-176) vs 166 CU (IQR 52-605); p=0.004). AAV diagnosis is more frequent in both MPO+ (80% *vs* 29%; p<0.001) and PR3+ (86% vs 29%; p<0.001) than DP. Non-AAV autoimmune disease diagnosis was more frequent in DP group than MPO+ or PR3+ (43% *vs* 20%; p<0.001 in both cases). DP present more IBD cases than MPO+ (17% *vs* 0%; p=0.025). A higher percentage of renal involvement was observed in both MPO+ and PR3+ patients than in DP (71% vs 40%; p=0.004 in both cases). DP patients show a higher percentage of gastrointestinal involvement than MPO+ (23% vs 6%; p=0.040). DP present a lower incidence of lung (40% vs 69%; p=0.016), cutaneous (0% vs 26%; p=0.002) and ophthalmological (0% vs 34%; p<0.001) involvement than PR3+.

Conclusion: Patients with an MPO+PR3+ result present a lower probability of a vasculitis diagnosis than patients with a simple-positivity, although a diagnosis of non-AVV autoimmune disease is more likely. Thus, double-positivity may suggest an unspecific immune activation state.

Immunology laboratory landscape in the repeated determination of extractable nuclear antigens.

Juan López Pérez[1], Mercedes Inda Landaluce[1]

[1]*Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain*

Purpose: Specificities of the extractable nuclear antigen (ENA) are frequently required for the diagnosis of systemic autoimmune disorders. Nonetheless, immunology laboratories receive requests for ENA from patients who have already been diagnosed, even though many of these specificities are not recommended for autoimmune disease follow-up or who have had negative results in the past. The aim of this study is to examine the results of patients with repeatedly detected ENAs.

Methods: A retrospective study was carried out on patients from our centre, where the presence of ENAs was determined from 2008 to 2023 by immunodot. Both the frequency of seroconversion and the frequency of repeat immunodot of ENAs were determined.

Results: Our lab received 34498 requests for ENA detection between 2008 and 2023; of these, 25300 (73.3%) were negative and 9198 (26.6%) were positive (26.6%). 5719 patients had more than one ENA determination, and a median of 2 determinations (interquartile range: 2-4) and a median of 272 days (interquartile range: 142-512) between determinations. 4738 individuals (82.8%) had no variance in their results; Of these, 3451 (60.3%) had consistently negative results and 1287 (22.5%) had consistently positive results. Seroconversion was observed in 981 patients, representing 17.2% of the total. On the other hand, only patients with more than four determinations (n=1557) were taken into consideration in order to exclude results that were not validated in subsequent analyses. Of these patients, 500 showed some variation in the ENA result. However, only 245 showed a change that could be verified in subsequent analyses.

Among them, there were 110 patiens that had changes to positive, 55 changed to negative, and 80 that were temporary.

Conclusion: Repeat ENA gives the same result in 82.8% of cases. In addition, most of the changes in test results are not confirmed in subsequent determinations.

Plasmin-clipped beta-2-glycoprotein I: novel structures lead to increased antibody binding

Hannah Bradford[1], Christophe Lalaurie[2], Jayesh God[3], Xin Gao[3], Charis Pericleous[4], Stephen Perkins[3], Hannah Britt[3], Konstantinos Thalassinos[3;5], Ian Giles[6], Anisur Rahman[6], Mihaela Delcea[7], Paul Dalby[2], Thomas McDonnell[2]

[1]University College London, Division of Infection and Immunity and Institute of Immunity and Transplantation, London, United Kingdom; *[2]University College London, Department of Biochemical Engineering, London, United Kingdom*; *[3]University College London, Institute of Structural and Molecular Biology, London, United Kingdom*; *[4]Imperial College London, National Heart and Lung Institute, London, United Kingdom*; *[5]Birkbeck College, Institute of Structural and Molecular Biology, London, United Kingdom*; *[6]University College London,Centre for Rheumatology, Division of Medicine, London, United Kingdom*; *[7]University of Greifswald, Department of Biophysical Chemistry, Institute of Biochemistry, Greifswald, Germany*

Purpose: Beta-2-Glycoprotein-I (β2GPI) is the main autoantigenic target of antiphospholipid syndrome (APS), these autoantibodies drive clinical manifestations including strokes and recurrent miscarrriage. There are two known structural isomers of β2GPI, an extended and compact form. The functions of β2GPI are contradictory, being capable of both activating and dampening the complement and coagulation cascades, how these contrasting functions are regulated is unknown but stuctural shift is implicated. β2GPI is also a substrate of the protease plasmin, which cleaves within the fifth domain of β2GPI leading to significantly altered protein activity. Very little is currently known regarding the structure or function of plasmin-clipped β2GPI. We present the first comprehensive structural characterisation of plasmin-clipped β2GPI and the associated implications for pathogenic antibody binding for this protein.

Methods: β2GPI was purified from healthy control plasma and cleaved with plasmin. Cleavage was confirmed by electrophoretic mobility by SDS-PAGE. Structural characterisation was undertaken using dynamic light scattering (DLS), small angle X-ray scattering (SAXS), ion mobility mass spectrometry (IMMS) and molecular dynamics simulation (MD). Activity was tested using inhibition of β2GPI ELISAs with APS patient samples and cleaved or non cleaved β2GPI in the fluid phase. Cellular binding was assessed using flow cytometry using HUVEC cells.

Results: Structural characterisation showed significant change for plasmin-clipped β2GPI in comparison to non-clipped β2GPI. DLS revealed a significantly smaller hydrodynamic radius for plasmin-clipped β2GPI ($p=0.0043$) while SAXS and MD analysis revealed a novel S-like structure of β2GPI only present in the plasmin-clipped sample. Ion-mobility-mass-spectrometry (IMMS) showed a different structural distribution in plasmin-clipped compared to non-clipped B2GPI, FACS demonstrated cellular binding was lost post cleavage with significantly less binding of plasmin-clipped β2GPI binding to HUVECs (34% vs 4%). There was also an increased binding of autoantibodies for the plasmin-clipped β2GPI ($p=0.056$), implying a greater exposure of pathogenic epitopes following cleavage.

Conclusion: Cleavage of β2GPI by plasmin results in the production of a unique S-shaped structural conformation with higher patient antibody binding. This may cause increased β2GPI/antibody soluble immune complexes and potentially drive autoantibody production. The altered structure of plasmin-clipped B2GPI may explain its changed functionality in vivo.

Rationale and design of a study to investigate a possible association between group A streptococcal M-peptide antibodies and rheumatic heart disease

Taariq Salie[1], Caitlin Meyer[1], Liesl Zühlke[2], Mpiko Ntsekhe[1], Mark Engel[2]

[1]University of Cape Town, Cape Town, South Africa; [2]South African Medical Research Council, Cape Town, South Africa

Introduction: Rheumatic heart disease (RHD), a sequelae of a group A streptococcal (GAS) infection, is thought to have an auto-immune basis, given underlying inflammatory responses. Current diagnostic assessment for RHD, following clinical suspicion, needs echocardiographical confirmation, which is expensive and not readily available in high burden populations. Confirmation of findings from early studies reporting long-term persistence of GAS antibodies in sera of RHD patients, may present an opportunity for a an affordable point-of-care test (POCT) to identify at-risk individuals in low-resourced settings, especially In the absence of a vaccine for GAS.

Hypothesis: An underlying immune response drives the development of GAS-related sequela. GAS antibodies persist for an extended period, driving ongoing inflammatory processes including valvulitis, resulting in RHD. Here, we present the rationale and design of a study in RHD African patients to evaluate our hypothesis.

Methods: Previously-collected serum samples within the RHDGen repository, a large continental endeavour performing GWAS to predict RHD disease-susceptible genetic loci in African individuals, will be used for this study. RHD phenotypes in our collection comprise mild to chronic RHD disease states. Representative case (n=100) and control (n=100) samples from the South African cohort will be subjected to ELISA to assess immune responses to a panel of twenty-five Strep A antigens.

Implications and conclusions: This project is expected to provide insight into the role, if any, of GAS antibodies involved in RHD development. In addition to the potential of a POCT possibly identifying at-risk individuals, this work may also contribute to GAS vaccine efforts. Identification of potential biomarkers would assist the development of a diagnostic tool, capable of referring potential cases of ARF and RHD would alleviate the burden of healthcare systems in the developing world.

Role of microbial infections in instigated autoimmune responses: a large scale study

Dr. Vani Janakiram[1], Mugdha M[1], Siva V[1]

[1]*Indian Institute of Technology Madras, Chennai, India*

Virus infections act as predisposing factors for autoimmune responses. Using computational approaches, we have shown that alphaviruses share peptide signatures that are conserved amongst them and share homology with human peptides. Interestingly, these human proteins have been shown to be harbouring autoantibodies against them in arthritic conditions. During the pandemic, with this prior expertise and knowledge, we could address some of the important questions in COVID-19 disease pathology. The origins of extra pulmonary effects in COVID-19 remain enigmatic as the reason for multi-organ damage is **not** always multi-organ infection**.** We speculated autoimmune responses as a plausible cause of exacerbated inflammation and extra pulmonary effects in COVID-19. Using computational methods, we identified human proteins distributed in different organs harbouring regions homologous to SARS-CoV2 peptides that could possibly be acting as autoantigens in COVID-19 patients displaying extra pulmonary tissue damage. Interestingly, these conserved regions are amongst the experimentally validated B cell epitopes of SARS-CoV2 proteins. Thus, our findings formed the basis for explaining the origins of auto antibodies via molecular mimicry of the SARS-CoV2 antigens and provided important insights into a hitherto unprecedented involvement of autoimmune process that could be contributing to the COVID-19 immunopathology. This work resulted in 2 journal publications (https://doi.org/10.1093/infdis/jiaa703; https://doi.org/10.1016/j.molimm.2021. 06.021) and have received more than 60 citations in highly reputed medical journals. We have further analysed unique properties of all experimentally shown microbial peptides (bacterial and viral) that cause autoimmune conditions. Results of this work will be discussed.

Prediction of specific TCR-peptide binding from large dictionaries of TCR-peptide pairs for personalized cellular therapy.

Yoram Louzoun[1], Ido Springer[1]

[1]*Bar Ilan University, Ramat Gan, Israel*

Purpose: A central avenue of personalized medicine is cellular therapy. Such therapies are often based on the induction of an immune response, through natural or chimeric receptors. For such receptors to induce a response, binding between T cell receptors (TCR) and their cognate target must occur. To optimize such TCRs for a specific peptide-MHC combination (pMHC), good predictors for TCR-pMHC are required.

Methods: To address that, given any TCR and peptide, we employ new Natural Language Processing (NLP) based methods to predict whether they bind. We combined large-scale TCR-peptide dictionaries with deep learning methods to produce ERGO (pEptide tcR matchinG predictiOn), a highly specific and generic TCR-peptide binding predictor. Target peptides and TCRs have different generation mechanisms. To capture these differences, ERGO uses different parallel encoders. At the broad level, we encode the CDR3 of each TCR and each peptide into numerical vectors. The encoded CDR3 and peptide are concatenated and used as an input to a neural network to predict binding.

Results: A set of standard tests are defined for the performance of peptide-TCR binding (upper row plots):

- Single Peptide Binding –Testing whether an unknown TCR binds a predefined target, using TCRs known to bind to this target.
- Multi-Peptide Selection –Given a set of predefined peptides, predict which of those will be bound by a new TCR.
- TCR-Peptide Pairing - TPP-I -test whether a randomly chosen TCR binds a randomly chosen peptide. This was further extended to TPP-II and TPP-III where either the TCR or the peptide are new.

ERGO significantly outperforms current methods in these tests even when not trained specifically for each test. In SPB and MPS, ERGO was tested on previously tested TCR and peptides with better results on most peptides.

Conclusion: We proposed a generic NLP based classifier for TCR-peptide binding using all components of the TCR and the peptide-MHC. We have shown that it is better than current state-of-the-art methods.

The software implementation and data sets are available at https://github.com/louzounlab/ERGO, and http://tcr.cs.biu.ac.il/

Counting is almost all you need

Yoram Louzoun[1], Ofek Akerman[1]

[1]*Bar Ilan University, Ramat Gan, Israel*

Purpose: The immune memory repertoire encodes the history of present and past infections and immunological attributes of the individual. As such, multiple methods were proposed to use T-cell receptor (TCR) repertoires to detect disease history.

Methods: We propose detecting TCRs associated with a condition and simply counting them or combining them with an attention mechanism.

Results: We here show that the counting method outperforms two leading algorithms. We then show that the counting can be further improved using a novel attention model to weigh the different TCRs. The attention model is based on the projection of TCRs using a Variational AutoEncoder (VAE). Both counting and attention algorithms predict better than current leading algorithms whether the host had CMV and its HLA alleles. As an intermediate solution between the complex attention model and the very simple counting model, we propose a new Graph Convolutional Network approach that obtains the accuracy of the attention model and the simplicity of the counting model.

Conclusion: We present three models for predicting the condition of a host and its HLA from their TCR repertoire, and show they lead to much better predictions than all current algorithms. The code for the models used in the paper is provided at: https://github.com/louzounlab/CountingIsAlmostAllYouNeed.

Naive and memory T cells TCR–HLA-binding prediction

Yoram Louzoun[1], Ofek Akerman[1], neta glazer[1]

[1]*Bar Ilan University, Ramat Gan, Israel*

Purpose: T cells recognize antigens through the interaction of their T cell receptor (TCR) with a peptide-major histocompatibility complex (pMHC) molecule. Following thymic-positive selection, TCRs in peripheral naive T cells are expected to bind MHC alleles of the host. Peripheral clonal selection is expected to further increase the frequency of antigen-specific TCRs that bind to the host MHC alleles.

Methods: To check for a systematic preference for MHC-binding T cells in TCR repertoires, we developed Natural Language Processing-based methods to predict TCR–MHC binding independently of the peptide presented for Class I MHC alleles. We trained a classifier on published TCR–pMHC binding pairs.

Results: The classifier obtained a high area under curve (AUC) of over 0.90 on the test set. However, when applied to TCR repertoires, the accuracy of the classifier dropped. We thus developed a two-stage prediction model, based on large-scale naive and memory TCR repertoires, denoted TCR HLA-binding predictor (CLAIRE). Since each host carries multiple human leukocyte antigen (HLA) alleles, we first computed whether a TCR on a CD8 T cell binds an MHC from any of the host Class-I HLA alleles. We then performed an iteration, where we predict the binding with the most probable allele from the first round. We show that this classifier is more precise for memory than for naïve cells. Moreover, it can be transferred between datasets. Finally, we developed a CD4–CD8 T cell classifier to apply CLAIRE to unsorted bulk sequencing datasets and showed a high AUC of 0.96 and 0.90 on large datasets.

Conclusion: A novel classifier can predict the type of the cell (CD4/CD8) and the MHC it binds to.

CLAIRE is available through a GitHub at: https://github.com/louzounlab/CLAIRE, and as a server at: https://claire.math.biu.ac.il/Home.

Development of a novel machine-learning prognostic scoring system for patients presenting with spinal metastases utilizing analysis of existing datasets to predict prognosis, morbidity and mortality

Omar Hadidi[1;2], Meghan Mulqueen[2], Sandra O'Malley[2], Seamus Morris[2], Joanne Lysaght[1]

[1]*Trinity College Dublin, Dublin, Ireland*; [2]*National Spinal Injuries Unit, Dublin, Ireland*

Introduction: Patients with symptomatic spinal metastases comprise a large subset of all cancer patients. The goal of these patients' care is palliation and optimization of quality of life, focusing on pain relief, stabilisation of their spinal column, reversing or preventing neurological deficits. Decision-making in their care is driven by the need to initiate emergent treatment to prevent or reverse neurological injury. An accurate estimate of their predicted prognosis is central to this process. Although life expectancy is critical to clinical decision-making, current available prognostic tools are too inaccurate for reliable clinical use.

Methods: The aim of this project is to establish a comprehensive study database, combining data including inflammatory status, inflammatory-driven conditions such as sarcopenia, as well as novel immune treatments such as immune checkpoint inhibitors from patients who were previously treated for spine metastatic cancer, which will be used to develop and then test a machine learning model, which can more accurately calculate a patient's predicted prognosis. 80% of the data will be used to train a machine learning algorithm to create a model for predicting prognosis. The remaining 20% of the data will be used to validate the model and further validations will be performed using international data.

Results and Disussion: A key factor in determining suitability for surgical management is patient prognosis. Whilst a number of scoring tools have been developed to assess prognosis, they have been superseded by advances in immuno-oncology, radiotherapy and surgical care, rendering them less useful for clinical decision-making. The development of a model to predict prognosis will facilitate accurate predictions of patient prognosis to aid in clinical and specifically surgical decision-making. In addition, the use of a trained and validated machine learning algorithmic model will allow for ongoing future modifications of the model to reflect the impact of immuno-oncology treatments advances and others in the management on cancer patients' prognoses.

Leveraging multi-modal data and AI to dissect pathogenic mechanisms and identify novel immunometabolic targets in IBD

Nadine Biesemann[1], Lu Zhang[2], Nima Nouri[2], Samuel Lessard[2], Richard Xu[2], Ekaterina Zezina[1], Verawan Boonsanay-Michel[1], Özen Sercan-Alp[1], Dieter Schmoll[1], Zhaohui Du[2], Thomas Kreutzberg[1], Michael Tsabar[2], Giorgio Gaglia[2], Andre Kurlovs[2], David Habiel[3], Terry K. Means[4], Clément Chatelain[2], Heming Xing[2], Virginia Savova[2], Corneliu A. Bodea[2], Matthias Herrmann[1], Emanuele de Rinaldis[2]

[1]Sanofi, Immunology and Inflammation Research, Type 1/17 Cluster, Frankfurt, Germany; *[2]Sanofi, Precision Medicine and Computation Biology, Cambridge, United States*; *[3]Sanofi, Immunology and Inflammation Research, Type 2 Cluster, Cambridge, United States*; *[4]Sanofi, Immunology and Inflammation Research, Immune Regulation and Tolerance Cluster, Cambridge, United States*

Inflammatory bowel disease (IBD) is a chronic immune disease with increasing global burden. Although several drugs are approved, only a fraction of patients achieves remission. The etiology of IBD entails genetic and environmental factors. Immunometabolism and the underlying adaptation of immune and stromal cells to their microenvironment, have recently emerged as key drivers in the onset and progression of the disease.

We present the development and application of an analytical framework - *MetID* - which leverages the integrated analysis of multiple layers of orthogonal disease data and artificial intelligence/machine learning (AI/ML) to identify key nodal immunometabolic pathways playing a causal role in ulcerative colitis (UC) and Crohn's disease (CD). Our results highlight the role of lipid metabolism and point to *SPHK1*, a sphingosine kinase, as a disease driver for both, UC and CD. *SPHK1* is part of the clinically validated sphingolipid pathway. Our multi-omics data support additional targeting of fibroblast and macrophage metabolism via *SPHK1* and strengthen the relevance of these cell types in IBD.

Furthermore, we demonstrate a distinct role for *SPHK1* in disease relevant assays containing the above-mentioned cell types.

This work highlights the value of combining high-dimensional multi-modal features and AI/ML to identify immunometabolic disease drivers and paves the way to the discovery of novel therapeutic opportunities in IBD. We suggest lipid metabolism and *SPHK1* could be causal nodes and a common pathomechanism for both UC and CD conditions.

Identification of distinct NK cell and monocyte subpopulations in recurrent pregnancy loss and recurrent implantation failure through flow cytometry unsupervised analysis

Nabil Subhi-Issa[1], Raquel Gil Laborda[1], Maria Palacios Ortega[2], Lydia Pilar Suarez[2], Ignacio Cristobal[2], Silvia Sanchez Ramon[1]

[1]Fundacion de Investigacion Biomédica del Hospital Clínico San Carlos, Madrid, Spain; *[2]Hospital Clinico San Carlos, Madrid, Spain*

Purpose: Recurrent pregnancy loss (RPL) and recurrent implantation failure (RIF) pose significant challenges in reproductive medicine, often attributed to underlying immunological dysregulation when considered unexplained. This study aimed to investigate immune subpopulation alterations in RPL and RIF patients compared to controls using unsupervised flow cytometry analysis.

Methods: Peripheral blood samples were collected from RPL and RIF patients, and healthy controls (HC). Immune subpopulations were analyzed using flow cytometry with a panel of markers. Due to the limitations of manual gating, unsupervised analysis was employed to identify novel immune cell clusters based on distinct biomarker expression patterns.

Results: Unsupervised analysis revealed the presence of 14 distinct clusters in natural killer (NK) cells and 24 clusters in monocytes. Four clusters exhibited significant discrepancies between RPL/RIF patients and controls, characterized by distinct phenotypic marker expression profiles. Specifically, Cluster 2 ($NKp30^{-}TIGIT^{+}CD69^{+}$ cytotoxic NK cells) and Cluster 7 ($NKp30^{-}TIGIT^{+}CD69^{-}$ cytotoxic NK cells) were reduced in RIF group and Cluster 11 ($CD3^{+}CD56^{+}Perf^{+}TIGIT^{+}$) and 14 ($CD3^{+}CD56^{+}Perf^{+}TIGIT^{-}$) were reduced in RPL group compared to HC. Additionally, in the monocyte compartment, an increase in Cluster 5 ($CD14^{low}CD16^{+}$HLA-$DR^{+}CX3CR1^{+}CD69^{+}$) and 22 ($CD14^{high}CD16^{-}$HLA-$DR^{-}CX3CR1^{-}CD69^{+}CCR2^{+}$) was observed in RIF group while a reduction of Cluster 17 ($CD14^{low}CD16^{+}$HLA-$DR^{-}CX3CR1^{-}CD69^{+}$) in RIF group and Cluster 18 ($CD14^{high}CD16^{-}$HLA-$DR^{+}CX3CR1^{+}CD69^{+}CCR2^{+}$CD11b Activated^{+}) in RPL and RIF were noted. These alterations in the frequency and activation status of NK cell and monocyte subpopulations were observed in RPL/RIF patients, suggesting potential involvement in the pathogenesis of reproductive failure.

Discussion: The identification of immune subpopulation discrepancies in RPL and RIF patients provides valuable insights into the immunological mechanisms underlying these conditions. The utilization of unsupervised analysis enabled the detection of novel immune cell clusters that may have been overlooked using traditional manual gating approaches. These findings highlight the complexity of immune dysregulation in reproductive failure and underscore the importance of comprehensive immune profiling in understanding disease pathogenesis. Further research is warranted to elucidate the functional significance of the identified immune subpopulations and their potential as diagnostic or therapeutic targets in RPL and RIF.

Dynamicmicropatterns as a novel tool to study immune synapse formation and activation of B cells

Blanca Tejeda González[1;2;3], Sara Hernandez-Perez[4], Pieta Mattila[1;2;3]

[1]InFLAMES Research Flagship Center, University of Turku, Turku, Finland; *[2]Turku Bioscience, University of Turku and Åbo Akademi University, Turku, Finland*; *[3]Institute of Biomedicine and MediCity Research Laboratories, University of Turku, Turku, Finland*; *[4]Institute of Immunity and Transplantation, Division of Infection and Immunity, University College London, London, United Kingdom*

B lymphocytes form a critical part of the adaptive immune system. Their activation and differentiation into antibody-producing cells is dependent on the B cell receptor (BCR), which recognizes a vast repertoire of foreign antigens. While B cells can be activated by soluble antigens, it has emerged that probably the most typical form of antigen encounter is on the surface of antigen presenting cells (APC), which leads to the formation of the immune synapse (IS).

To study the formation of the IS and early B cell activation we use a novel dynamic biotinylation-based micropatterning technique. This method allows us to observe and image individual B cells before and after BCR engagement with high spatio-temporal control of the process. We can analyse both activatory (surrogate antigen) and non-activatory areas in the cell as well as different time points of the activation process, we can also introduce other factors like mechanical stress in the activation process by using different micropattern shapes. This method allows for an array of microscopy modalities to be used both in fixed and live samples.

We have observed several BCR signaling proteins (Btk, PLCg2, Akt and CD79A) in this system and found the different distribution of them along the activation process and the different substrates and the effect of two pattern shapes (5 µm dots and 15 µm triangles) in the protein distribution in the IS. We have also been able to observe the actin cytoskeleton upon activation and the formation of filipodia and lamelipodia during the spreading of B cells and the introduction of actin cytoskeleton inhibitors to observe their effects on IS formation.

Purpose: We discovered a novel type of extracellular vesicle (EV) secretion by B cells, termed autophagosome-like extracellular vesicle (ALV), and investigated its impact on B cell differentiation.

Methods: EVs were isolated from stimulated-B cell culture media using different centrifugal forces. Western blotting was performed to compare the ALV marker LC3-II among various combinations of stimuli. To investigate the molecular mechanism of ALV secretion, RNA was extracted from stimulated-B cells and subjected to RT-qPCR. Candidate protein expression was confirmed by western blotting. The role of the candidate gene was assessed using the genetic disruption CRISPR-Cas9 system and reconstitution experiments in B-lymphoma A20 cells. To explore the effects of ALV on B cell differentiation, primary B cells were treated with ALV with or without cytokines. B cells were collected, and flow cytometry was used to analyze exosome endocytosis and cell differentiation.

Results: Interleukin 4 combined with CD40 antibodies (IL-4:CD40) significantly enhanced LC3-II$^+$ALV secretion by B cells compared to other stimuli combinations. This phenomenon occurred by directing autophagosomes towards the endosomal pathway rather than the lysosomal pathway. Moreover, IL-4:CD40 preferentially enhanced the expression of RAB27a, which regulates exosome secretion, at both RNA and protein levels. The RAB27a mutant cells exhibited impaired LC3-II$^+$ALV secretion, which was restored by reconstitution with wild-type RAB27A. ALV combined with IL-4 induced germinal center reaction and IgG1 class switching in vitro, whereas the classical exosome (from IL-4 and lipopolysacchrides co-stimulated B cells) tended to promote plasma cell differentiation. Importantly, neither ALV nor the classical exosome alone affected B cell differentiation, highlighting the indispensable role of cytokines during exosome-mediated effects.

Conclusion: The external IL-4:CD40 co-stimulation enhances LC3-II$^+$ALV secretion by B cells through a RAB27a-dependent pathway. To our knowledge, ALV represents the first instance of secretory autophagy occurring after external stimulation without disrupting autophagosome-lysosome fusion. The secretion of ALV by activated B cells may serve as a positive feedback loop to enhance B cell differentiation, revealing a novel role of secretory autophagy in intercellular communication during B cell activation.

Human B-cell intersection between systemic and the upper respiratory tract

Eva Piano Mortari[1], Mattia Laffranchi[2], Bianca Laura Cinicola[2], Sabina Barresi[1], Valentina Marcellini[1], Marco Scarsella[1], Ezio Giorda[1], Gabriele Volpe[1], Silvano Sozzani[2], Rita Carsetti[1]

The upper airways are the main port of entry for respiratory pathogens. To prevent respiratory infection, immune protection is mostly needed at mucosal sites, particularly in the upper respiratory tract. B cells contribute to mucosal immunity by producing IgA and IgG antibodies. Antibodies of IgA isotype are secreted by plasma cells residing in the lamina propria and those of IgG isotype derive from systemic immunity and reach mucosal sites by transudation from the serum. Parenteral vaccination does not induce tissue-resident memory T cells (TRM) in the respiratory tract and tissue-resident memory B cells (BRM) have not been demonstrated. Local priming is necessary to generate TRM and BRM, able to rapidly respond to reinfection. In humans, TRMs provide immune surveillance at mucosal sites and can induce rapid antigen-specific recall responses but very little is known about BRMs and most of the data has been generated in mouse models.

Integrin adhesion molecules orchestrate lymphocyte migration and homing to normal and inflamed tissues. The expression of integrins is a prerequisite for the adhesion to the endothelium, but inside-out signaling through the B cell receptor causes the conformational changes that render integrins able to bind their ligands with higher avidity and mediate extravasation.

We have investigated integrin expression on memory B cells (MBCs) of vaccinated adults and children with or without previous COVID-19. We found that recently activated MBCs (actMBCs) and plasmablasts (PBs) in the peripheral blood express the highest levels of integrin molecules and that infection expands both populations. We compared sorted B cell populations from the peripheral blood to those found in nasal and oral swabs. By flow-cytometry, total single cell RNAseq, and VDJ analysis we show that B cells in the swabs are similar to actMBCs and secrete antibodies of IgA and IgG isotypes in vitro.

The frequency of B cells in the nasal and oral swabs is dependent on the local inflammatory conditions suggesting that immunity at mucosal surfaces is induced and does not persist without inflammation.

Thus, although vaccine-induced MBCs are perfectly functional, they cannot prevent infection in the upper airways, because their recruitment follows instead of preceding infection.

Early-Onset Common Variable Immunodeficiency in a Patient with Heterozygous Variants in Interferon Response-Associated Genes TRAF3 and IRF4

Kim My Le[1;2], Nanni Mamia[1], Meri Kaustio[3], Salla Keskitalo[4], Kaisa Kettunen[3;5], Markku Varjosalo[4], Mikko R.J Seppänen[1;2;6], Timi Martelius[7], Janna Saarela[3;8], Juha Grönholm[1;2]

[1]Translational Immunology Program, University of Helsinki, Helsinki, Finland; *[2]Pediatric Research Center, New Children's Hospital, University of Helsinki and HUS Helsinki University Hospital, Helsinki, Finland*; *[3]Institute for Molecular Medicine Finland (FIMM), HiLIFE, University of Helsinki, Helsinki, Finland*; *[4]Systems Biology Research Group and Proteomics Unit, Institute of Biotechnology, HiLIFE, University of Helsinki, Helsinki, Finland*; *[5]HUS Diagnostic Center, Laboratory of Genetics, University of Helsinki and Helsinki University Hospital, Helsinki, Finland*; *[6]Rare Diseases Center, University of Helsinki and HUS Helsinki University Hospital, Helsinki, Finland*; *[7]Adult Immunodeficiency Unit, Inflammation Center/Infectious Diseases, University of Helsinki and HUS Helsinki University Hospital, Helsinki, Finland*; *[8]Centre for Molecular Medicine Norway (NCMM), University of Oslo, Oslo, Norway*

Background: Common variable immunodeficiency (CVID) is the most common clinically relevant inborn error of immunity. Causes of CVID are poorly understood and the genetic cause remains unidentified in around 85% of the cases. Disturbed interferon response is known to occur in CVID. In this study, we describe a patient with early-onset CVID that displayed abnormal B cell differentiation, hypogammaglobulinemia, recurrent infections, autoimmune/lymphatic colitis, and lymphoid hyperplasia.

Objectives: This study aims to characterize a novel phenotype associated with heterozygous variants in two interferon response-associated genes, *TRAF3* and *IRF4*.

Methods: Genetic causes of the patient's symptoms were examined with WES. NanoString gene expression analysis was used to study the expression of 50 immune signaling-associated genes. The variants and the characteristics and function of the patient's immune cells were studied with RT-PCR, western blot, flow cytometry, and ELISA.

Results: WES analysis identified one rare missense and one novel protein-truncating variant in cis in *TRAF3:* NC_000014.8:g.[103336572G>A;103369748C>T], NM_145725:r.[34G>A;1116_1135del], p.[Ala12Thr;Gln373Profs*10]. Additionally, an ultra-rare missense variant was found in *IRF4*:NC_000006.11:g.398863C>A, NM_002460:r.(673C>A), p.(Pro225Thr). NanoString analysis demonstrated overexpression in type I interferon-stimulated genes in PBMCs. In concordance, stimulating fibroblasts with poly(I:C) revealed pronounced IFN-β excretion in the patient's cells. The immunophenotyping of the patient's lymphocytes revealed abnormal frequencies of B and T cell populations. The patient had normal total amounts of peripheral B cells with an increased proportion of naïve cells, indicating defective B cell function and differentiation. Although *in vitro* class-switch recombination assay showed that the patient's naïve B cells switch to IgG-producing plasma blasts to a greater extent than controls', IgG ELISA on the culture supernatants indicated nearly absent IgG secretion from the patient's B cells. Further analysis is underway to confirm the role of these variants in disease**.**

Conclusion: Our results suggest that the possible combined effect of *TRAF3* and *IRF4* variants disrupts interferon signaling and B cell differentiation. Further studies are required to elucidate how the variants in interferon response-associated genes contribute to CVID.

Enhanced Antibody Responses in CD19-Cre mice

Sara Hernandez-Perez[1;2;3;4], Diogo M. Cunha[2;3;4], Pieta Mattila[2;3;4]

[1]Institute of Infection and Immunity, London, United Kingdom; *[2]Turku Bioscience, University of Turku, Turku, Finland*; *[3]InFLAMES Research Flagship, Turku, Finland*; *[4]Institute of Biomedicine and MediCity Research Laboratories, Turku, Finland*

CD19-Cre is an important and widely used Cre-lox model for B cell-specific genetic manipulation in murine systems. Mice carrying one allele of CD19-Cre are, at the same time, rendered heterozygote for CD19, a crucial coreceptor of the B cell antigen receptor (BCR). As a result, CD19-Cre mice exhibit diminished expression levels of CD19, with potential, yet insufficiently examined, consequences in B cell activation. Here, we report significantly heightened antibody responses upon both T-dependent (NP-KLH) and T-independent (NP-Ficoll) immunizations as well as elevated levels of basal IgM immunoglobulin levels in CD19-Cre mice. *In vitro*, we observed enhanced class-switch recombination and a moderate reduction in B cell proliferation upon LPS and IFNg stimulation, yet no drastic differences in BCR signalling. Our findings warrant careful concideration in the use of CD19-Cre mouse model in B cell research.

Antigen-dependent regulation of the early stages of unwanted human B cell differentiation and antibody formation

Charlotte Menage[1;2], Mariël Duurland[2], Tineke Jorritsma[2], Anja ten Brinke[1;2], Marieke van Ham[1;2;3]

[1]Amsterdam institute for Immunology and Infectious Diseases, Amsterdam, Netherlands; *[2]Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands*; *[3]Swammerdam Institute for Life Sciences, Amsterdam, Netherlands*

Blood transfusion may be required in patients undergoing surgery or having specific diseases. Some patients form antibodies against the transfused red blood cells (RBCs) or platelets, a process called alloimmunization. These antibodies form a problem upon additional transfusion. B cells are ultimately responsible for antibody production. Once formed, antibody-producing plasma cells (PCs) may survive for decades and are challenging to eradicate. Preventing formation of long-lived PCs is thus highly desired. The underlying mechanism of alloimmunization and, more generally, the differentiation of B cells into long-lived PCs remains largely unknown. Limited data show that high antigen density on RBCs promotes alloimmunization, while low antigen density on RBCs induces tolerance[1]. Here, we investigate how antigenic context regulates the early steps of human T cell dependent B cell differentiation into antibody-producing PCs. To investigate this, we compare the effect of antigen in different contexts on B cell differentiation in human B/ CD4 T cell co-cultures. We compare soluble antigen, antigen in complexes (e.g. multimerization into tetramers and dextramers), and antigen incorporated into eukaryotic membranes (e.g. RBC with different amounts of antigen and antigen expressed on HEK293T cells). Our preliminary data show that we are able to detect an antigen specific response in our human B/T cell co-cultures when using soluble antigen. With this study, we intend to find key regulators of the pathways leading to wanted and unwanted antibody formation and thereby identify potential targets for intervention.

Regulation of B cell function and expression of CD11c, T-bet, and FcRL5 in response to different activation signals

Linn Kleberg[1;2;3], Alan Courey-Ghaouzi[1;2;3], Maximilian Julius Lautenbach[1;2;3], Anna Färnert[1;2;3], Christopher Sundling[1;2;3]

[1]Division of Infectious Diseases, Department of Medicine, Solna, Karolinska Institutet, Stockholm, Sweden; *[2]Center for Molecular Medicine, Karolinska Institutet, Stockholm, Sweden*; *[3]Department of Infectious Diseases, Karolinska University Hospital, Stockholm, Sweden*

The markers CD11c, FcRL5, and T-bet are commonly used to define a subset of B cells that expand during inflammatory conditions, such as infections and autoimmune disorders, where they can make up >30% of mature B cells. However, the association between the proteins and differentiation and function in the host response remain largely unclear. Using an *in vitro* system, we have assessed the co-expression of CD11c, T-bet and FcRL5 among naïve, memory and total B cells in response to stimulation via the B cell receptor (BCR), toll-like receptor 9 (TLR9), and different cytokines. Using flow cytometry, we observed different expression dynamics for all markers, with largely overlapping regulation of CD11c and FcRL5 in response to BCR and TLR9 activation, while T-bet was strongly dependent on IFN-g signalling. Naïve and memory B cells showed similar kinetics as total B cells, although CD11c was more rapidly upregulated on memory cells compared with naïve cells. To further investigate the phenotype of the *in vitro* generated B cells, we ran a qPCR array with 30 selected target genes on sorted naïve and memory B cells after stimulation. Whilst the results showed up- and downregulation of several genes in a manner that was consistent with the expected phenotypical expression of $CD11c^+$ B cells, not all did, indicating that the *in vitro* generated cells may only partially acquire the phenotype seen *in vivo*. Additionally, we observed an increase in gene expression assosciated with plasma cell formation. To further explore possible functions of the *in vitro* generated B cells we analysed the production of antibodies and cytokines, and antigen-presenting cell (APC) functions. There was no association between CD11c, FcRL5, or T-bet expression and antibody secretion or T cell help, rather the functions were associated with TLR9-signalling and B cell-derived IL-6 production, respectively. These results suggest that the expression of CD11c, FcRL5, and T-bet and plasma cell differentiation and improved APC functions occur in parallel and are regulated by similar activation signals, but they are not interdependent. This work helps to further understand the regulation and dynamics of CD11c, FcRL5 and T-bet expression in B cells.

FAHD1 as a novel regulator of B cell metabolism

Athanasios Seretis[1], Pidder Jansen-Duerr[1], Elia Cappuccio[1]

[1]*Institute for Biomedical Aging Research, Leopold-Franzens University of Innsbruck, Innsbruck, Austria*

Purpose: Fumarylacetoacetate hydrolase domain containing protein 1 (FAHD1) is mitochondrial protein that regulates the activity of the TCA cycle through the decarboxylation of oxaloacetate (OAA) into pyruvate and CO_2. Loss of FAHD1 activity results in accumulation of OAA and inhibition of Complex II activity. A pivotal point in the development of humoral responses is the germinal centre (GC) reaction, during which B cells undergo several cycles of intense proliferation and somatic hypermutation. Despite their high proliferation rates, GC B cells rely on fatty acid oxidation and oxidative phosphorylation instead of glycolysis for energy. We hypothesized that FAHD1 plays an important role in the regulation of TCA cycle activity in GC B cells.

Methods: To delineate the role of FAHD1 in B cell responses, we used our previously generated Fahd1-KO mouse strain. To confirm the expression of FAHD1 in B cells, we performed qPCR in sorted splenic cell populations. Furthermore, we performed flow cytometry analysis in spleens and mesenteric lymph nodes of Fahd1-KO and WT mice to detect any developmental or differentiation defects in the absence of FAHD1. Finally, we assessed mitochondrial activity by performing seahorse analysis in freshly isolated and in vitro activated Fahd1-WT or KO B cells.

Results: We were able to confirm the expression of FAHD1 in splenic B cell populations. Furthermore, our preliminary data show altered GC B cell percentages in the mesenteric lymph nodes of Fahd1-KO mice. Specifically, the proportion of dark zone GC B cells seems to be reduced in the absence of FAHD1. Preliminary seahorse analyses supports the hypothesis that loss of FAHD1 reduces mitochondrial robustness and TCA cycle activity in B cells.

Conclusion: In conclusion, FAHD1 is an emerging novel regulator of TCA cycle activity and metabolism. Here we provide the first insight into the importance of FAHD1 for B cell activity.

A TNFR2-specific TNF fusion protein with improved vaccine effectiveness

Yin Xiao[1], Nadine Hundhausen[1], Olena Zaitseva[2], Harald Wajant[2], Friederike Berberich-Siebelt[1]

[1]*University of Wuerzburg, Institute of Pathology, Wuerzburg, Germany*; [2]*Department of Internal Medicine II, University Hospital Würzburg, Wuerzburg, Germany*

The germinal center (GC) response plays a crucial role in generating high-affinity antibody producing plasma cells and memory B cells, which is essential for long-term immunity and effective vaccination. However, enhancing the antibody affinity poses a significant challenge. In this study, we discovered that 'NewSTAR2', i.e. targeting TNFRII by a TNFRII-specific TNF fusion protein, could increase the efficacy of keyhole limpet hemocyanin (NP-KLH) immunization. NewSTAR2 significantly enhanced the frequencies of follicular helper T cells and GC-B cells during NP-KLH immunization *in vivo*. Moreover, it augmented the total amount of immunoglobulins in the serum and improved the affinity of anti-NP-specific antibodies. Additionally, NewSTAR2 dramatically increased the expression of CD80 and CD86 on B cells, along with promoting the proliferation and the frequency of GC-B cells *in vitro*. Taking together, these findings suggest that NewSTAR2 could be employed as an adjuvant to promote vaccine effectiveness.

Unravelling the B cell immune synapse: septin cytoskeleton as a new master regulator of B cell activation

Diogo Cunha[1;2;3], Sara Hernandez-Perez[4], Luqman Awoniyi[1;2;3], Alexandre Carisey[5], Guillaume Jacquemet[1;2;6], Pieta Mattila[1;2;3]

[1]InFLAMES Research Flagship, Turku, Finland; *[2]Turku Bioscience, University of Turku, Turku, Finland*; *[3]Institute of Biomedicine and MediCity Research Laboratories, Turku, Finland*; *[4]Institute of Infection and Immunity, London, United Kingdom*; *[5]St Jude's Research Hospital, Turku, United States*; *[6]Faculty of Science and Engineering, Cell Biology, Åbo Akademi University, Turku, Finland*

The immune synapse (IS) is a cell-cell interaction platform critical in lymphocyte activation by specific antigens. Despite of B cells being able to also respond to soluble antigens, the in vivo importance of the IS and surface-tethered antigen recognition has strongly emerged in the recent years. The IS serves as a dynamic hub for multiple cellular actions but the molecular details of these functions, especially beyond the B cell antigen receptor (BCR) signalling, remain poorly understood. Here, to address the lack in the systems level understanding of the IS, we setup methodology for comprehensive investigation of the composition of primary mouse B cells' IS at proteome level. Utilizing functionalized magnetic beads to mimic antigen presenting cells and trigger IS formation on them, we developed a method to specifically and robustly extract the cell adhesions on the beads, namely the IS or transferrin receptor mediated adhesion as a control.

Our mass spectrometry analysis from the isolated synapses has already unveiled multiple potential new candidate proteins regulating the IS. From these, we are currently focusing on the role of septin7, a cytoskeletal GTPase, linked to several diseases such as Alzheimer's disease, schizophrenia and, notably, autoimmune disorders.

Our preliminary data, using a pharmacological septin inhibitor forchlorfenuron (FCF), support a key role of septins specifically in BCR signaling, immune synapse formation as well as antigen processing and lysosomal integrity.

Belimumab after rituximab combination therapy preferentially targets IgA2+ B cells in systemic lupus erythematosus

Dan McCluskey[1], Muhammad Shipa[1], Laura Cooney[2], Michael Ehrenstein[1]

[1]*University College London, London, United Kingdom*; [2]*Immune Tolerance Network, Ann Arbor, United States*

Purpose: Systemic lupus erythematosus (SLE) is a heterogenous autoimmune disease affecting multiple organs. The BEAT lupus clinical trial showed that combination B cell depletion therapy with rituximab, followed by belimumab, an inhibitor of B cell activating factor (BAFF), resulted in fewer severe flares in SLE patients compared to rituximab alone. Although a minor component of circulating antibodies, serum IgA2 anti-DNA antibodies and IgA2+ plasmablasts were specifically reduced after combination therapy. We sought to validate these findings and explore underlying mechanisms.

Methods: 27-parameter spectral flow cytometry followed by clustering analysis was performed on PBMCs from the CALIBRATE trial; a phase-two randomized trial involving 43 patients with lupus nephritis, treated with rituximab alone or in combination with belimumab for 48 weeks. Measurement of autoantibodies and BAFF were performed by ELISA.

Results: IgA2+ (but not IgA1+) plasmablasts and serum IgA2 (but not IgA1) anti-dsDNA antibody levels were reduced after combination therapy but not rituximab alone ($p = 0.04$ and $p = 0.002$ respectively). The expression of BAFFR and BCMA were higher in IgA2+ (vs IgA1+) B cells at baseline, suggesting an increased sensitivity to belimumab. Baseline serum BAFF positively correlated with serum IgA2 levels ($p = 0.0057$) and IgA2+ plasmablasts (0.034). BAFFR expression was decreased and BCMA expression increased in IgA2+ plasmablasts after treatment in the belimumab arm compared to rituximab alone, whereas IgA1+ plasmablasts were unaffected. IgA2+ B cells also possessed a distinct chemokine receptor profile at baseline, with increased expression of gut homing markers CCR9 and ITGB7, whereas mucocutaneous (ITGB1) and follicular (CXCR5) markers were reduced compared with IgA1+ B cells. Belimumab reduced expression of CCR9 ($p < 0.001$) and ITGB7 ($p = 0.017$) only in IgA2+ plasmablasts.

Conclusion: Belimumab after B cell depletion therapy in SLE targets IgA2 + B cells, possibly due to enhanced sensitivity to BAFF, with reciprocal regulation of BAFFR and BCMA expression, and modulation of their tissue homing capacity. These results not only reveal a potential mechanism of action of rituximab/belimumab combination therapy but also suggest that SLE patients with high IgA2 anti-dsDNA antibody production could be stratified for this therapeutic strategy.

Clinical and biological impact of CD6 expression in chronic lymphocytic leukemia

Laura Carrillo-Serradell[1], Juan Antonio Piñeyroa[2], Pablo Mozas[2], Pablo Bousquets-Muñoz[3], Violeta Planells-Romeo[1], Lucía Aragón-Serrano[1], Sergi Casadó-Llombart[1], Alejandra Leyton-Pereira[1], María Velasco-de Andrés[1], Xose S Puente[3], Julio Delgado[2], Francisco Lozano[1;4;5]

[1]Inmunoreceptores del Sistema Innato y Adaptativo, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; *[2]Servei d'Hematologia, Hospital Clínic Barcelona, Barcelona, Spain*; *[3]Instituto de Oncología, Departamento de Bioquímica y Biología Molecular, Universidad de Oviedo, Oviedo, Spain*; *[4]Servei d'Immunología, Centre de Diagnòstic Biomèdic, Hospital Clínic Barcelona, Barcelona, Spain*; *[5]Departament de Biomedicina, Universitat de Barcelona, Barcelona, Spain*

CD6 is one of the first lymphocyte surface receptors reported in T cells, though soon after it was also found expressed in the normal B1 cell subset as well as in poor and well differentiated B cell neoplasms. Extensive research focused on its role in T cell physiology revealed that CD6 physically associates with the TCR complex and modulates either positively or negatively the activation and differentiation signals delivered upon specific antigen recognition. Moreover, it plays an important role in T-APC synapsis stabilization through its interaction with CD166/ALCAM, a broadly expressed adhesion molecule (in epithelial, endothelial, activated T and B cells, macrophages and dendritic cells). By contrast, little is known about its role in B1 cell physiology. Early studies showed that CD6 ligation protects chronic lymphocytic leukemia (CLL) cells from soluble IgM crosslinking-induced apoptosis. More recently, data from *Cd6*$^{-/-}$ mice revealed an important contribution of *CD6* expression in natural antibody production and in anti-bacterial defense. Within this framework, we have evaluated the clinical and biological impact of *CD6* expression in a CLL patient cohort. Clinico-pathological correlation studies revealed that mRNA *CD6* expression levels were differentially associated with pre-defined CLL prognostic markers, such as the *IGHV* gene mutational status. Moreover, mRNA *CD6* expression levels could predict time-to-first treatment in both multivariate and univariate analyses. Further elucidation of this effect was pursued via transcriptomic data bioinformatic analysis (Gene Set Enrichment Analysis, GSEA), which showed, among other findings, altered expression of genes regulated by the proto-oncogene *MYC*. These results reinforce the notion that CD6 also has a relevant role in B cell physiology, which impacts the clinical behavior of B cell neoplasms.

Retrospective observational study of persistent polyclonal B cell lymphocytosis in our centre

Jorge Mannelli[1], Javier Galán Picón[1], Daniel García-Cuesta[1], Raquel De la Varga-Martínez[1]

[1]*Hospital Universitario Puerta del Mar, Cádiz, Spain*

Purpose: Persistent Polyclonal B-cell Lymphocytosis (PPBL) is a rare and generally benign lymphoproliferative haematological disease of unknown aetiology occurring almost exclusively in women, characterised by chronic, stable and persistent polyclonal lymphocytosis, presence of binucleated lymphocytes, polyclonal increase in serum immunoglobulin M (IgM) and association with the HLA-DR7 haplotype. Those affected are frequently asymptomatic or may present slight splenomegaly. Our objective was to identify all patients that received a PPBL diagnosis at our hospital between 2020-2023 and review their characteristics.

Methods: We compiled clinical and laboratory findings of our sample population regarding: smoking status, presence of splenomegaly, leukocytes & B-cells count, serum immunoglobulin-M (IgM) levels, blood smear morphology, HLA-DRB1 haplotype and BCL-2/IgH genes rearrangement status.

Results: A total of 6 patients were diagnosed with PPBL, all of whom were women with a mean age of 50.8 years (range: 27-70 years). 5 patients self-reported to be smokers or ex-smokers, and 2 of them presented splenomegaly during examination. All 6 patients had shown a mild to moderately-severe lymphocytosis (mean: 13,640/dL, range: 10,550-18,690/dL) with increased absolute count (mean: 3,169/dL, range: 2,378.75-5,291/dL) and percentage (mean: 46%, range: 27.5-74%) of polyclonal B-cells. Serum IgM levels (mean: 501.8mg/dL, range: 381-705mg/dL) were above the upper reference limit in all patients (normal values: 33-293mg/dL). Blood smears were performed in 3 patients; findings included binucleated lymphocytes, smudge cells (Gumprecht shadows) and activated lymphocytes. 5 patients were carriers of the HLA-DRB1*07 haplotype and none of them presented with rearrangements in BCL2/IgH.

Conclusion: Our findings report that PPBL is associated with elevated IgM levels and the HLA-DRB1*07 haplotype, which is in line with the literature. Further studies are needed regarding patient follow-up to determine whether this seemingly benign condition poses any threat of predisposition to other haematological diseases or becoming premalignant and slow-evolving (like monoclonal gammopathies of undetermined significance). Furthermore, it is important for physicians to be aware of PPBL as certain characteristics associated with this disorder such as blood smear anomalies, finding of isochromosome 3q, premature chromosome condensation or multiple BCL-2/IgH rearrangements could lead to a misdiagnosis as a non-Hodgkin lymphoma.

Regulatory B cells expressing granzyme B in renal graft tolerant transplant patients: highly differentiated B cells with a unique pathway, a specific regulatory profile and strong interactions with immune system cells

Nicolas Sailliet[1], Amandine Dupuy[1], François Brinas[1], Karine Renaudin[1;2], Luc Colas[1;3], Clarisse Kerleau[1], Cynthia Fourgeux[1], Jérémie Poschmann[1], Magali Giral[1;4], Nicolas Degauque[1], Hoa Le Mai[1], Richard Danger[1], Sophie Brouard[1;4]

[1]CHU Nantes, Nantes Université, INSERM, Center for Research in Transplantation and Translational Immunology (CR2TI), UMR 1064, ITUN, Nantes, France; *[2]CHU Nantes, Service d'Anatomie et Cytologie Pathologiques, Nantes, France*; *[3]CHU de Nantes, Plateforme transversale d'allergologie et d'immunologie clinique - Clinique dermatologique, Nantes, France*; *[4]LabEx IGO "Immunotherapy, Graft, Oncology", Nantes, France*

Spontaneous operational tolerance, described by the absence of clinical signs of rejection without immunosuppression, is the holy grail of transplantation, with patients maintaining perfect graft function without drug-induced complications. Granzyme B-expressing regulatory B cells (GZMB$^+$ B cells) have been found enriched in the blood of such spontaneous operational tolerant patients after kidney transplantation and we reported that these GZMB$^+$ B cells may be induced in vitro, while keeping their regulatory properties. In order to better characterize them, we analysed two single-cell RNA sequencing (scRNAseq) datasets of: 1) peripheral blood mononuclear cells (PBMC) including natural GZMB+ B cells from 10 kidney transplanted patients including patients with stable graft function on conventional immunosuppression (IS) (STA, n=3), drug-free tolerant patients (TOL, n=3) and patients with ABMR (n=3) and 2) *ex vivo* induced GZMB$^+$ B cells from 4 transplanted patients with same characteristics (TOL, STA, ABMR). We first showed that natural GZMB$^+$ B cells found in PBMCs exhibited a specific regulatory transcriptomic profile associated with reduced expression of HLA molecules-, apoptosis- and inflammatory response-related genes and were enriched in NK cells-specific genes such *NKG7* and *KLRD1*. A pseudo-temporal trajectory analysis showed that these natural GZMB$^+$ B cells were highly differentiated B cells with a *KLF13*-dependent trajectory distinct from that of memory B cells. E*x vivo* induced GZMB$^+$ cells shared with natural GZMB$^+$ B cells a 'regulatory' signature in all patients, exacerbated and highly conserved in tolerant patients, with genes encoding B cell regulatory molecules or associated with migration processes such as *CCR7*, *CCL3* or *CCL4*. In accordance with their migratory-related profile, we found that these GZMB$^+$ B cells were able to infiltrate the graft under inflammatory conditions, suggesting that they may act where immune events take place. In conclusion, these data suggest that GZMB$^+$ B cells acquire a specific phenotype that may be due to the progressive establishment of a protolerogenic environment in these patients. The conserved signature of these highly differentiated GZMB$^+$ B cells that keep their regulatory profile after induction *ex vivo* suggests that they could pave the way for future cell therapy protocols.

The actin regulator WASp associates with chromatin and regulates RNA polymerase II transcription.

Roberta D'Aulerio[1], Minghui He[1], Eusra Mohammad[1], Julien Record[1], Jean Gautier[2], Lisa S. Westerberg[1]

[1]Karolinska Institute, Stockholm, Sweden; *[2]Columbia University, New York City, United States*

Purpose: The role of Wiskott-Aldrich syndrome protein (WASp) in cytoplasmic actin regulation has been extensively studied, however, its role in the nucleus remains largely unexplored. We aimed to reveal the funtion of WASp in the nucleus of B cells during differentiation from naïve to activated B cells. Our hypothesis is that WASp-mediated actin polymerization in the nucleus may assist dynamic nuclear processes like chromatin remodeling and regulation of gene expression.

Methods: The B cells ability to undergo differentiation relies on processes regulated by the actin cytoskeleton, such as migration, cell-to-cell communication, proliferation, and genomic rearrangement. We examined B cells isolated from wildtype mice and mice lacking WASp or expressing overactive WASp (L272P- and I296T- WASp mutations). B cells were stimulated *in vitro* with LPS and IL-4 to induce their proliferation and differentiation. We performed nuclear cytosol fractionation of naïve and activated B cells, immunoprecipitation, flow cytometry, ChIP-seq and RNA-seq, to obtain a comprehensive view of the function of WASp in the nucleus of B cells.

Results: Nuclear-cytosol fractionation and WASp immunoprecipitation detected WASp in both the cytosol and nucleus of naïve and activated B cells. Using flow cytometry analysis of purified nuclei, we detected increased chromatin association of Histone 3 and RNA polymerase II when comparing wildtype activated to naïve B cells with the mutants. When compared to activated wildtype B cells, WASp KO and overactive WASp B cells had decreased Histone 3 and RNA Polymerase II, suggesting a role for WASp in chromatin dynamics and transcription. Using RNA pol II ChIP-seq and metagene analysis, WASp KO B cells had reduced RNA Pol II transcript coverage.

Conclusion: Our data provide evidence that WASp is directly associated with RNA polymerase II at transcriptional start sites. Moreover, WASp may have a role in chromatin remodeling. B cells represent a unique cell type to investigate WASp and actin in the nucleus and may give insights into the molecular mechanism underlying Wiskott-Aldrich Syndrome and related immune disorders.

Aberrant B Cell Receptor Signaling Responses in Double-negative B Cells of Ankylosing Spondylitis Patients

Rudi Hendriks[1], Rick Wilbrink[2], Stefan Neys[1], Anneke Spoorenberg[2], Frans Kroese[2], Odilia Corneth[1], Gwenny Verstappen[2]

[1]Erasmus MC, Rotterdam, Netherlands; *[2]UMCG, Groningen, Netherlands*

Purpose: B cells that have undergone immunoglobulin (Ig) heavy chain class switch recombination and lack expression of IgD and the CD27 memory marker are referred to as double-negative (DN) B cells. They make up a heterogeneous group of B cells that accumulate with advanced age, in chronic infections and autoimmune disease, in which contexts they have been associated with anergy, exhaustion or hyper-reactivity. Because signaling properties of DN B cells are not well characterized, we explored their B cell receptor (BCR) responsiveness.

Methods: We evaluated BCR responsiveness in DN subpopulations that on the basis of their CD21 and CD11c expression were divided into: DN1 ($CD21^{+}CD11c^{-}$), DN2 ($CD21^{lo}CD11c^{+}$) and DN3 ($CD21^{lo}CD11c^{-}$) B cells. To investigate downstream BCR signaling responses, peripheral blood mononuclear fractions were stimulated with anti-Ig or were left unstimulated, and the phosphorylation status of spleen tyrosine kinase (SYK), phosphoinositide-3-kinase (PI3K) p85, and extracellular signal regulated kinase (ERK)1/2 was quantified by phosphoflow cytometry.

Results: In healthy individuals, DN2 and DN3 B cell fractions displayed an anergic phenotype, because BCR-induced phosphorylation of SYK, PI3K p85, or ERK1/2 was absent or very low, compared to DN1 B cells, naïve B cells or $CD27^{+}$ memory B cells. Next, we studied patients with ankylosing spondylitis (AS), a chronic rheumatic autoinflammatory disease of unknown etiology that mainly affects spine joints. Although innate immune cells and T cells are thought to play a major role, autoantibodies have been shown to be present in the serum of patients with AS. In contrast to our findings in healthy controls (n=15), in patients with AS (N=28) the DN2 B cells – but not DN3 B cells - showed significant signaling responses upon BCR engagement.

Conclusion: Our findings indicate that DN2 and DN3 B cells are anergic in homeostatic conditions and that in patients with AS DN2 B cells, but not DN3 B cells, become sensitive to BCR stimulation. As a result, in AS and perhaps also in systemic autoimmune diseases, specifically DN2 B cells may differentiate more easily into pathogenic antibody-secreting cells.

TLR-mediated innate signaling drives early B cell differentiation after influenza virus infection

Nicole Baumgarth[1;2;3], Emma Keller[3], Jonathan Lam[3;4]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States; *[2]Johns Hopkins School of Medicine, Baltimore, United States*; *[3]University of California Davis, Davis, United States*; *[4]Massachussetts Institute of Technology, Boston, United States*

Infection-induced B cell activation occurs in discrete steps and in the context of complex innate immune responses, including the elaboration of cytokines, PAMPS and DAMPS and the remodeling of secondary lymph tissues draining lymph nodes. Our long-term goal is to understand how innate signals regulate the adaptive humoral response. Using a mouse model of influenza virus infection, we and others demonstrated immediate early, Type I IFN-induced B cell activation in the respiratory tract draining lymph nodes (dLN) 2-3 days post infection (dpi), prior to the formation of antibody-secreting cells (ASCs) in extrafollicular foci (EF). Among other changes, Type I IFN caused upregulated of TLR3 and TLR7 expression but not of TLR4 by B cells after infection. Using single and double gene-targeted mice, we also showed that protective EF responses required B cell intrinsic signaling via both TLR adaptors, MyD88 and TRIF, which drove upregulation of the transcriptional master regulator of differentiation, IRF4. While MyD88-mediated B cell activation is known to support clonal expansion, the role of TRIF in B cell stimulation is little understood. Here we report that TLR3 is upstream of B cell intrinsic TRIF-signaling during influenza infection and directs B cells towards enhanced B cell differentiation and EF formation. In the context of MyD88-deficiency, the B cell intrinsic lack of TLR3 strongly abrogated EF development. In vitro, stimulation of TLR3 alone did not affect B cell proliferation but acted synergistically with TLR7 to enhance B cell clonal expansion. Moreover, stimulation via TLR3 enhanced upregulation of Blimp-1 and J-chain, markers of ASCs. Mechanistically, TLR3 stimulation in vitro caused upregulation of costimulatory molecules CD69 and CD86 and of the high affinity IL-2 receptor CD25. Addition of IL2 further supported B cell differentiation, while in vivo blockade of CD25 inhibited EF formation. Thus, the EF B cell fate is regulated through TLR-mediated signals that synergize during early influenza virus infection to support differentiation to ASCs. The effects of this early drive towards EF on germinal center formation will be discussed.

Tyrosine kinase 2 modulates splenic B cells through type I IFN and TLR7 signaling

Marta Jaén Castaño[1], Estíbaliz Alegría Carrasco[1], Alejandro Arrabal Sierra[2], Pablo Delgado-Wicke[3], Irene Bodega Mayor[2], Belén de Andrés Muguruza[2], Maria Luisa Gaspar Alonso-Vega[2], Elena Fernández Ruiz[1;4]

[1]Molecular Biology Unit, Biomedical Research Institute La Princesa (IIS-IP), Madrid, Spain; *[2]Immunobiology Unit, National Center for Microbiology, Carlos III Health Institute, Majadahonda, Madrid, Spain*; *[3]Department of Immunology, Biomedical Research Institute La Princesa (IIS-IP), Madrid, Spain*; *[4]Faculty of Medicine, Universidad Autónoma de Madrid, Madrid, Spain*

Tyrosine kinase 2 (TYK2) is involved in type I interferon (IFN-I) signaling, which is crucial in early antiviral responses. In humans, TYK2 deficiency increases susceptibility to infections, and TYK2 loss-of-function variants protects against autoimmunity. However, the role of TYK2 in splenic B cells is not fully understood yet.

Splenic B cell subpopulations [marginal zone (MZ), follicular (FO) and aged (ABC) B cells] from C57BL/6 (WT) and *Tyk2*$^{-/-}$ mice were analyzed *ex vivo* by flow cytometry. Purified B cell subpopulations obtained by fluorescent activated cell sorting were used to study differential gene expression by RNA-seq. CD19^{+} B cells were stimulated *in vitro* with TLR ligands (CL097, Imiquimod, LPS), IFN-α, and anti-CD40 plus IL-4 to evaluate their effect in cell proliferation and differentiation. In addition, cytokine and immunoglobulin secretion were quantified by Cytometric Bead Array and ELISA, respectively.

An altered splenic B cell distribution was observed in *Tyk2*$^{-/-}$ mice: an increase in ABC cells and a decrease in MZ B cells. Transcriptome studies in homeostasis conditions identified genes whose expression was downregulated, such as IFN-I stimulated genes and TLR7. B cell cultures showed that *Tyk2*$^{-/-}$ B cells proliferated and differentiated into plasmablasts (CD138^{+}) to a lesser extent than WT B cells in the presence of TLR7 ligands, whereas TLR4- and T-dependent activation (anti-CD40 plus IL-4) remained unchanged. Analysis of culture supernatants revealed a significant reduction of IL-6 and IL-10 secretion and humoral response in *Tyk2*$^{-/-}$ B cells.

These results highlight the existence of a crosstalk between TYK2 and TLR7 mediated by IFN-I feedback loop, which contributes to the establishment of MZ B cells and B cell proliferation and differentiation.

Extracellular vesicles produced by regulatory B cells: new approach in kidney transplantation

Amandine Dupuy[1], Rousselière Amélie[1], Drapeau Léo[1], Nguyen Thi-Van-Ha[1], Nicolas Sailliet[1], Grangier Alice[2], Cam Sylvain[2], Richard Danger[1], Brun Amanda[2], Gazeau Florence[2], Sophie Brouard[1], Mai Hoa[1]

[1]Nantes Université, INSERM, Centre de Recherche en Transplantation et Immunologie Translationnelle, UMR 1064, Nantes, France; *[2]MSC-med, INSERM U7057, Université de Paris, Paris, France*

Purpose: Kidney transplantation remains the best therapeutic option for patients with end-stage renal disease. However, it requires lifelong immunosuppressive therapy, with side-effects and an overall negative impact on long-term graft survival. Some patients display operational tolerance after discontinuation of these treatments. The search for clinical history and biomarkers has enabled us to identify in these patients an increase of regulatory B cells that inhibit the proliferation of effector CD4+/CD8+ T cells. However, the mechanism of action of these cells remains poorly understood. Given the ability of various immunomodulatory cells, such as Tregs, to mediate their mechanism of action through the secretion of extracellular vesicles, we hypothesized that the suppressive effect of Breg cells might be mediated by the secretion of EVs.

Methods: GzmB+ Bregs were expanded for 3 days and subjected or not to mechanical stimulation. EVs produced spontaneously or by stimulation were isolated from the supernatant by differential centrifugation. We characterized their type by cryo-electron microscopy and western blot, and their content by mass spectrometry and in situ hybridization compared with EVs from unstimulated B cells. EVs were then cultured for 72 h with anti-CD3/CD28 bead activated CD4+ T cells to characterize their regulatory potential.

Results: We demonstrated that GzmB+ Bregs release exosomes that are able to dose-dependently inhibit CD4+ T cell proliferation and induce their apoptosis in vitro. We showed that EVs from GzmB+ Bregs are less immunogenic with lower expression of MHCII molecules compared with EVs from non Breg cells. Analysis of their contents revealed a significant reduction in 11 pro-inflammatory miRNA and an enrichment in 11 proteins involved in the regulation of proliferation and programmed cell death of effector T cells. Finally, we showed that shear stress by mechanical stimulation increased EV production by a factor of 3, without altering their suppressive properties.

Conclusion: Due to their inhibitory potential, their lesser immunogenicity, and the possibility to increase their secretion, EVs from GzmB+ Bregs open new approaches in kidney transplantation, as therapeutic targets and biomarkers.

Regulatory factor X 7 limits B cell activation and lymphomagenesis

Berenice Fischer[1], Hanif Javanmard Khameneh[1], Jessica Guerra[1], Alessandro Zenobi[1], Pedro Ventura[1], Alessandra Pfister[1], Jessica Barizzi[2], Lara Mattei[2], Daniele Cavalli[2], Andrea Rinaldi[3], Simone Moro[1], Ivo Kwee[4], Egle Radice[1], Marcus Thelen[1], Davide Rossi[3;5], Greta Guarda[3]

[1]Institute for Research in Biomedicine, Università della Svizzera italiana, Bellinzona, Switzerland; *[2]Cantonal Institute of Pathology EOC, Locarno, Switzerland*; *[3]Institute of Oncology Research, Università della Svizzera italiana, Bellinzona, Switzerland*; *[4]BigOmics Analytics SA, Lugano, Switzerland*; *[5]Division of Hematology, Oncology Institute of Southern Switzerland, EOC, Bellinzona, Switzerland*

Regulatory Factor X 7 (RFX7) is a transcription factor emerging as an important regulator of immunity. We previously found that it is required for maintaining natural killer (NK) cells' homeostasis by limiting their activation and metabolic rate. Interestingly, elevated metabolism is a hallmark of cancer and *RFX7* mutations have been reported in Burkitt's lymphoma as well as in diffuse large B cell lymphoma (DLBCL), two B cell malignancies originating from antigen-experienced B cells. We thus set out to study the role of RFX7 in B cell lymphomagenesis and activation.

We observed that *RFX7* mutations found in Burkitt's lymphoma and DLBCL cause loss of transcription factor function. Notably, *in vivo* deletion of Rfx7 in B cells accelerated pathogenesis in a Bcl6-driven murine lymphoma model, suggesting relevance for RFX7 in B cell activation processes of the germinal center (GC). Accordingly, Rfx7-deficient B cells exhibited stronger activation in response to B cell receptor triggering *in vitro* and, upon immunization, mice with Rfx7-deleted B cells produced larger germinal centers (GCs). Comparison of activated Rfx7-deficient and control follicular B cells transcriptome revealed alterations hinting at underlying mechanisms that we are currently testing through genetic rescue approaches.

Collectively, these data demonstrate that RFX7 acts as a tumor suppressor in lymphoid malignancy by regulating GC B cell activation. These findings broaden our understanding of the physiological relevance of RFX7, but also our knowledge of the mechanisms controlling B cell-dependent immunity and immune disorders.

Regulation of humoral immune responses differs from COVID-19 in MIS-C cases

Abdurrahman Simsek[1], muhammed ali kızmaz[1], Tugce Bozkurt[1], Eren Cagan[2], Ali Eren Iskin[1], Ferah Budak[1]

[1]Bursa Uludag University, Faculty of Medicine, Department of Immunology, , Bursa, Turkiye; *[2]Department of Pediatric Infectious Diseases, Bursa Yuksek Ihtisas Training and Research Hospital, Bursa, Turkiye*

Purpose: MIS-C (multisystem inflammatory syndrome in children) is a clinical condition that may be manifested by symptoms such as fever, abdominal pain, headache, vomiting, and diarrhea that may occur in children with SARS-CoV-2 infection. B regulatory cells (Bregs) are immunosuppressive cells that support immune tolerance and suppress pathological immune responses. B cell exhaustion is associated with weaker antibody responses to pathogens. This study aimed to investigate the role of B cell subsets in the pathogenesis of MIS-C.

Methods: 17 MIS-C cases, 17 pediatric COVID-19 and 17 healthy controls were included in the study. Flow cytometric evaluation was performed using a 10-color mAb panel from peripheral blood samples.

Results: $CD19^+$ B cells were significantly increased in MIS-C compared with COVID-19 and the healthy control group. Consistent with this increase, IgM and IgD expression were found to be increased in MIS-C patients compared to COVID -19 patients and healthy controls. Naive B cells ($CD27^-IgD^+$) were found to be increased in MIS -C patients compared with COVID-19. Switched memory and IgM memory cells ($CD27^+IgD^-$ and $CD27^+$ IgD^+) also showed a similar profile. A significant decrease in MIS-C cases was observed in immature/transient B cells ($CD24^{high}CD38^{high}$) and primary memory B primarily cells ($CD24^{high}CD38^-$) compared to COVID-19 and healthy controls. Regulatory B10 cells ($CD24^{high}CD27^-$) was decreased in COVID-19 and MIS-C compared to the healthy control group. Late/exhausted memory cells ($CD27^-IgD^-IgM^-$) were decreased in MIS-C compared to COVID-19. $CD21^-$exhausted B cells and $PD\text{-}1^+$ B cells followed similar course.

Conclusions: According to the data obtained, the B-cell profile in MIS-C cases differs from COVID-19 in favor of inflammation. The effect of inflammation-limiting regulator B cells seems to be lower in MIS-C than in COVID-19, suggesting the presence of an aggressive and poorly regulated humoral immune response in MIS-C.

Regulatory B cell exhaustion: molecular characteristics and mechanisms of reversion

Elina Zheremyan[1], Ksenia Kubenko[2], Alina Ustiugova[1], Elena Pushkova[1], Anastasia Radko[3], Elvina Bogomolova[1], Denis Demin[1], Aksinya Uvarova[1], Ekaterina Stasevich[1], Ekaterina Gorshkova[1], Violetta Gogoleva[1], Denis Kamelskikh[4], Olga Aleshina[4], Nataliya Melnikova[1], Alexey Dmitriev[1], Apollinariya Bogolyubova[4], Dmitry Kuprash[1], Kirill Korneev[1]

Regulatory B cells (Bregs) maintain immunological tolerance in health, and their dysfunction is implicated in various pathological conditions. Chronic lymphocytic leukemia (CLL), characterized by disruptions in B cell homeostasis, offers a unique model to study Breg biology. In this study, we focused on one of the major subpopulations of regulatory B cells in human peripheral blood, memory Bregs (mBregs) that harbor high amounts of cell adhesion molecule CD24 and express co-stimulatory immune checkpoint CD27. CD24hiCD27+ B cells were isolated from peripheral blood of CLL patients and healthy donors using fluorescence-activated cell sorting. Only treatment-naive CLL patients were enrolled in the study to avoid any potential bias introduced by prior treatment. We performed RNA-sequencing on Illumina NextSeq 550 platform and conducted bioinformatic analysis to compare immunosuppressive profiles of mBregs from two cohorts. Our analysis revealed that CLL-mBregs exhibited significantly higher expression of immune exhaustion markers but lower expression of Breg-characteristic functional molecules, indicating compromised immunoregulatory potential. In order to find possible molecular mechanisms regulating the shift from active to exhausted state of Bregs, we employed correlation analysis and discovered genes positively correlating with well-established molecular characteristics of active Bregs and negatively correlating with the exhaustion markers (or vice versa). Expression of these candidate genes (with the majority of them belonging to long noncoding RNAs) was further verified by RT-PCR with subsequent functional validation of their effects using genetic knockdown or overexpression. Our findings provide insights into the molecular mechanisms underlying Breg exhaustion, with potential implications for understanding immune dysregulation across diseases marked by imbalances in pro- and anti-inflammatory responses.

Immunomodulatory effects of epitope-specific CD37 targeting in mouse

Philipp M. Hagemann[1], Frauke Koops[1], Gesine Rode[1], Erwin Duitman[1], Sebastian Schulz[2], Friedrich Koch-Nolte[3], Friedrich Haag[3], Hans-Martin Jäck[2], Zane Orinska[1]

[1]Research Center Borstel/Leibniz Lung Center, Airway Research Center North (ARCN), Member of the German Center for Lung Research (DZL), Borstel, Germany; *[2]Division of Molecular Immunology, Internal Medicine III, Nikolaus-Fiebiger-Center of Molecular Medicine, University Hospital Erlangen, Erlangen, Germany*; *[3]Institute for Immunology, UKE Hamburg, Hamburg, Germany*

CD37 is glycosylated membrane protein highly expressed in B cells. As other members of tetraspanin family CD37 is involved in regulation of incoming receptor-derived signals, lateral membrane protein interactions and intracellular signal processing. Here we characterize mouse CD37-specific monoclonal antibodies and investigate the effects of CD37 targeting *in vitro* and *in vivo*.

Generated monoclonal antibodies recognized two epitopes in the large extracellular loop of CD37. Clones A23 and A69 both recognize a linear CD37 epitope available on B-lymphocytes, T-lymphocytes and myeloid cells. Clone B1 recognizes a conformational CD37 epitope accessible exclusively on B cells. CD37 antibody clones differ in binding affinity and induction of internalization. Generated monoclonal antibodies were applied to characterize CD37 expression and functional consequences of CD37 targeting *in vitro*. Cells isolated from *Cd37-/-* mice were used as negative control. CD37-specific antibodies were neither activating B cells nor affecting BCR-signaling assessed by Ca^{2+} influx. Added to the purified B cells, CD37 antibodies induced homotypic aggregation and B cell death, strongly potentiated by antibody crosslinking, and abrogated by IL-4 addition. Furthermore, antibody addition to B cells, stimulated with IL-4 and LPS, inhibit B cell proliferation and immunoglobulin class switch to IgG1. Targeting of different CD37-epitopes led to depletion of different B cell subsets *in vivo* studied by flow cytometry and immunohistochemistry. Although B cell depletion was induced in a clone-specific manner, it was not correlating with CD37 expression levels since transitional cells with highest CD37 expression were not depleted by the antibody treatment. Maximal CD37 targeting by single injection of an antibody mix induced a rat IgG_{2a}-specific immune response (IgM and IgG_1) analyzed by bead-based assay accompanied with strong germinal center response. Thus, immunomodulatory effects of CD37 targeting by monoclonal antibodies consist of B cell depletion potentially interesting for treatment of autoimmune diseases and induction/enhancement of immune response important in development of new vaccine technologies.

The B-cell function in patients with chronic lymphocytic leukemia

Aviwe Ntsethe[1], Bongani Nkambule[1], Phiwayinkosi Vusi Dludla[2]

[1]University of KwaZulu-Natal, Durban, South Africa; *[2]South African Medical Research Council, Cape Town, South Africa*

Chronic lymphocytic leukemia (CLL) is characterized by the proliferation of dysfunctional B cells, resulting in significant immune dysregulation. Patients with CLL exhibit varied responses to B-cell receptor (BCR) targeted therapies, emphasizing the need for tailored immunotherapy approaches. This study investigated B cell function in untreated patients with CLL, and we further explored the effects of ex vivo protein kinase C activation on immune checkpoint expression and B cell profiles. Peripheral blood samples were collected from 21 untreated patients with CLL at King Edward Hospital in South Africa, between 2019 and 2022. B cells were stimulated with phorbol myristate acetate (PMA) and ionomycin. Using flow cytometry, the study explored the levels of B cell subsets and immune checkpoint proteins programmed cell death-ligand 2 (PD-L2) and cytotoxic T-lymphocyte associated protein 4 (CTLA-4) expression on various B cell subsets. PMA and ionomycin B cell stimulation upregulated CTLA-4 and PD-L2 expression on B cell subsets ($p < 0.0001$). As expected, monoclonal antibodies targeting PD-1, PD-L1 and CTLA-4 significantly downregulated the CTLA-4 expression of B cell subsets ($p < 0.05$), while PD-L2 exhibited varied responses in different B cell subsets. In addition, these monoclonal antibodies increased the levels of memory B cells ($p < 0.0128$) and activated memory B cells ($p < 0.01$). Protein kinase C activation on B cells stimulates immune checkpoint expression. The use of monoclonal antibodies on B cells play a critical role in the B cell function through the reduction of CD38 expressing activated B cells and upregulation of memory B cells. Moreover, the monoclonal antibody targeting PD-1, PD-L1 and CTLA-4 are effective in reducing the expression of CTLA-4 on B cell subsets.

Mass cytometry immunophenotyping reveals significantly decreased frequencies of circulating B cells in Autoimmune Polyendocrine Syndrome type 1

Shahinul Islam[1], Bergithe E. Oftedal[1;2], kari lima[3;4], Anders P. Jørgensen[5], Jorn skavland[2], Eystein S. Husebye[1;2], Anette S.B. Wolff[1]

[1]Department of Medicine, Haukeland University Hospital, Bergen, Norway, Bergen, Norway; *[2]Department of Clinical Science, University of Bergen, Bergen, Norway, Bergen, Norway*; *[3]Department of Endocrinology, Akershus University Hospital, Lørenskog, Norway, Lørenskog, Norway*; *[4]Department of Paediatric Medicine, Oslo University Hospital, Oslo, Norway*; *[5]Department of Endocrinology, Oslo University Hospital, Oslo, Norway, Oslo, Norway*

Background: AIRE mutation and Aire-dependent regulatory pathway dysfunction result in Autoimmune Polyendocrine Syndrome Type 1 (APS-1) development. Reduced B cell frequencies have previously been observed (ref), but broader proteomic mapping has not been established to fill the research gap in understanding the disease mechanism.

Aim and methods: Aim 1) We aim to create a comprehensive map of the primary immune system subsets and their systemic distribution. **Aim 2)** in-depth understanding of the most associated immune subsets with Autoimmune Polyendocrine Syndrome Type 1 (APS-1). We have adopted a single cell mass cytometry panel with 37 antibody marker panels in Norwegian APS-1 patients (N=18) compared to age and gender-healthy matched controls (N=19).

Results: APS-I patients had significantly decreased numbers of B cells, specifically within the naïve B cell subset, compared to healthy controls. Memory B cells compartment does not show the discrepancies (including switch and non-switch memory cells). We observed similar frequencies of CD38+ plasmablasts among germinal center B cells and transitional B cells. Interestingly, NK and NKT cells were also diminished, although these reductions did not reach statistical significance.

Conclusion: The proteomic mapping has provided additional evidence to support the previous findings that systemic B cells are declining. This new information can help us gain a better understanding and identify the need for further research to explore potential solutions.

Helicobacter infection increases the mitochondrial metabolism of B cells

Zeynep Nur Senturk[1], Bahar Deniz[1], Ayça Sayi Yazgan[1]

[1]*Istanbul Technical University, Department of Molecular Biology and Genetics, Istanbul, Turkey*

Purpose: *Helicobacter felis* (*H. felis*) is a gram-negative, microaerophilic, and spiral-shaped bacterium, which belongs to *Helicobacter spp*. like *H.pylori. H. felis* infection can lead to multiple gastro pathologies such as chronic gastritis, gastric cancer, and peptic ulcer disease. Mitochondria and immune cell functions are closely linked to each other. Studies have shown that high mitochondrial mass and membrane potential indicate active mitochondria. The mitochondrial metabolism of *Helicobacter*-stimulated B cells has yet to be elucidated. Therefore, we investigated the mitochondrial metabolism of B cells upon *H. felis* antigen stimulation.

Methods: B cells were isolated from the spleens of C57BL/6 mice and stimulated with *H. felis* antigen (10 ug/ml), TLR2-ligand PAM3CSK4 (2.5 ug/ml), or TLR4-ligand LPS (10 ug/ml) for various time points. Mitochondrial mass and membrane potential of B cells were assessed using Mitoview Green and Mitoview 633, or TMRE dyes, respectively, via flow cytometry. Additionally, the mtDNA(Cox1 gene)/nDNA(Rps18 gene) ratio and expression of Tfam were measured using Q-PCR to evaluate mitochondrial biogenesis. The mitochondrial ATP5a protein level was also determined using the MetFlow method.

Results: Stimulated B cells exhibited a 20-30% increase in mitochondrial mass and membrane potential at 24 hours, and a 50-60% increase at 48 hours. However, they reduced the mtDNA/nDNA ratio at 24 and 48 hours and increased Tfam expression at 6- and 24-hours post-stimulation. Furthermore, *H.felis*-activated B cells showed elevated expression of ATP5a, a key oxidative phosphorylation protein, compared to the non-stimulated controls.

Conclusions: The findings suggest that activated B cells enhanced their mitochondrial activity and oxidative phosphorylation during *Helicobacter* infection. Despite a decrease in mtDNA content at specific time points, increased Tfam expression indicates ongoing mitochondrial biogenesis. Further investigations are warranted to elucidate the metabolic changes in immune cells within the stomach during *Helicobacter* infection.

Novel GPR84 agonists prime macrophages to enhance phagocytosis and killing of Gram-negative bacteria

Kacper Kurzyp[1], Vincent Luscombe[1], Pinqi Wang[2], Isobel Davis[1], Annabell Roberti[1], Rachel Exley[1], Angela Russell[2], Christoph Tang[1], David Greaves[1]

[1]Sir William Dunn School of Pathology, University of Oxford, Oxford, United Kingdom; *[2]Department of Chemistry, University of Oxford, Oxford, United Kingdom*

Purpose: Immune adjuvant therapy provides a novel approach for treating bacterial infections. GPR84 is a pro-inflammatory G-protein coupled receptor expressed by neutrophils, monocytes and macrophages. Previous work has shown that activation of GPR84 increases phagocytosis of killed *Escherichia coli* and latex beads by murine macrophages. We investigated the impact of GPR84 agonists on the interaction of macrophages with Gram negative bacteria.

Methods: We investigated the effect of a range of established and in house GPR84 agonists on phagocytosis and killing of viable *E. coli* by THP-1 monocyte derived macrophages (MDM) at different time points. A gentamicin protection assay was used to quantify the number of live intracellular bacteria, with modifications used to quantify bacterial association and attachment. The half maximal effective concentration (EC_{50}) was determined using a four-parameter dose-response curve fit. We examined the uptake of live bacteria using confocal immunofluorescence microscopy and differential staining pre- and post-cell permeabilization to detect internalised and surface attached bacteria. Bone marrow derived macrophages (BMDM) from GPR84 WT and KO C57BL/6 mice were used to examine whether effects on bacterial recovery were GPR84-specific.

Results: We observed a >70% decrease in recovery of *E. coli* from THP-1 MDM stimulated upon addition of GPR84 agonists compared to vehicle treated cells despite increased phagocytosis observed by microscopy described previously. The increased killing was dependent on the dose of agonist, with two synthetic agonists showing picomolar EC_{50}s. Examination of infected cells using confocal microscopy showed a decrease in the number of intracellular but not surface attached bacteria. The effect is rapid, first observed at 30 minutes post agonist stimulation. GPR84 agonist effects were sustained for at least 1 hour after removal of the compounds. This effect was also observed in murine BMDMs. Experiments performed using GPR84 KO BMDM confirmed GPR84-specificity of 6-OAU; two novel agonists were found to act in part *via* GPR84.

Conclusion: Our findings show that GPR84 low molecular weight agonists can reduce bacterial survival in human and murine macrophages in a GPR84-dependent manner. Future experiments will test the effect of GPR84 agonists on Gram-negative bacterial survival using *in vivo* models.

Diuretics alone or combined with captopril modulate the phagocytosis of Staphylococcus aureus by mouse macrophages

Paweł Bryniarski[1], Bernadeta Nowak[1], Martyna Cieślik[1], Magdalena Gębicka[1], Paulina Skalska[1], Angelika Fedor[1], Krzysztof Bryniarski[1], Katarzyna Nazimek[1]

[1]*Jagiellonian University Medical College, Department of Immunology, Krakow, Poland*

Purpose: In experimental and clinical conditions, diuretics have been shown to exert an immunomodulatory effect, promoting the anti-inflammatory activation of immune cells. However, these effects may vary depending on the drug and the underlying mechanisms remain unclear. Therefore, understanding these mechanisms is of great importance for improving the treatment of patients with comorbid inflammatory diseases, including hypertension or chronic heart failure. In such cases, diuretics are administered concomitantly with other antihypertensive drugs, such as angiotensin-converting enzyme inhibitors, which likely modifies the effects of diuretics on the immune system. Thus, our current studies aimed at investigating the impact of selected diuretics administered alone or in combination with captopril on macrophage ability to phagocytose *Staphylococcus aureus*.

Methods: CBA mice were administered intraperitoenally with physiological saline solution of captopril (5mg/kg), furosemide (5mg/kg) or hydrochlorothiazide (10mg/kg), administered alone or in combination (diuretic plus captopril) for 8 consecutive days. On the 3rd day of drug treatment mice were injected with mineral oil, and macrophage-enriched peritoneal exudates were collected 5 days later. To determine phagocytic activity, macrophages were incubated for 20 minutes at 37°C with live *Staphylococcus aureus* (MOI 10), and the growth of surviving bacteria was assessed through microbiological cultures. In parallel, macrophages incubated with heat-killed bacteria were analyzed cytometrically.

Results: Diuretics alone or combined with captopril increased macrophage phagocytic activity, with captopril having the greatest effect. On the other hand, hydrochlorothiazide administration changed the proportion of peritoneal macrophages exposed to bacteria, favoring the infiltrating population and the shift towards pro-inflammatory phenotype with highest expression of surface markers of antigen presentation.

Conclusion: In geriatric population, it is important to find the proper anti- and pro-inflammatory balance to avoid unwanted suppression of antimicrobial immunity for reducing the risk of serious infections which can occur due to age-related immune system dysfunction. Our current studies suggest that furosemide and hydrochlorothiazide do not impair the antimicrobial activity of macrophages, and captopril enhances these beneficial effects, thus contributing to the discussion on the safety of drug use in the elderly.

Helminth Co-infection diminishes Antibody Responses to Natural SARS-CoV-2 Infection but not to COVID-19 vaccination: Insights from a Ghanaian Study

Julia Meyer[1], Ute Klarmann-Schulz[1], Alexander Yaw Debrah[2;3], Linda Batsa Debrah[3;4], Achim Hoerauf[1;5], Tomabu Adjobimey[1;6]

[1]Institute for Medical Microbiology, Immunology and Parasitology, Bonn; *[2]Faculty of Allied Health Sciences, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana*; *[3]Kumasi Centre for Collaborative Research in Tropical Medicine, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana*; *[4]Department of Clinical Microbiology, School of Medicine and Dentistry, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana*; *[5]German Center for Infectious Disease Research (DZIF), Bonn-Cologne Site, Germany*; *[6]Laboratoire de Biologie intégrative pour l'Innovation thérapeutique, Université d'Abomey Calavi (BioInov), Faculté des Sciences et Techniques (FAST), Abomey Calavi, Benin*

Purpose: The mild COVID-19 outcomes in Sub-Saharan Africa, against expectations, prompted investigation into local factors like helminthic infections, such as Lymphatic Filariasis (LF), which can modify immune responses. The present study examines LF's influence on SARS-CoV-2 immune reactions and COVID-19 vaccination in a Ghanaian cohort to understand its effect on the pandemic's regional dynamics and vaccine efficacy.

Methods: Blood samples were collected from 222 individuals diagnosed with LF in Ghana's Upper-East-Region. The presence of SARS-CoV-2 and filarial-specific antibodies (IgG, IgA) was measured using ELISA and SARS-CoV-2-variant-specific neutralizing capacity was analyzed using Luminex. Analyses were performed using the Kruskal-Wallis followed by Dunn's post-hoc test or Mann-Whitney U tests, along with Spearman correlation analyses.

Results: A notable fraction of unvaccinated participants (n=141) showed seropositivity for SARS-CoV-2 IgA (56%) and IgG (39%) antibodies, despite lacking any confirmed COVID-19 infection history. Vaccinated individuals with Lymphatic Filariasis (LF), post-receiving the AstraZeneca vaccine, demonstrated significantly ($p<0.0001$) enhanced IgA (72X) and IgG (60X) antibody responses specific to the SARS-CoV-2 Spike protein. This enhancement was consistent across IgA and IgG antibodies, improving neutralization efficacy against five critical variants: Alpha (B.1.1.7), Beta (B.1.351), Gamma (P.1), Delta (B.1.617.2), and Omicron (B.1.1.529), regardless of the severity of LF pathology or filarial infection status. Conversely, individuals seropositive for *Ascaris lumbricoides* who had recovered from COVID-19 (n=28) exhibited a diminished ($p=0.0264$) IgA response to the infection, though this did not extend to their IgG response or the ability to neutralize the virus. Furthermore, a moderate negative correlation ($r=-0.32$) was identified between *Ascaris* seropositivity and the intensity of COVID-19 symptoms among those who exhibited symptoms (n=36). Notably, individuals with a higher symptom score (n=12) showed a significantly lower ($p=0.0455$) response to *Ascaris*-specific antibodies compared to those with moderate symptoms (n=24).

Conclusion: Our data suggest that COVID-19 vaccination elicits strong immune responses in LF patients, despite the potential influence of filarial infection on natural antibody production against SARS-CoV-2. These findings highlight the intricate ways in which helminthic infections may affect the immunogenicity and clinical outcomes of COVID-19, emphasizing the need for further research into their role in vaccine efficacy and disease progression in endemic regions.

Deep immunophenotyping to decipher immunological changes in post-infectious fatigue after SARS-COV-2 infection

Silke Sommen[1;2], Lise Lund-Berven[1], Sunniva Segtnan[2], Joel Selvakumar[2], Lise Beier Havdal[1], Tonje Stiansen-Sonerud[1], Siri Mjaaland[3], Unni Nygaard[3], Ratnadeep Mukherjee[3], Vegard Wyller[1;2]

[1]Akershus University Hospital, Oslo, Norway; *[2]University of Oslo, Oslo, Norway*; *[3]National Institute of Public Health, Oslo, Norway*

Background: The development of therapeutic strategies against long-lasting symptoms after COVID-19, caused by SARS-CoV-2 virus and referred to as "Long COVID", relies on better understanding of the disease pathophysiology. The immunological correlate of Long COVID, which presents with fatigue and shares features with chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME), has not been demonstrated yet. Therefore, we undertook a prospective cohort study of SARS-CoV-2 infected and uninfected individuals for identifying immune cellular signatures of Long COVID and CFS/ME.

Methods: This Norwegian cohort study included nonhospitalized individuals (aged 12-25 years) who tested positive (n= 404) and negative (n= 105) for SARS-CoV-2 by RT-PCR. All participants underwent a clinical examination, completion of a questionnaire and biomarker analyses at the early convalescent stage and at 6-month follow-up. Participants were classified according to the World Health Organization case definition of Long COVID at follow-up. Mass cytometry was used to profile peripheral blood mononuclear cells (PBMC) collected from selected participants (n=80) divided into four groups (n =20/group) based on SARS-CoV-2 status and chronic fatigue symptoms at follow-up. Pair-wise comparison of immune cell frequencies between Long COVID, recovered convalescents, fatigued controls and healthy controls was performed by negative binomial regression model. Cell types significantly associated with patient categories were put into a machine learning classification model to identify unique signatures of Long COVID.

Results: We demonstrate that higher baseline frequencies of CD56lo-CD16hi Terminal NK cells are associated with chronic fatigue and Long COVID. Moreover, these cells also showed increased PMA-induced inflammatory cytokine production in fatigued and Long COVID patients. Fatigued patients also had decreased frequencies of Transitional and Marginal Zone B cells with a concurrent reduction of Double Negative B cells as compared to healthy controls. Increased frequencies of Tregs were also found to be associated with chronic fatigue and Long COVID. Multivariate analysis and machine learning revealed increased frequencies of Terminal NK cells as the most important feature of chronic fatigue and Long COVID. Moreover, in our analysis, we did not find any difference in immune cellular patterns between chronic fatigue and Long COVID.

Conclusion: Our results indicate a common immune signature in Long COVID and CFS/ME.

The role of microbiota and co-localization in the dissemination of vector transmitted pathogens

Leon Melo[1], Matheus Carneiro[1], Chukwunonso Nzelu[1], Shokouh Ahmadi[1], Emily Bennett[1], Jenny Yoo[1], Markus Geuking[1], Cláudio Meneses[2], Nathan Peters[1]

[1]Snyder Institute for Chronic Diseases, Department of Microbiology, Immunology, and Infectious Diseases, Cumming School of Medicine, and Faculty of Veterinary Medicine, Calgary, Canada; *[2]Vector Molecular Biology Section, Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, United States*

Insect vectors are important agents in the transmission of infectious diseases. Through a process called dissemination, many pathogens can enter a host through the bite of an insect vector and then exit the skin to cause a systemic infection. The details about how and when dissemination occurs are still unclear and elucidating this is important for understanding disease pathogenesis and the development of new therapies and vaccines. Leishmaniasis is a vector-borne disease, and in its visceral form, *Leishmania* spp. parasites can disseminate from the skin to internal organs. Various factors from the host, vector, and parasite have been implicated in the dissemination process, including the microbiota derived from the insect vector gut. However, while vector microbiota is required for dissemination, it is not sufficient. The goal of this study is to determine whether the micro-colocalization of parasites, vector- and host-derived factors, including the microbiota that occurs following sand fly transmission is a requirement to facilitate dissemination. The results obtained will contribute to a better understanding of the pathophysiology of leishmaniasis. We hypothesize that bacteria, co-localized with other host and vector factors, influence the physiology of the skin and facilitate the dissemination of *Leishmania* spp. To evaluate this, we are studying dissemination in wild type mice and mice deficient in IL-1b employing a novel model of *Leishmania* spp. infection, the skin prick, that co-localizes these factors in the skin. Later, we will determine the requirement of bacteria and co-localization, using skin-prick model of infection in Germ-Free (GF) mice allied with techniques of flow cytometry. Our initial results suggest that after *L. infantum* and sandfly gut-derived bacteria challenge via skin prick there is an enhanced influx of neutrophils to the inoculation site in the skin. Future experiments will determine whether sandfly gut-derived bacteria impacts on the dissemination from the skin to the internal organs.

Colony morphotype governs innate and adaptive pulmonary immune responses to Mycobacterium abscessus infection in C3HeB/FeJ mice

Kia Ferrell[1;2], Erica Stewart[1;2], Claudio Counoupas[1;2;3], James Triccas[1;3]

[1]*School of Medical Sciences, Faculty of Medicine and Health, The University of Sydney, Sydney, Australia*; [2]*Tuberculosis Research Program, Centenary Institute, Sydney, Australia*; [3]*Sydney Institute for Infectious Diseases and the Charles Perkins Centre, The University of Sydney, Sydney, Australia*

Purpose: *Mycobacterium abscessus* is a mycobacterial pathogen responsible for pulmonary infection in immune compromised individuals. *M. abscessus* grows with two distinct colony morphotypes, smooth (S) and rough (R), the latter of which is associated with worse patient outcome. While *M. abscessus* colony morphotypes differ in their pathogenicity, It is unknown how immune responses to S and R *M. abscessus* differ in an acute pulmonary infection setting. The purpose of this study was to characterise immunological outcomes of *M. abscessus* infection with S and R morphotypes in an immune competent murine model.

Methods: Female C3HeB/FeJ mice were infected by intranasal (i.n.) route with S or R *M. abscessus*, and at 1, 7 and 21 days post infection (dpi) lungs, spleen and draining lymph node (dLN) were collected for analysis of bacterial burden. Extensive characterisation of innate and adaptive immune responses in the lung was performed by flow cytometry, cytokine/chemokine bead array and histopathological analysis at differing time points following infection. Local immune responses in dLN were also examined by antigenic restimulation and flow cytometry at 7 and 21dpi.

Results: R *M. abscessus* infection was associated with the rapid production of inflammatory chemokines in the lung, combined with the recruitment of activated, MHC-II$^+$ Ly6C$^+$ macrophages both lung and lung draining LN (dLN) at 7dpi. The induction of T helper type 1 responses occurred following both R and S *M. abscessus* infection, but this response was markedly delayed in mice infected with S colony morphotypes. However, despite differences in the development of innate and adaptive immune responses, *M. abscessus* colony morphotype did not affect the rate of bacterial clearance or the development of pulmonary histopathology.

Conclusion: *M. abscessus* colony morphotype is instrumental in shaping the development of pulmonary immune responses following infection, with S *M. abscessus* displaying an 'immunologically silent' phenotype compared to the inflammatory R *M. abscessus* morphotype. This study further informs our understanding of *M. abscessus* host-pathogen interactions.

Funding: This study was supported by the NHMRC Centre of Research Excellence in Tuberculosis Control (1153493).

Repeated Plasmodium falciparum infection in humans drives the clonal expansion of an adaptive γδ T cell repertoire

Anouk von Borstel[1], Priyanka Chevour[1;2], Daniel Arsovski[1;2], Jamie Rossjohn[1], Edward Giles[1], Boubacar Traore[3], Kim Williamson[4], Kirsten Lyke[5], Peter Crompton[6], Martin Davey[1;2]

Repeated *Plasmodium falciparum* infections drive the development of clinical immunity to malaria in humans; however, the immunological mechanisms that underpin this response are only partially understood. We investigated the impact of repeated *P. falciparum* infections on human γδ T cells in the context of natural infection in Malian children and adults, as well as serial controlled human malaria infection (CHMI) of U.S. adults, some of whom became clinically immune to malaria. In contrast to the predominant Vδ2$^+$ T cell population in malaria-naïve Australian individuals, clonally expanded cytotoxic Vδ1$_{effector}$ T cells were enriched in the γδ T cell compartment of Malian subjects. Malaria-naïve U.S. adults exposed to four sequential CHMIs defined the precise impact of *P. falciparum* on the γδ T cell repertoire. Specifically, innate-like Vδ2$^+$ T cells exhibited an initial robust polyclonal response to *P. falciparum* infection that was not sustained with repeated infections, whereas Vδ1$^+$ T cells increased in frequency with repeated infections. Moreover, repeated *P. falciparum* infection drove waves of clonal selection in the Vδ1$^+$ T cell receptor repertoire that coincided with the differentiation of Vδ1$_{naïve}$ T cells into cytotoxic Vδ1$_{effector}$ T cells. Vδ1$^+$ T cells of malaria-exposed Malian and U.S. individuals were licensed for reactivity to *P. falciparum* parasites in vitro.Together, our study indicates that repeated *P. falciparum* infection drives the clonal expansion of an adaptive γδ T cell repertoire and establishes a role for Vδ1$^+$ T cells in the human immune response to malaria.

Dynamics of vaginal immunity during murine filarial and Herpes-Simplex-Virus-2 co-infection

Lisa Wadephul[1], Alexander Palmen[1], Kathrin Arndts[1;2], Gnatoulma Katawa[3], William Horsnell[4;5], Achim Hoerauf[1;2;6], Manuel Ritter[1;2]

[1]Institute for Medical Microbiology, Immunology and Parasitology (IMMIP), University Hospital Bonn (UKB), Bonn, Germany; *[2]German-West African Centre for Global Health and Pandemic Prevention (G-WAC), Partner Site, Bonn, Germany*; *[3]Ecole Supérieure des Techniques Biologiques et Alimentaires, Université de Lomé, Lomé, Togo*; *[4]Wellcome Centre for Infectious Diseases Research in Africa, Institute of Infectious Disease and Molecular Medicine, Department of Pathology, Division of Immunology, University of Cape Town, Cape Town, South Africa*; *[5]Medical Research Council Centre for Medical Mycology, University of Exeter, Exeter, United Kingdom*; *[6]German Centre for Infection Research (DZIF), Neglected Tropical Disease, Partner site, Bonn, Germany*

Purpose: More than 1 million sexually-transmitted infections are acquired every day. Sub-Saharan Africa bears approximately 40% of the global burden of STIs, which overlaps with high rates of helminth infections. Host immunity to helminths entails the induction of type 2 immune responses aids in controlling the infection, while increased immune regulation induced by the helminths supports parasite survival. This helminth-driven immune modulation dampens type 1 immune responses, which can lead to impaired control of bacterial and viral infections. Although helminths do not directly colonize or pass through the female reproductive tract, they are a risk factor for HIV and HPV infection. However, the mechanisms remain uncertain. Thus, we developed a chronic filaria HSV-2 co-infection mouse model to analyze immune cell composition and the parasite-caused influence on viral pathology.

Methods: We infected BALB/c wildtype and eosinophil-deficient (dblGATA) mice with the filarial nematode *Litomosoides sigmodontis* (L.s.) (25, 35 or 72 days) followed by an HSV-2 infection for 7 days. To assess pathological, immunological and parasitological data sets, we analyzed samples of the perigonadal adipose tissue (PAT), vagina tissue and lavage (site of HSV-2 infection), and lung tissue and pleural lavage (site of parasite infection) using flow cytometry, Luminex technology and immunofluorescence-based immunohistochemistry.

Results: In HSV-2 and *L. sigmodontis* (L.s.) co-infected mice, we observed increased numbers of eosinophils in the vaginal tissue and lumen and PAT compared to mono-infected mice. Furthermore, we observed increased pro- and anti-inflammatory cyto- and chemokines like Eotaxin-1 in the vaginal lumen. We also showed increased pathology in eosinophil-deficient mice compared to wildtype mice highlighting that L.s.-induced eosinophils play a crucial role in vaginal immunity and pathology during HSV-2 infection. Moreover, we revealed delayed HSV-2 progression towards neurons and reduced epithelial cell lysis within the vaginal tissue of co-infected mice.

Conclusion: Our data demonstrates that the immune-modulation of filarial nematodes affects uncolonized tissues and subsequent STIs. Moreover, the data indicate a crucial role of eosinophils for the vaginal pathology and immunity against viral infections. In detail, we hypothesize that the significantly increased eosinophil numbers might delay HSV-2 progression through the tissue and that L.s. infection exacerbated HSV-2-driven vaginal inflammation.

Imbalance of CCR6+ CD4 T cells and IFN-γ CD8 T cells in patients with Long-COVID

Pedro Martinez-Fleta[1], Celeste Marcos[1], Daniel Jimenez-Carretero[2], Jose Maria Galvan-Roman[1], Rosa Giron[1], Ana Arcos[1], Hortensia De la Fuente[1], Laura Esparcia-Pinedo[1], Javier Aspa[1], Julio Ancochea[1], Arantzazu Alfranca[1], Francisco Sánchez-Madrid[1]

[1]*Hospital Universitario de la Princesa, Madrid, Spain*; [2]*Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, Spain*

Purpose: Post-acute COVID-19 or Long-COVID (LC) can affect around 20% of convalescent individuals. It is characterised by persistent symptoms (mainly dyspnoea, fatigue and chest pain) for at least 3 months after infection. Among different possible causes driving LC, several authors have pointed towards a dysregulation of the immune system, triggering a persistent hyperinflammatory state. LC patients present differences in activation and exhaustion states of innate and adaptive compartments, as well as in T regulatory cells. However, the role of cells co-expressing different chemokine receptors (CCR), such as CCR6, remains unexplored. The objective of this study is to assess differences in circulating T cell subpopulations co-expressing different CCRs in LC patients.

Methods: Peripheral blood mononuclear cells (PBMCs) from healthy, non-long COVID (NLC) and LC patients were treated with SARS-CoV-2 peptides, including spike (S) and nucleoprotein (NP). T cell subpopulations were determined by flow cytometry and changes in T cell frequencies were assessed by means of unsupervised clustering analysis.

Results: Higher levels of CCR6+CCR9+ and CCR6+ CCR4+ CD4 T cells were found in COVID-19 convalescent individuals upon activation with SARS-CoV-2 S peptides. Further analyses showed a decrease in SARS-CoV-2 specific CD4 T cells co-expressing CCR6 in LC patients compared to NLC, whereas CXCR3+ CCR6- (Th1) and CCR4+ CCR6- (Th2) CD4 T cells were increased in this group. In addition, LC patients showed lower IFN-γ-secreting CD8 T cells after stimulation with SARS-CoV-2 S protein.

Conclusion: These data reveal a possible role of CCR6+ cells in LC pathophysiology. We describe an imbalance of Th1/Th2/Th17 effector cells and of CD8 IFN-γ cells in LC patients, which highlights the role of adaptive immunity during the course of LC.

Metabolic profiling of lymphocytes in diseases caused by intracellular pathogens

Shilpa Sengupta[1], Mitali Chatterjee[1]

[1]*Dept. of Pharmacology, Institute of Postgraduate Medical Education and Research, Kolkata, Kolkata, India*

Background: Tuberculosis (TB) and Leishmaniasis are caused by intramacrophagic pathogens, namely *Mycobacterium tuberculosis* and *Leishmania donovani* respectively. Till now, studies pertaining to TB and Post Kala-Azar Dermal Leishmaniasis (PKDL) are restricted to their immunopathogenesis, but their immunometabolic profile remains unexplored and was the focus of this study.

Aim: Characterizing the metabolic status of immune cells in patients with TB and PKDL, and delineating their association with the functional status of lymphocytes.

Methods: In peripheral blood mononuclear cells of PKDL (n=16) and TB (n=20) patients along with healthy controls (n=10), the T-cell frequency (CD4/CD8), their activation (CD69) and exhaustion (CD279) status was determined by flow cytometry. The metabolic bioenergetics of lymphocytes was studied in terms of oxidative phosphorylation (OXPHOS) and glycolysis as measured by Extracellular flux analyzer along with quantitative PCR to study expression of OXPHOS (*sdha, Atp synthase, pdk1*) and glycolytic (*hk2 and ldha*) genes, as also *PI3KCA, AKT, mTOR, HIF1A, GLUT1, Smad3 and Cpt1A*.

Results: In comparison to healthy controls, TB cases showed an altered CD4/CD8 ratio, significantly raised T cell activation ($CD69^+$), a metabolic switch towards glycolysis and enhanced expression of glycolytic genes as also raised expression of *PI3KCA*, *AKT, mTOR*, *HIF1A* and *GLUT1*. In contrast, PKDL cases showed T-cell exhaustion ($CD279^+$), OXPHOS was upregulated along with enhanced *Smad3* and *Cpt1A*.

Conclusion: Although TB and PKDL are caused by intramacrophagic pathogens, TB cases demonstrated T-cell activation, upregulation of the PI3K-AKT pathway that resulted in increased *GLUT1*, and a shift towards glycolysis. Conversely, PKDL cases demonstrated T-cell exhaustion, activated *Smad3* and *CPT1* that translated into enhanced OXPHOS. Taken together, drugs targeting immunometabolism can be promising therapeutic options for TB and PKDL.

Innate – Adaptive Synergy in Malaria

Pengjun Xi[1;2], Patrick Sandoz[3], Maximilian Julius Lautenbach[1;2], Björn Önfelt[3], Anna Färnert[1;2], Christopher Sundling[1;2]

[1]1Division of Infectious Diseases, Department of Medicine Solna, Center for Molecular Medicine, Karolinska Institutet, Stockholm, Sweden; *[2]Department of Infectious Diseases, Karolinska University Hospital, Stockholm, Sweden*; *[3]3Department of Applied Physics, Science for Life Laboratory, KTH Royal Institute of Technology, Stockholm, Sweden*

Purpose: Natural killer (NK) cells play an important role in the interplay between innate and adaptive immunity in the host response against malaria. Different NK cell subsests have been indicated to play specific roles during the infecion, and memory has been implicated upon reinfection. However, the cellular and molecular regulation of NK cell sudsets after infection remain poorly understood. This study takes advantage of longitudinal prospective blood samples from donors infected with malaria parasites to understand the impact of malaria infection on NK cell diversity and function over time.

Methods: The cohort consists of individuals experiencing their first malaria infection and those with prior exposure. Blood samples were collected at the time of diagnosis, 10 days, and 1, 3, 6 and 12 months post-diagnosis. PBMCs were isolated from these samples for NK phenotypic analysis by flow cytometry and transcriptomic profiling using targeted single-cell RNA sequencing. NK cell cytotoxicity was assessed for different subsets over time through confocal live cell imaging and via flow cytometry.

Results: Analysis revealed a significant reduction in total $CD56^+$ NK cell counts during the acute phase of malaria infection across both primary and recurrent infection cohorts, compared to convalescent stages. However, there were no significant differences between primary and recurrent infections at any time point. Notably, NK cells isolated during acute infection demonstrated better killing capability in live cell imaging assays than the ones at convalescence. Consistent with this, expressions of two key molecular effectors of NK cell cytoxicity, PRF1 (perforin) and GZMB (granzyme B), were significantly up-regulated in NK cells from the acute stage. Proteomic analysis also showed highly elevated levels of soluble granzyme B in plasma, supporting enhanced NK cell cytotoxicity in response to malaria infections.

Conclusion: Our findings show that acute malaria infection significantly but transiently enhances NK cell cytotoxicity for certain cell subsets. This indicates an important role during the acute phase of the immune response against malaria parasites. Further studies to identify the specific signals leading to more efficient NK cell function may improve our understanding and management of malaria parasitemia.

Myeloid-Derived Suppressor-like Cells as a Prognostic Marker in Critically Ill Patients: Insights from Experimental Endotoxemia and Intensive Care Patients

Schrijver Irene[1], Herderschee Jacobus[1], Theroude Charlotte[1], Kritikos Antonios[1], Leijte Guus[2], Didier Le Roy[1], Maelick Brochut[1], Chiche Jean-Daniel[1], Perreau Matthieu[1], Pantaleo Giuseppe[1], Guery Benoit[1], Kox Matthijs[2], Peter Pickkers[2], Calandra Thierry[1], Thierry Roger[1]

[1]Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland; *[2]Radboud University Medical Center, Nijmegen, Netherlands*

Objective: Polymorphonuclear and monocytic myeloid-derived suppressor cells (PMN-MDSCs and M-MDSCs) are immunosuppressive immature myeloid cells expressed at low levels at homeostasis. Patients admitted to the intensive care unit (ICU) often experience endotoxemia, nosocomial infections and sepsis. MDSCs can have an important impact on the development of infectious diseases, but little is known about their potential predictive value in critically ill patients. Our objective was to characterize the dynamics of MDSCs in healthy subjects challenged with endotoxin and the clinical predictive value of MDSCs for patients admitted to intensive care unit (ICU).
Methods: Blood was sampled from eight healthy volunteers 0-168 hours after endotoxin challenge, and from critically ill patients at risk of developing infections sampled at ICU admission (n=32) and ICU discharge (n=17). Blood was analyzed by multivariate flow cytometry and unsupervised clustering, and by multiplex bead assay to quantify leukocyte subpopulations and cytokines.
Results: PMN-MDSCs and M-MDSCs increased 4-8 hours after endotoxin challenge and returned to baseline levels after 24 hours. PMN-MDSCs and M-MDSCs were elevated in patients at ICU admission and normalized at ICU discharge. A subpopulation of M-MDSC cells expressing intermediate levels of CD15 (CD15int M-MDSCs) negatively correlated with IL-31 concentrations (r=-0.48, P=0.049) and was associated with overall mortality (P=0.02). High abundance of PMN-MDSCs and CD15int M-MDSCs was a good predictor of mortality (P=0.0046 and 0.014), with area under the ROC curve for mortality of 0.70 (95% CI = 0.4-1.0) and 0.86 (0.62-1.0), respectively.
Conclusions: Elevated levels of PMN-MDSCs and CD15int M-MDSCs were independent predictors of mortality in ICU patients. Our observations support the idea that MDSCs represent biomarkers for sepsis, and that flow cytometry monitoring of MDSCs may be used to risk stratify ICU patients for targeted therapy.

Characterization of the MAIT cell response to Staphylococcus aureus and the influence of bacterial immune evasion

Elisa J.M. Raineri[1], Elli Mouchtaridi[1], Marion Humbert[1], Caroline Boulouis[1], Karolinska IHOPE study group[1], Johan K. Sandberg[1]

[1]*Karolinska Institutet, Stockholm, Sweden*

Mucosa-associated invariant T (MAIT) cells are a subset of unconventional T cells displaying innate-like characteristics, with rapid secretion of pro-inflammatory cytokines and killing of bacterially infected cells. MAIT cells are abundant in the blood of humans and act as guardians of both mucosal and non-mucosal barriers. Major questions remain regarding the contribution of human MAIT cells in the immune response to invading pathogens such as *Staphylococcus aureus* and the role of potential bacterial immune evasion mechanisms. Here, we studied the MAIT cell-pathogen interplay using peripheral blood from healthy individuals, palatine tonsils and human organ donor matched blood, mucosal barrier, and lymphoid tissues. We also characterized the interplay between the MAIT cell response to *S. aureus* and the immune-evasive function of virulence factors, including the HlgAB leukocidin toxin. Peripheral blood MAIT cells respond to *S. aureus* leading to robust production of cytokines and granzyme B. MAIT cell activation by *S. aureus* is dependent both on IL-12 and IL-18, and activation via TCR triggering in response to MR1-presented antigen. MAIT cells are partially resistant to HlgAB leukocidin toxicity as compared to CD14+ monocytes. This coincides with higher expression level of CCR2, CXCR1 and CXCR2 on monocytes. Interestingly, activation of MAIT cells via TCR triggering or IL-12 and IL-18 reduces MAIT cells susceptibility to HlgAB toxicity. Additionally, MAIT cells display phenotypic and functional diversity according to their tissue localization and stimulation environment, leading to a differential susceptibility to *S. aureus* virulence factors.

T cell responses in patients infected with Neoehrlichias mikurensis

Linda Wass[1], Catharina Lewerin[2], Daniel Jaén-Luchoro[1;3], Seija Brundin[2], Christine Lingblom[1], Christine Wennerås[1]

[1]Department of Clinical Microbiology, Sahlgrenska University Hospital, Gothenburg, Sweden; *[2]Department of Hematology and Coagulation, Sahlgrenska University Hospital, Gothenburg, Sweden*; *[3]Department of Clinical Microbiology, Gothenburg, Sweden*

Purpose: *Neoehrlichia mikurensis (N. mikurensis)* is a bacterial species that is transmitted to humans via tick bites. These intracellular bacteria are believed to infect vascular endothelial cells and may cause asymptomatic infections or the infectious disease neoehrlichiosis. Typical symptoms are fever, localized pain, and vascular events. Patients with compromised B-cell immunity suffer from more severe neoehrlichiosis. The aim of this study was to investigate T-cell responses in patients infected with *N. mikurensis*.

Methods: T-cell responses were investigated by stimulating peripheral blood mononuclear cells from infected lymphoma patients (n=8) with recombinant bacterial peptides followed by measurement of T-cell proliferation using flow cytometry. The cells were also incubated with metal tagged monoclonal antibodies for analysis of T-cell populations by multiparameter phenotyping by using mass cytometry. Non-infected lymphoma patients were also analyzed for comparison (n=8). Infection with *N. mikurensis* was determined by PCR analysis of blood samples.

Results: It was only the T cells from the infected patients that responded with proliferation upon stimulation with bacterial peptides, not the T cells from the non-infected control patients. The T-cell responses evoked by this intracellular pathogen in infected patients featured perforin-expressing CD4+ and CD8+ populations that upregulated CXCL10 and interferon-g in response to bacterial peptides. In addition, individuals infected with *N. mikurensis* had higher proportion of perforin-expressing γδ T cells.

Conclusion: Patients infected with *N. mikurensis* develop T cell responses featuring Th1 cells, cytotoxic T cells and γδ T cells, which most likely are important in the defense against this intracellular pathogen.

Using weight loss to predict outcome and define a humane endpoint in preclinical sepsis studies

Maelick Brochut[1], Tytti Heinonen[1], Tiia Snäkä[1], Charly Gilbert[1], Didier Le Roy[1], Thierry Roger[1]

[1]*Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland*

Objective. Preclinical models are critical for understanding the pathophysiological response to infections and sepsis. In keeping with ethic values, researcher follow guidelines to monitor the health status and minimize suffering of mice. Weight loss is a criteria used as a humane end point, a cut-off value at which animals are euthanized. However, there is no official recommendation for a maximum weight loss leading to euthanasia. Our objective was to analyze the robustness of weight loss cutoff values used in preclinical models of sepsis.

Methods. Data were obtained from 2400 mice infected with *Listeria monocytogenes*, *Streptococcus pneumoniae*, *Candida albicans* and H1N1 influenza virus. Experiments were run over 10 years of research in the laboratory, without weight loss used as a humane endpoint or using a cutoff value of 30%. We performed statistical analyses applying different weight loss thresholds, and in-house data-based power calculation and simulation-based power calculation (more than 100’000 runs).

Results. The proportion of mice that did not survive infection was higher for *L. monocytogenes* (56.1%) and *S. pneumoniae* (57.3%) than for *C. albicans* (38.1%) and H1N1 (45.2%). In all models, independently of the conditions applied to the mice, weight loss segregated mice that survived from mice that did not survive. Statistical analyses indicated that fixing maximum weight loss thresholds at 25%, 20% and 10% of initial weight increased mortality rates (by 5%-13, $p < 0.01$-0.001) of infection by *C. albicans* and H1N1 IV, *L. monocytogenes* and *S. pneumoniae* infection, respectively. In-house data-based and simulation-based power calculations revealed great variability and/or reduction of power as weight loss thresholds approached 20% for *S. pneumoniae* and *L. monocytogenes* models.

Conclusion. To our knowledge, this represents the most extensive study exploring the relationship between weight loss threshold and outcome of sepsis. Our data indicate that weight loss is a valuable predictor of mortality. Yet, weight loss thresholds need to be adapted to each model of infection used in the laboratory to minimize mouse suffering without compromising statistical power and scientific objectives.

Unveiling Trypanosoma cruzi extracellular vesicles as masters of host immune regulation

Armanda Rodrigues[1], Mafalda Meunier[1], Victória Tavares[1], Aleska Silva[1], Graça Alexandre-Pires[2;3], Cláudia Moreno[1], Isabel Pereira da Fonseca[2;3], Gabriela Santos-Gomes[1]

[1]Global Health and Tropical Medicine, GHTM, Associate Laboratory in Translation and Innovation Towards Global Health, LA-REAL, Instituto de Higiene e Medicina Tropical, IHMT, Universidade NOVA de Lisboa, UNL, Lisboa, Portugal; *[2]Centre for Interdisciplinary Research in Animal Health, CIISA, Faculty of Veterinary Medicine, FMV, University of Lisbon, ULisboa, Lisbon, Portugal*; *[3]Associate Laboratory for Animal and Veterinary Sciences (AL4AnimalS)., Lisbon, Portugal*

Purpose: Deepening our understanding on the intricate communication and interaction between parasites and the host immune system may prove to be crucial in addressing the challenges posed by several emerging diseases, such as Chagas disease (CD). Caused by a protozoan parasite, *Trypanosoma cruzi*, CD constitutes a world health problem requiring an integrated and multidisciplinary approach to human and animal health. *T. cruzi* has evolved strategies to persist and disperse inside the mammal host, by evading and subverting host immune defenses. The present work aims to better understand CD related cardiomyopathies, by addressing non-classical *T. cruzi* hosts, allied with innovative *in vitro* cell models and exploiting natural produced parasitic extracellular vesicles (*Tc*EVs).

Methods: Cardiac co-cultures were established combining cardiac explants from *Ovis aries* and *Capra hircus* with autologous peripheral blood mononuclear cells (PBMCs), mimicking the cardiac microenvironment. Co-cultures were exposed to *T. cruzi* parasites or *Tc*EVs, previously isolated, and multiparametric flow cytometry was employed to assess the immunocompetency of the cells, analyzing the expression of major histocompatibility complex class I (MHCI) and class II (MHCII) molecules, along with CD3, CD4, and CD8 markers. Innate immune receptors and cytokines generation were analyzed by real-time-qPCR.

Results: *Tc*EVs rapidly interact with cells, generating a specific immune response, increasing MHCII and CD8 expression in PBMCs. Likewise, *Tc*EVs favors TLR2 and TLR4 gene expression, indicating that *Tc*EVs may activate these receptors. The presence of *Tc*EVs significantly enhances the generation of crucial pro-inflammatory cytokines, including interleukin (IL)-1β and IL-12.

Conclusion: Co-cultures were able to reconstitute the inflammation of the cardiac tissue associated with the establishment of severe cardiomyopathies *in vivo* for different hosts. TcEVs exposition promotes a cytotoxic response which might contribute to control parasite dissemination in cardiac tissue. However, this process may also further increase lymphocytic infiltration and tissue damage. Altogether, these results also highlight that parasitic EVs constitute an intrinsic part of *T. cruzi* biology and may play a role in cardiomyopathies establishment.

Gut helminth infection promotes lung anti-viral immunity in a monocyte dependent manner

Matthew Burgess[1;2], Karla Berry[1], Piotr Janas[1], Amanda McFarlane[3], Mariana Beltran-Sierra[1], Neil Henderson[1], Calum Bain[1], Henry McSorley[4], Jurgen Schwarze[1]

[1]Centre for Inflammation Research, University of Edinburgh, Edinburgh, United Kingdom; *[2]The Institute of Medical Sciences, Aberdeen, United Kingdom*; *[3]Beatson Institute for Cancer Research, University of Glasgow, Glasgow, United Kingdom*; *[4]University of Dundee, Dundee, United Kingdom*

Purpose: Infant respiratory viral infections are a major cause of infant hospitalisation and a risk factor in the development of persistent wheeze, airway allergic responses and ultimately asthma. We have previously shown that ongoing infection in mice with the gut helminth Heligmosomoides polygyrus (H. polygyrus) protects against respiratory syncytial virus (RSV) infection, reducing viral load, subsequent immunopathology and airway impairment. This protective effect was independent of adaptive immune responses or helminth secretory/excretory products, and dependent upon the induction of type-I interferons (IFN-I) in the gut and/or lung.

Methods: Mice were infected with H. polygyrus. Flow cytometry and single cell RNA sequencing characterised immune populations in bone marrow, blood and lung. Antibody mediate depletion and adoptive transfers of monocytes prior to RSV infections.

Results: Ongoing H. polygyrus infection induces bone marrow monocytopoiesis, in turn driving an increase in both circulatory monocyte populations and recruited macrophages in the lung. IFN-I signalling is required for the elevation of blood monocytes and lung macrophages. Treatment of infected animals with an anti-CCR2 antibody to deplete the expanded monocyte populations ablates the H. polygyrus induced anti-viral state, whereas elevating monocyte numbers by adoptive transfer replicates the anti-viral effect.

Single cell RNA sequencing of the lung macrophages further characterises the cells responsible for the anti-viral activity. A Ly6C-hi macrophage cluster is significantly expanded in H. polygyrus infection and shows enrichment for antiviral gene expression. RSV infection also induces elevated recruited macrophage counts as early as 8 hours post infection and this is enhanced by ongoing H. polygyrus infection. These RSV induced macrophages show similar anti-viral gene induction to the H. polygyrus induced cells, with co-infection further enhancing this cell signature.

Conclusion: During H. polygyrus infection systemic monocytosis leads to increased numbers of recruited macrophages within the lung that possess an anti-viral gene expression phenotype and are sufficient and essential for mounting an effective immune response to RSV infection.

Impact of tissue micromilieu factors on the secretion of extracellular vesicles by Leishmania major and on its survival in phagocytic cells

Noor-A-Kasida Islam[1], André Gemeinhardt[2], Tobias Utikal[2], Anna Kashkanova[2], Vahid sandoghdar[2], Ulrike Schleicher[1], Didier Soulat[1], Christian Bogdan[1]

[1]Mikrobiologisches Institut - Klinische Mikrobiologie, Immunologie und Hygiene, Universitätsklinikum Erlangen, Friedrich-Alexander-Universität (FAU) Erlangen-Nürnberg, Germany, Erlangen, Germany; *[2]Max-Planck-Institut für die Physik des Lichts, Erlangen, Germany*

Leishmania (L.) major is responsible for chronic but ultimately self-healing forms of cutaneous leishmaniasis (CL). The control of CL requires interferon (IFN)-γ and tumor necrosis factor (TNF) that activate phagocytic host cells for the killing of *L. major* by reactive oxygen (ROS) and reactive nitrogen species (RNS). Besides cytokines, the immune response is shaped by tissue micromilieu factors such as oxygen concentration, temperature or pH, all of which will influence both host cells and parasites. *L. major* is likely to respond to changes in the microenvironment, e.g., by secretion of extracellular vesicles (EVs). EVs manipulate macrophages, the classical antimicrobial effector cells, but presumably also stromal cells (e.g., reticular fibroblasts) in draining lymph nodes, which can function as safe target cells for *Leishmania* and thereby contribute to parasite persistence.

Here, we studied the impact of several micromilieu factors on the secretion of EVs by *L. major* and on the intracellular fate of parasites in macrophages and reticular fibroblasts. Using innovative interferometric nanoparticle tracking analysis (iNTA), we found that a temperature shift from 28°C to 37°C or exposure to acidic pH (pH 6.7) caused an increase or decrease of the number of detected EVs per min, respectively. Next, we pre-treated macrophages and fibroblasts for 2hrs with EVs to study their effect on the infection with *L. major* promastigotes and observed a minor increase in the infection rate as compared to untreated cells. We also explored the influence of hypoxia (3% O_2) or pH 6.7 on the infection of fibroblasts with *L. major* amastigotes or promastigotes for 24-48 hrs. Under these conditions, we saw no change in the infection rate or the number of parasites per infected cell as compared to control cultures, whereas normoxic stimulation with IFNγ and/or TNF led to a decrease of the infection rate.

These findings indicate that the secretion of EVs is regulated by micromilieu factors and that *L. major* is capable to withstand hypoxia and acidity in fibroblasts. In ongoing single cell RNAseq studies, we aim to characterize the host cell niches for *Leishmania* and the impact of micromilieu factors *in vivo* in a more holistic fashion.

Pertussis vaccine-induced regulatory T cells suppress protective nasal tissue-resident memory T cells, which can be overcome using novel adjuvants and nasal vaccination.

Caitlín Ní Chasaide[1], Pauline Schmitt[1], Béré K. Diallo[1], Charlotte Leane[1], Lisa Borkner[1], Lucy Curham[1], Seyed Davoud Jazayeri[1], Mieszko Wilk[1;2], Kingston Mills[1]

[1]*Trinity College Dublin, Dublin, Ireland*; [2]*Jagiellonian University, Kraków, Poland*

Purpose: Respiratory tissue-resident memory T (T_{RM}) cells are essential for sustained protective immunity against *Bordetella pertussis* infection of the nasal mucosa. Current alum-adjuvanted acellular pertussis (aP) vaccines protect against severe disease but fail to prevent nasal infection with *B. pertussis* and suppress induction of T_{RM} cells. With most deaths from pertussis occurring in infants under 1 year old, this failure leaves the youngest infants at risk. This study examined the mechanism of suppression of aP vaccines and explored strategies to induce T_{RM} cells and enhance bacterial clearance from the nose using novel adjuvants and immunization approaches.

Methods: Mice were immunized with the aP vaccine on days 0 and 28 and were challenged with live *B. pertussis* 14 days later. Respiratory T_{RM} cells were assessed by flow cytometry and protection was assessed by CFU counts in respiratory tissues. Draining lymph node (dLN) and spleen cells from immunized mice were used to assess antigen-specific T cell responses and to establish *B. pertussis*-specific T cell lines.

Results: The aP vaccine induced antigen-specific IL-10-producing CD4 and CD8 T cells in dLN and spleen. *B. pertussis*-specific CD4 and CD8 T cell lines established from aP-immunized mice secreted IL-10, expressed the Treg markers, LAG-3 and CD49b and suppressed antigen-specific IL-17 production by CD4 T cells from convalescent mice. Depletion of CD8 T cells in mice at time of immunization with an aP vaccine ameliorated suppression of nasal T_{RM} cells. Blockade of IL-10 signalling during aP immunization or *B. pertussis* challenge enhanced bacterial clearance in the nose and promoted the induction of respiratory IL-17-secreting T_{RM} cells. A novel intranasally delivered adjuvant, LP-GMP, comprising TLR2 and STING agonists, when used instead of or in addition to alum in an aP vaccine, reversed the suppression of antigen-specific IL-17^+ T_{RM} responses and promoted bacterial clearance from the nasal tract.

Conclusion: Our study demonstrates that alum-adjuvanted aP vaccines suppress induction of protective T_{RM} responses by inducing IL-10-seceting Treg cells, but this is reversed by nasal delivery of the aP vaccine with a novel adjuvant.

Chlamydia caviae infection in human epithelial lung cells

Tamara Weinmayer[1], Madeleine Haas[1], Irma Schabussova[1], Ursula Wiedermann[1], Aleksandra Inic-Kanada[1]

[1]*Institute of Specific Prophylaxis and Tropical Medicine, Center for Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria*

Purpose: *Chlamydia caviae*, belonging to the Chlamydia genus, primarily affects guinea pigs but has recently been reported to infect humans, occasionally leading to severe pneumonia. The extent and clinical impact of *C. caviae* infections in humans remain unclear, underscoring the need for additional research to elucidate its health implications.

Methods: We investigated whether *C. caviae* could infect human alveolar basal epithelial cells (A549 cell line). To monitor the progression of the infection, immunofluorescent staining was performed after 6h, 24h, 32h and 48h. We then examined alterations in the expression of E-cadherin, a guardian of epithelial phenotype, α-smooth muscle (α-SMA), a mesenchymal marker, as well as in TGFß1 and TGFß2, involved in epithelial-mesenchymal transition-inducing signaling pathways utilizing qRT-PCR and Western blot. We quantified cytokine secretion in the A549 cells supernatants post-*C. caviae* infection using ELISA.

Results: A549 cells were successfully infected with *C. caviae*, as evidenced by visible inclusions within the cells. qRT-PCR analysis identified a trend towards increased expression of TGFβ1, TGFβ2, E-cadherin, and α-SMA in infected cells. Western blot analysis highlighted a statistically significant decrease in E-cadherin levels in *C. caviae*-infected cells when compared to uninfected controls. In contrast, α-SMA levels remained unchanged between the two groups. Notably, among the various cytokines examined, only the expression levels of IL-6 and IL-8 were statistically significant, with both showing increased levels in A549 cells infected with *C. caviae* compared to the non-infected control cells.

Conclusion: The capability of *C. caviae* to infect human alveolar basal epithelial cells reveals its potential impact on human health beyond its known effects in guinea pigs. The significant changes in IL-6 and IL-8 levels, alongside the decrease in E-cadherin expression in infected A549 cells, imply a specific inflammatory response upon infection. Our work opens new avenues for understanding how *C. caviae* may contribute to respiratory conditions in humans, emphasizing the importance of further research in this area.

Candida-triggered oral tumorous epithelial cell responses at the posttranscriptional regulatory level

Renata Toth[1], Marton Horvath[1], Attila Gacser[2;3;4]

[1]Department of Microbiology, University of Szeged, Szeged, Hungary; *[2]HCEMM-USZ Fungal Pathogens Research Group, Department of Microbiology, University of Szeged, Szeged, Hungary*; *[3]HUN-REN-USZ Pathomechanisms of Fungal Infections Research Group, University of Szeged, Szeged, Hungary*; *[4]University of Szeged, IKIKK, Competence Centre for Molecular Biology, Bionics and Biotechnology, Szeged, Hungary*

Oral candidiasis is frequently observed among the immunocompromised, especially in oral cancer patients. Our prior findings suggest that certain *Candida* species, e.g. *Candida albicans,* enhance oral squamous cell carcinoma progression via several mechanisms, such as altering metabolism, matrix metalloprotease activity, migration and pro-tumour signaling in oral epithelial cells. Here, we aimed to reveal what are the underlying processes, particularly, the posttranscriptional regulatory mechanisms responsible for this phenomenon. As different *Candida* species trigger distinguishable host responses, we further aimed to examine if a 'species-specific' effect is present. To identify tumour-specific effects, we compared the tumorous oral epithelial cell responses to non-tumorous epithelial cell responses.

Therefore, during the study we examined tumour-associated as well as potentially contributing inflammatory responses in oral epithelial cell lines to *C. albicans* and *C. parapsilosis* by wet-lab methods and *in silico* analyses.

Under non-tumorous conditions, *C. albicans* induced strong inflammatory processes, while *C. parapsilosis* activated responses independent of inflammation, but related to hypoxia, carbohydrate metabolism and vascularization. The species-specific effect also manifested in the identified miRNA profiles with no overlap. Under the tumorous condition, *C. albicans* altered the expression of a higher number- and different species- of miRNAs, compared to *C. parapsilosis*, and besides inflammation, general signalling pathways related to transcription factor and receptor regulator activity were also changed. *C. parapsilosis* elicited similar host responses as in non-tumorous epithelial cells. Comparison of the non-tumorous and tumorous conditions showed that the number of differently expressed genes was highest after *C. albicans* presence and cancer-associated genes were most effected in the tumorous condition. According to miRNA-target mRNA analyses, we identified 6 *C. albicans*-induced oral tumor-associated genes under miRNA regulation, that will be in the focus of our subsequent investigations.

To summarize, tumorous oral epithelial cells vigorously discriminate between *C. parapsilosis* and *C. albicans*, as both species evoke a distinguishable host response. Furthermore, the pro-tumor effect of *C. albicans* also manifests at the miRNA level.

Dermaseptin S4 improves the innate immunity of gingival cells against oral pathogens (C. albicans and E. faecalis).

Mahmoud Rouabhia[1], Jamila Chakir[2]

[1]*Université Laval, Quebec, Canada*; [2]*Institut Universitaire de Cardiologie et de Pneumologie de Québec, Quebec, Canada*

Purpose: Multiple oral pathogens, including C. albicans and E. faecalis cause significant oral infections such as oral candidiasis and root canal infection, respectively. The use of antibiotic/antifungal molecules is limited by possible drug resistance. These limitations could be elevated using antimicrobial peptides (AMPs). Frog skin AMPs (such as dermaseptins) have shown antimicrobial activity against several pathogens and thus could be a medical alternative to prevent/treat these oral infections.

Objectives: To evaluate the effect of dermaseptin S4 (DS4) on oral pathogens (C. albicans and *E. faecalis)*, and gingival cell innate immunity.

Methods: Microorganisms (C. albicans and *E. faecalis*) were exposed to different concentrations (0 to 20 ug/ml) of DS4, then the bacterial growth was assessed after different time points (3 to 24 h). The effects of the DS4 inhibiting biofilm formation were evaluated qualitatively and quantitatively after 3 days. We also evaluated gingival (fibroblast and epithelial cells) and dental pulp stem cells (DPSC) adhesion proliferation after exposure to DS4. Finally, we studied the effect of DS4 reducing proinflammatory responses of the gingival cells when exposed to 5 ug/ml of lipopolysaccharide (LPS).

Results: DS4 showed significant effects, decreasing the growth of C. albicans and E. faecalis. Such growth reduction was confirmed by a significant inhibition of biofilm formation after 72 h exposure to DS4 as shown by scanning electron microscopy and crystal violet staining. The peptide reduced the yeast-to-hyphae transition of C. albicans. Interestingly, gingival fibroblasts, epithelial cells, and DPSC cultured in the presence of DS4 adhered and grew similarly to non-treated cells. Cells stimulated with LPS showed high levels of proinflammatory cytokines (IL-1β, IL-6, IL-8, and TNFa). DS4 significantly reduced the levels of these cytokines.

Conclusion: While it was not toxic to gingival cells, DS4 showed good control of the growth and biofilm formation by C. albicans and *E. faecalis.* Overall, this study suggests using dermaseptin as a medication to control oral infections, including oral candidiasis and root canal infections.

Innate immunity in tuberculosis among type 2 diabetes patients: characterization and clinical correlations

Alisha Arora[1], Archana Singh[1], Yashdeep Gupta[1], Anant Mohan[1]

[1]*AIIMS New Delhi, New Delhi, India*

Background: The increased susceptibility to bacterial infections like tuberculosis is one of the hallmarks of type 2 diabetes, however the underlying mechanisms remains poorly characterized. Alteration in host innate immune responses at early-stage infection might be a reason for inefficient clearance of bacteria, thus leading to dissemination of infection and increased immune pathology. In this study, we have tried to characterize the immune responses of major professional phagocytes, namely polymorphonuclear cells and macrophages which are one of the first cells to encounter Mtb during early infection.

Methods: 20 individuals were recruited under four group namely uncontrolled DM patients with or without pulmonary TB (PTB+DM and DM respectively), only PTB and healthy controls. PMNs and PBMCs were isolated from peripheral blood using density gradient centrifugation. Monocyte derived macrophages were cultured using GM-CSF. Cellular counts and surface marker expression were studied by flow cytometry. Phagocytosis activity was studied by fluorescent labelled bacteria. Bacterial clearance was studied by Colony Forming Unit assays.

Results: Our results revealed reduced phagocytic ability and bacterial clearance capacity of both PMNs and macrophages in PTB+DM patients as compared to PTB patients. Characterization of these innate immune cells have shown altered phenotypes in PTB+DM patients. Reduced number of activated PMNs ($CD62L^{low}$ $CD66b^{high}$) were found in PTB+DM compared to PTB and DM. Also, increased levels of CD47 and CXCR4 were found which positively correlated with increased neutrophilia in PTB+DM patients. Macrophages in PTB+DM patients were found to have an altered phenotype of $CD11b^{low}$ $MARCO^{low}$ $CD206^{high}$.which is positively correlated with the clinical sputum grades(+1,+2,+3).

Conclusion: This study suggests that diabetic milieu induce altered phenotypes of innate immune cells resulting in dysregulated effector immune responses against Mycobacterium tuberculosis. These alterations can potentially be a contributing factor in inability of the host to clear out infection at an early stage and increased immune pathology.

Distinct profiles of cytokines and chemokines in cerebrospinal fluid can differentiate bacterial meningitis from viral meningitis.

Ramona Cerasela Caragheorgheopol[1], Cătălin Țucureanu[1], Veronica Lazăr[2], Simin-Aysel Florescu[3], Dragoș Ștefan Lazăr[3], Iuliana Caraș[1]

[1]'Cantacuzino' National Medical-Military Institute for Research and Development, Bucharest, Romania; *[2]Faculty of Biology, University of Bucharest, Bucharest, Romania*; *[3]'Dr. Victor Babeș' Clinical Hospital for Infectious and Tropical Diseases, Bucharest, Romania*

Purpose: Distinguishing between bacterial meningitis (BM) and viral meningitis (VM) presents a significant clinical challenge, as timely and precise identification of the causative agent is pivotal for selecting the correct treatment approach and enhancing patient prognosis significantly. Given the inflammatory cascade characteristic of BM, analyzing the patterns of pro- and anti-inflammatory cytokines/chemokines (CTs/CKs) in both cerebrospinal fluid (CSF) and serum could serve as valuable, sensitive markers for distinguishing BM from VM.

Methods: The study aimed to investigate the capacity of cytokines and chemokines (CTs/CKs) to distinguish between BM and VM. To achieve this, biochemical markers and CT/CK profiles were examined in 145 CSF samples and 153 serum samples, split into three groups: BM, VM, and a control group C, consisting of patients with meningism.

Results: In the BM group, CSF levels of TNF-α, MCP-1, MIP-1α, IL-1β, IL-6, ENA-78, IL-10, IL-8, proteins, and white blood cells were significantly elevated, while CSF glucose concentrations were decreased compared to both the VM and C groups ($P<0.01$). Correlation analysis revealed strong positive correlations in CSF for MIP-1α/IL-1β ($r=0.64$), IL-1β/ TNF-α ($r=0.64$), MIP-1α/TNF-α ($r=0.69$) and for IL-6/TNF-α ($r=0.75$). Fewer correlations were observed in the serum (IL-8/MCP-1, IL-1β/MCP-1, and IL-1β/IL-8 ($r=0.83$; $r=0.72$; $r=0.78$, respectively). To determine the optimal cytokine/chemokine (CT/CK) patterns for predicting and classifying BM and VM, a dataset comprising 119 BM and VM CSF samples was split into training (n=90) and testing (n=29) subsets for input into a Random Forest (RF) machine learning algorithm. The RF algorithm correctly classified with 92% sensitivity and 93% specificity 28 out of 29 test samples (15 BM and 14 VM). For serum samples, although the CT/CK levels in the BM serum samples were higher than in VM, the classification of the two groups using the RF algorithm was weak.

Conclusion: These findings suggest that the CSF patterns of CT/CK levels could be used as a valuable tool for differentiating BM and VM

Centro Nacional de Investigaciones Cardiovasculares Carlos III (CNIC), Madrid, Spain*

Background: Current evidence establishes a causal relation between *Clostridioides difficile* infection (CDI), one the most common and severe nosocomial infections, and colon inflammation. Its prognosis and recurrence prediction are still an unsatisfied need, just based on clinical criteria which are not sufficiently accurate. Therefore, the determination of immune profile could throw relevant information about the progression and gravity of CDI.

Objectives: To describe the evolution of the immunological profile in peripheral blood (PB) on a mouse model of CDI over time.

Methods: CDI was induced in 18 C57BL/6 female mice following Cussó et al. (DOI: 10.1007/s11307-019-01408-4) protocol. Mice were divided into mild (ribotype 001, low toxin production) and severe (ribotype 027, high toxin production) groups. Clinical signs score (CSS) was obtained for each animal over time. PB samples of 100 µl were collected at basal, pre-infection (0d), post-infection (+2d) and recovery (+15d); and incubated with 2 multiparametric antibodies panels to analyse lymphoid and myeloid populations. Then erythrocytes were lysate and samples were acquired by flow cytometry using a 16-channel flow cytometer.

Results: Both groups showed a decrease of monocytes (Mo) and dendritic cells (DC) post-infection, compared to basal levels. Within lymphoid populations, activated CD8+ and CD4+ T cells, especially Th1, and NKT cells were increased at post-infection, values recovered after 15 days.; while B lymphocytes raised gradually according to CDI progression. However, at recovery, severe group showed an increase of Th17 cells, pro-inflammatory Mo and mature DC compared to mild group, indicative of more intense inflammatory response. Besides, CSS at recovery positively correlated with these phenotypes, therefore the immune analysis enabled distinguishing between CDI different severity degrees.

Conclusion: The designed antibodies panels are enough sensitive to detect immunological changes and discriminate between CDI stages and severity degrees employing minimal PB samples.

Advancing towards systems immunology: understanding immunological dynamics in human experimental enterotoxigenic Escherichia coli infection through cytometry, proteomics, and computational approaches

Sehee Rim[1], Sunniva Todnem Sakkestad[2], Oda Barth Vedøy[1], Hans Steinsland[3;4], Dimitrios Kleftogiannis[5], Kurt Hanevik[1;6]

[1]Department of Clinical Science, Faculty of Medicine, University of Bergen, Bergen, Norway; *[2]Department of Internal Medicine, Helse Bergen, Bergen, Norway*; *[3]Centre for Intervention Science in Maternal and Child Health (CISMAC), Centre for International Health, Department of Global Public Health and Primary Care, Faculty of Medicine, University of Bergen, Bergen, Norway*; *[4]Department of Biomedicine, Faculty of Medicine, University of Bergen, Bergen, Norway*; *[5]Department of Clinical Medicine, Faculty of Medicine, University of Bergen, Bergen, Norway*; *[6]National Centre for Tropical Infectious Diseases, Department of Medicine, Haukeland University Hospital, Bergen, Norway*

Purpose: Systems immunology provides a comprehensive framework for understanding complex interplay of immune responses. Enterotoxigenic *Escherichia coli* (ETEC) is a major contributor to childhood diarrhea in low- and middle-income countries. Thorough characterization of systemic immune responses may guide vaccine development. In this study, we combined cytometry, proteomics, and computational analyses to investigate immunological dynamics following human experimental ETEC infection.

Methods: Buffy coats and plasma samples were collected from nine volunteers infected with ETEC before, three, and seven days after dose ingestion. Mass cytometry was employed to analyze lymphocytes with 32 markers, yielding 33 cell populations. Plasma samples underwent analysis using 27 markers for inflammation, mucosal injury, kynurenine pathway metabolites, and vitamin B using mass spectrometry and ELISA. Computational methodologies, including Spearman tests, factor analysis (FA), and principal component analysis (PCA) were employed to examine datasets comprising fold changes from baseline, in proportions of cell populations, and protein concentrations, separately for day 3 and day 7 after dose ingestion.

Results: Spearman analysis revealed various significant correlations in fold changes on both days. Notably, N1-methyl-nicotinamide correlated positively with dendritic cells but negatively with gammadelta T cells, Th17-like cells, and plasmablasts. Kynurenine correlated negatively with MAIT cells, gammadelta T cells, TEMRA cells, Th17-like cells. Additionally, S100A9, a calprotectin subunit, showed negative correlations with MAIT cells, gammadelta T cells, and T cell subsets. FA and PCA on day 3 identified inflammatory proteins such as serum amyloid A (SAA), and C-reactive protein (CRP), alongside innate immune cells like gammadelta T, mucosal-associated invariant T, and natural killer T cells, as key variables that explained a significant portion of the total variance. On day 7, key variables encompassed SAA, CRP, tryptophan metabolites, vitamin B1, and calprotectin, with calprotectin negatively correlating with the other key variables. Adaptive immune cell populations, including plasmablasts and Th17-like effector and central memory cells demonstrated notable contributions to systemic immune responses on day 7, with $CD4^+$ TEMRA cells positively correlating with them.

Conclusion: Multivariate analysis characterized immune responses against ETEC, validating univariate findings, and revealing novel biological associations involving gammadelta T cells, TEMRA cells, and calprotectin in a dataset with small sample size.

Elucidating the role of IL4/IL13 signaling in tuberculous granuloma formation

Miriam Herbert[1], Mark R. Cronan[1]

[1]*Max Planck Institute for Infection Biology, Berlin, Germany*

Tuberculosis (TB), an infectious disease that has coexisted with humans for several millennia, remains a significant global health challenge, causing approximately 1.5 million fatalities annually. The persistence of TB is partly due to the complex interactions between the human immune system and *Mycobacterium tuberculosis* (Mtb), the causative agent of TB. A critical aspect of this interaction is the formation of tuberculous granulomas. These structured aggregates of immune cells arise following infection with Mtb and related mycobacteria. Granuloma act as a double-edged sword: they contain the infection but can also lead to tissue necrosis, promote disease progression and impede antibiotic penetration. Within the granuloma a layer of epithelioid macrophages shields the necrotic core harboring the bulk of the bacterial burden from immune cells and antibiotics in the outer layers. The transcription factor STAT6 has been shown to be vital for the epithelioid transformation of macrophages and necrotic granuloma formation. Since STAT6 is induced by IL4R signaling, we investigate here the influence of IL4 and IL13 signaling on tuberculous granuloma formation and persistence.

To delineate the contribution of IL4/IL13 signaling pathways to the development and architecture of tuberculous granulomas, we employed a zebrafish *(Danio rerio)*-*M. marinum* infection model, which closely mimics human tuberculosis pathology. Genetically modified zebrafish were used to disrupt IL4, IL13 or IL4/IL13 signaling. Development of granuloma was monitored by histological and immunofluorescence staining. Induction and spatial distribution of IL4/IL13 was evaluated by RNAScope over the course of the infection and granuloma forming process (7-21 dpi). Additionally, the bacterial burden was assessed at 14 dpi.

Preliminary findings suggest that IL4/IL13 signaling plays a pivotal role in granuloma formation and maintenance, with expected variations in granuloma structure and bacterial containment between modified and wild-type zebrafish.

By targeting IL4/IL13 pathways, this research aims to unveil the significance of IL-4/IL-13 signaling in the immunopathology of tuberculous granulomas, thereby contributing to the development of potential host-directed adjunctive treatments for tuberculosis.

Exploring distinct T-cell subsets in the upper respiratory tract during Influenza A and Bordetella pertussis infections

Anna Kratochvílová[1], Jana Holubová[2], Ondrej Stanek[2], Veronika Niederlová[1], Juraj Michálik[1], Peter Sebo[2], Ondrej Stepanek[1]

[1]*Institute of Molecular Genetics of the Czech Academy of Sciences, Prague, Czech Republic*; [2]*Institute of Microbiology of the Czech Academy of Sciences, Prague, Czech Republic*

Purpose: The upper respiratory tract (URT) is a site of entry for many public health-concerning pathogens such as SARS-CoV-2, the Influenza virus, or *Bordetella pertussis*. Although the URT represents an important site for initiating and transmitting infection, understanding of the site-specific immunity in the nasal tissue during respiratory infections is limited. The adaptive immune system of URT consists of highly organized nasal-associated lymphoid tissue and dispersed Tissue-resident memory T cells (Trm). Trm cells are a subset of memory T cells, which reside in non-lymphoid tissues. Due to their advantageous location, they can be part of the first line of defense against infections. The development, diversity, and function of T cells in the respiratory tract are not yet completely understood. We hypothesized that different infections such as intracellular viral infection or extracellular bacterial infection give rise to phenotypically and functionally distinct $CD4^+$ and $CD8^+$ T-cell subsets.

Methods: To address this hypothesis we utilized two mice infection models: viral infection (Influenza A) and bacterial infection (*Bordetella pertussis*). Samples from murine URT and lungs were analyzed by flow cytometry and T-cells were sorted for single-cell RNA sequencing.

Results: We observed striking differences between both $CD4^+$ and $CD8^+$ T cells after the infections. Particularly, we identified a unique subset of $CD8^+$ T cells arising after *Bordetella pertussis* infection. These cells were highly clonally expanded and obtained an atypical phenotype characterized by the expression of Granzyme K, transcription factor Eomes, checkpoint-inhibition receptors as well as IL-10 receptor.

Conclusion: We identified a unique subset of $CD8^+$ T cells after *Bordetella pertussis* infection. The function and specificity of these cells will be further studied.

IL-36 receptor expression is required to mount effective dendritic cell responses upon exposure to Staphylococcus aureus

Sam McGlynn[1;2;3], Patrick T. Walsh[1;2;3]

[1]Trinity Translational Medicine Institute, School of Medicine, Trinity College Dublin, Dublin, Ireland; *[2]All Island Vaccine Training and Research Alliance (AIVRT), Dublin, Ireland*; *[3]HEA North-South Research Programme, Dublin, Ireland*

Purpose: There has been a steady increase in the incidence and severity of antimicrobial resistant infections in healthcare settings worldwide. The need to develop novel treatment approaches to counteract antibiotic resistant pathogens has grown in importance. *Staphylococcus aureus (S. aureus)*, particularly the methicillin resistant strain, is one such pathogen which has emerged as a significant problem in healthcare settings. A deeper understanding of the mechanisms through which *S. aureus* drives inflammation and immunity will be critical towards defining new approaches to counteract infection. The ability of *S. aureus* to drive inflammation in the skin via the IL-36 pathway has recently been documented. Based on these observations, we hypothesised that IL-36 cytokines may also play a role in the ability to mount effective immunity to *S. aureus* and influence the severity of disease outcomes.

Methods: To investigate the mechanisms through which IL-36 contributes to the pathogenesis of *S. aureus* infection, we examined the induction of innate and adaptive immune responses to *S. aureus* exposure in wild type (*wt*) and *il36r-/-* mice using *in vitro* and *in vivo* methods.

Results: Bone marrow derived dendritic cells (BMDCs) from *il36r -/-* mice exhibited a reduced capacity to release inflammatory cytokines (IL-6, IL-12 and IL-23) and chemokines (CXCL1) upon stimulation with heat-killed *S. aureus*, when compared to *wt* cells. In contrast, *S. aureus* mediated induction of surface markers of activation (CD80, CD86, CD40) were not altered. In association with diminished secretion of T cell instructive cytokines, *il36r-/-* BMDCs also displayed a reduced capacity to induce primary activation of effector CD4+ T cell responses under co-culture conditions, with diminished IL-17a and IFN-γ expression after 72 hours. These effects were mirrored *in vivo*, with *il36r-/-* mice having a reduced capacity to mount effective Th17 and Th1 recall responses after sub-cutaneous immunisation with heat-killed *S. aureus*.

Discussion: This data identifies an important role for the IL-36 pathway in regulating innate immune responses to *S. aureus* which impacts the subsequent generation of effector CD4+ T helper responses. The influence of IL-36 cytokines may be an important consideration in the development of effective therapeutic approaches towards combatting *S. aureus* infection.

Intracellular bacteria pose significant challenges to the human immune system. Plasmacytoid dendritic cells (pDC) are immune innate cells renowned for their role in antiviral responses, because of their exceptional capacity to produce huge amounts of type I interferon (IFN). pDC have also been implicated in host responses against bacterial infections, although the operating molecular mechanisms remain unclear. Signaling Lymphocyte Activation Molecule Family (SLAMF) members act as microbial sensors and modulate immune functions in response to infectious agents, but their precise role in human pDC is still to be unraveled. Here, human blood transcriptomics revealed the involvement of SLAMF7 and SLAMF8 in various infectious diseases, with elevated levels associated with type I IFN and inflammatory responses in salmonellosis and brucellosis patients. Spectral flow cytometry findings indicate that pDC display the highest basal levels of SLAMF7^{+} or SLAMF8^{+} cells among cell sub-populations, and such expression is heightened by TLR7/8 agonists. Using an acute inflammation inducing-pathogen, *Salmonella*, and a stealthy chronic one, *Brucella*, we further identified SLAMF7 and SLAMF8 as human pDC function regulators. SLAMF receptors absence hinders the maturation state of infected pDC and abrogates cytokine production. SLAMF7 and SLAMF8 signal through NF-kB, IRF7 and STAT-1, and limit mitochondrial ROS accumulation upon Salmonella infection. This SLAMF7/8-dependent control of mitochondrial ROS levels favors bacterial persistence and NF-kB activation. This work constitutes a mechanistic demonstration of pDC anti-bacterial response positively modulated by SLAMF receptors, bridging a critical gap in understanding their molecular activation mechanisms during infection, and envisioning implications for diagnosis and therapeutic development.

The role of extracellular vesicles in oral squamous cell carcinoma- Candida interaction

Éva Veres[1], Zóra Szilovics[1], Dóra Adamecz[2], Gergő Svorenj[1], Krisztina Buzás[3], Mónika Kiricsi[2], Attila Gacser[4;5;6]

[1]Department of Microbiology, University of Szeged, Szeged, Hungary; *[2]Department of Biochemistry and Molecular Biology, University of Szeged, Szeged, Hungary*; *[3]Synthetic and System Biology Unit, Hungarian Academy of Sciences, Biological Research Centre (BRC), Szeged, Hungary*; *[4]HCEMM-SZTE Pathogen Fungi Research Group, University of Szeged, Szeged, Hungary*; *[5]HUN-REN-SZTE Pathomechanisms of Fungal Infections Research Group, University of Szeged, Szeged, Hungary*; *[6]University of Szeged, IKIKK, Competence Centre for Molecular Biology, Bionics and Biotechnology, Szeged, Hungary*

Oral squamous cell carcinoma (OSCC) accounts for 90% of oral cancer cases worldwide. In OSCC, the normal oral microbiota is often altered, which may predispose to local infections such as oral candidiasis. A previous study by our laboratory showed that in the case of OSCC, the number and diversity of colonizing yeasts in the oral cavity increases significantly compared to healthy individuals. In addition, the presence of *Candida albicans*, the causative agent of oral candidiasis, contributes to tumor progression by enhancing tumor cell oncometabolite production, the activity of secreted matrix metalloproteinases (MMPs), and signaling pathways involved in tumor progression *in vitro* and *in vivo*. However, the main component causing the changes has not yet been identified. Therefore, in our work, we investigate the effect of *Candida*-derived extracellular vesicles (EV) on the progression of OSCC. As we hypothesize that EVs play a crucial role in cell-cell communication, they may also play an important role in host-pathogen interaction.
