Inflammatory bowel disease (IBD) is a complex chronic gut inflammatory disorder, encompassing Crohn's disease (CD) and ulcerative colitis (UC). It predominantly impacts young individuals during their most active and productive years. Despite considerable progress in IBD research, its underlying causes remain elusive and there is still no definitive cure. Evidence suggests the existence of a preclinical phase in IBD, marked by immunological changes, occurring years before symptoms manifest and diagnosis is made. A deeper understanding of this preclinical period holds promise for advancing our knowledge of disease development, designing therapeutic approaches, and enhancing the ability to predict and prevent the onset of the disease.
We have taken advantage of the unique preclinical PREDICTS cohort, containing multiple longitudinal samples many years preceding diagnosis. Analysis of preclinical serum samples by nanoLC-ESI-MS, up to 6 years before IBD diagnosis, revealed the identification of a specific glycosylation signature on circulating antibodies (IgGs) that remained stable until disease diagnosis. This glycan trait correlated with specific anti-microbial antibodies, detected in serum, that predates by years the development of CD. Also, we have demonstrated *in vitro* the effect of these particular antibodies in eliciting a pro-inflammatory response, mainly in triggering innate immune response. This was also concomitant with a significant increased expression of genes involved in pro-inflammatory signalling pathways, such as TNF and NF-κB signalling pathways. Later, we validated *in vivo* the pathogenic properties of these particular IgGs, through adoptive IgG transfer of these selected IgG in WT mice, associated with increased susceptibility to intestinal inflammation.
Overall, this work has identified a specific glycome signature in IgGs, years before CD onset, that may play a pivotal role in the initiation of inflammation many years before CD diagnosis, acting as a promising new biomarker for CD prediction.

Relationships between plasma immune protein profiles, extent of inflamed tissue, and density of intestinal infiltration reveal discrete disease courses amongst therapy-naïve ulcerative colitis patients

Beatriz Calado[1], Maud Heredia[1], Mohammed Charrout[2], Renz C.W. Klomberg[3], Danielle M. H. Barendregt[1], Danielle H. Hulleman-van Haaften[1], Bastiaan Tuk[1], Lisette A. van Berkel[1], Brenda Bley Folly[1], Johanna C. Escher[3], Lissy de Ridder[3], Janneke N. Samsom[1]
[1]Erasmus University Medical Center, Laboratory of Pediatrics, Rotterdam, Netherlands; *[2]Delft Bioinformatics Lab, Delft University of Technology, Delft, Netherlands*; *[3]Erasmus University Medical Center - Sophia Children's Hospital, Rotterdam, Netherlands*

Ulcerative colitis (UC) is a chronic intestinal inflammation driven by inflammatory memory T helper cells (Th_M) reactivation. Heterogeneity in clinical disease and variability in response to treatment require new strategies targeting the patient's underlying immune disease. As in UC inflammation only affects the intestinal mucosa, it is debated whether peripheral blood immune responses could reliably reflect ongoing intestinal immune disease. To unequivocally establish this, we performed a deep immune characterization of therapy-naïve pediatric UC patients (n=34) and controls (n=55) by measuring 92 plasma immune proteins, analysing circulating Th_M subpopulations and performing intestinal mRNA expression and immunohistochemistry. Extensive clinical follow-up was used to relate immune responses to clinical disease severity and therapy response.
At diagnosis, 23 plasma proteins were differentially abundant in UC compared to controls. Increased protein concentrations mainly related to the IL-17 pathway (IL-17, IL-8, CCL20), tissue remodelling (MMP-10, MMP1, HGF), acute phase response (IL-6, OSM) and chemokinesis (CXCL9, CXCL10, CCL3) . Interestingly, intestinal mRNA expression of highly abundant plasma proteins similarly increased whereas no proportional changes in circulating Th_M were detected. Clustering of plasma immune profiles yielded two clusters of UC patients, UC_A with significantly increased concentrations of Th17/neutrophil-pathway-related proteins versus UC_B with lower concentrations. In UC_A, 17 proteins were increased versus UC_B. These included IL- 17A as most increased, OSM a neutrophil product previously associated with anti-TNF therapy resistance and CXCL9/CXCL11, IFN-γ-induced chemokines. Strikingly, this UC_A immune profile directly related to increased size of the affected intestinal surface and degree of infiltrating IL-$17A^+$ cells and neutrophils. Clinically, UC_A patients had more severe intestinal disease, including larger disease extent, higher clinico-pathological parameters at diagnosis and required earlier treatment intensification during >1 year follow-up, compared to UC_B patients.
These data firmly establish that peripheral blood immune protein responses reliably reflect ongoing intestinal immune disease in UC. Addition of immune profiling to routine clinical characterization at diagnosis could support tailored treatment with earlier start and more intensive immunomodulatory treatment in UC_A patients to target the more severe immune disease and avoid tissue damage.

Investigation of the role of Interleukin-11 (IL-11) in paediatric IBD patient non-responsiveness to therapeutic intervention.

Debopriya Saha[1;2], Larissa Bless[1;2], Sarah Cooper[1;2], Anna Dominik[1;2], Seamus Hussey[1], Shrikanth Chomanahalli Basavarajappa[1;2], Patrick T. Walsh[1;2]
[1]Children's Health Ireland, Crumlin, Dublin 12, Dublin, Ireland; *[2]Trinity Translational Medicine Institute, School of Medicine, Trinity College Dublin, Dublin, Ireland*

Purpose: Inflammatory bowel disease (IBD) is a chronic inflammatory disorder affecting the gastrointestinal tract which comprises two disease states, Crohn's Disease (CD) and Ulcerative Colitis (UC). While the advent of biotherapeutics has revolutionized the management of IBD, a subset of patients remain unresponsive to front-line therapeutic options. The underlying mechanisms that mediate this non-responsiveness remain unknown. This study is aimed at uncovering the role of Interleukin-11 (IL-11) signaling in IBD patient non-responsiveness to therapeutic intervention. IL-11, a member of the IL-6 cytokine family, has important roles in mediating gastrointestinal homeostasis, epithelial integrity and inflammation. Recent studies indicate a crucial involvement of IL-11 signaling pathways in the pathogenesis and progression of IBD. However, its potential impact on patient therapeutic non-responsiveness remains undefined.
Methods: We conducted a comprehensive analysis utilizing colonic biopsy samples from treatment naive paediatric IBD patients, with a subsequent two-year clinical follow-up, to determine whether an association exists between expression levels of an *IL11* gene signature and patient non-responsiveness. This was carried out in tandem with preliminary mechanistic analysis of the role of IL-11 in disease using the dextran sodium sulphate (DSS) murine model of colitis and *in vitro* primary cell culture models.
Results: Our findings reveal that an *IL11* gene signature is significantly upregulated in the colons of UC patient non-responders compared to responder patients and healthy controls. Interestingly, analysis of matrix metalloproteinase 3 (*MMP3*), which has also been previously associated with biotherapeutic non-responsiveness, showed a similarly elevated gene expression pattern among UC patients. Both *il11* and *mmp3* expression were also elevated in the inflamed intestines of mice undergoing colitis. Moreover, the induction of colitis in mice led to the acquisition of altered IL-11 responsiveness by colonic fibroblasts. These 'inflammatory' fibroblasts responded to IL-11 stimulation with significantly enhanced expression of *mmp3*.
Conclusion: These data identify a potentially novel mechanism through which IL-11 may promote IBD patient non-responsiveness to therapeutic intervention. Targeting the IL-11 pathway may improve clinical outcomes in paediatric IBD patients.

Deep immune phenotyping reveals endometrial immune modulation in women with endometriosis

Ana Kisovar[1], Christian M Becker[1], Ingrid Granne[1], Jennifer Southcombe[1]
[1]*Nuffield Department of Women's and Reproductive Health, University of Oxford, Oxford, United Kingdom*

Background: Endometriosis is a chronic disease affecting 6–10% of women. Despite being a major cause of infertility and chronic pelvic pain, the aetiology remains unclear, with strong implications for altered systemic and local immunity. The endometrial mucosa is the inner lining of the uterus, containing both innate and adaptive immune cells. These cells can be found either as single cells across the stroma and epithelium or in lymphoid aggregates. We aimed to determine if the phenotypic and histological characteristics of immune cells in the endometrium across the cycle can help us reveal relevant immune modulation in endometriosis-associated subfertility, which could be detrimental to embryo implantation and pregnancy.
Methods: A 36-parameter panel for full-spectrum flow cytometry (Cytek® Aurora) was developed to study immune populations in matched endometrial and peripheral blood samples from 20 patients with surgically confirmed endometriosis, of which 4 were subfertile, and 8 non-endometriosis controls. Additionally, 3 full-thickness uterine biopsy samples were histologically examined during the different cycle phases with multiplex immune imaging (ZellScannerONE®) to study the spatial organization of single immune cells and lymphoid aggregates.
Results: We identified novel immune cell phenotypes, activation/regulatory markers, and cytokine receptors across the cycle phases. Among 861,796 endometrial CD45+ cells, CD161+ CD8+ T cells and CD11c-CD14- macrophages were increased, while early endometrial NK cells were decreased in patients with endometriosis compared to controls. Increased regulatory CD4+ T cells and decreased CCR5+ CD8+ T cells and naïve B cells were found in patients with endometriosis-associated subfertility versus fertile endometriosis patients. Systemic changes were observed in patients with endometriosis versus controls but not between subfertile and fertile endometriosis patients. Histologically, we explored differences in endometrial and myometrial immunity across the menstrual cycle and between patients and controls.
Conclusions: Findings indicate the systemic phenotype of endometriosis, while patients with endometriosis-associated subfertility only show localized immune dysregulation. Qualitative differences in endometrial and myometrial immune populations across menstrual phases and in endometriosis versus controls indicate opportunities for future research to understand potential mechanisms at the foetal-maternal interface impacting embryo implantation and immune tolerance.

The gut homing profile of B cells and T cells is altered in experimental models of arthritis.

Vicky Alexiou[1;2], Persephone Jenkins[1;2], Diana Matei[1;2], Elizabeth Rosser[1;2]
[1]*Centre for Rheumatology Research, Division of Medicine, University College London, London, United Kingdom*;
[2]*Centre for Adolescent Rheumatology Versus Arthritis at University College London, University College London Hospital and Great Ormond Street Hospital, London, United Kingdom*

Gut perturbations such as dysbiosis of the gut-microbiome have been linked to autoimmune diseases including rheumatoid and juvenile idiopathic arthritis. Gut-derived signals are known to affect B and T cell development and influence their pro-inflammatory potential. Immune cells from gut-associated lymphoid tissues (GALT) enter the circulation and migrate to the intestinal mucosa. This recirculation process is orchestrated by gut-homing markers, CCR9 and integrin α4β7 (LPAM-1). It remains unknown whether alterations in gut-recirculating B and T cells impact arthritis pathology. Here, to address this gap, we profiled the gut-homing phenotype of B and T cells across peripheral and gut-associated lymphoid tissues in animal models of arthritis.
Antigen induced arthritis (AIA) was induced by subcutaneous injection of methylated bovine serum albumin (mBSA) in complete Freund's adjuvant (CFA), followed by an intra-articular injection of mBSA (n=5). Collagen induced arthritis (CIA) was induced by intra-dermal injection with type II chicken collagen in CFA (n=5). Age-matched naïve mice were included as controls (n=4 per experiment). Multi-parameter spectral flow cytometry was used to characterise the phenotype of CD45+ leucocytes from the spleen, inguinal draining lymph nodes (iLN), Peyer's patches (PP), mesenteric lymph nodes (mLN), and colonic lamina propria (cLP). One-way ANOVA was used to assess differences between groups.
In the AIA, CCR9-LPAM-1+ B cells were reduced in the PP ($p=0.0174$) but increased in the cLP ($p=0.0473$) compared to controls, with similar trends observed for CCR9-LPAM-1+ T cells ($p=0.0060$ in PPs; $p>0.005$ in cLP). Conversely, in CIA, there was an increase in the proportion of CCR9+LPAM-1- splenic B cells ($p=0.0023$) which was associated with a decrease in CCR9-LPAM-1+ B cells in both the spleen and mLN ($p=0.0485$ in spleen; $p=0.0435$ in mLN) compared to controls. In CIA, there was also an increase in CCR9-LPAM-1+ T cells in the PP and iLN compared to controls ($p=0.0235$ in PP; $p=0.0028$ in iLN).
This pilot study demonstrates that there are differences in the gut homing profiles of immune cells between arthritis and non-disease states, with features of altered gut recirculation across multiple lymphoid tissues. Our data highlights that differences in gut-homing profiles are distinct to different experimental models of arthritis.

Microbiota-related biomarkers in the serum of patients with DLBCL

Katarína Krempaská[1], Lucie Dlouha[2], Markéta Tenglerová[1], Johana Rehakova[2], Michaela Brichova[3], Kateřina Benešova[2], Miloslav Kverka[1], Jarmila Heissigerova[3], Petra Svozilkova[3], Štěpán Coufal[1], Iva Ondečkova[2], Jana Senavova[2], Vaclav Herman[2], Marek Trneny[2], Klára Kostovčíková[1]
[1]Institute of Microbiology of the Czech Academy of Sciences, Prague, Czech Republic; *[2]1st Faculty of Medicine, Charles University and General University Hospital in Prague, 1st Department of Internal Medicine – Department of Hematology, Prague, Czech Republic, Prague, Czech Republic*; *[3]1st Faculty of Medicine, Charles University and General University Hospital in Prague, Department of Ophthalmology, Prague, Czech Republic, Prague, Czech Republic*

Purpose: Microbiota composition is significantly different in patients with diffuse large B-cell lymphoma (DLBCL) when compared to healthy subjects. In addition, dysbiotic microbiota often compromise the gut barrier function. Here, we focused on the levels of several serum biomarkers monitoring the gut barrier condition or inflammation and related them with therapy response.
Methods: The inclusion criteria were newly diagnosed DLBCL with subsequent immunochemotherapy. Patients in complete remission and those that remained in remission for at least three months after the treatment were assessed as responders. Patients who did not achieve complete remission or progressed within three months after treatment termination or died within this period were non-responders. The serum samples were collected in three time-points: at the diagnosis (0), after the therapy (<6m) and follow up about six months later (>6m). We analyzed the serum levels of intestinal fatty acid-binding protein (i-FABP), soluble CD14, lipopolysaccharide-binding protein (LBP), mannose-binding lectin (MBL) and insulin-like growth factor-2 (IGF-2) by commercially available ELISA kits. Data were statistically analyzed by non-parametric Mann-Whitney t-test.
Results: All biomarkers showed increased levels in non-responders when compared with responders in the time 0. However significant difference was measured only in i-FABP (p= 0.005), CD14 (p=0.002) and IGF-2 (p= 0.016). In addition, CD14, IGF-2, MBL and LBP were increased in non-responders also in the second collection (<6m) though only IGF-2 showed significant difference between non-responders and responders (p=0.017). Finally, in non-responders, higher IGF-2 and LBP (p=0.049) levels were measured in the third collection (>6m).
Conclusion: The analysis of microbiota-related biomarkers could help to improve personalized treatment of patients with the most common type of Non-Hodgkin Lymphoma – DLBCL.
The study was supported by grant nr. NU22-03-00370 from the Ministry of Health of the Czech Republic.

Spatially resolved proteogenomic uncovers a sympathetically mediated link between colitis and salivary glands pathology

Gustavo Monasterio[1], Francisca Castillo[1], Joyce van de Ven[1], Valentina Olmedo[1], Ludvig Larsson[2], Annika Frede[3], Jennifer Fransson[1], Dagmara Pietrzak[1], Srustidhar Das[1], Eduardo Villablanca[1]
[1]Division of Immunology and Allergy, Department of Medicine Solna, Karolinska Institute and University Hospital., Stockholm, Sweden; *[2]Science for Life Laboratory, Department of Gene Technology, KTH Royal Institute of Technology, Stockholm, Sweden*; *[3]School of Infection & Immunity, University of Glasgow, Glasgow, United Kingdom*

Inflammatory bowel disease (IBD) affects not only the lower gastrointestinal tract but also the distal extraintestinal organs. Up to 16% of ulcerative colitis (UC) patients exhibit upper gastrointestinal tract (UGIT) manifestations, including esophageal and oral ulcers and hyposalivation, suggesting an oral-gut organ connection that is still poorly understood. Here, we used mouse models of colitis and spatial transcriptomics (ST) of the UGIT to investigate the distal consequences of intestinal inflammation on the upper GI tract. Combining ST with a newly developed mounting method to unbiasedly interrogate the oral, esophageal and gastric mucosa, we revealed a previously unknown secretory organ in the retropharyngeal region of the murine UGIT. We propose that it is the homologue of a recently described human salivary gland, and we termed it the retropharyngeal salivary gland (RPG). We observed that the RPG is distally affected by colitis, so we aimed to investigate the effect of colitis in other SGs. Using various models of chronic or acute colitis, we observed significant atrophy and dysfunction in the submandibular and sublingual salivary glands. Colitis-induced SG pathology is characterized by an early decrease in salivary production, followed by transient ductal atrophy, decreased cellularity, accumulation of IgG+ plasma cells, and changes in secreted salivary IgA. Using the CD19iDTR mouse, we observed that B cell depletion partially rescued SG from atrophy, whereas plasma cell depletion in the CD138DTR mouse did not. Next, based on bulkRNAseq data showing early upregulation of adrenergic receptor genes on salivary glands during colitis, we explore the hypothesis that autonomic innervation may link colitis to SG pathology. We performed chemical sympathetic denervation, which completely restored SG architecture and function during colitis. These findings highlight a previously unappreciated link between intestinal inflammation and salivary gland pathology via sympathetic hyperactivation and disruption of humoral secretory immune responses in the oral cavity, which may play a role in a bidirectional oral-gut pathogenic loop.

Intraepithelial lymphogram in the diagnosis of celiac disease in adult patients: a validation cohort.

Rafael Rodriguez Ramos[1], Miren Garbiñe Roy Ariño[1], Ana De Andres Martin[1], Roberto Pariente Rodríguez[1], Laura Crespo Pérez[1], Ivan Garcia De La Torre[1], Vivian Lizeth Stewart DelCid[1], Daniel Albert Mendoza Bravo[1], Elena Manterola Navarro[1], José Luis Veiga González[1], Carlota García-Hoz Jiménez[1]
[1]*Hospital Universitario Ramón y Cajal, Madrid, Spain*

Purpose: Celiac disease is a systemic autoimmune disorder associated with an abnormal response to gluten, highly prevalent and with a highly heterogeneous clinical presentation. There are several biomarkers that allow for its diagnosis, although there are cases where making a correct diagnosis is challenging. The analysis of duodenal intraepithelial lymphocytes (IELs) by flow cytometry (lymphogram) is becoming an increasingly useful and necessary tool for establishing a diagnosis of celiac disease and differentiating between its various forms of expression. In this research, we aim to validate the duodenal lymphogram as a diagnostic test and as a biomarker of treatment response in patients with celiac disease.
Methods: In this retrospective study, we analyzed a cohort of 780 patients, among whom 217 had active celiac disease, 195 were on a gluten-free diet, 25 had potential celiac disease and atypical forms of celiac disease, and 413 were non-celiac controls. Cut-off values for IELs were established to calculate the diagnostic accuracy of the lymphogram.
Results: 80% of confirmed celiac disease patients, whether active, potential, or atypical, exhibit a characteristic lymphogram of celiac disease (≥14% T cell receptor [TCR]-γδ IELs along with ≤4% surface-negative [sCD3-] IELs), while the remaining percentage of celiac disease patients showed a lymphogram with a partial profile (≥14% TCR-γδ IELs or ≤4% sCD3- IELs), with lower diagnostic certainty. It is worth noting that none of these patients had a non-celiac lymphogram. Quantifying the imbalance between TCR-γδ vs. sCD3- as a ratio (≥5) could be a discriminative index to rule out or suspect celiac disease at diagnosis.
Conclusion: In our cohort, the lymphogram analysis demonstrates a diagnostic accuracy of 79% sensitivity with 98% specificity, yielding a likelihood ratio of 36.2. It has been evidenced that the increase in TCR-γδ IELs serves as a reliable marker for celiac enteropathy. On the other hand, changes in the percentage of sCD3- IELs correspond to dynamic alterations during the course of celiac disease, thus proving useful as a biomarker for mucosal injury.

Segment-specific regulation of intestinal motility by colitis and the adaptive immune system

Raquel Gomez-Bris[1;2], Pilar Rodriguez-Rodriguez[2], Marina Ortega-Zapero[1;3], Santiago Ruvira[2], Angela Saez[1;4], Silvia M Arribas[2], Jose M Gonzalez-Granado[1;3;5]
[1]LamImSys Lab, Instituto de Investigación Sanitaria Hospital 12 de Octubre (imas12), Madrid, Spain; *[2]Departamento de Fisiología, Facultad de Medicina, Universidad Autónoma de Madrid (UAM), Madrid, Spain*; *[3]Department of Immunology, Ophthalmology and ENT, School of Medicine, Universidad Complutense de Madrid (UCM), Madrid, Spain*; *[4]Facultad de Ciencias Experimentales, Universidad Francisco de Vitoria (UFV), Pozuelo de Alarcón, Spain*; *[5]CIBER de Enfermedades Cardiovasculares (CIBERCV), Madrid, Spain*

The intestine, a precisely organized organ with multifaceted functions, consists of a complex cellular structure. This investigation delves into the motility patterns of distinct intestinal sections under homeostasis and amidst inflammatory bowel disease (IBD), with a focus on the participation of the adaptive immune system. Employing an organ bath system, we scrutinized the ileum and various segments of the colon in wild-type mice and those deficient in T and B cells, inducing IBD with dextran sulfate sodium salt (DSS).
In these intestinal segments, numerous motility parameters were finely modulated by colitis and the ensuing recovery process, significantly influenced by the adaptive immune system. This role of the immune system in motility was apparent even in healthy states.
In essence, intestinal motility in the ileum and colon is intricately regulated across segments, with the adaptive immune system assuming a crucial role. These discoveries advance our comprehension of IBD pathology, underscoring the importance of investigating gastrointestinal motility and the immune system within the realm of IBD research.

Vaccine induced memory CD8+ T cells efficiently prevent viral transmission from the respiratory tract

Jinglin Zhou[1], Ida Uddbäck[1], Jacob Kohlmeier[2], Jan Christensen[1], Allan Thomsen[1]
[1]Department of Immunology and Microbiology, University of Copenhagen, Copenhagen, Denmark; *[2]Department of Microbiology and Immunology, Emory University, Atlanta, United States*

Introduction: Mucosal immunization eliciting local T-cell memory has been proposed to provide better protection with improved breadth against constantly evolving respiratory viruses that are able to evade pre-existing antibodies. However, it is uncertain if T-cell targeted vaccinations are sufficient to block viral transmission, and how essential local immunity is in this context.
Methods: To study the impact of T-cell vaccination on the course of viral respiratory infection and subsequent transmission, we used a mouse model involving natural murine parainfluenza infection with a luciferase encoding virus and an adenovirus based nucleoprotein targeting vaccine.
Results and discussion: Strong mucosal CD8+ T cell immunity induced by combined intranasal and parenteral immunization rapidly shut down the incipient infection and completely inhibited contact based viral spreading. If without local T-cell memory, as in mice only received parenteral immunization, circulating memory T cells also accelerated viral clearance and reduced the intensity of inter-individual transmission. These findings underscore the importance of mucosal T cells for optimal protection of individuals as well as herd immunity, while also explaining why induction of a strong systemic T-cell response may still impact viral transmission. We are currently investigating if priming only the upper respiratory tract can exert the same extent of viral control as that following immunization of the entire respiratory tract. Preliminary data suggested that even with lower numbers of CD8+ T cells induced in the lungs, transmission of the virus to and from the immunized mice were both limited by intranasal immunization alone.

Finding Their Place: Maintenance of Tissue Resident Memory T Cells in Lung Infections

Jean-Christophe Lone[1], Gonçalo Malpica[1], Lisa Dratva[2], Cristina Ferreira[1], Leandro Barros[1], Rui do Amaral Vieira[1], Catarina Mendes[1], Afonso Basto[1], Sarah Teichmann[2], Luís Graça[1], Marc Veldhoen[1]

Immune responses and immunotherapies rely on T cells. Among these, tissue resident memory T cells (TRM) located in non-lymphoid tissues such as the lungs, play a key role to fight infections. While the role of these non-circulating T_{RM} cells in infections and re-infection is well established, the aspects of their differentiation and maintenance are not fully understood. In particular, the identity of the factors that determine the fate of T_{RM} cells and at what point after activation the T_{RM} cells act. Understanding how to replenish the T_{RM} compartment could lead to strategies to promote residency of T cells to control respiratory disease. Therefore, we aim to investigate whether the differentiation of T_{RM} cells from naïve T cells is predetermined and to identify the factors that drive this process.
To achieve our objective, we used an adoptive transfer of CD45.1 T cells into CD45.2 recipients followed by a type 1 (*Influenza* H3N2 virus), type 2 (*Nippostrongylus brasiliensis*) and a type 3 (*Aspergillus fumigatus*) infection. Then, we assessed the transferred CD45.1 cells and endogenous CD45.2 cells in spleens and lungs at 1, 2, 3 and 4 weeks post-infection. At each timepoint, we used single cell RNA sequencing, to analyze gene expression and VDJ recombination of each single T cell.
Our study generated a unique dataset of 96,429 polyclonal T cells upon infection. This dataset includes various T cell types such as naïve T cells, T_{RM} cells, T_{FH} cells, and T_{EM} cells. Surprisingly, we were also able to identify a tissue resident regulatory T (Treg) and a CCL5 T cell population. We take advantage of the transcriptomic data of the CD45.1 T cells to precisely characterize T_{RM} cell development in time. We show that T_{RM} cells express specific marker genes like b*hlhe40*, *nr4a1* and *cd69*, while suppressing others like *lef1*, *klf2* and *s1pr1*, while discussing whether the TCR can reliably predict the development of TRM cells.

Impact of murine allergic airway inflammation on pIgR-mediated airway immunity and pneumococcal colonization

Alexander Pausder[1;2], Julia Boehme[1;2], Dunja Bruder[1;2]
[1]*Institute of Medical Microbiology and Hospital Hygiene, Magdeburg, Germany*; [2]*Helmholtz Centre for Infection Research, Braunschweig, Germany*

Background: The transport of secretory immunoglobulin A and M (sIgA, sIgM) through the epithelial cell barrier into the mucosal lumen by the polymeric immunoglobulin receptor (pIgR) is an important mechanism of mucosal host defense in the respiratory tract. Human asthma is associated with impaired secretory immunity and increased risk for severe pneumococcal infections of the airways. The identification of immunomodulating substances that increase epithelial *Pigr* gene expression might have therapeutic implications with regard to an improved immune exclusion – and thus an augmented respiratory mucosal immunity. The aim of this project is to analyze the impact of allergic airway inflammation (AAI) on secretory immunity and pneumococcal colonization under homeostatic and immunomodulating conditions in distinctive areas of the murine upper and lower respiratory tract.
Methods: Mice exhibiting AAI were generated by i.n. treatment with house dust mite (HDM) extract. *Pigr* gene expression in lung, trachea and nasal-associated lymphoid tissue (NALT) as well as IgA levels in nasal lavage (NAL) and bronchoalveolar lavage (BAL) of AAI and non-AAI mice were determined under homeostatic conditions and in reaction to i.n. IFN-γ treatment by quantitative real-time PCR and ELISA, respectively. AAI and non-AAI mice were i.n. treated with PBS or IFN-γ and i.n. or o.p. colonized with *Streptococcus pneumoniae* serotype 19F. Bacterial burden was assessed in nasopharynx, NAL, NALT, trachea, BAL and lung.
Results: AAI mice exhibited increased *Pigr* gene expression in lung and elevated IgA levels in BAL compared to non-AAI mice. IFN-γ treatment of i.n. colonized non-AAI mice led to increased IgA levels in BAL and decreased bacterial burden in NAL. IFN-γ treatment of i.n. colonized AAI mice caused decreased IgA levels in BAL and had no effect on pneumococcal colonization. O.p. colonized AAI mice exhibited decreased bacterial burden in BAL and lung compared to non-AAI mice.
Conclusion: Murine AAI is associated with improved pIgR-mediated secretory immunity as well as antipneumococcal defense in the lower respiratory tract. Airway-associated secretory immunity can be partly modulated by IFN-γ. IFN-γ has a context-dependent effect on antipneumococcal immunity in healthy *vs*. pre-diseased individuals.

Cross-reactive T cells directed to commensal and food-derived yeasts drives cytotoxic TH1 cell responses in Crohn's disease

Gabriela Rios-Martini[1;2], Ekaterina Tikhonova[1;2], Elisa Rosati[1], Laura Sievers[1;3], Florian Tran[1;3], Stefan Schreiber[1;3], Petra Bacher[1;2]
[1]Institute of Clinical Molecular Biology, Christian-Albrechts-University of Kiel and University Medical Center Schleswig-Holstein, Kiel, Germany; *[2]Institute of Immunology, Christian-Albrechts-University of Kiel and University Medical Center Schleswig-Holstein, Kiel, Germany*; *[3]Department of Internal Medicine I, University Medical Center Schleswig-Holstein, Kiel, Germany*

Purpose: Inflammatory bowel diseases (IBD) are considered to involve a close interaction between altered intestinal microbiota, reduced epithelial barrier function and aberrant mucosal immune reactions. Dysregulated CD4+ T cell reactions against intestinal antigens are considered a causal or driving factor for IBD. However, the disease-relevant microbial species and the corresponding microbe-specific, pathogenic T cell phenotypes remain largely unknown. Most studies to date have implied a role of commensal bacteria in the etiology and maintenance of IBD. However, fungal microbes are increasingly recognized as important modulators of the human immune system. IBD patients have been reported to be more heavily colonized by *Candida* species, suggesting a possible involvement of commensal fungi in the disease pathology.
Methods and Results: Using the highly sensitive technology Antigen-Reactive T cell Enrichment (ARTE), we characterized reactive CD4+ T cells against a panel of different bacterial and fungal microbes in healthy individuals and IBD patients. Interestingly, while reactivity against the analyzed bacteria remains unchanged, we found increased T cell reactions to *Candida* species and *Saccharomyces cerevisiae* in Crohn's disease (CD) but not Ulcerative Colitis (UC) patients. Using single cell RNA and T cell receptor repertoire analysis, we found that yeast-reactive CD4+ T cells in CD display a cytotoxic T helper cell (T_H1 cell) phenotype and show selective expansion of T cell clones that are highly cross-reactive to other commensal, as well as food-derived fungal species. This suggests cross-reactive T cell selection by continuous encounter with conserved fungal antigens in the context of chronic intestinal disease.
Conclusion: We identified increased frequencies of yeast-reactive T cells in CD, as well as functional alterations of highly-crossreactive yeast-reactive T cells in a subset of CD patients. Our data highlights a role of yeasts as drivers of aberrant CD4+ T cell reactivity in patients with CD and suggests that gut-resident fungal commensals and diet-derived yeasts contribute to the chronic activation of inflammatory CD4+ T cell responses in these patients. Our data make an important contribution towards understanding the role of fungi for IBD pathogenesis. The dissection of heterogenous T helper cells against disease-relevant microbes will facilitate the development of targeted therapeutic strategies.

Genetic and inflammatory factors regulate monocyte expression of the TGFβ-activating integrin αvβ8 in IBD

Daniel Brice[1], Sezin Günaltay-Schenk[1], Mike Burkitt[2], Mark Travis[1]
[1]Lydia Becker Institute, University of Manchester, Manchester, United Kingdom; *[2]Manchester University NHS Foundation Trust, Manchester, United Kingdom*

Purpose: Inflammatory bowel disease (IBD) is a chronic inflammation of the gastrointestinal (GI) tract caused by an uncontrolled immune response to normally occurring gut constituents. Transforming growth factor β (TGFβ) is a potent regulator of the immune system and a key molecule promoting immunological tolerance in the GI tract. All cells that produce TGFβ do so as an inactive complex which must be activated to function. We have previously shown that monocytes and macrophages activate TGFβ via expression of the integrin αvβ8. This is an important anti-inflammatory pathway, and in IBD expression of αvβ8 is significantly reduced on intestinal monocytes and macrophages. However, molecular mechanisms that downregulate this pathway are poorly defined. Additionally, the single nucleotide polymorphism (SNP) rs149169037 has been associated with IBD and is predicted to influence ITGB8 expression (which encodes the integrin β8 subunit). The purpose of this project is to define molecular and genetic factors that regulate expression of integrin αvβ8, and so determine important pathways that regulate immune tolerance in the intestine.
Methods: Intestinal biopsies were obtained from IBD and control patients, cultured ex vivo, and supernatants used for soluble cytokine quantification and stimulation of immune cells. These supernatants and recombinant proteins were also used to treat human blood immune cells, and integrin expression analysed by RT-qPCR and flow cytometry.
Results: Ex vivo stimulation of cells with supernatants derived from IBD patient intestinal biopsies significantly decreased αvβ8 expression on blood monocytes. Expression of αvβ8 is increased on monocytes stimulated with lipopolysaccharide (LPS) or interleukin-6 (IL-6), and decreased by IL-4, IL-33, or interferon γ (IFNγ) stimulation. Individuals homozygous for the major allele of the *ITGB8* associated polymorphism rs149169037 show high levels of αvβ8 expression on monocytes, and lower LPS-induced TNFα production. Conversely, individuals homozygous for the minor allele show low αvβ8 expression on monocytes and high LPS-induced TNFα production.
Conclusions: Cytokine signalling, microbial antigens, and genetics all contribute to αvβ8 expression on human monocytes. Identifying mechanisms that regulate αvβ8 expression to promote anti-inflammatory TGFβ signalling represents a novel approach in IBD.

Isolation of single cells from human Peyer's Patches obtained from biopsies

Adrian Huck[1], Inka Freise[1], Nadine Sommer[1], Carl Weidinger[1], Britta Siegmund[1], Rainer Glauben[1]
[1]*Charité - Universitätsmedizin Berlin - Department of Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany*

Objective: Peyer's Patches (PPs) are specialized lymphoid follicles, located in the terminal ileum. They are important for the development of oral tolerance against food antigens and the protection against pathogens. To understand the involvement of different immune subsets in this process, it is important to carefully decipher immune activation in the PPs and the surrounding lamina propria. As the isolation of immune cells from human PPs presents several challenges, we established an optimized pipeline for the isolation of single cells out of PP from ileal biopsies for single cell sequencing.
Methods: Immune cells were isolated from ileal biopsies from healthy individuals obtained during routine endoscopy and after written consent. Single cells were then isolated using enzymatic digestion and mechanical force and purified using fluorescent activated cell sorting (FACS). The solution was used to prepare libraries for single cell sequencing using the Scipio Bioscience Asteria^{TM} kit and remaining cells were used for flow cytometry.
Results: Human biopsies of PP were obtained by specifically trained endoscopists during routine endoscopy from healthy individuals, characterized by no active inflammation. After mucus removal, PPs in the biopsies were identified and mechanically dissected using a stereomicroscope. The number of PPs varies between 0-3 out of 4 ileal biopsies. Afterwards, biopsies were enzymatically digested followed by mechanical force. Single cells were further purified using FACS as living immune ($CD45^+EpCAM^-7\text{-}AAD^-$) cells. Additionally, the successful identification of PPs was proven by elevated B-cell frequency compared to lamina propria (LP) samples with PPs between 30%-45% and LP <10%. The optimized isolation protocol of the biopsies led to an accelerated processing time, increased cell number as well as viability. First samples were collected and successfully processed to perform single cell sequencing.
Conclusions: With our optimized sample processing pipeline, we are able to isolate a sufficient number of single cells from the limited material of PP containing ileal biopsies to perform benchtop single cell sequencing sample and library preparation. The obtained data will be used to design targeted panels to study human PP specific immune cell subsets in a broader cohort in the context of intestinal inflammation by a multiplexed spatial approach.

Cigarette smoke-induced dysregulation of iron metabolism alters alveolar macrophage response to Streptococcus pneumoniae: implications for chronic obstructive pulmonary disease

Lynne Faherty[1], David Hearne[1], Patrick Mitchell[1], Shane O'Brien[1], Seamas Donnelly[1], Natalia Muñoz-Wolf[1], Claire Healy[1], Suzanne Cloonan[1;2]
[1]School of Medicine, Trinity College Dublin, Dublin, Ireland; *[2]Division of Pulmonary and Critical Care Medicine, Joan and Sanford I. Weill Department of Medicine, New York, NY, United States*

Chronic obstructive pulmonary disease (COPD) is an inflammatory disease characterized by emphysema and chronic bronchitis. Excess iron accumulation in the lung associates with COPD severity, with lung-resident alveolar macrophages (AMs) constituting the main iron positive cell. *Streptococcus pneumoniae* is the one of the most commonly cultured pathogens from the COPD lung and associates with exacerbation events, which contribute significantly to morbidity and mortality. While all bacteria require iron to survive and proliferate, how increased iron levels in the COPD lung microenvironment alters macrophage-*S. pneumoniae* interactions remains unclear.
To investigate this *in vitro*, foetal liver-derived alveolar macrophage-like cells (FLAMs) were treated with cigarette smoke extract (CSE) as a model of COPD, with cellular and mitochondrial iron loading confirmed through graphite furnace-atomic absorption spectrometry (GF-AAS) and confocal microscopy. Alterations in expression of factors governing host iron metabolism at the mRNA and protein level were assessed through qPCR and immunoblotting, respectively, revealing blunted expression of several factors associated with cellular and mitochondrial iron handling. The effects of CSE treatment on macrophage response to infection were assessed through ELISA (IL-6, TNF-α, lipocalin-2) and enumeration of intracellular colony forming units (CFU), revealing CSE treatment attenuates pro-inflammatory cytokine production and increases *S. pneumoniae* intracellular replication. The sensitivity of *S. pneumoniae* intracellular replication to host iron chelation was also assessed through *ex vivo* treatment of human alveolar macrophages retrieved via bronchoalveolar lavage with the iron chelator deferiprone. These results highlight the role of dysfunctional iron metabolism in promoting bacterial virulence and suggest the targeted manipulation of macrophage iron as a therapeutic avenue in COPD.

Innate immunity changes predict progression of septic shock and perturb mucosal immunity in model of iPSC derived model of lung organoid

Marcela Hortova-Kohoutkova[1;2], Filip Kafka[1;3], Zuzana Tomášiková[1], Veronika Bosáková[1;3], Ioanna Papatheodorou[1;3], Martin Helán[1], Jan Frič[1;4]
[1]International Clinical Research Center, St. Anne's University Hospital Brno, Brno, Czech Republic; *[2]International Clinical Research Center, Faculty of Medicine, Masaryk University, Brno, Czech Republic*; *[3]Department of Biology, Faculty of Medicine, Masaryk University, Brno, Czech Republic*; *[4]Institute of Hematology and Blood Transfusion, Prague, Czech Republic*

Background: Sepsis and septic shock are characterized by dynamic immune system changes resulting in deregulated inflammation and homeostasis failure. Circulating neutrophils, monocytes and other innate immune cells are the first responders recognizing and clearing pathogens while producing plethora of immune mediators. This prompt activation of the immune system results eventually in negative outcome, including induction of fundamental damage of mucosal tissues leading to further tissue remodulation, which can eventually dampen the process of patient's recovery after sepsis.
Objectives: This project aimed to identify novel biomarkers reflecting the dynamic of sepsis and its progression but also depict factors, which govern the damage and further remodulation of mucosal tissue impeding full recovery using morel of iPSCs derived lung organoids.
Methods: Blood samples from septic shock patients were collected within first 12 hours of ICU admission. Using flow cytometry phenotyping, proteomic and global expression analysis we have proposed several candidates correlating the early septic shock mortality. Serum proteins and cytokines were measured by ELISA or bead assays. Mucosal iPSCs derived organoids were stimulated with these mediators to characterize their potential ability to remodel the tissue.
Results: We described specific changes of monocytes subsets as well as polymorphonuclear cells associated with their altered activation. The levels of cytokines including MCP-1, IL-6, IL-8, IL-10, IL-18, as well as hepcidin, ferritin and alarmin S100A8/9 show changed production. We established hepcidin-to-ferritin ratio with high predictability for non-favorable sepsis outcome. We also characterized the role of cytokines in the sepsis-induced remodeling of mucosal tissues.
Conclusion: This project identified several valuable markers of sepsis progression, pinpointing the vulnerable patients within first 12 hours after their ICU admission. Such an approach may improve their survival of septic shock by future personalized therapy targeting the altered monocyte and polymorphonuclear functions, as well as altered tissue environment.

Adaptive T cell-mediated immunity to gluten is elicited in the gut mucosa of type 1 diabetes patients only in presence of celiac disease comorbidity

Stefania Picascia[1], Ilaria Mottola[2], Serena Vitale[2], Alessandra Camarca[3], Martina Cesarano[2], Mariantonia Maglio[4], Renata Auricchio[4], Riccardo Troncone[4], Carmen Gianfrani[2]
[1]Institute of Genetics and Biophysics "A. Buzzati-Traverso" - CNR, Naples, Italy; *[2]Institute of Biochemistry and Cell Biology - CNR, Naples, Italy*; *[3]Institute of Food Science - CNR, Avellino, Italy*; *[4]Department of Translational Medical Science & European Laboratory for the Investigation of Food-Induced Diseases, University Federico II, Naples, Italy*

Purpose: Type-1 Diabetes (T1D) and Celiac Disease (CeD) are two autoimmune disorders strongly associated, as they share genetic risk factors (HLA-DQ2/DQ8 genes) and immunopathogenic mechanisms. Different studies suggested an implication of wheat gluten proteins, the causative antigen of CeD, in the T1D pathogenesis. We previously showed that gluten elicit an inflammatory response in jejunal mucosa of T1D patients in *in vitro* organ culture (1). Here, we investigated the intestinal T-cell response to gluten in children with T1D, with or without CeD-comorbidity.
Methods: Thirty-three patients were enrolled (median age 10 years, range 1-24). Nineteen were T1D patients and of them, six patients had T1D and were negative for anti-tissue transglutaminase antibodies (CeD-associated autoantibodies), six had T1D and potential-CeD (positive serology and normal mucosa histology), and seven had acute-CeD (positive serology and villous atrophy) in comorbidity. The remaining fourteen had CeD and were negative for T1D. All enrolled subjects undergo the endogastroscopy and jejunal biopsy explants were processed to perform an *ex vivo* phenotypic analysis by flow-cytometry and for generation of gluten-raised T-cell lines (iTCLs). Gluten-specificity was assessed by functional IFNγ-ELISPOT in presence or absence of IL10R and TGF-β monoclonal antibodies (MoAbs) neutralizing regulatory T cells (2).
Results: No substantial differences were found in the phenotype and activation status of intestinal T cells among T1D patients with or w/o CeD-comorbidity. No IFNγ production to gluten was observed in iTCLs from T1D that were negative for CeD serology, neither in the presence of anti-IL10R and anti-TGF-β neutralizing MoAbs. By contrast, all iTCLs from T1D patients that had CeD, either potential or acute, showed a significant infiltrate of gluten-specific T cells in the gut mucosa ($p<0.05$).
Conclusions: Gluten-reactive T cells can be detected only in the intestinal mucosa of T1D patients that had CeD-comorbidity, either potential or acute disease. No IL10/TGFβ dependent regulation of T-cell response to gluten were observed in T1D mucosa in the absence of CeD. In conclusion, these data do not support the hypothesis of a role of adaptive immunity to dietary gluten in T1D pathogenesis.

Nanoconjugates of lactoferrin for treatment of viral infection

Martyna Janicka[1], Marcin Chodkowski[1], Klaudia Bylinska[1], Katarzyna Ranoszek-Soliwoda[2], Emilia Tomaszewicz[2], Grzegorz Celichowski[2], Jaroslaw Grobelny[2], Malgorzata Krzyzowska[1]
[1]Military Institute of Hygiene and Epidemiology, Warsaw, Poland; *[2]Faculty of Chemistry, University of Lodz, Lodz, Poland*

Lactoferrin plays an important role in immune regulation and defence mechanisms against bacteria, fungi and viruses. Recently, much effort has been devoted to the development of biomedical applications of nanoparticles.
The aim of this work was to test whether lactoferrin conjugates can protect the olfactory route from in vitro and in vivo corona virus infection.
Lactoferrin modified AgNPs or AuNPs sized 5 and 30 nm were synthesized and characterised using in-house methods. Antiviral potential was tested in vitro using HCoV-229e infected human epithelial MRC-5 cells or MHV- infected NCTC cell line and a mouse model of corona infection with MHV (Murine hepatitis coronavirus). MHV-infected mice were treated with nanoconjugates by repeated instillations and further analysed for clinical signs of infection, cellular, cytokine and chemokine response in respiratory tract as well as within the olfactory tract.
Tests performed in HCoV-229e- and MHV-JHM-infected cell lines demonstrated that inhibition of HCoV-229e/MHV infection was metal and size-dependent with LF-modified 30 nm AgNPs showing the most promising anti-viral activity. During intranasal infection with MHV-JHM – only lactoferrin conjugates of 5 nm Ag/AuNPs showed significant decrease in total brain/lung titers at 7 days post infection. Lactoferrin-functionalised Au/AgNPs showed stimulation of monocyte early response withing the epithelial mucosa, thus leading to induction of local antiviral response.
Therefore, lactoferrin functionalized gold and silver nanoparticles can consist good candidates for effective anti-viral microbicide to be used in vivo due to their effectiveness at lower concentrations and induction of an anti-viral response.

Role of the cholesterol metabolizing enzyme Cyp27a1 in intestinal regeneration and tumorigenesis

Xinxin Luo[1], Srustidhar Das[1], Sara Martina Parigi[2], Francisca Castillo[1], Eduardo Villablanca[1]
[1]*Karolinska Institute, Stockholm, Sweden*; [2]*The Rockefeller University, New York, United States*

The intestinal epithelial barrier is continuously challenged by environmental stressors and therefore undergoes continuous homeostatic and damage-associated tissue renewal. However, uncontrolled regeneration leads to neoplastic transformation, which must be prevented by pathways that disengage tumour growth from regenerative processes. We have previously identified liver X receptor (LXR) as a novel pathway capable of promoting tissue repair while limiting tumorigenesis (*Das S. et al.; Under revision)*. Yet, the mechanisms underlying LXR activation in response to tissue damage remain to be determined. Using single-cell and bulk RNA sequencing datasets from murine models of intestinal damage and repair, we identified a selectively increased expression of *Cyp27a1*, a cholesterol metabolizing and oxysterol-producing enzyme, within the damaged intestinal crypts niche during regeneration. *Cyp27a1* deletion dampened intestinal regeneration in both DSS colitis and irradiation-induced damage, which was rescued by the administration of the LXR synthetic ligand GW3965. In humans, we observed an increased expression of *CYP27A1* in the terminal ileum and colon of active ulcerative colitis patients compared to those in remission, suggesting a conserved axis upon tissue injury across species. Notably, when challenged for tumorigenesis, *Cyp27a1*$^{-/-}$ mice displayed more and larger tumours, and this phenotype was rescued in GW3965-fed mice. Extending these findings to humans, we further confirmed downregulation of *CYP27A1* in the colonic epithelium of patients with colorectal cancer compared to healthy controls. Altogether, our results unveiled an intestinal stem cell niche adaptation to damage and tumorigenesis whereby Cyp27a1 upregulated in response to injury drives LXR activation in intestinal epithelial cells promoting intestinal regeneration while restraining tumorigenesis.

Targeting Skin-resident Antigen Presenting Cells to Activate Skin-resident CD4+ Memory T cells during Staphylococcus aureus Vaccination

Megan Smith[1], Jonah Clegg[1], Giovanni Cova[2], Alberto Carignano[2], Emiliano Chiarot[2], Simona Tavarini[2], Chiara Sammicheli[2], Bruna Clemente[2], Emilio Siena[2], Monia Bardelli[2], Michela Brazzoli[2], Fabio Bagnoli[2], Rachel McLoughlin[1], Elisabetta Soldaini[2]
[1]Trinity College, Dublin, Ireland; *[2]GSK, Siena, Italy*

Staphylococcus aureus (SA) is a leading cause of skin and soft tissue infections worldwide. The virulence and increasing numbers of antibiotic-resistant strains being reported highlights the urgent need for alternative therapies. To date, no vaccine has been approved due to the lack of efficacy reported in clinical trials. Experimental, clinical, and genetic evidence has shone light on the importance of Th17/IL-17 and Th1 in protection against SA infections. We have shown that subcutaneous (SC) infection of C57BL/6 mice induces $CD4^+$ skin-resident memory T cells (Tsrm) that readily produce IL-17 upon re-infection, similarly to what we have described in human skin. Therefore, we aimed to identify skin-resident antigen presenting cells (APCs) responsible for the activation of these Tsrm, which are the adaptive sentinels ready to fight against SA skin infections. To achieve this goal, we analyzed leukocytes present in the skin of mice infected SC with SA and sacrificed at different timepoints by single-cell RNA sequencing (scRNA-seq). By doing this we identified 14 cellular populations, comprising both novel and previously characterized cells. This analysis confirmed the infiltration of $CD4^+$ effector memory T cells at Day 14 post infection (p.i.) and the presence of $CD4^+$ Tsrm at Day 43 p.i. Regarding APCs involved in the response to SA, we identified a DC2 population as well as a population that we named "$CCR7^+$ DCs", which has been recently identified by scRNA-seq only in the context of tumors. Using an unbiased approach, we identified a chemokine/cytokine network revealing that DC2 are the principal trigger for Th17, while $CCR7^+$ DCs trigger a Th1 response. Flow cytometry has allowed us to identify these DC populations both the murine and human skin models. Future experiments will be aimed to confirm the role of these DCs in the context of cutaneous SA infection. Harnessing these DCs as potential targets for the activation of Tsrm could be a step toward novel vaccine strategies.

A novel myeloid cell population: Embryonic tissue-resident neutrophils

Laura Lintukorpi[1;2;3], Julian Hofmann[1;2;3], Emmi Lokka[1;2;3], Sheyla Cisneros Montalvo[1], Venla Ojasalo[1;2;3], Marko Salmi[1;3;4], Pia Rantakari[1;2;3]
[1]Institute of Biomedicine, University of Turku, Turku, Finland; *[2]Turku Bioscience Centre, University of Turku, Turku, Finland*; *[3]InFLAMES Research Flagship Center, University of Turku, Turku, Finland*; *[4]MediCity Research Laboratory, University of Turku, Turku, Finland*

Purpose: Neutrophils represent the most abundant leukocyte population in the circulatory system acting as the first line of defense against pathogens. Some neutrophils infiltrate the tissue and display tissue-specific phenotypes. However, neutrophils in fetal tissues have not been described before. While studying embryonic tissue-resident macrophages, we were surprised to find a remarkable, previously unidentified Ly6G$^+$ neutrophil population in the prenatal mouse testis. This population starts to diminish after birth and disappears completely when the mouse passes puberty. The purpose is to describe and define embryonic neutrophils in testis and other tissues for the first time and to see if they share functional similarities to adult neutrophils. This study will deepen the knowledge of male reproductive health and helps to acquire tools for clinical studies in battling against male reproductive disorders like infertility and testicular cancer.
Methods: High-dimensional single-cell analyses, such as fluorescence-activated cell sorting (FACS) and single-cell-RNA-sequencing were employed to analyse the gene and protein expression of neutrophils, following the kinetics from E17.5 to adult mice. To assess the spatial localization of tissue-resident neutrophils, optical tissue-clearing techniques for whole-mount imaging was combined with advanced confocal microscopy. Several functional assays were used to compare neutrophil activity between embryonic and adult neutrophils. Neutrophil depletion models were utilized, in addition to inducible fate-mapping models, enabling tracking of neutrophils throughout the development.
Results: We noticed great heterogeneity among neutrophil populations in several embryonic tissues. Many functional abilities were similar to those observed in classical, adult circulating neutrophils: ROS production is comparable to adult bone marrow neutrophils, and embryonic neutrophils go through the same maturation steps as adult ones. However, they have inferior capacity to phagocytose particles compared to adult neutrophils *in vitro*.
Conclusion: Since many developmental complications originate from incomplete function or the lack of myeloid cells, defects in neutrophils during development may also be harmful for the developing individual. This study provides genuinely novel insight on the myeloid cell heterogeneity and formation of the immune system during embryogenesis, and our results provide foundation for advancing future treatments in immune related diseases.

Establishing the role of the V-ATPase-associated heme transporter HRG1 in regulating endolysosomal function and cellular heme-iron homeostasis.

Neil O'Sullivan[1], Jean O'Keeffe[1], Ken Nally[1;2], Rosemary O'Connor[1]
[1]*School of Biochemistry and Cell Biology, University College Cork., Cork, Ireland*; [2]*APC Microbiome Ireland, University College Cork., Cork, Ireland*

Heme is a cofactor for essential metabolic enzymes, and constitutes the majority of iron present in the body. Heme is also emerging as a key regulator of immunity, particularly being associated with innate immune cell activation. Excess free heme causes oxidative stress, inflammatory cell death, and tissue damage. Therefore, heme levels must be tightly regulated at the cellular, tissue, and systemic levels. This is accomplished by a network of proteins that regulate heme biosynthesis, transport, and degradation.
Heme Responsive Gene-1 (HRG1, *SLC48A1*) is a 16kDa protein that is expressed throughout the endolysosomal pathway. HRG1 was identified as both a V-ATPase-interacting protein which promotes endolysosomal acidification, as well as an essential mediator of heme transport from lysosomes during erythrophagocytosis. The broader function of HRG1's role in regulating the cellular response to heme is poorly understood. This project aims to elucidate HRG1's role in regulating endolysosomal pH, trafficking, and heme-iron homeostasis, with a particular focus on macrophages.
HRG1 expression is predominantly associated with erythrophagocytic macrophages of the spleen and liver. Analysis of transcriptomic datasets demonstrates that HRG1 expression is elevated in various tissue-resident macrophage populations. Interestingly, HRG1 expression is also elevated in distinct populations of hematopoietic cells involved in erythropoiesis. This suggests that HRG1 may regulate broader tissue heme-iron homeostasis, and function to support both erythrocyte development and degradation.
Autophagy is a critical component of the immune response. Previous data from our lab shows that HRG1 stabilises the V-ATPase complex and promotes V-ATPase activity. However, overexpression of HRG1 in epithelial cells promotes the stability of various endocytosed receptors, including the transferrin receptor. This is accompanied by a concomitant decrease in the expression and activity of components of the canonical autophagy pathway, which is associated with HRG1-dependent regulation of intracellular pH levels.
Overall, our data indicates that HRG1 is expressed across various tissue-resident macrophage populations, likely contributing to the regulation of local tissue heme-iron homeostasis. At the cellular level, HRG1 modulates endolysosomal dynamics through regulating the pH of intracellular compartments.

Early precursor-derived pituitary macrophages, cells connecting the immune and endocrine systems

Henna Lehtonen[1;2;3], Heli Jokela[1;2;3], Julian Hofmann[1;2;3], Lauriina Tola[1;2;3], Arfa Mehmood[3;4], Florent Ginhoux[5;6], Burkhard Becher[7], Melanie Greter[7], Marko Salmi[2;3;8], Pia Rantakari[1;2;3]
[1]Turku Bioscience Centre, University of Turku and Åbo Akademi University, Turku, Finland; *[2]Infection and Immunity Research Unit, Institute of Biomedicine, University of Turku, Turku, Finland*; *[3]InFLAMES Research Flagship Center, University of Turku, Turku, Finland*; *[4]Cancer Research Unit, Institute of Biomedicine, University of Turku, Turku, Finland*; *[5]Shanghai Institute of Immunology, Department of Immunology and Microbiology, Shanghai Jiao Tong University School of Medicine, Singapore, China*; *[6]Gustave Roussy Cancer Campus, Villejuif, France*; *[7]Institute of Experimental Immunology, University of Zürich, Zürich, Switzerland*; *[8]MediCity Research Laboratory, University of Turku, Turku, Finland*

The endocrine system involves multiple peripheral glands and organs forming complex pathways and feedback loops throughout the body. The pituitary gland is the major endocrine regulatory organ which primary function is to produce and release several hormones. The physical location of the pituitary gland underneath the brain, though outside the protective blood-brain barrier, leads to a unique immune environment of the pituitary. Macrophages are the foremost immune cell population in the pituitary gland, but studies describing macrophage subpopulations, their ontogeny, or their role in pituitary function have not been performed. Combining single-cell transcriptomics, fate mapping, and imaging, we defined the development, diversity, niche-specific heterogeneity, and origin of the pituitary gland macrophage subsets. In this study, we created a high-density transcriptional map of pituitary resident macrophages and discovered multiple subsets that showed kinetical progression during mouse development. Our comprehensive ontogeny analysis using different genetic fate-mapping approaches, showed that pituitary gland macrophages exclusively originate from the primitive yolk sac-derived macrophages and rely on proliferation for self-maintenance. To study the spatial heterogeneity of diverse pituitary macrophage subpopulations, we utilised high-resolution 3D imaging, and discovered distinct macrophage subsets residing in different sub-tissular niches suggesting that pituitary macrophages carry out varying functional roles in the gland. Moreover, we found macrophages associated with hormone-producing cells in the anterior lobe. To determine the importance of macrophages in pituitary function, macrophage depletion experiments unveiled essential role of early macrophages in the hormonal production of the pituitary and post-pubertal expression of genes related to the sexually dimorphic processes regulated by the pituitary gland. Altogether, our study provides novel information on pituitary macrophage ontogeny and heterogeneity, their role in pituitary function and macrophage-endocrine communication.

Assessing the maturation stages of PMN-MDSC to dissect the immunosuppressive mechanisms within TME

Maria Teresa Bilotta[1], Piera Filomena Fiore[1], Sergio Forcelloni[1], Lorenzo Moretta[2], Paola Vacca[1], Nicola Tumino[1]
[1]*Immunology Research Area, Innate Lymphoid Cells Unit, Bambino Gesù Children's Hospital IRCCS, Rome, Italy*;
[2]*Tumor Immunology, Bambino Gesù Children's Hospital IRCCS, Rome, Italy*

Purpose: The impact of tumor microenvironment (TME) on cancer therapy is one of the major challenges nowadays. One of the major immunosuppressive and pro-tumoral cellular component within TME is represented by myeloid-derived suppressor cells (MDSC), in particular the polymorphonuclear (PMN) subset. PMN-MDSC are immature neutrophils that in pathological conditions (e.g. cancer, infection, and inflammation) accumulate in peripheral blood (PB) and in the inflamed tissues. In this study, we wanted to clarify the differentiation and immunosuppressive function of PMN-MDSC.
Methods: Samples used: PB and bone marrow (BM) of G-CSF mobilized healthy donor (HD-mob-PMN-MDSC) and PMN-MDSC purified from PB or BM of cancer patients (CP). After PBMC separation, PMN-MDSC were isolated by immuno-magnetic bead. Their inhibitory function was assessed on NK cell cytotoxicity.
Results: To asses the different stages and functions of PMN-MDSC, we compared PMN-MDSC isolated from PB or BM of HD and CP. We found out that PB-HD-mob-PMN-MDSC and PB-CP-PMN-MDSC showed an immunosuppressive activity. Instead, PMN-MDSC freshly isolated from BM (both HD and CP) did not show immunosuppressive functions. These data identify the BM-PMN-MDSC-like cells as the initial point of differentiation, the HD-mob-PMN-MDSC as an intermediate stage and the PB-CP-PMN-MDSC as the final stage. The short half-life of these cells (48-72 hours) is a challenge to study them *in vitro*. Thus, to prolong their viability *in vitro* (10 days), we set up a culture system with cytokines or malignant Pleural Effusion (mPE), that recreate TME. Notably, these PMN-MDSC maintained the immunosuppressive function or acquired it in culture (after 10 days), indicating that soluble factors render PMN-MDSC-like cells at early stage in fully competent PMN-MDSC, sustaining their development and function *in vitro*.
Conclusion: PMN-MDSC affect the tumor growth and immunotherapy efficacy, for this reason studying their development and inhibitory mechanisms is crucial. Our results are pivotal to clarify these processes and improve/develop new immunotherapeutic approaches.

Mast cell-specific expression of non-functional cofilin-1 leads to a mast cell-deficient mouse model fully susceptible to imiquimod-induced psoriasis, 1-fluoro-2,4-dinitrobenzene-induced contact hypersensitivity, and vaccinia virus infection

Johanna Kramer[1], Nadine Kamenjarin[2;3], Sonja Moos[4], Cinthia Silva-Vilches[4], Günter Küblbeck[5], Katrin Hodapp[2;3], Beate Hilbert[6], Volodymyr Tsvilovskyy[6], Marc Freichel[6], Hans Christian Probst[2;3], Florian Kurschus[4], Karsten Mahnke[4], Yvonne Samstag[1]

Remodelling of the actin cytoskeleton is essential for many processes in immune cells. A large number of actin-binding proteins (ABPs) dynamically regulate actin remodelling. The ABP cofilin-1 is a member of the actin depolymerising factor (ADF)/cofilin family. Cofilin-1 is expressed in non-muscle cells including immune cells and promotes actin rearrangements by actin severing and depolymerisation. Its importance is underlined by the fact that a global knock-out of cofilin-1 in mice is embryonic lethal.
The role of cofilin-1 in mast cells *in vivo* has remained elusive. Using the Cre/loxP system, we generated mice expressing a non-functional form of cofilin-1 instead of the wild-type protein in connective tissue mast cells. These mice completely lacked connective tissue mast cells in the peritoneum and in the skin. Consequently, the knock-in mice were not sensitive to the induction of a systemic anaphylactic reaction. The immune cell compartments analysed in the spleen and lymph nodes of the knock-in mice were virtually unaffected by the absence of mast cells. Mast cell-deficient mice were normally susceptible to 1-fluoro-2,4-dinitrobenzene (DNFB)-induced contact hypersensitivity and imiquimod-induced psoriasis. In addition, clearance of vaccinia virus skin infection was normal.
Our study highlights the critical importance of the protein cofilin-1 for connective tissue mast cell development. Furthermore, it describes the generation of a c-kit-independent mouse model of mast cell deficiency without gross alterations in immune cell compartments other than mast cells. Finally, the study demonstrates that mast cells are not critically involved in the development and onset of the skin diseases CHS and psoriasis, or in the clearance of vaccinia virus infection.

Purpose: Tumor-associated macrophages are heterogeneous cells. Nevertheless, up to 90% of macrophages in the peritoneal fluids of ovarian cancer patients express a membrane-bound form of IL-18 (mIL-18). These macrophages were identified as a subpopulation of unpolarized macrophages (M0) differentiated from monocytes of healthy donors. mIL-18 expression persists during IL-4-driven M2 polarization but not upon stimulation with pathogen-derived products. This work studies extensively mIL-18+ macrophages and explores their presence in tissues of cancer patients.
Methods: Monocytes were purified from PBMC of healthy donors and differentiated towards M0. mIL-18+ and mIL-18- subpopulations were sorted and studied in terms of proteomics, metabolisms, and cytomorphology. Peritoneal fluids were collected from adult cancer patients, while bone marrow (BM) aspirates from pediatric neuroblastoma (NB) patients.
Results: Proteomic analysis shows in mIL-18+, in respect of mIL-18- counterpart, an increased expression of proteins associated with pathogen recognition, activation, migration, vesicle-mediated transport, and lipidic catabolism. Moreover, Seahorse Xp reveals reduced glycolysis, mitochondrial respiration, and ATP production. Accordingly, Transmission Electron Microscopy shows round-shaped mitochondria with altered cristae. Finally, mIL-18+ macrophages have increased endocytic properties and are highly enriched in the peritoneal fluids of adults suffering from different types of cancer (e.g. ovarian, gastric), with a phenotype partially overlapped with that observed in M0. They are also present in the BM of NB patients with a higher inter-individual heterogeneity as compared to the peritoneal site. Unsupervised hierarchical clustering analysis of 166 genes characterizing mIL-18+ macrophages was carried out on the gene expression of 498 NB tumors of all stages profiled at diagnosis. Heat map visualization evidenced significantly distinct clusters of patients and genes.
Conclusions: This study provides a wide and multidisciplinary characterization of human healthy and pathological mIL-18+ macrophages and analyzes their prognostic role in neuroblastoma patients.

Development and characterization of pro-inflammatory M1 macrophage-like cell models

Celine Buchmann[1], Gilles Gasparoni[2], Ann-Katrin Wentz[1], Heiko Heilmann[1], Jörn Walter[2], Julia Schulze-Hentrich[2], Bernd Bufe[1]
[1]University of Applied Science Kaiserslautern, Zweibrücken, Germany; *[2]Saarland University, Dept of Genetics/Epigenetics, Saarbrücken, Germany*

More than 80 different protocols for the differentiation of monocytic cell lines into M0, M1 and M2 macrophage-like cells exist. In comparison to native cells, all differentiated cell models show considerable deviations, which significantly hampers their suitability for physiological studies. Phorbol-12-myristate-13-acetate (PMA) concentration is the most critical factor that varies strongly between different methods usually ranging from 2 to 500 nM with 100 nM being the most common concentration. Current data on marker gene expression and functional studies however indicate that lower PMA concentrations are beneficial for the polarisation into mature macrophage subtypes.
We therefore systematically compared the influence of low (10 nM) versus classic (100 nM) PMA concentration using two differentiation protocols for monocytic cell line-derived M0 and M1 macrophages on two independent cell lines (THP-1 and U-937). Immunocytochemistry experiments for the classical markers CD11b and CD14 revealed that in THP-1 cells differentiated to M0 macrophages, CD11b expression is PMA-dependent while CD14 expression is PMA-independent. In U-937, both markers showed no PMA-dependent regulation. Interestingly, the PMA-differentiation step critically influenced the subsequent M1 polarisation. CD80, an important hallmark of the M1 type, was detected in 57,86 ± 5.44% of the polarized cells when using 10 nM PMA, while 100 nM PMA resulted in only 29.95 ± 7.38% $CD80^+$ cells. To investigate the physiological relevance of our improved protocol, we examined the function of formyl peptide receptors (FPRs), a family of pattern recognition receptors important for chemotactic migration and MMP-9 release in native monocytes and macrophages. qPCR experiments revealed that FPR1, FPR2 and FPR3 expression was below the detection limit after differentiation with PMA alone, whereas we detected robust FPR1 expression in >80% in both cell lines after our improved M1 polarisation. Next, we observed a co-expression of FPRs with MMP-9 and an increased FPR-dependent matrix-metalloproteinase 9 activity that is typical for native M1 cells but absent in all standard protocols. These findings argue that lower PMA concentrations improve M1 macrophage cell models. To investigate the general effects of our optimized differentiation protocol for physiological studies, we currently perform RNAseq-experiments.

Diagnosis of FISH negative acute promyelocytic leukemia due to molecular biology techniques and optical genome mapping

Lucía Ballesta Alcaraz[1], Mónica Bernal[1], Jose Ramón Vilchez[1], Maria del Carmen Barrera Aguilera[1], Juan Francisco Gutiérrez-Bautista[1], Beatriz Fernandez Perea[1], Pilar Jimenez[1]
[1]*Hospital Universitario Virgen de las Nieves, Granada, Spain*

Acute promyelocytic leukemia (APL) is a subtype of acute myeloid leukemia in which malignant transformation and uncontrolled proliferation of aberrant promyelocytes occur. This subtype of leukemia cells has a very specific abnormality that affects chromosomes 15 and 17, leading to the formation of a‘fusion’gene called PML/RARα.
We present the case of a 66-year-old man who went to the emergency room for 3 weeks and developed general malaise, dysthermic sensation asthenia and weight loss Blasts were observed in the peripheral blood smear, so a bone marrow puncture was performed, confirming the presence of 67% of myeloid blasts with Auer sticks and splinters, suggesting atypical promyelocytes. An immunophenotype compatible with APL (CD117+, weak CD15, CD13+, CD11b-) is observed and treatment with all-trans retinoic acid (ATRA) is initiated.
The FISH (Fluorescent Hybridization in situ) technique was performed with 200 uncultured interphase nuclei using the XL t(15,17) Dual fusion probe and the XL RARα break apart probe in which normal signals for the RARα gene were obtained.
Despite negative results for FISH, the sample was processed for molecular study. Depending on the breakpoint of the PML gene, different possible isoforms are generated: intron 6 (BCR1), exon 6 (BCR2) and intron 3 (BCR3), while the RARα breakpoints always occur at intron 2. A positive result for BCR1 was observed.In addition, a partial amplification (exons 1-6) of the PML gene was detected in the copy number variation study, which was compatible with the gain of 15q24.
One week after the start of treatment, the bone marrow immunophenotype showed the same clone detected at diagnosis but with greater maturation (CD117 negative in up to 40% of blasts and CD15 partial gain). This sample was studied with the technique of optical genome mapping and a partial gain of the PML gene was observed and an insertion into this gene of about 100,000 pairs of bases of origin still to be determined. Our aim in successive studies is to determine whether this fragment of unknown origin is the RARα gene, and if so, why it has not been detected in FISH.

Objective: HL-60 cell line is an acute myeloid leukemia cell line and is used as a model in studies at different myeloid maturation levels. These cells are known to differentiate into granulocyte and/or monocyte/macrophage-like cells by some factors. Myeloid-derived suppressor cells (MDSC) are myeloid cells that leave the bone marrow at different maturation levels as a result of chronic inflammation and join the peripheral circulation and can perform immune regulation. Although these cells have a key role in many pathologies, there is no cell line that can be used in mechanistic studies. In this study, the effects of all-trans retionic acid (ATRA), 1a,25-dihydroxyvitaminD3 (D3), secreted factors from MDA-MB-231 or MDA-MB-468 cells on MDSC-like transformation on HL-60 cells were investigated.
Method: In order to evaluate MDSC-like chracteristics of HL-60 cells, were stimulated with ATRA and D3 for 24, 48 and 96 hours and/or were co-cultured with MDA-MB-231 and MDA-MB-468 conditioned medium (CM) for 72 hours to 8 days. Stimulated cells were evaluated by Giemsa staining for morphological changes; surface markers of CD11b, CD11c, CD14, CD15, CD16, CD33, CD40, CD62L, CD66b, CD70, CD114, TRAIL, TLR4, HLA-DR and Lox-1 were evaluated by flow cytometry; stimulated HL-60 cells on T cell proliferation were evaluated by CFSE assay; ROS (reactive oxygen species) and NO (nitric oxide) production capacities were investigated via flow cytometry. NOX2, MPO, COX2, IDO1, NOS2, ARG1, ARG2 mRNA trancription levels were evaluated by qRT-PCR.
Results and Conclusion: ROS production, NOX2 and MPO mRNA expression levels were increased in response to ATRA-stimulation. CD11b expression increased in all conditions compared to unthereated HL-60, CD14 positivity increased especially in D3-stimulated conditions. However, no difference was observed in NO production and NOS2 mRNA level in cells stimulated with ATRA and D3. CD114 and Lox-1 expression were detected on $CD11b^{high}$ in MDA-MB-231 or MDA-MB-468 CM threated HL-60 cells. Especially, LOX-1 expressio was increased in response to CM from MDA-MB-231/MDA-MB-468 on day 8. HL-60 cell lines was exhibit granulocytic (G)-MDSC-like phenotype when stimulated with MDA-MB-231/MDA-MB-468 CM. Lox-1 surface marker which is critial for G-MDSC phenotype, upregulated successfully with CM induction.

M2c-like macrophage associated immunomodulatory function on CD44/CD24 phenotype in triple negative breast cancer (TNBC) subgroups

Onur Etgu[1;2], Salih Haldun Bal[2;3], Fatmanur Dündar[1;2], Batuhan Yağcıoğlu[1;2], Elif Özalp[1;2;4], Barbaros Oral[2;3], Diğdem Yöyen Ermiş[2;3]
[1]Bursa Uludag University, Graduate School of Science, Bursa, Turkey; *[2]Bursa Uludag University, Faculty of Medicine, Department of Immunology, Bursa, Turkey*; *[3]Bursa Uludag University, Experimental Animal Breeding and Research Unit, Bursa, Turkey*; *[4]Semmelweis University, Budapest, Hungary*

Objective: CD44+/CD24- breast cancer stem cell-like cells are the dominant subgroup of triple negative breast cancer(TNBC) but we have limited understanding of their immunomodulatory effect. This study aims to evaluate M2c-, M2- and M0-like monocyte/macrophage dependent immunofunctional difference on T cells in TNBC and their effect on CD44/CD24 associated phenotype.
Material and method: THP-1 (monocytic), phorbol 12-myristate 13-acetate(PMA)-Induced THP-1(M0/macrophage),M2clike THP-1(CD169+CD163+CD206dim) cells differentiation status were confirmed by NGS and flow cytometry. MDA-MB-231 or MDA-MB-468 triple negative breast cancer (TNBC) cells co-cultured with monocyte/macrophage-like cells were purified with FACS according to their CD44/CD24 expression status. To measure these myleoid cells primed TNBC cells were cocultured with PBMCs obtained from healthy donors and CD4+ or CD8+ T cell proliferation was tested with CFSE dilution by flow cytometry. CD80,CD86,PD-L1 and PD-L2 expression on cancer cells and immune cells were tested by flow cytometry for costimulation. Purified different CD44/CD24 cell subpopulation were plated for scratch assays and analyzed with ImageJ.
Results and discussion: CD44+/CD24- subpopulation collected from M2c-like THP1cells/cancer cells co-culture condition, displayed less metastatic and more immunomodulatory capacity than THP-1 and PMA-Induced THP-1 conditions. In addition,CD163,CD169 vs CD14 expression were decreased on M2c-like THP-1 cells(CD44+/CD24- cancer cells primed).CD44+CD24+ population was decreased in THP-1 derived monocytic/macrophagelike cells coculture.In co-cultures between MDA-MB-468 cell lines and THP-1 derived monocytic/macrophage-like cells, especially CD44+CD24+ population was decreased.CD4+ or CD8+ T cells proliferation were affected to monocyte/macrophage-like cells primed CD44/CD24 sub-populations.In this study,CD44/CD24 phenotype in TNBC and their effects on monocytic/macrophage cell activation polarization were evaluated.In addition, the metastatic character and T cell responses of this interaction were detected,and the first preliminary data that could help immunotherapy approaches.

Clinical and electrophysiological findings of peripheral neuropathy and sensory fiber involvement in Sjögren's syndrome

Hacer Erdem Tilki[1], Furkan Erbaş[1]
[1]*Department of Neurology, Ondokuz Mayıs University, Samsun, Turkey*

Introduction and Objective: Sjögren's syndrome (SS) is a chronic, progressive, systemic inflammatory disease characterised by lymphocytic infiltration of exocrine glands. The study's primary objectives were to determine phenotypical patterns of peripheral nervous system involvement and the frequency of peripheral and central sensory involvement. We have also aimed to show the topography and extent of peripheral and central involvement by electrophysiological methods and to examine the correlation of clinical and electrophysiological findings in patients with primary Sjögren's syndrome (pSS).
Methods: Thirty patients with Sjögren's disease were examined clinically with sensory symptoms, neurologic examination, modified Toronto Clinical Neuropathy Score and electrophysiologically with nerve conduction studies and somatosensory evoked potentials (SEP). The control group consisted of 30 healthy volunteers matched with the study group regarding age and gender.
A statistically significant difference was found in the mean median motor latency, mean tibial motor latency and mean tibial minimum F latency in the nerve conduction study parameters compared between the patient and control groups.
Results: In the patient group, polyneuropathy was detected in two patients. All of these patients had pure sensory neuropathy. Entrapment neuropathy was found in a total of 12 patients, 10 in the patient group and two in the control group. It was found that 10 of the entrapment neuropathies were carpal tunnel syndrome and two were cubital tunnel syndrome. The frequency of entrapment neuropathy was found to be higher in the patient group than in the control group. In the SEP examination, no difference was detected in P37 latency, P37-N45 amplitude and P37-TP latency between the two groups. No significant difference was observed in SEP parameters in the presence of SSA antibodies. There was no significant difference in P37 latency in the presence of SSB antibody, but the mean P37-N45 amplitude was significantly different in the patient group compared to the control group.
Conclusion: Sjögren's syndrome may have sensory involvement. It can be said that sensory involvement is due to peripheral nerve involvement and that sensory fibers in the spinal cord and spinal column are relatively spared. Electrophysiologic investigations provide a noninvasive objective measure of sensory involvement in Sjögren's syndrome.

Insights from a Non-Human Primate Study: Understanding the Fluid Dynamics of Neurovascular and Immunological Factors in the Vulnerability of Substantia Nigra Dopaminergic Neurons

Tiziano Balzano[1], Natalia López-González del Rey[1], Noelia Esteban-García[1], Alejandro Reinares-Sebastián[1], José Angel Pineda-Pardo[1], Inés Trigo-Damas[1], José Angel Obeso[1], Javier Blesa[1]
[1]*HM CINAC (Centro Integral de Neurociencias Abarca Campal), Hospital Universitario HM Puerta del Sur, HM Hospitales., Madrid, Spain*

Purpose: The purpose of the study was to investigate the contribution of glial cell activation and immune cell infiltration to the selective vulnerability of ventral dopaminergic neurons within the midbrain in Parkinson's disease (PD).
Methods: The study employed a non-human primate model of PD, induced by administering 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) systemically. Assessment of glial cell activation and immune cell infiltration was conducted in the midbrain of MPTP-treated monkeys, alongside the evaluation of structural characteristics of the vasculature in specific midbrain regions.
Results: MPTP-treated monkeys exhibited significant microglial and astroglial activation in the whole midbrain, without major sub-regional differences. Additionally, the ventral substantia nigra displayed a higher level of vascularization compared to other areas. Interestingly, a substantial increase in the infiltration of both T- and B-lymphocytes was observed exclusively within the ventral substantia nigra.
Conclusion: The elevated vascular density in the ventral area of the substantia nigra could play a significant role in the specific vulnerability of dopaminergic neurons in the midbrain. Additionally, the heightened infiltration of T- and B-cells, alongside other molecules or toxins, might also contribute to the increased susceptibility of dopaminergic neurons in Parkinson's disease.

Peripheral Natural Killer cells profiling in Progressive Supranuclear Palsy and Parkinson's disease.

Valentina Lopardo[1], Marina Serio[2], Maria Francesca Tepedino[2], Annibale Alessandro Puca[1], Paolo Barone[1], Marina Picillo[1], Elena Ciaglia[1]
[1]Department of Medicine, Surgery and Dentistry "Scuola Medica Salernitana", Baronissi (SA), Italy; *[2]"San Giovanni di Dio e Ruggi d'Aragona " University Hospital, Salerno, Italy*

Purpose: Recently neuropathologists have illustrated how distinct neuroimmune proteins might underlie unique mechanisms in neurodegenerative condition. Progressive supranuclear palsy (PSP) is a parkinsonism characterized by pathologic deposit of the tau protein in different brain anatomic areas and cell types. A deep analysis of immune signature of anterior cingulate cortex of PSP patients makes Natural Killer (NK) cells a highly relevant cell types to study in this context. Indeed, while in Parkinson's disease (PD), an alpha-synucleinopathy characterized by the loss of nigral dopamine neurons and the accumulation of Lewy bodies, NK cells can effectively clear α-synuclein, the impact of peripheral immune cells on PSP and the exact role of NK cells is elusive in this field. This study is focused on the phenotyping of NK cells in peripheral blood from patients diagnosed with PSP and PD for comparison.
Methods: Peripheral blood mononuclear cells(PBMCs) were extracted by Ficoll density gradient from peripheral blood of patients diagnosed with PSP (n=8) or PD (n=8) and healthy donors HD (n=8). PBMCs were stained with mAb against human canonical markers of NK cells to characterize cell subsets in the different conditions through FACS analysis. Plasma cyto-chemokines profile was also established.
Results: PSP patients showed a lower frequency of CD3-CD56+ NK cells (1,35%±0,98, p= 0,0234) with respect to healthy donors (2,97%±1,23) and PD patients (2,03%±0,86). Considering the NKs subsets distribution, a selective decrease of $CD56^{bright}CD16^{-/dim}$ cells was found in the periphery of PSP but not PD patients. Furthermore, exclusively in PSP patients, $CD56^{bright}CD16^{-/dim}$ cells displayed higher surface levels of chemokine receptor CX3CR1. On the contrary, T cell frequency was not affected both in people with PSP and PD compared to HD. Finally, a statistically significant elevation in the concentrations of CCL2/MCP-1, CXCL8/IL-8, and IL-1β is noted in plasma of PSP but not in PD *versus* healthy donors.
Conclusions: The selective plasma profile and the low frequency of $CD56^{bright}CD16^{-/dim}$ cells, putatively recruited to the sites of inflammation, highlight for the first time that peripheral NK cells could be implicated in the pathophysiology behind PSP and could have a promising value in discriminating tauopathies from other neurodegenerative processes.

The role of transient receptor potential channel subfamily M member 7-kinase in a multiple sclerosis mouse model

Katharina Jacob[1;2], Anna Thomann[3], Christian Weber[2], Thomas Gudermann[1], Anneli Petes[3], Susanna Zierler[1;4]
[1]*Walther-Straub-Institut for Pharmacology and Toxicology, LMU, Munich, Germany*; [2]*Institute for Cardiovascular Prevention (IPEK), LMU, Munich, Germany*; [3]*Institute of Clinical Neuroimmunology, University Hospital, LMU, Munich, Germany*; [4]*Institute of Pharmacology, Faculty of Medicine, JKU, Linz, Austria*

Purpose: The transient receptor potential channel subfamily M member 7 (TRPM7), is a cation channel with a C-terminal fused serine/threonine kinase. It is strongly linked to immune cell function, as an important signaling protein in lymphocytes. Recently, TRPM7 kinase activity was shown to be essential for the differentiation of proinflammatory T_H17 cells. Here we tested if the TRPM7 kinase is involved in the development of the autoimmune disease Multiple Sclerosis (MS.) MS is characterized by inflammation and demyelination in the central nervous system (CNS), and T_H17 cells are known to be important drivers of pathogenesis.
Methods: To investigate whether and to what extent the TRPM7 kinase plays a role in the development and progression of MS, we use an animal model of MS, the experimental autoimmune encephalomyelitis (EAE), in our established mouse line carrying a point mutation in the active site of the kinase (*Trpm7$^{R/R}$*).
Results: We were able show that the TRPM7 kinase promotes the development EAE. We found a significantly milder course of passive EAE in *Trpm7$^{R/R}$* mice compared to *Trpm7$^{+/+}$* controls with reduced incidence, score and weight-loss. We found an increased number of FoxP3$^+$ T-cells in the CNS of *Trpm7$^{R/R}$* mice exhibiting symptoms, and fewer infiltrating T_H17 cells in the CNS compared to *Trpm7$^{+/+}$* mice with and without symptoms. In addition, we found that *Trpm7$^{R/R}$* cells require IL-1β to be able to differentiate into T_H17 cells. Significantly less Trpm7$^{R/R}$ T-cells differentiated into T_H17 without IL-1β comparted to Trpm7$^{+/+}$ with and without IL-1β, respectively. And regarding the possible translation from mice to humans, pilot recordings from cerebrospinal fluid (CSF) lymphocytes, derived from MS patients show prominent TRPM7 currents.
Conclusion: Our results indicate that the TRPM7 kinase activity promotes EAE in mice. The inactivation of kinase activity may represent a promising therapeutic strategy in the treatment of MS.

Anti-Caspr2 Autoantibodies and Abnormal Prostate Specific Antigen Levels: A Novel Biomarker for Prostate Cancer?

Antonio Costa Anzola[1;2], Rocío Aguado Álvarez[1;2], Raquel Bernardo[1;2], Laura Carrero[1;2], Ana Navas[1;2], Aurora Jurado Roger[1;2]
[1]Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Córdoba, Spain, Córdoba, Spain; *[2]Hospital Universitario Reina Sofía, Córdoba, Spain, Córdoba, Spain*

Purpose: Contactin-associated protein 2 (Caspr2) plays a crucial role in the organization of the potassium channel Kv1 at the juxta-paranodal nodes of myelin axons. The presence of anti-Caspr2 autoantibodies (anti-Caspr2-Ab) is associated with peripheral pain hypersensitivity and disrupts Caspr2 function in the hippocampus.
Methods: We report four cases of middle-aged male individuals exhibiting high titers (1/100) of anti-Caspr2-Ab and abnormal prostate-specific antigen (PSA) levels.
Results: All patients presented with neurological symptoms, including ataxia, aphasia, memory loss, neuropathic pain, polyneuropathy, or insomnia, consistent with autoimmune encephalitis. One patient was diagnosed with prostate adenocarcinoma (PA), while the remaining three were diagnosed with benign prostatic hyperplasia (BPH).
Conclusion: Anti-Caspr2-Ab has been linked to various neoplastic conditions, with thymoma being the most common. Clinical cases exhibiting positive anti-Caspr2-Ab and elevated PSA levels, indicative of BPH or PA, are increasingly observed. Additionally, BPH has been associated with an elevated risk of developing PA. Therefore, the unexpected presence of anti-Caspr-2-Ab in middle-aged male patients presenting neurological symptoms could signify emerging prostatic pathologies, suggesting these autoantibodies as potential sentinel markers warranting close monitoring.

Mycophenolate Mofetil for First-Line Treatment of Anti-NMDA Receptor Encephalitis: A Randomized Clinical Trial

Xue Gong[1], Kundian Guo[1], Xingjie Li[1], Yue Liu[1], Xiaolin Deng[1], Xueying Kong[1], Aiqing Li[1], Dong Zhou[1], Jingmei Li[1], Zhen Hong[1]
[1]*Department of Neurology, West China Hospital, Sichuan University, Chengdu, China*

Purpose: Anti-N-methyl-D-aspartate receptor encephalitis (NMDARE) is the most prevalent and severe type of autoimmune encephalitis with heavy economic and social burden. Recommended first-line treatment for NMDARE is intravenous immunoglobulin (IVIg), high-dose glucocorticoids, or plasma exchange (PLEX), but variable responses, long term relapse risk, and side effects are serious disadvantages.
Methods: In this multicenter, open-label, randomized, controlled trial conducted in West China, we assigned patients with NMDARE, in a 1:1 ratio, to first-line treatment only (standard care) or combined first-line treatment plus long-term mycophenolate mofetil. The primary efficacy outcome was the number of patients with relapse and the difference in the time to relapse, assessed in a per-protocol analysis. Secondary outcomes were response rates, long-term profile of disease outcome, side effects, and serious adverse events.
Results: A total of 100 patients with NMDARE underwent randomization (52.0% female; mean age, 21 years [range 14 to 60]) and were followed for at least 2 years after beginning trial treatment. The mycophenolate mofetil plus group experienced few disease relapse (hazard ratio, 4.18; 95%CI, 1.49-11.65; P=0.006), better treatment response (94.12% patients achieving ≥1 point mRS score improvement within 4 weeks after randomization, P=0.03), greater prognosis (88.23% of patients having mRS score less than 2 point at 12 months after randomization vs. 63.26%; P=0.04), and favored long-term outcome profile including less physical fatigue than the first-line treatment-only group. We found no evidence of a difference between the groups in time of standard tapering prednisone, extent of IgG reduction, or treatment side effects, including infection.
Conclusion: The adjunctive of mycophenolate mofetil to first-line treatment of NMDARE resulted in a lower risk of relapsed, better outcome, and well tolerated. Future studies of large sample size are needed to further understand the quality-of-life outcomes and health economics profile of mycophenolate mofetil.

Determining the Relationship between NLRP3 Inflammasome Activation and Mitophagy in a Neuronal Progenitor Cell Line Derived Alzheimer's Disease Model

Basak Aru[1], Nur Ekimci Gürcan[2], Utku Ozbey[3], Ömer Faruk Bayrak[4], Gülderen Yanıkkaya Demirel[1;5]
[1]Immunology Department, Faculty of Medicine, Yeditepe University, Istanbul; *[2]Department of Molecular Biology and Genetics, Faculty of Engineering and Natural Sciences, Biruni University, Istanbul*; *[3]Yeditepe University Cell and Gene Therapy Excellence Center, İstanbul*; *[4]Medical Genetics Department, Faculty of Medicine, Yeditepe University, İstanbul*; *[5]Stem Cell Laboratory, Yeditepe University Training and Research Hospital, İstanbul*

Purpose: Alzheimer's Disease (AD) is an irreversible neurodegenerative disease characterized by the formation of amyloid (αβ) plaques and neurofibrillary tangles consisting of hyperphosphorylated tau protein. Previous studies have show that aβ accumulation and tau tangles cause oxidative stress and inflammation in the brain. In our current study, we aimed to evaluate the relationship between mitophagy and NLRP3 inflammasome in a neuronal progenitor cell line derived *in vitro* AD model.
Methods: In our study, an *in vitro* AD model bearing Swedish and Indiana mutations was established by viral transduction. Transduced cells were positively selected with fluorescence-activated cell sorting. Cells underwent neuronal differentiation were characterized according to their aβ40/42 expressions and tau phosphorylation. Oxidative stress was evaluated with flow cytometry. NLRP3 inflammasome components and mitophagy markers were evaluated at the gene and protein levels with qPCR and flow cytometry, respectively.
Results: Our results indicated that in the AD model group, an increase in oxidative stress and autophagy was detected following aβ accumulation and the formation of neurofibrillary tangles, in addition to a significant increase in the autophagy marker LC3B and PINK and PARKIN proteins involved in mitophagy. Autophagy was also confirmed by confocal microscopy. However, despite the increase in NLRP3 levels, no significant increase was detected in the levels of ultimate pyroptosis markers; caspase-1, IL-1β and IL-18.
Conclusion: Mitophagic activation positively correlated with the characteristic features of AD is consistent with the literature. However, although *in vivo* studies have shown the therapeutic importance of suppressing NLRP3 and pyroptosis in AD, NLRP3 inflammasome activation was not observed in the *in vitro* model established in our study, suggesting that NLRP3-mediated pyroptosis in AD cases may not be simulated in neuronal culture due to the lack of glial cells. Moreover, our findings underline the necessity of further research on neuron-derived extravesicular NLRP3 release.

Differentiation between viral and autoimmune limbic encephalitis (D-VALE): a prospective multicentre cohort study with development and validation of diagnostic model

Xueying Kong[1], Kundian Guo[1], Xu Liu[1], Xiaolin Deng[1], Aiqing Li[1], Linjun Cai[1], Xue Gong[1], Xingjie Li[1], Ruixi Ye[1], Zhen Hong[1]
[1]*Department of Neurology, West China Hospital of Sichuan University, Chengdu, China*

Purpose: We aimed to develop and validate a diagnostic prediction model to differentiate viral and autoimmune limbic encephalitis (ALE).
Methods: The model was based on data from a prospective observational multicentre study, which enrolled patients who identified autoimmune encephalitis (AE) and viral encephalitis (VE) (ChiCTR1800019762) at four large comprehensive hospitals in western China. The derivation cohort was from one center, and the external validation cohort was from the others. The demographic data, clinical features, and laboratory test results were collected and subjected to logistic regression analyses. The diagnostic model was displayed as a web-based nomogram and then modified into a novel scored prediction tool. Model performance was assessed for discrimination and calibration in both derivation and external validation cohorts.
Results: A total of 2423 individuals were recruited, and 1001 (496 VE, 505 ALE) patients were included. Based on the derivation cohort (n = 777, 389 VE, 388 ALE), the model was developed with eight variables including age at onset, acuity, fever, headache, nausea/vomiting, psychiatric or memory complaints, status epilepticus, and CSF white blood cell count. The classification threshold of a predicted probability of 0.570 showed good discrimination and calibration in both derivation cohort (area under the receiver-operating curve [AUC] 0.890; 0.868-0.913) and external validation (n=224, 107 VE, 117 ALE, AUC 0.872; 0.827-0.917) cohorts. The scored prediction tool based on this model had a total point that ranged from -4 to 10, with a cutoff value of 5 points, showing good discrimination and calibration in both derivation (AUC 0.885, 0.863-0.908) and external validation (AUC 0.868, 0.823-0.913) cohorts.
Conclusion: The D-VALE model (Differentiation between Viral and Autoimmune Limbic Encephalitis) provides a reliable and user-friendly tool for differentiating between the VE and ALE, which would benefit early diagnosis and appropriate treatment and alleviates economic burdens on both patients and society.

Lipid-accumulating microglia in Alzheimer's disease

Xiaoting Wu[1], Christiane Ruedl[1]
[1]*Nanyang Technological University, Singapore, Singapore*

Lipid-accumulating macrophages (LAMs) are distributed among several tissues, such as the white adipose tissue and the brain, where they accumulate lipids present in the tissue microenvironment. LAMs exhibiting impaired phagocytotic activity, excessive reactive oxygen species (ROS) production, and pro-inflammatory secretion have been described in aged and diseased brains, e.g., in neurodegenerative disorders such as Alzheimer's disease (AD). Whether these dysregulated brain LAMs promote or mitigate AD progression remains unclear. Here, we investigated the potential role of LAMs in AD using a novel transgenic mouse model showing a phenotype of reduced lipid-droplet (LD) formation in microglia (*CX3CR1*^{CreERT2}*Fit2*$^{fl/fl}$ mouse lines). Microglia impaired in LD formation showed perturbed lipid-related gene expression, reduced LD size, increased phagocytosis and efferocytosis compared to WT microglia. Furthermore, mice with Fit2 deficiency in microglia showed decreased Aβ load in the brain. Our observations constitute a step forward in understanding whether lipid accumulation in microglia affects the progression of neurodegenerative disorders.

Comparison of immune response in different experimental models of retinal degeneration

Kateřina Palacká[1], Barbora Hermankova[1], Eliska Javorkova[1], Vladimir Holan[1]
[1]*Institute of Experimental Medicine of the Czech Academy of Sciences, Prague, Czech Republic*

Purpose: During retinal degenerative diseases, activated microglia and macrophages represent one of the main populations supporting the local harmful inflammatory reaction and the induction of angiogenesis. Thus, focus on the modulation of immune response could provide promising innovation in the treatment of retinal pathologies. The application of sodium iodate ($NaIO_3$) is widely used approach for the induction of experimental retinal degeneration in mice and rats. The process of degeneration of retinal cells by $NaIO_3$ is well documented, but there is a limited information about the mechanism of immune response in the retina. For this reason, we analyzed the local immune reaction in the four types of induced retinal degeneration in mice at the different time points.
Methods: We compared infiltration of the retina by immune cells in the model of chronic retinal degeneration (induced by repeated intraperitoneal application of 25 mg/kg $NaIO_3$), model of acute retinal degeneration (induced by single intraperitoneal application of 40 mg/kg $NaIO_3$), direct degeneration of retina (induced by a single intravitreal application of $NaIO_3$) and a model of retinal inflammation (induced by the intravitreal application of IFN-γ, IL-17 and TNF-α). Retinas were examined on day 2, 7, 14 and 21 after induction of degeneration.
Results: Our results show that the majority of immune cells infiltrating the retina were $CD11b^+$ and $F4/80^+$ (macrophages/microglia) and $CX3CR1^+$ $P2RY12^+$ (specific combination of markers for microglia). There were differences in the range of immune cell infiltration among the experimental models at the different time points. In addition, the activation of immune reaction was imprinted in the submandibular lymph nodes (which are drainage for eyes). We have shown that the numbers of activated B-lymphocytes ($CD19^+CD40^+$ cells) and activated T-lymphocytes ($CD3^+CD25^+$ cells) were increased in the lymph nodes of mice with degenerated retina.
Conclusion: Our results provide valuable information about the mechanism of immune reaction in the retina, which should be considered in the use of experimental model of induced retinal degeneration.

NADPH oxidase (NOX2)-mediated regulation of microglial NLRP3 inflammasome activation in traumatic brain injury

Janeen Laabei[1], Gloria Vegliante[1], Nathan Ryzewski Strogulski[1], Sahil Threja[1], Carly Douglas[1], Marie Hanscom[1], Andrew Pearson[2], Aurore Nkiliza[2], Joseph Ojo[2], David Loane[1]
[1]Neurotrauma and Neuroimmunology Research Group, School of Biochemistry and Immunology, Trinity College Dublin, Dublin, Ireland; *[2]The Roskamp Institute, Sarasota, Florida, United States*

Background: NADPH oxidase 2 (NOX2) is an enzyme complex responsible for phagocytic reactive oxygen species (ROS) production. Chronic NOX2 expression induces oxidative stress, drives neuroinflammation and leads to progressive cortical and hippocampal degeneration. NOX2 also acts as a priming signal for NLRP3 inflammasome activation which has been implicated in many neurodegenerative diseases such as Alzheimer's Disease, Multiple Sclerosis, and plays a pivotal role in secondary traumatic brain injury (TBI). GSK2795039 is a small molecule, brain penetrable drug that inhibits NOX2 in an NADPH competitive manner. The goal of this study was to investigate the therapeutic potential of GSK2795039 in models of microglial activation *in vitro* and to translate findings to an experimental TBI model in mice.
Methods: Immortalised Microglial (IMG) or primary microglia from p1 Wistar rat pups were pre-treated with GSK2795039 or MCC950 (NLRP3 inhibitor) and stimulated with lipopolysaccharide (LPS) and nigericin to induce NOX2/ROS and NLRP3 inflammasome activation. ROS and cell viability were measured using CM-H2DCFDA and MTT assays, respectively, while conditioned media was analysed for cytokines by ELISA, and lactate dehydrogenase (LDH) to measure pyroptosis. Protein expression of NLRP3, cleaved-Caspase-1, cleaved-IL-1β and ASC were assayed by Western immunoblot.
Results: Our *in vitro* studies demonstrated that GSK2795039 attenuated LPS/nigericin-induced microglial NOX2 activity, ROS, LDH, IL-1β and IL-18 release, as well as NLRP3 and cleaved-caspase-1 expression. *In vivo* studies using controlled cortical impact in adult male C57Bl/6J mice and multi-dimensional flow cytometry demonstrated increased infiltration of NOX2/ROS/Caspase-1/IL-1β^+ inflammatory monocytes compared to sham. Systemic administration of GSK2795039 (100mg/kg; IP) starting at 2 hours post-injury attenuated NOX2$^+$/IL-1β^+ microglia/macrophage activation. In addition, GSK2795039 reduced numbers of IL-1R$^+$CD4$^+$ and IL-1R$^+$CD8$^+$ T cells indicating that microglial-T cell crosstalk was altered by treatment. These neuroimmune changes were associated with improved motor function recovery post-TBI.
Conclusions: These translational studies indicate that GSK2795039 may be a promising therapeutic drug for mitigating the damaging effects of NOX2-mediated neuroinflammation in microglia, and peripheral immune cells, following experimental TBI in mice.

Menni, Fondazione Poliambulanza Istituto Ospedaliero, Brescia, Italy*; *[4]Fondazione Policlinico Universitario "Agostino Gemelli" IRCCS, Rome, Italy*; *[5]Department of Translational Neurosciences, University of Antwerp, Antwerp, Belgium*

Purpose: Neuroinflammation, a response to trauma, infection or neurodegenerative disease, involves both resident innate immune cells such as microglia but also adaptive immune cells that are actively and constantly recruited, triggering a loop that fuels the neuroinflammatory process. Mesenchymal stromal cells from the amniotic membrane and their secretome (CM-hAMSC) are capable of fostering the polarization of immune cells by triggering the acquisition of features that are typical of M2 macrophages and T regulatory cells. However, in the context of neuroinflammation, the effect CM-hAMSC on the recruitment of inflammatory immune cells into an inflammatory brain environment remains to be defined.
Methods: In this study, a murine C57BL/6 iPSC-derived neurospheroid (NSPH) cell culture model containing neurons and astrocytes was applied to study the migratory capacity of syngeneic splenocytes into NSPHs upon pro-inflammatory stimulation. Hereto, NSPHs were stimulated with IL-1β, IFN-γ and TNF-α, while splenocyte activation was induced with LPS. Following 3 or 10 days of splenocyte migration, NSPHs were fixed, embedded in OCT, cryosectioned, and subjected to immunofluorescence staining for immune infiltrate identification. Additionally, the effect of CM-hAMSC treatment was studied by two approaches: either a single administration of high-concentration or three consecutive administrations of lower concentration.
Results: Already 3 days after the initiation of NSPH/splenocyte co-cultures, activated splenocytes effectively infiltrated cytokine-primed NSPHs, which was further extended into deeper NSPH layers by day 10. Further immunocytochemical characterisation demonstrates that Iba-1+ monocytes and CD4+ T lymphocytes are the predominant migrating subpopulations, while CD19+ B lymphocytes exhibited limited invasion. NK1.1+ NK cells and CD8+ T cells displayed minimal invasion. Most remarkably, both tested approaches with CM-hAMSC treatment displayed a high reduction in the number of infiltrating immune cells, particularly evident in the innermost regions of the NSPHs being completely devoid of splenocyte infiltration.
Conclusion: Using a miPSC-derived NSPH model, we demonstrate the potency of CM-hAMSC to inhibit syngeneic immune cell migration into a brain-like environment. This positions CM-hAMSC, or still to be defined factors therein, as a potential therapeutic candidate to counteract detrimental immune cell migration into numerous brain pathologies. Consequently, our research is now extending these findings using human (iPSC-derived) cell culture models.

Background and purpose: Several studies highlighted the link between metabolic pressure and Multiple Sclerosis (MS) pathogenesis. Obesity and dyslipidemia are associated with a higher risk of onset and worse progression of MS. Excess of nutrients hyper-activates the nutrients/energy sensing mTOR pathway, leading to a decreased number of regulatory T (Treg) cells and expansion of Th17 cells, leading to an imbalanced immunotolerance. Here we investigate the impact of specific nutrient overload (lipids, carbohydrates or proteins) on immune-homeostasis and on the pathogenesis of Experimental Autoimmune Encephalomyelitis (EAE) in mice.
Methods: Mice were fed the following dietary regimens: standard diet (SD), High-fat diet (HFD), high protein diet (HPD) or high-carbohydrates diet (HCD). Mice were immunized with MOG_{35-55} peptide to induce EAE. Immune infiltration in CNS and immune asset in periphery have been analyzed by flow cytometry. A panel of Th1/Th17/Treg cytokines was dosed by Luminex both in plasma samples and in supernatant of splenocyte cultures. We tested the capacity of Treg cells to suppress the proliferation and pro-inflammatory cytokine production of conventional T cells (Tconv) in co-culture assays.
Results: HFD and HCD mice displayed a worse progression of EAE than SD and HPD groups, as indicated by clinical parameters (weight loss, clinical score), enhanced CNS immune cell infiltration (measured as $CD45^{high}CD3^{+}$ cell percentage) and increased serum pro-inflammatory cytokines. At the peripheral level, $CD4^{+}$ and $CD8^{+}$ T cells from HFD and HCD mice exhibited a more activated and proliferative profile than the other groups, with a polarization toward a pro-inflammatory profile when they were *in vitro* re-challenged with MOG_{35-55} peptide, as testified by higher levels of several pro-inflammatory cytokines (IFN-g, IL-6, Leptin) and lower levels of anti-inflammatory cytokines (IL-4, IL-10) in supernatant of splenocyte cultures. Moreover, Treg cells of not immunized mice from HFD and HCD groups displayed a reduced capacity to suppress Tconv proliferation and pro-inflammatory cytokine production in co-culture assays.
Conclusions: Metabolic overwork derived by an excess of lipids or carbohydrates induces an increased inflammatory state in periphery and an impairment of Treg cell suppressive function, leading to an exacerbated EAE progression.

Uncovering the brain-homing nature of T cells at single-cell resolution in people with multiple sclerosis

Jasper Rip[1], Eric Bindels[2], Laurens Bogers[1], Ana Marques[1], Sanne Reijm[1], Kirsten Kuiper[1], Fabienne van Puijfelik[1], Annet Wierenga-Wolf[1], Marie-Jose Melief[1], Marvin van Luijn[1], Joost Smolders[1;3;4]
[1]Department of Immunology, MS Center ErasMS, Erasmus MC, Rotterdam, Netherlands; *[2]Department of Hematology, Erasmus MC, Rotterdam, Netherlands*; *[3]Department of Neurology, MS Center ErasMS, Erasmus MC, Rotterdam, Netherlands*; *[4]Neuroimmunology Researchgroup, Netherlands Institute for Neuroscience, Amsterdam, Netherlands*

Purpose: Distinct $CD4^+$ and $CD8^+$ memory T-cell subsets have been implicated in the pathogenesis of multiple sclerosis (MS). We previously showed that Th17.1 and $CD20^{dim}$ $CD8^+$ T cells are enriched in the MS brain and are associated with a brain-homing phenotype. As these specific T-cell populations also exist in healthy individuals, we hypothesize that Th17.1 and $CD20^{dim}$ CD8+ T cells consist of different subpopulations, of which some have both pathogenic and brain-homing properties to contribute to MS.
Methods: To perform deep profiling of these T-cell subsets, we have optimized a scRNA-seq workflow using the 10x Genomics pipeline that includes analysis of several proteins by CITE-seq and T-cell receptor repertoire on enriched rare circulating subsets. Furthermore, we have set-up protocols for isolating and performing scRNA-seq on single-cell suspensions from post-mortem donor CNS compartments.
Results: From peripheral blood of MS patients prior and after treatment with natalizumab (NTZ; n=6) and healthy donors (n=3), we yielded ~15k Th17.1 cells for subsequent scRNA-seq analysis. We observed several clusters with a distinct effector memory program within Th17.1 cells, including three clusters with cytotoxicity-associated features. Interestingly, one of these clusters was defined by both *EOMES* and *PRF1* (perforin) expression and reduced in all paired post- versus pre-NTZ samples. Another cluster with a central memory profile was seemingly increased upon NTZ treatment and characterized by genes associated with functional programming of IL-17-expressing cells (*NR3C2*, *KDM6A* and *PRKCA*). From post-mortem MS brain donor material, we yielded approximately 3k T cells from brain tissue (meninges, normal-appearing white matter (NAWM) and lesion). Thus far, we found clonally expanded T-cell populations within several compartments including clonal expansion of $CD20^{dim}$ CD8+ T cells in NAWM tissue.
Conclusion: In summary, we found that Th17.1 cells consist of several subpopulations based on their RNA profile and that subset composition changes upon NTZ therapy. We also found clonally expanded populations of *ex vivo* $CD20^{dim}$ CD8 T cells from MS brain as compared to other compartments.

Loss of Bmal1 in myeloid cells accelerates age-related migration of immune cells to the outer retina.

Eleanor Noone[1], Lucia Celkova[2], Kieva Byrne[2], Sarah Doyle[1]
[1]Department of Clinical Medicine, School of Medicine, Trinity College Dublin, Dublin, Ireland; *[2]Smurfit Institute of Genetics, School of Genetics and Microbiology, Trinity College Dublin, Dublin, Ireland*

Age is the primary risk factor for the development of Age-Related Macular Degeneration (AMD). One of the key hallmarks of AMD is an increased incidence of peripheral immune cells into the retina, which are hypothesised to have a pro-inflammatory phenotype.
Previous reports have demonstrated that loss of Brain Muscle Arnt-like protein (Bmal1) in myeloid cells results in a hyperinflammatory phenotype. Bmal1 is the master clock gene, its deletion ablates circadian rhythmic activity. As humans age, the amplitude of circadian rhythmicity lessens, and notably Bmal1 knockout mice present with an accelerated ageing phenotype.
We hypothesised that specific knockdown of Bmal1-/-in myeloid cells may provide insights into the role of inflamm-ageing of peripheral myeloid immune cells in the development of retinal degeneration.
Bmal-/-LysMCre+ and Bmal+/+LysMCre+ mice were aged to 18-months. Their retinal health was examined using Optical Coherence Tomography (OCT) at 3, 6, 12 and 18-months. Retinal tissues were prepared for protein, cryosection and flatmounts and examined using H&E staining and immunofluorescence (IF) for mononuclear phagocyte markers. Bone marrow derived macrophages (BMDMs) were isolated and examined for baseline activity and following stimulation with TLR ligands. Serum was collected for circulating cytokines and assessed using ELISA's and multiplex methods. Additionally, immune cells from patients with AMD were assayed for circadian rhythm amplitude and features of inflamm-ageing.
At the 12- and 18-month timepoints, OCT demonstrated an increase in the number of infiltrating cells in Bmal-/-LysMCre+ compared to Bmal+/+LysMCre+ controls. This was confirmed using IF staining on retinal tissue, with significantly more F4/80+ and Iba-1+ cells in the retina of Bmal-/-LysMCre+ mice. Furthermore, BMDMs isolated from Bmal-/-LysMCre+ mice had an enhanced pro-inflammatory phenotype compared to Bmal+/+LysMCre+ controls. Immune cells isolated from patients with AMD had increased levels of the DNA-damage marker γH2AX compared to aged-matched healthy patients.
The increased number of infiltrating immune cells in the Bmal-/-LysMCre+ mice confirms that deletion of Bmal1 from myeloid cells drives a clock-regulated age-dependent migration of immune cells into the retina. This model strongly supports a role for the peripheral immune system in the underlying mechanism of AMD.

Early-to-mid stage idiopathic Parkinson's disease shows enhanced cytotoxicity and differentiation in CD8 T-cells in females

Christophe Capelle[1], Fanny Hedin[1], Lukas Pavelka[2], Antonio Cosma[1], Rejko Krüger[1], Markus Ollert[1], Feng Hefeng[1]
[1]Luxembourg Institute of Health, Esch-sur-Alzette, Luxembourg; [2]Centre Hospitalier de Luxembourg, Esch-sur-Alzette, Luxembourg

Parkinson's disease (PD) is the second most common neurodegenerative disease, affecting approximately 10 million people worldwide. Neuroinflammation in the brain contributes to the pathogenesis of PD, but the potential dysregulation of peripheral immunity has not been systematically investigated for idiopathic PD (iPD). Here we showed an elevated peripheral cytotoxic immune milieu, with more terminally-differentiated effector memory (TEMRA) CD8 T, $CD8^+$ NKT cells and circulating cytotoxic molecules in fresh blood of 28 patients with early-to-mid iPD aged 60-70 years vs 24 age- and sex-matched HC, after analyzing >700 innate and adaptive immune subsets or functional features. This profile, also reflected by fewer $CD8^+FOXP3^+$ T cells, was confirmed in another subcohort. Although PD is a male-dominant disease, our observation is particularly true for female patients. Co-expression between cytotoxic molecules was selectively enhanced in CD8 TEMRA and effector memory (TEM) cells. Single-cell RNA-sequencing analysis demonstrated the accelerated differentiation within CD8 compartments, enhanced cytotoxic pathways in CD8 TEMRA and TEM cells, while CD8 central memory (TCM) and naïve cells were already more-active and transcriptionally-reprogrammed. Interestingly, the frequency of CD8 TEMRA was negatively correlated with disease duration, suggesting a contribution to PD pathogenesis. In line with our recent observation of 'younger' immune system in PD patients and rodent models with loss-of-function mutations in a specific familial PD gene, these findings suggest that specific CD8 T cell differentiation process was disturbed in early-to-mid stage iPD. Our work provides a comprehensive map of dysregulated peripheral immunity in iPD, proposing candidates not only for early diagnosis, but also for early intervention before being too late for the still-incurable ageing-associated disease.

IL-34 empowers regulatory T cells with novel non-canonical function to safeguard brain barrier integrity in neuroinflammation.

Janne Verreycken[1;2], Lien Van Hoecke[3;4], Lore Van Acker[3;4], Laura Amelinck[3;4], Junhua Xie[3;4], Jonas Castelein[3;4], Elien Van Wonterghem[3;4], Griet Van Imschoot[3;4], Marlies Burgelman[3;4], Sarah Vanherle[5], Ilse Dewachter[5], Paulien Baeten[1;2], Bieke Broux[1;2], Roosmarijn Vandenbroucke[3;4]
[1]University MS Center, Diepenbeek, Belgium; *[2]Hasselt University, Department of Immunology and Infection, Diepenbeek, Belgium*; *[3]VIB Center for Inflammation Research, Ghent, Belgium*; *[4]Department of Biomedical Molecular Biology, Ghent University, Ghent, Belgium*; *[5]Hasselt University, Department of Neuroscience, Diepenbeek, Belgium*

Purpose: In the pursuit of strategies to address brain damage, brain-associated regulatory T cells (Tregs) have garnered increasing attention in recent years. Beyond their established role in immunoregulation, Tregs have emerged as significant contributors in the response to brain trauma and the restoration of damaged brain tissue in neuroinflammatory diseases. Here, we report a previously undescribed, non-canonical function of Tregs in preserving the integrity of both the blood-brain barrier (BBB) and the blood-cerebrospinal fluid (CSF) barrier (BCSFB).
Methods: Using fluorescently labeled dextrans, BBB and BCSFB integrity was assessed in *in vivo* and *in vitro* settings. Furthermore, using flow cytometry, investigations into disturbances in IL-34 expression in Tregs were conducted on samples from people with multiple sclerosis (MS), Alzheimer's disease (AD), and mild cognitive impairment (MCI). In addition, the therapeutic potential of IL-34 in the experimental autoimmune encephalomyelitis (EAE) and amyloid-β precursor protein (APP) mouse model was explored.
Results: Our results have established that Tregs are crucial for the maintenance of BBB and BCSFB integrity *in vivo*. Additionally, we have identified the cytokine IL-34 as a pivotal factor in this newfound role of Tregs. Mechanistically, IL-34 influences the expression and localization of the tight junction protein ZO-1 in BBB endothelial cells and choroid plexus epithelial cells, reinforcing the integrity of the brain barriers.
Considering the established phenomenon of compromised brain barriers and the involvement of immunological elements in neurological conditions, we observed reduced IL-34 expression in Tregs derived from MS, AD, and MCI patients. Furthermore, our study unveils the potential of IL-34 therapy in restoring the integrity of brain barriers in MS and AD animal models.
Conclusion: These discoveries illuminate the intricate interplay between Tregs, IL-34, and the maintenance of brain barrier integrity, opening up novel avenues for therapeutic interventions aimed at alleviating brain barrier dysfunction in the context of neuroinflammatory disorders.

Neurotransmitter acetylcholine produced by CD4 T cells drive the differentiation of regulatory CD4 T cells during gut inflammation

Namrita Halder[1], Souparni Ghosh[1], Sourabh Yadav[1], Snigdha Dhali[1], Dharmendra Kumar[2], Girdhari Lal[1]
[1]*National Centre for Cell Science, Pune, India*; [2]*Armed Forces Medical College, Pune, India*

Purpose: The parasympathetic nervous system extensively uses acetylcholine (ACh) as the neurotransmitter. The choline acetyltransferase (ChAT) enzyme helps the production of acetylcholine in neuronal and non-neuronal cells. How do neurotransmitter ACh produced by CD4 T cells affect differentiation and function of effector and regulatory CD4 T cells during gut inflammation and autoimmunity?
Methods: Various subsets of CD4 T cells (Th1, Th2, Th17, and Tregs) were purified from PBMC of inflammatory bowel disease (IBD) patients or non-IBD control individuals using a flow cytometry sorter. In mice, acute colitis was induced by dextran sodium sulfate (DSS) in drinking water. RT-PCR, flow cytometry, and immunofluorescence microscopy were used to detect expression of molecules.
Results: IBD patients (n=10) had significantly higher ChAT-expressing Th17 cells ($CD4^+CXCR3^-CCR6^+$ cells), whereas lower Th2 ($CD4^+CD294^+$ cells) and Tregs ($CD4^+CD25^+CD127^{low}$) as compared to the control individual (n=13). Colonic biopsies of IBD patients showed a significantly decreased ChAT expression and were strongly correlated with serum acetylcholine levels. DSS treatment with ChAT-eGFP transgenic mice showed significantly reduced $CD4^+eGFP^+$ T cells in the gut-associated lymphoid tissues (GALTs). Further, DSS-treated $ChAT^{fl/fl}CD4^{cre}$ mice (CD4 T cells deficient of ChAT) showed an increased colitic disease severity and had a significantly increased frequency of Th1 and Th17 cells and lower Th2 and Tregs in the GALTs compared to control mice. CD4 T cells showed an increased GM-CSF, IL-17A, and decreased IL-10 and IL-4 expression in the CD4-$ChAT^{-/-}$ mice compared to CD4-$ChAT^{+/+}$ mice during colitis.
Conclusion: Our results showed that autocrine production of ACh by CD4 T cells reduces the differentiation of Th1 and Th17 cells and promotes Treg differentiation, suggesting the importance of the non-neuronal cholinergic system in controlling gut inflammation and autoimmunity.

Immune-related soluble factors associated with anti-LGI1 encephalitis

Guillermo Muñoz[1], Mar Guasp[2;3], Laura Naranjo[1;2], Rocio Soledad Couso[1], Mari Carmen Anton[1], Maria Antonia Romera[1], Amaia Muñoz Lopetegi[2;3], Eugenia Martinez Hernandez[2;3], Laia Prades[2], Francesc Graus[2;3], Josep Dalmau[2;4], Raquel Ruiz García[1;2]
[1]Immunology Department, Hospital Clinic de Barcelona, Barcelona, Spain; *[2]Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain, Barcelona, Spain*; *[3]Neurology Department, Hospital Clinic de Barcelona, Barcelona, Spain*; *[4]Department of Neurology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States*

Purpose: Understanding the cytokine profiles associated with anti-LGI1 encephalitis could provide valuable insights into disease pathogenesis, phenotypic variability, and new therapeutic targets. This study aimed to investigate the levels of 28 immune-related soluble factors in a cohort of patients with anti-LGI1 encephalitis.
Methods: We included 55 patients diagnosed with anti-LGI1 encephalitis. Overall, 90 samples (42 cerebrospinal fluid [CSF] and 48 sera; 34 of them CSF-serum paired) obtained during the acute phase of the disease, before immunotherapy, were included in the study. 24 serum samples and 21 CSF samples from age-matched participants with non-inflammatory neurological diseases served as controls. Levels of sCD40L, Fraktalkine, G-CSF, GM-CSF, IFNγ, IL-1α, IL-1β, IL-1RA, IL-6, IL-8, IL-10, IL-12 (p40), IL-17A, IL-18, IL-22, IP-10, MCP-1, MIG, TNFα, APRIL, BAFF, BCA1, Granzime, IL-21, IL-23, IL-35, SDF1, MIP3A, 6-KINE and Lymphotactine were quantified with a Milliplex® custom MAP Human Cytokine/Chemokine/Growth panel and analyzed with LUMINEX® xMAP100. Clinical data comprising demographic information, neurological symptoms, disease duration and severity of the disease were also collected.
Results: Our analysis revealed significant alterations in the levels of several inflammatory cytokines in patients with anti-LGI1 encephalitis. Specifically, CSF levels of Fraktalkine, IL-10, Il-6, IP-10 /CXCL10, MIG, TNFa, APRIL and IL8, and serum levels of IL-10, Il-18 and IL-1RA were significantly increased in the anti-LGI1 encephalitis cohort compared with HC. Moreover, the ratio of IL-6 level between CSF and serum was markedly elevated in LGI-1 patients with a more severe disease according to modified ranking scale (mRS). Patients with a mRS ≥3 (n=19) had a median IL-6 ratio of 1.67 pg/mL [IQR 0.50-8.20] compared to 0.37 pg/mL [IQR 0.08- 1.09] of those with mRS <3 (n=13) [p=0.0068].
Conclusion: Our findings help to elucidate the initial mechanisms underlying immune dysregulation. Whereas the increased levels of TNFa and APRIL highlight the relevance of T and B cell interaction, the higher levels of chemokines, such as CXCL10 or Fraktalkine, reinforce the significance of cell migration to the CNS in the development of the disease. These might lead to novel treatment strategies.

Investigation of brain inflammation in complete Freund's' adjuvant-free experimental autoimmune encephalomyelitis

Suzana Stanisavljević[1], Goran Stegnjaić[1], Bojan Jevtic[1], Milica Lazarević[1], Mirjana Dimitrijević[1], Miljana Momčilović[1], Neda Nikolovski[1], Dorde Miljkovic[1]
[1]*Institute for Biological Research "Siniša Stanković" - National Institute of the Republic of Serbia, Belgrade, Serbia*

Purpose: Experimental autoimmune encephalomyelitis (EAE) is an animal model of multiple sclerosis, which is typically induced with the use of complete Freund's adjuvant (CFA). As this adjuvant impedes the translation of the results of EAE studies to multiple sclerosis, we developed and characterized a new subtype of the EAE model induced in DA rats without CFA, using whole spinal cord homogenate (SCH) only. Despite the genetic homogeneity of the experimental animals and the controlled environmental conditions, different clinical courses of EAE were observed in the SCH-immunized DA rats: mild, moderate, severe, and lethal. This study aimed to investigate brain inflammation in correlation to clinical expression variability in this model.
Methods: Immune cells from lymph nodes draining the site of immunization were isolated in the inductive phase of the disease, and exposed to myelin basic protein (MBP), myelin oligodendrocyte glycoprotein (MOG), or β-synuclein (βSyn). Levels of IFN-γ and IL-17 in cell culture supernatants were detected by ELISA. Relevant brain structures (pons, cerebellum, hippocampus, and cortex) were isolated in the later stage of the disease (day 24-28 post-induction) and the composition of immune cells present in the structures was determined by flow cytometry. Samples obtained from moderate and severe groups were compared.
Results: Elevated levels of IFN-γ and IL-17 were detected in lymph node cell cultures exposed to MBP, MOG, or βSyn, thus implying that SCH immunization elicited T cell response against each of the antigens. Different immune cells were detected in all brain structures studied, particularly T cells, macrophages, and microglia. The distribution and number of these cells varied between structures, and in moderate vs. severe EAE. Namely, the lowest number and percentage of infiltrates and T cells were observed in the cortex. Further, a higher abundance of infiltrates, $CD4^+CD11bc^+$ and $CD8^+CD11bc^+$ macrophages was observed in severe EAE.
Conclusions: These results suggest that the heterogeneity of infiltration of brain structures in rats may be important for understanding the different clinical outcomes of EAE, making our model a perspective tool for the study of MS pathogenesis where the brain is the major target organ of autoimmunity.

Porphyromonas gingivalis as an etiologic factor in neuroinflammation

Noemie Dudzinska[1], Marta Kaminska[1], Piotr Mydel[1;2]
[1]*Broegelmann Research Laboratory, Department of Clinical Science, Faculty of Medicine, University of Bergen, Bergen, Norway*; [2]*Department of Microbiology, Faculty of Biochemistry, Biophysics and Biotechnology, Jagiellonian University, Krakow, Poland*

Purpose: Alzheimer's disease (AD), the most prevalent form of dementia, represents an unmet challenge in the aging population. AD patients exhibit neuroinflammation consistent with microbial infection, including microglial activation, inflammasome and complement activation as well as altered cytokine profiles. Infectious agents, such as viruses (HSV-1, HIV), bacteria (spirochetes, *Ch. pneumoniae*, and *P. gingivalis*), and fungi have been found in AD patients' brains. The presence of these germs was postulated to be an etiologic factor in AD, but robust evidence of causation has not yet been established. Herein we aimed to delineate the effect of *P. gingivalis,* a keystone pathogen in the development of chronic periodontitis, and its virulence factors on microglia cells, and whether the presence of this bacterium generates hallmark AD phenotypes.
Methods: We assessed the differences in gene expression of proinflammatory markers and cytokines between non-exposed microglia, microglia exposed to wild type *P. gingivalis*, and to mutant *P. gingivalis* (deprived of the key virulence factors gingipains) *via* quantitative PCR. Using mass cytometry, we evaluated *P. gingivalis* and its key proteases', gingipains, impact on the phenotype of microglia by profiling 36 surface and intracellular antigens.
Results: The microglia proinflammatory response to *P. gingivalis* was characterized by strong up-regulation of NOS2, COX2, IL1b and TNFa. We observed gingipains to negatively impact the microglia inflammatory response to *P. gingivalis*. Next, using mass cytometry we observed significant phenotypic shifts in microglia in response to infection with periodontopathogens. For instance, a subpopulation highly expressing CD68 and PD-L1 was four times more abundant upon infection of microglia with the wild-type strain of *P. gingivalis* than the gingipain-incompetent mutant, while almost no cells bearing this characteristic were detected in the absence of infection.
Conclusion: Infection with *P. gingivalis* promotes clustering of microglia into distinct populations, some of which may play a role in the AD pathology. *P. gingivalis'* key virulence factors, gingipains, modulate the response (including the proinflammatory one) of microglia.

Microbiota-induced intestinal Treg cells modulate neuroinflammation

Rebecca Jasser[1], Tommy Regen[1], Ari Waisman[1]
[1]*Institute of Molecular Medicine, University Medical Center Mainz, Mainz, Germany*

Purpose: This study aims to investigate microbial metabolites influencing the development of intestinal Treg cells, which can modulate neuroinflammation and enhance long-term recovery in experimental autoimmune encephalomyelitis (EAE), with the goal of translating these experimental findings into clinical applications.
Methods: Metabolomics analysis was performed to identify and quantify metabolites, focusing on short-chain fatty acids (SCFAs) and secondary bile acids. Seventy-five wild-type (WT) mice were divided into three groups: an EAE-induced experimental group, and two control groups—naïve mice and a technical control group receiving complete Freund's adjuvant (CFA) without antigen. Stool samples were collected before EAE induction, at disease onset, peak, and recovery phases. During peak and recovery phases, half of the mice were sacrificed, and tissues including plasma, liver, spleen, stool, ileum, cecum, colon, and central nervous system (CNS) were collected for metabolomic analysis. Additionally, fifty WT mice were divided into the same groups, and tissues were collected for flow cytometry analysis, including mesenteric lymph nodes (mLN), inguinal lymph nodes (iLN), spleen, brain, dura mater, spinal cord, colon, and liver.
Results: The latest experiment showed a significant rise in Treg cells across most organs in the experimental group compared to the naïve group. In addition to activation markers, other Treg markers such as KLRG1, ST2, and RORgt were upregulated in the EAE cohort in many organs compared to the control groups.
Conclusion: The study highlights the involvement of Treg cells and altered microbiota in EAE development. By modulating the gut microbiota to induce immunosuppressive Treg cells, this research aims to understand microbiota-induced alterations in EAE and translate these findings into potential clinical interventions. Additionally, the investigation intends to analyze and compare Treg cell responses in the gut, shedding light on the epigenetic and transcriptional profiles of different Treg cell subpopulations. This comparison will elucidate how the pathogenesis of EAE affects the Treg cell compartment in the gut and the implications of these changes for disease progression.

The Presence of Anti-NMDA Receptor and Anti-GABA-B Autoantibodies in an Elder Patient with Hallucinations

Antonio Costa Anzola[1;2], Rocío Aguado Álvarez[1;2], Antonio Trujillo[1;2], Sara Cantisán[1;2], Alba Rodriguez[2], Aurora Jurado Roger[1;2]
[1]Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Córdoba, Spain, Córdoba, Spain; *[2]Hospital Universitario Reina Sofía, Córdoba, Spain, Córdoba, Spain*

Purpose: Autoimmune encephalitis is a group of neuroinflammatory disease characterized by neuropsyquiatric symptoms that can be caused by various autoantibodies that affect neuronal cells surface proteins their receptors or even ion channels and some of them are often associated with the presence of tumors or oncological diseases.
Methods: An 80-year-old male patient consulted his neurologist due to a four-month history of visual and sensory hallucinations without cognitive impairment. During the neurological examination, a slight loss of trunk muscle tone was detected, while the rest of the evaluation was unremarkable. Complete blood analysis was performed including autoimmunity testing, revealed the presence of Anti-NMDA receptor antibodies at a 1/100 titration and Anti-GABA-B antibodies at a 1/10 titration. Head and thoracic computed tomography scans were performed, showing frontal-predominant cortical atrophy in the brain, but no signs of neoplasms in the thorax or brain were found. Aripiprazole was initiated, and the patient continued follow-up in neurology consultations.
Conclusion: This case highlights the diagnostic and therapeutic challenges encountered in elderly patients presenting with psychiatric symptoms and the presence of autoimmune encephalitis antibodies.

Anti-MOG Antibody in a Pediatric Patient with Autism Spectrum Disorder

Antonio Costa Anzola[1;2], Rocío Aguado Álvarez[1;2], Antonio Trujillo[1;2], Sara Cantisán[1;2], Juan Eduardo Molina Alcaide[1;2], Aurora Jurado Roger[1;2]
[1]Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Córdoba, Spain, Córdoba, Spain; *[2]Hospital Universitario Reina Sofía, Córdoba, Spain*

Purpose: The Autism spectrum disorder is a complex neurodevelopmental pathology that affects behavior, sensory reception, and social communication in humans. When occurring alongside other neurological diseases such as autoimmune disorders, it sets a diagnostic challenge due to overlapping clinical presentations.
Methods: A 6-year-old male patient, diagnosed with a medical history at the age of 2, began experiencing recurrent exanthematous infections and hemorrhagic gingivostomatitis. Shortly after the onset of behavioral changes, including avoidance of eye contact and poor language development, he was diagnosed with autism spectrum disorder. At the age of 6, he was brought to his pediatrician by his mother due to worsening fine and gross motor skills, coordination issues, and recurrent episodes of insomnia over the past year. Physical examination revealed no significant findings other than his underlying pathology.
Results: Comprehensive blood analysis, including autoimmune testing, revealed high serum serotonin levels (752.4 mcg/l) and neuron-specific enolase levels (42.42 mcg/l). Additionally, the presence of Myelin Oligodendrocyte Glycoprotein antibodies at a titration of >1/100 was detected. Treatment commenced with a high dose of intravenous methylprednisolone at 20mg/kg administered in three sessions. After one month of follow-up, there was notable improvement in motor skills and the emergence of new cognitive abilities, such as drawing. Autoimmune tests were repeated, showing a decrease in Myelin Oligodendrocyte Glycoprotein antibody titration to 1/32.
Conclusion: This case highlights the possibility of neurological autoimmune diseases coexisting with autism spectrum disorder, thereby complicating both diagnosis and treatment in these patients.

Temporal analysis of the infiltration dynamics of pro-inflammatory cytokine producing innate and adaptive immune cells following experimental traumatic brain injury in mice

Sahil Threja[1], Nathan Ryzewski Strogulski[1], Janeen Laabei[1], Carly Douglas[1], Béré K. Diallo[2], Kingston Mills[2], David Loane[1]
[1]Neurotrauma and Neuroimmunology Research Group, School of Biochemistry and Immunology, Trinity College Dublin, Dublin, Ireland; *[2]Immune Regulation Research Group, School of Biochemistry and Immunology, Trinity College Dublin, dublin, Ireland*

Background: Traumatic brain injury (TBI) is the leading cause of death and disability in young adults, resulting in severe cognitive and physical disabilities in survivors. After the primary insult, secondary injury follows which is characterized by the activation of inflammatory pathways, leading to the infiltration of immune cells into the brain parenchyma. Pro-inflammatory cytokines such as interleukin(IL)-1 beta (IL-1β), tumor necrosis factor- alpha (TNF-α), IL-6, IL-17, and interferon-γ (IFNγ) significantly contribute to the pathophysiology of TBI, exacerbating neuronal damage and negatively impacting functional recovery. This preclinical study examined the primary cellular sources of pro-inflammatory cytokines following experimental TBI in mice.
Methods: Adult C57BL/6J male mice underwent moderate-level controlled cortical impact or sham surgery. Mice were humanely euthanized and brains were harvested acutely at 3 hours (h), 6h, 12h, 24h post injury, sub-acutely at 3, 10 days post-injury (DPI), or chronically at 28 DPI. Mononuclear-cells were obtained by percoll density gradient and FACS stained to identify infiltrating innate and adaptive immune cells in the brain (Neutrophils, Monocytes, Dendritic cells, T-cell subsets (CD4+, CD8+, TCRγδ+)), as well as levels of intracellular cytokine production (IL-1β, TNF-α, IL-6, IL-17 and IFN-γ).
Results: Following TBI, neutrophils rapidly infiltrated the injured brain as early as 3h post-injury, with monocytes and dendritic cells following at 6h post-injury; all innate immune cells produced IL-1β, IL-6, TNF-α. In contrast, T cell infiltration peaked at 10 DPI and persist through 28 DPI. Notably, IL-17 production was observed at 3 DPI and peaked at 10 DPI, and was mainly produced by γδ T cells. IFN-γ was primarily produced by brain infiltrating CD4+, CD8+, and NK T cells, which peaked at 10 DPI.
Conclusions: In summary, this temporal analysis revealed that IL-1β, IL-6 and TNF-α are primarily produced by innate immune cells in the acute phase post-injury, whereas IL-17 is produced by γδ T cells, and IFN-γ by CD4+, CD8+, NK T cells at chronic time points. This new preclinical study identifies targets for reducing cellular infiltration after TBI, which may be important in regulating neuroimmune responses and neurological outcomes post-TBI.

The Role of A20 in Microglia in Preventing CD8 T Cell-Mediated Neuronal Alterations

Yogita Mallu Kattimani[1], Melanie Müller[1], Alma Nazlie Mohebiany[2], Ari Waisman[1]
[1]*Institute for Molecular Biology, Mainz, Germany*; [2]*VIB-UAntwerp Center for Molecular Neurology, Antwerpen, Belgium*

A20 also known as Tumor-necrosis-factor-alpha-induced protein 3 (TNFAIP3) is an ubiquitin editing enzyme. It has the role of antiinflammation in mammals by negatively regulating canonical nuclear factor κB (NF-κB) signalling. Our study highlights the crucial role of A20 in maintaining brain homeostasis. In the absence of A20 in microglia (A20Δmg), there is a shift from a homeostatic to a proinflammatory state. We observed spontaneous infiltration of CD8+ T cells in the CNS that had acquired the viral response signature. These CD8+ T cells produce IFN-γ actively influence a shift in the microglial population towards an interferon response. Interestingly, the absence of these CD8+ T cells in the CNS results in no changes in A20Δmg microglial morphology or numbers, confirming the changes are due to IFN-γ secreting CD8+ T cells.

The infiltration of CD8+ T cells and activation of A20Δmg microglia altered synaptic connectivity between microglia and neurons. This increased excitatory synaptic currents in pyramidal neurons, while the density of Parvalbumin-expressing inhibitory interneurons in the cortex decreased. Notably, neurogenesis is reduced, as evidenced by a decrease in the presence of doublecortin-expressing neurons in the hippocampus. These changes in the neuronal population increase the likelihood of behavioural alterations in these animals.

The increased CD8+ T cell population in A20Δmg mice persists throughout the lifespan. Additionally, deep single-cell transcriptomic data reveal the expression of senescence signatures in the microglia population. Therefore, this research raises the question of whether the persistent inflammation in the CNS of A20Δmg mice accelerates the ageing phenotype.

The beneficial effects of N-methyl-D-aspartate receptor antagonism on experimental autoimmune encephalomyelitis in aged rats

Jasmina Djuretić[1], Ivana Ćuruvija[2], Veljko Blagojević[2], Ivana Prijić[2], Biljana Bufan[3]
[1]Department of Pathobiology, Faculty of Pharmacy, University of Belgrade, Belgrade, Serbia; *[2]Department of Research and Development, Institute of Virology, Vaccines and Sera, Torlak, Belgrade, Serbia*; *[3]Department of Microbiology and Immunology, Faculty of Pharmacy, University of Belgrade, Belgrade, Serbia*

Purpose: Life expectancy is only slightly affected by multiple sclerosis (MS), and it is a disease that often lasts for several decades. The proportion of patients with late-onset MS has increased significantly and the mean age at diagnosis has shifted towards older age. Older age at disease onset is associated with a shorter time to disability. Immune cells, such as macrophages, microglia and lymphocytes, express *N*-methyl-D-aspartate receptors (NMDARs). Our aim was to elucidate the effects of ageing on the role of NMDARs in the pathogenesis of experimental autoimmune encephalomyelitis (EAE).
Methods: Young adult (3-month-old) and aged (24-month-old) female Dark Agouti rats were used in this study. Memantine, a non-competitive NMDAR antagonist, was administered by oral gavage for 7 consecutive days from the first day post-immunization (dpi) in the first set of experiments or from the 7th dpi in the second set of experiments. Mononuclear cells were isolated from the spinal cord or draining lymph nodes and analysed by flow cytometry. Spinal cord tissue was collected for RT-qPCR.
Results: Administration of an NMDAR antagonist during the induction phase of EAE diminished the proportion of Th1 and Th17 cells and increased the proportion of IL-10^{+} regulatory T cells in the lymph nodes draining the site of immunization in aged rats. Memantine increased the proportion of CD163^{+} and IL-10^{+} cells within CD11b^{+} cells in the draining lymph nodes of aged rats, whereas these effects were absent in young rats. Treatment with memantine from the 7th dpi resulted in a shift of microglia towards the anti-inflammatory M2 phenotype, characterized by an increase in the expression of CD163 and a decrease in the expression of MHCII molecules, with an increase in the proportion of IL10^{+} microglia and the expression level of arginase 1 in the spinal cord of aged rats at the peak of the disease.
Conclusion: NMDARs contribute significantly to the pathogenesis of EAE in aged rats in both the induction and effector phases. Our results suggest that targeting NMDARs in elderly MS patients may help to tailor treatment to the elderly MS population.

Investigation of the Effect of Complement System Components C5a and C5a Receptor C5aR1 in an in vitro Alzheimer's Disease Model

Abdullah Demir[1;2], Gizem Gürel[1], Furkan Aydin[1], Basak Aru[1], Gülderen Yanıkkaya Demirel[1;2]
[1]Immunology Department, Faculty of Medicine, Yeditepe University, Istanbul, Turkey; [2]Stem Cell Laboratory, Yeditepe University Training and Research Hospital, Istanbul

Purpose: Along with C5aR1 (CD88), which is expressed on both myeloid and non-myeloid cells, C5a has been implicated in the pathogenesis of neurodegenerative diseases, including Alzheimer's disease (AD), but the effect of complement components on AD has not been fully elucidated. Here, we aimed to investigate the effects of C5a on the hallmarks of AD in an *in vitro* AD model established from human neuronal progenitor cells.
Methods: The cellular AD model was established by transducing the progenitor cells with a viral vector expressing familial AD mutations, Swedish and Indiana followed by neuronal differentiation. Optimal concentration of C5a was determined by MTS assay and differentiated neurons were cultured in the presence of C5a, C5aR1 inhibitor PMX53 or C5a with PMX53. C5Ar1, Aβ40, Aβ42, and amyloid precursor protein levels were measured by flow cytometry. Total and phosphorylated tau levels were assessed by Western blotting.
Results: C5Ar1 expression was significantly enhanced in the AD group in comparison with the control group while PMX53 administration has decreased its expression. C5a treatment has significantly decreased Aβ40, and Aβ42 levels compared to the AD group, though did not have a significant effect on tau phosphorylation.
Conclusion: Our results highlight the important involvement of the complement system and its components in AD and emphasize the need for further studies to be added to the literature in this regard.

Impact of parasite antigens on neuroinflammation and tissue remodelling in neurocysticercosis

Luz Toribio[1;2], Deborah L W Chong[1], Hector H. Garcia[2;3], Jon S Friedland[1]
[1]*Infection and Immunity Institute. St. George's University of London, London, United Kingdom*; [2]*Universidad Peruana Cayetano Heredia, Lima, Peru*; [3]*Bloomberg School of Public Health. Johns Hopkins University, Baltimore, MD, United States*

Purpose: Neurocysticercosis (NCC) is a parasitic disease in which *Taenia solium* larvae (cysticercus) invades the central nervous system and is the most prevalent cause of acquired epilepsy worldwide. The cysticercus establishes as a viable cyst evading the host response, but degenerating cysts may trigger neuroinflammation. Astrocytes are key regulators of neuroinflammation and tissue remodelling in CNS infection. The impact of monocyte-astrocyte networks activated by cysticercal antigens on neuroinflammation and tissue remodelling due to matrix metalloproteinase (MMP) secretion during NCC are ill-defined.
Methods: The effect of cysticercal antigens (total and specific recombinant antigens) was investigated in human monocyte and astrocyte primary cultures. Gene expression and secretion of cytokines, (TNF-α, IL-1b, IL-6, IFN-γ), and MMPs-1, -3, -9, -10 as well as specific tissue inhibitors of MMPs (TIMP-1 and -2) were measured by RT-PCR and ELISA/Luminex. Lastly, we optimised a novel co-culture model using conditioned medium from monocytes stimulated with NCC antigens (ComNCC) to investigate monocyte-astrocyte networks.
Results: Cysticercal antigens induce pro-inflammatory responses in monocytes, at 4h and peaking after 48h (TNF-α: 802.22 vs 13125.45pg/ml, IL-1b: 19.64 vs 233.95pg/ml, IL-6: 80.63 vs 8052.69pg/ml and IFN-γ: 84.89 vs 633.44pg/ml) ($p<0.015$). MMP secretion increased at 24h post-stimulation with antigens compared to control (MMP-1: 19.25 vs 1473.75pg/ml, MMP-9 39.75 vs 3389.55pg/ml and MMP-10: 18.42 vs 289.13pg/ml). Similarly, gene expression of inflammatory cytokines and MMPs were significantly increased ($p<0.01$). TIMP-1 and -2 secretion was constitutive, but TIMP-1 was increased markedly at 48h (control 130.13 vs 1401.56pg/ml) and TIMP-2 secretion increased three times ($p<0.025$). Finally, using our co-culture model, significant increase in IL-6, IL-8, MMP-1 and MMP-9 secretion were observed in astrocytes stimulated with ComNCC.
Conclusion: These data provide new insights into monocyte-astrocyte networks that activate neuroinflammation and tissue remodelling in NCC. Improving the understanding of neuroinflammatory responses induced by cysticercal antigens in NCC is crucial for identification of biomarkers to allow early therapeutic intervention and timely control of innate immune response.

Inflammatory and bioenergetic abnormalities in patients with ischemic stroke

Eleonora Kovacheva[1;2], Maria Gevezova[1;2], Margarita Koeva[3], Vasilka Kormova[3], Emanuela Kostadinova[3], Yulia Kostadinova[3], Maria Kazakova[1;2], Victoria Sarafian[1;2]
[1]Department of Medical Biology, Medical University-Plovdiv, Plovdiv, Bulgaria; *[2]Research Institute, Medical University-Plovdiv, Plovdiv, Bulgaria*; *[3]University hospital "Pulmed", Plovdiv, Bulgaria*

Purpose: Stroke is a major cause of mortality and remains the second leading cause of death worldwide, accounting for 55% of all neurological disabilities. These grim statistics call for targeted scientific and clinical research focused on both prevention and early diagnosis and prognosis in stroke. The aim of the present study is to identify changes in inflammatory processes and cellular bioenergetics in ischemic stroke patients, before and after therapy, and healthy controls.
Methods: PBMCs and plasma from patients with ischemic stroke, before therapy (n=9), after therapy (n=4) and healthy controls (n=9) were isolated. All patient groups underwent a clinical evaluation by assessing the severity of neurological symptoms using the National Institutes of Health Stroke Scale (NIHSS) and assessing consciousness using the Glasgow-Liege Coma Scale (GLCS). The protein levels of IL-6 in plasma were measured by ELISA. In addition, the metabolic studies of the isolated PBMCs were performed using a Seahorse XFp analyzer.
Results: The data revealed that the patients with ischemic stroke before therapy have significantly increased IL-6 levels and decreased spare respiratory capacity compared to the control group. On the other hand, patients with ischemic stroke after therapy have significantly decreased IL-6 levels and increased spare respiratory capacity compared to the patients with ischemic stroke before therapy.
Conclusion: A better understanding of the inflammatory processes and mitochondrial function may reveal new targets for neuroprotection, therapeutic monitoring, and prediction of the disease severity.

Consequtive occurrence of relapsing polychondritis and mononeuritis multiplex leading to diagnosis of Sjogren's syndrome

Milica Terzic[1], Sladjana Andrejevic[1], Vesna Tomic-Spiric[1], Sanvila Raskovic[1]
[1]*Clinic of Allergology and Immunology, University Clinical Centre of Serbia, Belgrade, Serbia*

Background: Relapsing polychondritis (RPC) is a rare immune-related disorder characterized by recurrent inflammation of the cartilaginous tissue. RPC is associated with other diseases in about one third of patients, most notably with connective tissue diseases and vasculitides.
Case presentation: A 43-year old female presented with left retro orbital pain and double vision. Examination of ocular motility proved the diagnosis of left abducens nerve palsy. Thirteen days later, the same symptoms appeared on the right side. Otherwise neurological and MRI findings were normal. Laboratory findings showed increased inflammatory markers and high/medium concentration of anti-Ro/SSA/La/SSB antibodies respectively. She was found to have symptoms of dry eye without symptoms of dry mouth, with positive tests for dry eye, low unstimulated whole saliva flow rate and salivary gland involvement by dynamic scintigraphy. Finally, she was diagnosed with Sjogren's syndrome (SS) according to ACR/EULAR classification criteria (with total score of 5) accompanied with bilateral abducens nerve palsy, indicative of mononeuritis multiplex (MNM) type of cranial nerve lesion. Ten days later her left ear auricle became swollen and tender. During the three previous years she experienced repetitive swelling and redness of her nose and both auricle. These episodes were treated with oral corticosteroids with favorable response. Based on these parameters she met modified Damiani criteria for the diagnosis of RPC. She received pulses of methylprednisolone followed by oral prednisone and manifestations of both RPC and MNM gradually improved and resolved within two months.
Conclusion:
Herein we report a rare association of RPC as initial clinical presentation followed by MNM that led to the diagnosis of SS in a patient who was then treated successfully with steroids. Physicians should be aware that although rare, immune related diseases can coexist or even present one after another.

Inflammatory and autophagy markers as a discriminative tool of bacterial and viral infections in the central nervous system

Maria Kazakova[1;2], Yordan Kalchev[2;3;4], Valentin Dichev[1], Petya Argirova[5;6], Kiril Simitchiev[7], Mariana Murdjeva[2;3;8], Victoria Sarafian[1;2]
[1]Medical University - Plovdiv, Department of Medical Biology, Plovdiv, Bulgaria; *[2]Research Institute at Medical University – Plovdiv, Plovdiv, Bulgaria*; *[3]Medical University - Plovdiv, Department of Medical Microbiology and Immunology "Prof. Dr. Elissay Yanev", Plovdiv, Bulgaria*; *[4]Laboratory of Microbiology, St. George University Hospital, Plovdiv, Plovdiv, Bulgaria*; *[5]Medical University - Plovdiv, Laboratory of Microbiology, St. George University Hospital, Plovdiv, Plovdiv, Bulgaria*; *[6]Department of Infectious Diseases, Parasitology and Tropical Medicine, Faculty of Medicine, Plovdiv, Bulgaria*; *[7]Department of Analytical Chemistry and Computer Chemistry, Faculty of Chemistry, University of Plovdiv, Plovdiv, Bulgaria*; *[8]Laboratory of Microbiology, St. George University Hospital, Plovdiv, Plovdiv, Bulgaria*

Purpose: The aim of our study was to evaluate the discriminative value of gene and protein expression levels of inflammatory marker (YKL-40) and autophagy-related proteins (LAMPs) in patients with central nervous system (CNS) infections.
Methods: Thirty hospitalized patients with CNS infections and undefined etiology, and 6 healthy subjects as a control group, were included in the study. The cerebrospinal fluid (CSF) of suddenly deceased healthy individuals was isolated. Total RNA was extracted from white blood cells. Gene expression of YKL-40, LAMP1 and LAMP2 was determined by qPCR. Plasma and CSF levels were examined by ELISA.
Results: Our results showed that mRNA levels of YKL-40 were significantly downregulated in patients compared to controls. Plasma YKL-40 concentrations were higher than in the control group. The CSF glycoprotein levels were significantly higher compared to plasma levels. Decrease in LAMPs expression in patients compared to controls was observed. Significantly higher plasma and CSF LAMP-1 levels in patients in comparison with the control group were found. Low plasma LAMP-2 concentrations were detected while CSF levels were higher in patients compared to controls. In addition, we separated patients depending on the etiological agent - bacterial or viral. We found significant difference between plasma levels of YKL-40 in the control group and in both disease subgroups. Higher CSF YKL-40 levels compared to plasma levels in patients with viral infection were detected. Concentrations of the glycoprotein were higher in patients with bacterial infections compared to viral ones.
We revealed that LAMP1 plasma levels significantly increased in patients with viral CNS infections in comparison with regard to healthy individuals without any difference with bacterial CNS infections.
Conclusion: We suggest that decreased mRNA expression of YKL-40 and higher protein levels result from post-translational regulation of the *YKL-40* gene. We could speculate that YKL-40 and LAMP1 levels might serve as a fast discriminative tool to determine bacterial and viral infections in CNS infections.

Neutrophil Heterogeneity and Susceptibility of NETs Formation in Patients Suffering from Autoimmune Neurological Disorders

Eliška Krčmářová[1;2], Jiri Hrdy[1], Viktor Cerny[1], Petra Petrásková[1], Olga Novotná[1], Petra Nytrová[3], Michaela Týblová[3], Jana Lízrová[3], Helena Pilsová[3], Barbora Berousková[3], Helena Posová[4]
[1]Institute of Immunology and Microbiology, First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic; *[2]Faculty of Science, Charles University, Prague, Czech Republic*; *[3]Department of Neurology and Centre of Clinical Neuroscience, First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic*; *[4]Laboratory of Clinical Immunology and Allergology, Institute of Clinical Biochemistry and Laboratory Diagnostics First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic*

Neutrophils defend against pathogens via several mechanisms such as degranulation, phagocytosis, cytokine release, and forming neutrophil extracellular traps (NETs). NETosis, ejecting DNA and antibacterial proteins, is key to their defense. While traditionally associated with acute inflammation due to their rapid response and short lifespan, neutrophils also contribute to chronic inflammatory processes, including autoimmune neurological disorders (ANDs). These reactive neutrophils may tend to develop dysregulated NETosis, which can sustain long-term inflammation. A pivotal aspect of their contribution in ANDs lies in their ability to modulate the integrity of the blood-brain barrier and enhance antigen spreading, especially during reactive states.
This study focuses on neutrophils' role in the ANDs, such as neuromyelitis optica spectrum disorders (NMOSD), multiple sclerosis (MS), and myelin oligodendrocyte glycoprotein-antibodies associated disorder (MOGAD). We hypothesize that patients with ANDs will have different signatures in the neutrophil compartment during the remissions compared with relapses in each disorder and in intergroup comparison (NMOSD vs MS vs MOGAD).
The proportion of particular neutrophil subsets will be determined based on the presence of cell surface markers (CD14, CD15, CD16, CD62L, CD64, CD49d, CD10, CD11b, CD11c, CD101, CD35, CD71) by flow cytometry. To examine the functional properties of neutrophils, phagocytosis will be quantified using flow cytometry, while NETosis will be observed and measured through fluorescent time-lapse microscopy.
Patients suffering from ANDs have altered proportional and functional characteristics of neutrophils, with a notable rise in immature $CD15^{+}CD16^{-}$ neutrophils. Despite comparable phagocytic activity to healthy individuals, AND patients' neutrophils display a heightened propensity for NETosis during relapses, together with increased pro-inflammatory markers expression. This shift is most pronounced in patients with MS, where a substantial increase in reactive neutrophils, inclined towards NET formation together with elevation in the expression of CD64, underscoring the heightened inflammatory response. Conversely, the various treatments administered for ANDs appear to have a minimal effect on the specific proportional characteristics of neutrophil subsets.
Patients suffering from ANDs have altered proportional and functional characteristics suggesting that neutrophils could contribute to the disease onset and progression.

Correlation between inflammatory and bioenergetic parameters abnormalities in Autism Spectrum Disorder– a possible clue to cellular dysfunction?

Maria Gevezova[1;2], Zdravko Ivanov[1], Iliana Pacheva[3;4], Elena Timova[4], Maria Kazakova[1;2], Eleonora Kovacheva[1;2], Ivan Ivanov[3;4], Victoria Sarafian[1;2]
[1]Department of Medical Biology, Medical University - Plovdiv, 4000, Bulgaria; *[2]Research Institute at Medical University - Plovdiv, 4000, Bulgaria*; *[3]Department of Pediatrics and Medical Genetics, Medical University - Plovdiv, 4000, Bulgaria*; *[4]Pediatrics Clinic, St. George University Hospital, 4000, Bulgaria*

Purpose: The aim is to evaluate cellular metabolic status and inflammation-related molecules such as IL-1β, IL-9 and YKL-40 in Autism Spectrum Disorder (ASD) children with and without regression compared to healthy controls.
Methods: Children with ASD (n=56) and typically developing children (TDC, n=12) aged 2 to 11 years were studied. The diagnosis ASD was set based on generally accepted clinical assessment scales (ADOS) and on the ASD diagnostic criteria according to DSM 5. Mitochondrial activity was examined in peripheral blood mononuclear cells (PBMCs) isolated from children with ASD and from the control group, using a metabolic analyzer (Seahorse XFp). Expression (qPCR) and protein levels (ELISA) of IL-1β, IL-9, and YKL-40 were investigated in parallel.
Results: Our results showed that PBMCs of the ASD subgroup of regressed patients (ASD R(+)) had a specific pattern of mitochondrial activity with significantly increased maximal respiration, spare respiratory capacity and proton leak compared to the non-regressed group (ASD R(-)) and TDC. The observed unique phenotype of ASD R(+) is most likely due to an adaptive response and reflects an alteration in pathways affecting mitochondrial function. Furthermore, we found an imbalance in the studied proinflammatory molecules and increased levels in ASD R(-) proving the involvement of inflammatory changes.
Conclusion: The results of this study provide new evidence for specific bioenergetic profile of immune cells and elevated inflammation-related molecules in ASD. For the first time, data on a unique metabolic profile in ASD R(+) and its comparison with a random group of children of similar age and sex are provided. In addition, we report novel evidence for increased levels of proinflammatory molecules in a subset of ASD R(-) patients compared to ASD R(+). Therefore, targeting mitochondrial and immune regulation could reduce bioenergetic and inflammatory disorders, and might help the development of new therapeutic strategies in ASD.

Relationship between miRNAs and immune -bioenergetic dysfunction in Autism Spectrum Disorder

Nikolay Mehterov[1;2], Maria Gevezova[1;2], Iliana Pacheva[3;4], Elena Timova[4], Ivan Ivanov[3;4], Victoria Sarafian[1;2]
[1]Department of Medical Biology, Medical University - Plovdiv, 4000, Bulgaria; *[2]Research Institute at Medical University - Plovdiv, 4000, Bulgaria*; *[3]Department of Pediatrics and Medical Genetics, Medical University - Plovdiv, 4000, Bulgaria*; *[4]Pediatrics Clinic, St. George University Hospital, 4000, Bulgaria*

Purpose: The aim of the current study was to investigate the involvement of a panel of inflammatory and mitochondrial activity-related miRNA with the relation to the immune and bioenergetic alterations in Autism Spectrum Disorder (ASD).
Methods: Thirty children with ASD and typically developing children (TDC, n=7) were included in the study. Expression levels of a pannel of five miRNA (miR-101, miR-130, miR-143, miR-181, miR-320) and COX-2, surving as an inflammatory marker, were measured in white blood cells (WBC). Mitochondrial activity in peripheral blood mononuclear cells (PBMCs) isolated from both ASD and TDC was examined using a Seahorse XFp (Agilent) analyzer.
Results: The panel of 5 poorly investigated in ASD, miRNAs, showed differential expression between patients and controls. Among the five investigated miRNA, a significant down-regulation was observed in miR-130, miR-101, miR-143 in the ASD. Patients group had increased spare respiratory capacity and expression levels of COX-2 compared to controls. In addition, a correlation between miRNA regulation and mitochondrial bioenergetics/COX-2 levels was also observed.
Conclusion: These results underline the existance of a relationship between miRNA, COX-2 and mitochondrial function in the ASD. Moreover, the observed miRNA disregulation might be a part of mechanisms leading to mitochondrial and immune dysfunction in ASD.

Plant-derived cannabinoids: Regulators of NLRP3 inflammasome signaling in immune cells with relevance to Multiple Sclerosis

Almudena Otálora Alcaraz[1], Melody Cui Sun[1], Jack Prenderville[2], Eric J. Downer[1]
[1]*Department of Physiology, School of Medicine, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland*; [2]*Transpharmation Ireland Ltd, Institute of Neuroscience, Trinity College Dublin, Dublin, Ireland*

Multiple sclerosis (MS) is a chronic autoimmune disorder associated with sensory and motor impairments. In Ireland, MS currently afflicts over 9,000 people, with approximately 290 people diagnosed with MS in Ireland each year. A range of disease-modifying therapies (DMTs) are available for symptom management in MS, nevertheless, most DMTs present with side-effects. There is a need for new therapeutic strategies in MS. Although MS is a complex disease, there is evidence indicating the role of neuroinflammation in MS pathogenesis. The NLRP3 inflammasome has a well-established function in innate immunity, and current evidence suggests that targeting the inflammasome is a key therapeutic target in the disease. Cannabidiol (CBD) and tetrahydrocannabinol (THC) are protective in murine models of MS, and sativex (a 1:1 combination of THC:CBD), is clinically available for symptom management in MS. The goals of this study are to define the role of the NLRP3 inflammasome in MS and develop inflammasome assays to assess the efficacy of novel therapeutics, (components of *Cannabis sativa* L.), as inflammasome inhibitors in immune cells with relevance to MS. This study assessed the expression profile of inflammasome markers (IL-1β/IL-18) in plasma samples from healthy control cases and people with MS. In addition, this has developed inflammasome assays to assess the efficacy of THC/CBD as inflammasome inhibitors in immune cells with relevance to MS. Our findings indicate the components of the hemp plant *Cannabis sativa* L. have the propensity to target inflammasome signalling in immune cells with relevance to MS.

Interferon-gamma induces tolerogenic phenotype and activity in monocyte-derived dendritic cells from patients with multiple sclerosis and healthy donors

Brian Parra-Tello[1], Constanza Vilchez[1], Karin Jimenez[1], Carlos Guevara[2], Rodrigo Naves[1]
[1]*Program of Immunology, Institute of Biomedical Sciences, Faculty of Medicine, Universidad de Chile, Santiago, Chile*; [2]*Department of Neurology and Neurosurgery, Faculty of Medicine, Hospital Clínico Universidad de Chile, Santiago, Chile*

Purpose: Multiple Sclerosis (MS) is an autoimmune disease of the central nervous system. Our previous results have shown that low doses of interferon-gamma (IFN-γ) induce differentiation of murine bone marrow-derived dendritic cells (BMDCs) with tolerogenic phenotype and function and with therapeutic activity in experimental autoimmune encephalomyelitis (EAE), a pre-clinical model of MS. In this study, we determined the impact of IFN-γ on the differentiation and function of monocyte-derived dendritic cells (moDC) from patients with multiple sclerosis and healthy donors (HD).
Methods: Monocytes were isolated from peripheral blood mononuclear cells from untreated MS patients (n=11) or HD (n=9) by CD14-specific immunobeads. moDC were differentiated using GM-CSF and IL-4 (1000 U/ml) in the absence (UN-moDC) or presence of increasing concentrations (1 to 1000 ng/ml) of IFN-γ (IFN-γ-moDC). Lipopolysacharide (LPS, 1 mg/ml) was added during the last 24 h to obtain mature moDC (m-moDC) and to evaluate functional stability of IFN-γ-moDC (LPS-IFN-γ-moDC). Cell viability, DC yield and tolerogenic phenotype were determined by flow cytometry. The tolerogenic function was evaluated in a mixed lymphocyte reaction (MLR) assay by co-culturing IFN-γ-moDC or LPS-IFN-γ-moDC with Cell Trace Violet (CTV) labelled allogenic peripheral blood mononuclear cells from HD. $CD4^+$ and $CD8^+$ T **cell proliferation and activation were determined by flow cytometry.**
Results: IFN-γ-moDC from MS patients and HD exhibited a tolerogenic phenotype characterized by significantly lower levels of CD80 than m-moDC and significantly higher levels of PD-L1 than UN-moDC. Additionally, IFN-γ-moDC from HD had significantly lower levels of CD86 and CD83 than m-moDC. Remarkably, IFN-γ-moDC and LPS-IFN-γ-moDC from MS patients significantly inhibited $CD4^+$ T cell proliferation and activation. IFN-γ-moDC from HD significantly inhibited $CD4^+$ T cell proliferation and activation. IFN-γ-moDC from MS patients and HD significantly inhibited $CD8^+$ T **cell proliferation and activation.**
Conclusion: Our results demonstrate that IFN-γ induces differentiation of moDC from MS patients and HD with tolerogenic phenotype and function.

Therapeutic role of interferon-gamma in experimental autoimmune encephalomyelitis is mediated through a tolerogenic subset of splenic CD11b+ myeloid cells

Gabriel Arellano[1;2;3], Eric Acuña[1], Eileah Loda[2], Lindsay Moore[2], Juan Tichauer[1], Cristian Castillo[1], Favián Vergara[1], Paula I Burgos[4], Pablo Penaloza-MacMaster[2;3], Stephen Miller[2;3], Rodrigo Naves[1]
[1]Program of Immunology, Institute of Biomedical Sciences, Faculty of Medicine, Universidad de Chile, Santiago, Chile; *[2]Department of Microbiology-Immunology, Feinberg School of Medicine, Northwestern University, Chicago, IL, United States*; *[3]Center for Human Immunology, Feinberg School of Medicine, Northwestern University, Chicago, IL, United States*; *[4]Department of Clinical Immunology and Rheumatology, School of Medicine, Pontificia Universidad Católica de Chile, Santiago, Chile*

Cumulative evidence has established that interferon-gamma (IFN-γ) has both pathogenic and protective roles in multiple sclerosis (MS) and the animal model, experimental autoimmune encephalomyelitis (EAE). However, the mechanisms whereby IFN-γ may promote neuroprotection in EAE are not well understood. In this study, we addressed the impact of IFN-γ on peripheral and CNS infiltrating $CD4^+$ T cell subpopulations in EAE. The frequency of regulatory T (Treg) cells in spinal cords from chronic EAE mice treated with IFN-γ was significantly increased with no effect on Th1 and Th17 cells. Consistently, depletion of FOXP3-expressing cells blocked the protective effects of IFN-γ, indicating that the therapeutic effect of IFN-γ depends on the presence of Treg cells. However, IFN-γ did not trigger direct *in vitro* differentiation of Treg cells. *In vivo* administration of blocking antibodies against either interleukin (IL)-10, transforming growth factor (TGF)-β or program death (PD)-1, revealed that the protective effects of IFN-γ in EAE were also dependent on TGF-β and PD-1, but not on IL-10, suggesting that IFN-γ might have an indirect role on Treg cells acting through antigen-presenting cells. Indeed, IFN-γ treatment increased the frequency of a subset of splenic $CD11b^+$ myeloid cells expressing TGF-β-Latency Associated Peptide (LAP) and program death ligand 1 (PD-L1) in a signal transducer and activator of transcription (STAT)-1-dependent manner. Furthermore, splenic $CD11b^+$ cells from EAE mice preconditioned *in vitro* with IFN-γ and myelin oligodendrocyte glycoprotein (MOG) peptide exhibited a tolerogenic phenotype with the capability to induce conversion of naïve $CD4^+$ T cells into TGF-β-secreting Treg cells. Remarkably, adoptive transfer of splenic $CD11b^+$ cells from IFN-γ-treated EAE mice into untreated recipient mice ameliorated clinical symptoms of EAE and limited central nervous system infiltration of mononuclear cells and effector helper T cells. Therefore, IFN-γ promotes beneficial effects in EAE by endowing splenic $CD11b^+$ myeloid cells with tolerogenic and therapeutic activities.

Interferon-gamma induces tolerogenic dendritic cells with suppressive activity in experimental autoimmune encephalomyelitis

Constanza Vilchez[1], Brian Parra-Tello[1], Luis González[1], Carolina Prado[2], Rodrigo Pacheco[2], Rodrigo Naves[1]
[1]*Program of Immunology, Institute of Biomedical Sciences, Faculty of Medicine, Universidad de Chile, Santiago, Chile*; [2]*Fundación Ciencia y Vida, Facultad de Medicina y Ciencia, Universidad San Sebastián, Santiago, Chile*

Purpose: Multiple Sclerosis (MS) is an autoimmune disease of the central nervous system. Our previous results have shown that interferon-gamma (IFN-γ) suppresses experimental autoimmune encephalomyelitis (EAE), a pre-clinical model of MS, by inducing splenic $CD11b^+$ myeloid cells with tolerogenic and therapeutic activities. Here, we determined the effect of IFN-γ on the differentiation, tolerogenic phenotype, and therapeutic activity of murine bone marrow-derived dendritic cells (BMDCs).
Methods: BMDCs precursors from mice were differentiated into dendritic cells (DC) with GM-CSF (20 ng/ml) for 7 days in the absence (iDC) or presence of IFN-γ (IFN-γ-DC). Different concentrations of IFN-γ (5 to 50 ng/ml) were added starting from day 0, 2 or 4 of differentiation. Lipopolysacharide (LPS, 100 ng/ml) was added during the last 24 h to obtain mature DC (mDC) and to evaluate phenotypic and functional stability of IFN-γ-DC (LPS-IFN-γ-DC). Cell viability, DC yield, phenotypic profile, and expression of indoleamine 2,3-dioxygenase 1 (IDO-1) and Aryl hydrocarbon receptor (AhR) were determined by flow cytometry. The tolerogenic function was evaluated in a mixed lymphocyte reaction (MLR) assay. IFN-γ-DC or LPS-IFN-γ-DC pulsed with ovalbumin (OVA) peptide were co-cultured with Cell Trace Violet (CTV) labelled $CD4^+$ T cells isolated from the spleens of OT-II mice at different DC:T cell ratios and $CD4^+$ T cell proliferation and activation were determined by flow cytometry. EAE mice were i.v. transferred with IFN-γ-DC or LPS-IFN-γ-DC pulsed with myelin oligodendrocyte glycoprotein (MOG) peptide at the peak of disease and clinical progression was monitored daily.
Results: DC differentiated in the presence of IFN-γ exhibited a tolerogenic phenotype characterized by significantly lower levels of CD80, CD86, and MHC-II, and significantly higher levels of PD-L1 than mDC. LPS-IFN-γ-DC showed a stable phenotype. Induction of tolerogenic IFN-γ-DC was associated with increased expression of IDO-1 and AhR. Tolerogenic IFN-γ-DC and LPS-IFN-γ-DC inhibited OVA-specific $CD4^+$ T cell proliferation and activation. Remarkably, adoptive transfer of either IFN-γ-DC or LPS-IFN-γ-DC ameliorated clinical symptoms of EAE.
Conclusion: Low doses of IFN-γ induce differentiation of murine tolerogenic DC with therapeutic activity in EAE. Therefore, our results reveal a previously unknown protective mechanism of IFN-γ in a neuroinflammatory context.

Neuroimmune interactions shape vascular inflammation: evidences from mouse and human studies

Sarajo Mohanta[1;2], Yuanfang Li[1], Ting Sun[1], Shu Lu[1], Zhe Ma[1], Benjamin Förstera[1], Mingyang Hong[1], Xinyi Deng[1]
[1]Ludwig-Maximilians-University (LMU) Munich, Munich, Germany; [2]German Center for Cardiovascular Research (DZHK), partner site Munich Heart Alliance, Munich, Germany

Purpose: Atherosclerosis is a chronic inflammatory disease of medium and large-size arteries that affects millions of people. Atherosclerotic plaques emerge in the inner intimal layer of arteries and plaque instability triggers clinically significant cardiovascular disease including heart attack and stroke. As plaques lack innervation, the impact of neuronal control on atherosclerosis remains unknown. However, the immune system responds to plaques by forming leukocyte infiltrates in the outer connective tissue coat of arteries, i.e. the adventitia. Because the peripheral nervous system uses the adventitia as its principal conduit to reach distant targets, we hypothesized that the peripheral nervous system may directly interact with diseased arteries via adventitia immune cells to sense and affect atherosclerosis.
Methods: We used detailed aorta imaging, gene expression analyses, tissue clearing approaches, retrograde virus tracing, in-vivo ultrasound plaque imaging, extracellular nerve recording, systemic and local sympathetic denervation, normo- and hyper-lidemic mouse models, human cardiovascular tissues including coronary arteries from ischemic/dilated cardiomyopathy patients, and abdominal aortas from abdominal aortic aneurysms with or without atherosclerosis and arteries/aortas from healthy donors.
Results: In hyperlipidemic mice and human atherosclerotic tissues, we identified wide-spread neuroimmune interactions between nerves, immune cells and arteries as a key component that drives atherosclerosis: diseased adventitia segments showed expanded axon networks including growth cones at axon endings near immune cells and media smooth muscle cells. Murine vascular neuroimmune interfaces established a structural artery-brain circuit: abdominal adventitia nociceptive afferents entered the central nervous system through spinal cord lower thoracic dorsal root ganglia, and were traced to higher brain regions including parabrachial and central amygdala neurons; and sympathetic efferents projected from medullary and hypothalamic neurons to the adventitia through spinal intermediolateral neurons and both celiac and sympathetic chain ganglia. Moreover, central and peripheral components of the artery-brain circuit were activated in parallel to disease progression. When this crosstalk is disrupted by systemic or local sympathetic denervation, plaque-associated immune cell aggregates in the adventitia are destabilized, plaques shrink and become more stable.
Conclusion: Our data demonstrated that the tripartite neuroimmuen cardiovascular interactions shape vascular inflammation such as atherosclerosis, and suggested that these interactions could be targeted to treat atherosclerosis.

Astaxanthin-loaded polyarginine nanocapsules inhibit astrocyte reactivity

Jimena Cordero-Machuca[1;2], Constanza Vilchez[3], Brian Parra-Tello[3], Luis González[3], Felipe Oyarzún-Ampuero[1;2], Rodrigo Naves[3]
[1]Department of Sciences and Pharmaceutical Technology, Faculty of Chemical and Pharmaceutical Sciences, Universidad de Chile, Santiago, Chile; *[2]Advanced Center of Chronic Diseases (ACCDiS), Santiago, Chile*; *[3]Program of Immunology, Institute of Biomedical Sciences, Faculty of Medicine, Universidad de Chile, Santiago, Chile*

Astaxanthin (AST) is a carotenoid obtained from natural sources that has extremely strong antioxidant, anti-inflammatory, and neuroprotective activity. However, the therapeutic application of AST is hindered by its low aqueous solubility and poor stability. In order to improve AST stability and bioavailability as well as its potential application in neuroinflammation, we have developed polyarginine (PARG) oil-in-water nanocapsules (NCs) loaded with AST. PARG is a cationic polymer that has been reported to enhance interaction and transport through cell membranes. The NCs were synthesized using a modified solvent displacement method. PARG was tested at different concentrations (0.06 - 0.25 mg/mL). Stable PARG-NCs were obtained in the range of 157-204 nm, with PDI values of between 0.1-0.2, and positive zeta potential between 33.8 and 57.5 mV, confirming the adherence of polyarginine on the oily droplet´s surface. To determine cytotoxicity of PARG-NCs, rat astrocytes (DI TNC1) were incubated with NCs synthetized with different concentrations of PARG (0.06, 0.125, and 0.25 mg/ml) and at volumes from 5-25% of cell culture medium volume. After 48 hours, cell viability was assessed by flow cytometry. The results showed that cell viability was higher than 90% in the presence of PARG-NCs at concentrations of 0.06 mg/mL and 0.125 mg/mL PARG and at volumes lower than 15%. To evaluate the *in vitro* anti-inflammatory activity of AST-PARG-NCs, rat astrocytes activated with interferon-gamma (100 ng/ml) and lipopolysaccharide (100 ng/ml) were treated with PARG-NCs loaded with 5, 10 or 20 µM AST for 24, 48, 72 and 96 hours. The expression of the glial fibrillary acidic protein (GFAP) was determined by flow cytometry. The results showed that activated astrocytes treated with PARG-NCs containing 5 and 10 µM AST for 72 h or with PARG-NCs containing 5, 10 and 20 µM AST for 96 h exhibited a significantly lower expression of GFAP than control cells. Blank (empty) PARG-NCs or free AST had no significant effect. Therefore, these results indicate that PARG-NCs are safe and might be useful as a nanosystem for AST delivery with potential anti-inflammatory application in neuroinflammatory diseases.

DICAM+ infiltrating monocytes: a mode to control neuroinflammation?

Marina von Essen[1], Marie Mathilde Hansen[1], Sahla El Mahdaoui[1], Finn Sellebjerg[1]
[1]*Danish Multiple Sclerosis Center, Department of Neurology, Copenhagen University Hospital – Rigshospitalet, Glostrup, Denmark*

Background and purpose: Multiple sclerosis (MS) is a chronic inflammatory disease of the central nervous system (CNS). CNS-infiltrating monocytes are found in large numbers within the injured areas of the brain where they play a central role in driving disease progression through demyelination and tissue destruction. However, infiltrating monocytes can also poses a protective function. With this study we investigate a potential protective role of infiltrating monocytes expressing DICAM (dual Ig domain containing cell adhesion molecule) in MS.
Methods: In this study, freshly drawn cerebrospinal fluid (CSF) from 21 treatment-naïve patients with relapsing-remitting MS (RRMS), 14 symptomatic controls and 12 patients treated with natalizumab was analysed by flow cytometry to measure frequency and absolute numbers of DICAM expressing monocytes. Soluble DICAM in CSF was measured by ELISA, and *in vitro* LPS-stimulation studies was performed on freshly isolated blood monocytes.
Results: Analysing CSF of treatment-naïve patients with RRMS showed a reduced frequency of infiltrating-monocytes compared to controls, and furthermore, a decrease in the proportion of infiltrating monocytes that expressed DICAM. When patients were treated with natalizumab, an antibody blocking migration of blood leukocytes to the CNS, we observed that $DICAM^+$ monocytes were still recruited to the CSF and that the level of soluble DICAM in CSF was significantly increased compared to untreated patients. Stimulating monocytes *in vitro* with LPS induced production of proinflammatory cytokines; a production that was effectively reduced by a signal through surface bound DICAM.
Conclusion and discussion: The high frequency of infiltrating $DICAM^+$ monocytes in controls and natalizumab-treated patients in which disease is effectively controlled suggests an immunomodulatory role of these cells. Also, the ability of surface expressed DICAM to regulate the outcome of cell-stimulation in an anti-inflammatory direction, indicates a direct role of DICAM in controlling neuroinflammation. Studies from other groups have shown that DICAM can interact with DICAM on other cells and likewise control their inflammatory profile. Our observation of an increased level of soluble DICAM in natalizumab-treated patients therefore may contribute to control of disease activity through a paracrine action. Altogether, this makes DICAM a possible therapeutical molecule to control inflammation.

Significance of second-generation psychotic drugs in regulation mast cell response: an in vitro study

Justyna Agier[1], Elżbieta Kozłowska[1], Milena Donizy[1], Magdalena Wiktorska[2], Paulina Żelechowska[1]
[1]Department of Microbiology, Genetics and Experimental Immunology, Center for Molecular Research of Civilization Diseases, Medical University of Lodz, Poland, Lodz, Poland; *[2]Department of Molecular Cell Mechanisms, Medical University of Lodz, Poland, Lodz, Poland*

Purpose: One of the most significant health issues facing the globe today is mental illness and neurodegenerative diseases, which presents a public health dilemma. Epidemiological indicators point to a rise in the prevalence of cognitive conditions like schizophrenia, bipolar, manic, or addiction-related disorders. Pharmacological treatment with neuroleptics is the most common therapy used in these states. Neuroleptics are psychotic drugs divided into two classes: “classic” first-generation antipsychotics and second-generation or "atypical" antipsychotics. The concept that inflammation contributes to the development of cognitive disorders, proposed over a century ago, has gained substantial support considering recent research findings. Immune cells, notably mastocytes, play a pivotal role in the development and functioning of the central nervous system. Mast cells profoundly affect their environment and neighbouring cells, including the behaviour or activation of cells involved in neurogenesis and neurodegeneration, such as astrocytes, microglia, and neurons. Considering the hypothesis that mast cells play a role in neuroinflammation, this study aims to assess the *in vitro* response of these cells to second-generation antipsychotics: aripiprazole, olanzapine, risperidone, and quetiapine.
Methods: The study used mast cells isolated from the peritoneal cavity of Wistar rats. Flow cytometry was used to examine the impact of selected drugs on mast cell viability and drug-induced changes in cell surface receptor expression. Histamine release from mast cell granules was measured using a spectrofluorimetric method to assess degranulation levels. The Boyden chamber method was used to determine mast cell migration to neuroleptics.
Results: Risperidone has the highest mast cell toxicity. All tested drugs, regardless of the concentration, cause strong degranulation and histamine release from mast cells, with olanzapine being the most potent activator of degranulation. Strong mast cell chemotactic activity toward olanzapine and quetiapine has been demonstrated. The expression level of the TLR4 receptor decreases under the influence of all tested drugs, regardless of the concentration.
Conclusion: New methods for the pharmacological treatment of neuropsychiatric disorders may be developed based on information on the causative roles played by mast cells and neuroinflammation in the onset of these conditions.

Selective alteration to CD4 subset differentiation by heterozygous IRF4 L116R protects against neuroinflammation

Rebecca A. Jaeger[1], Nadia A. Roberts[1], Cynthia Turnbull[1], Sandali Seneviratne[1], Jessica A. Pettitt[1], Fiona D. Ballard[1], Rebecca L. Buckland[1], Anselm Enders[1], Anne Bruestle[1]
[1]*The John Curtin School of Medical Research, The Australian National University, Acton, Canberra, Australia*

The decision of naïve T cells to differentiate into a specific Th cell subset after antigen encounter is a critical pivot point of the immune response and, when out of balance, can lead to autoimmunity, allergy or immunodeficiency. Th subset differentiation is determined by expression of transcription factors including IRF4. We here describe a point mutation (L116R) in the DNA-binding domain of IRF4 leading to a dysregulation of CD4-T cell subsets and their functions. This point mutation does not alter overall protein expression. In sharp contrast to IRF4 null mice neither the CD4/CD8 ratio nor T cell activation and memory is altered in naïve mice carrying the point mutation. However, $IRF4^{L116R}$ T cells are reduced in their capability to differentiate into Th1, Th17 and Treg cells in a dose dependent manner contrasting with the findings in $IRF4^{KO}$ T cells. Particularly striking is the loss of Th1-differentiation in T cells from homozygous I$rf4^{L116R/L116R}$ mice while T cells completely lacking IRF4 show no reduction in Th1 differentiation. Furthermore, despite maintained ability to generate Th17 cells, expression of the $IRF4^{L116R}$ variant protects mice against disease development in the Th17 cell dependent EAE mouse model of neuroinflammation. This contrasts with IRF4 knock-out mice, where expression of one wild-type allele of IRF4 is sufficient for full disease development. Together our results show that the L116R point mutation in IRF4 can selectively alter the differentiation and function of some CD4 T cell subsets and suggest that the L116R mutation is not a classical loss- or gain of function variant.

Serum Neurofilament light as a biomarker of cognitive status in patients with polymyalgia rheumatica

Patricia Harkins[1], Sharon Cowley[1], Robert Harrington[1], Jean Dunne[1], David Kane[1], Niall Conlon[1], Richard Conway[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Purpose: In Polymyalgia Rheumatica (PMR), cognitive impairment is prevalent, affecting up to 80% of those with the condition.[1] The identification of a serum biomarker for the early detection of cognitive decline, and prediction of cognitive impairment severity is an unmet need. Therefore, the aim of this study is to test the hypothesis that serum neurofilament light (NfL) is a biomarker of cognitive impairment in patients with polymyalgia rheumatica.
Methods: Participants were consecutively recruited from a dedicated PMR clinic. Each participant underwent cognitive testing using the Montreal Cognitive assessment (MOCA) test, with a score of <25 identifying those with cognitive impairment. 10 healthy controls were also included. The serum NfL levels of each participant were assayed.
Results: In total, the study enrolled 19 patients with PMR and cognitive impairment, and 20 PMR patients with normal cognitive status. Using analysis of variance (ANOVA), a significant difference in serum NfL levels was observed between cognitively impaired PMR patients and age matched healthy controls (p=0.015). Moreover, a significant difference in serum NfL levels were observed between the combined (normal and impaired cognition) PMR patient results and those of the healthy controls (p=0.02). However, there was no significant difference in serum NfL levels between cognitively impaired PMR patients and PMR patients with normal cognition. There was also no statistically significant difference in the acute phase reactants, c-reactive protein and erythrocyte sedimentation rate, between groups at the time of testing.
Conclusion: Whilst the purpose of this pilot study was to assess the role of serum NfL as a biomarker for cognitive impairment in PMR, the significantly higher serum NfL in the combined PMR group versus healthy controls was an unexpected finding. Whilst the reasons for this are potentially multifold, our findings provide impetus for further research with larger patient cohorts to assess the association of serum NfL with cognitive trajectories in PMR patients, in addition to elucidating the precise disease specific relationship in PMR.

Flow cytometry live cell-based assay display higher sensitivity to detect autoantibodies against myelin oligodendrocyte glycoprotein (MOG-IgG)

Daniel Lorca-Arce[1], Laura Naranjo-Rondán[1;2], Rocío Soledad Couso[1], Maria Antonia Romera[1], Mari Carmen Anton[1], Arnau Trillas[1], Juan Francisco Luchoro[1], Jose María Cabrera[3;4], Maria Sepúlveda[3;4], Albert Saiz[3;4], Yolanda Blanco[3;4], Thais Armangue[3;4], Eugenia Martinez Hernandez[3;4], Raquel Ruiz García[1;2]
[1]Immunology Department, Centre Diagnostic Biomèdic CDB, Hospital Clínic de Barcelona, Barcelona, Spain., Barcelona, Spain; *[2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Universitat de Barcelona, Barcelona, Spain., Barcelona, Spain*; *[3]Neuroimmunology and Multiple sclerosis Unit, Service of Neurology, Hospital Clinic de Barcelona, and Universitat de Barcelona, Barcelona, Spain, Barcelona, Spain*; *[4]Neuroimmunology Program, Fundació de Recerca Clínic Barcelona- Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain, Barcelona, Spain*

Purpose: This study aims to comprehensively compare the diagnostic performance of two distinct live cell-based assays, indirect immunofluorescence assay (IFA) and flow cytometry (FACS), for the detection of autoantibodies against myelin oligodendrocyte glycoprotein (MOG-IgG) that are diagnostic of MOG antibody-associated disease (MOGAD).
Method: The presence of MOG-IgG was assessed in 244 serum samples and 27 cerebrospinal fluid (CSF) samples by both IFA and FACS assays. Samples were obtained from 248 patients (23 paired serum/CSF samples). HEK293 cells were transfected with a MOG GFP-tagged cDNA clone and incubated with sera (1/160 dilution) or CSF (1/2 dilution). Finally, MOG-IgG from patients were detected using AF-594-conjugated goat F(ab)2 anti-human IgG (IFA) or AF-647-conjugated goat Fc anti-human IgG (FACS) secondary antibodies. For FACS, the IgG binding index of each sample was calculated as the ratio of the cell population´s average MFI: MFI GFP-Positive/MFI GFP-Negative. The mean IgG index value for negative samples tested by both techniques was 1.5, so we established a conservative cutoff ratio of 2.
Results: Out of the 244 sera examined, 197 yielded negative results, and 35 displayed positivity by both assays. Similarly, 25 out of 27 CSF samples were found to be negative, with one positive result for FACS and IFA. Notably, FACS identified 12 positive sera and 1 positive CSF sample that remained undetected by IFA. Conversely, no samples were positive only by IFA. Among the 12 discrepant sera, 6 patients had suggestive features of MOGAD, 3 samples were from patients with previous positive results and diagnosed with MOGAD, 1 patient had a diagnosis of multiple sclerosis, and 2 patients had no available clinical data. Furthermore, the discordant CSF sample came from a patient with MOGAD and positive MOG-IgG in serum. Overall, FACS-based determination of MOG-IgG demonstrated an almost perfect agreement with IFA (Cohen's kappa = 0.81; 95% CI [0.70-0.91]).
Conclusion: The findings of this study underscore a remarkable level of concordance between IFA and FACS in the identification of MOG-IgG. Moreover, the determination based on FACS showed higher sensitivity than that based on IFA, but it remains to determine whether its specificity is also superior.

Liposomal packaging enhances treatment efficacy in neuroinflammation

Nadia A. Roberts[1], Jessica A. Pettitt[1], Jason Price[1], Tony Xu[1], Rebecca L. Buckland[1], Ines Atmosukarto[1], Anne Bruestle[1]
[1]*John Curtin School of Medical Research, Canberra, Australia*

Purpose: Liposomes are drug vehicles which may be applied for treatment targeting in multiple sclerosis (MS). These nanoparticles typically accumulate at sites of disrupted vasculature, as seen in the inflamed central nervous system (CNS), and are also commonly internalised by phagocytic innate immune cells, offering an opportunity to modulate both spatial- and cellular-level drug targeting.
Methods: To address these aims, mice were induced with MS neuroinflammation model experimental autoimmune encephalomyelitis (EAE) and dosed with fluorescence-labelled liposomes or liposome-packaged chemotherapeutic mitoxantrone (MX). The cell specific uptake and longevity, as well as the treatment impact of liposome packed MX, was characterised using multicolour flow cytometry and imaging.
Results: On a spatial level, liposomes were found to traffic to the CNS in an inflammation-dependent manner. Further, liposomes were found to preferentially interact with a specific innate immune cell population also depleted by treatment with liposome-packaged MX. Alteration of delivery modality was also found to improve treatment efficacy, where weekly intravenous delivery of 0.5mg/kg liposomal MX was sufficient to prevent clinical signs of EAE in contrast to freely delivered MX, which offered minimal protection.
Conclusion: These results highlight the applicability of liposome drug vehicles in treatment of neuroinflammation and indicate potential key mechanisms enhancing treatment efficacy.

The peripheral immune landscape in a humanized mouse model of Alzheimer's disease

Ruchi Gera[1], Sumonto Mitra[1], Simone Tambaro[2], Per Nilsson[2], Maria Eriksdotter[1;3]
[1]Karolinska Institutet, Center for Alzheimer Research, Department of Neurobiology, Care Sciences and Society (NVS), Division of Clinical Geriatrics, Stockholm, Sweden; *[2]Karolinska Institutet, Center for Alzheimer Research, Department of Neurobiology, Care Sciences and Society (NVS), Division of Neurogeriatrics, Stockholm, Sweden*; *[3]Karolinska University Hospital, Theme Inflammation and Aging, Stockholm, Sweden*

Purpose: Increasing epidemiological, clinical, and experimental evidence suggests that Alzheimer's disease (AD) pathogenesis is closely associated with systemic abnormalities, including dynamic processes in the peripheral immune compartment and inflammation. Recent reports in transgenic AD animal models propose a role of dysregulated peripheral immune system in memory impairment. In this regard, the contribution of peripheral immune response in driving different pathological stages in AD is less understood. Therefore, utilizing a novel App knock-in mouse model ($App^{NL\text{-}G\text{-}F}$) exhibiting robust Aβ pathology, neuroinflammation and memory impairment, we have explored the relation of Aβ pathology development in the brain with alterations in the peripheral immune compartment.
Methods: Using flowcytometry, we characterized the $App^{NL\text{-}G\text{-}F}$ mice at different stages of Aβ pathology (2-month-old: early, pre-plaques; 7-month-old: plaques + early memory impairment; 12-month-old: late stages) and investigated the distribution and activation status of various splenic immune cells.
Results: Among various immune cells from innate immunity, significant increases in macrophage number in $App^{NL\text{-}G\text{-}F}$ mice were observed. While the percent distribution of B cells from adaptive immunity was reduced in the 12 month-old mice, no significant changes in total T cell distribution in any age group compared to wild-type controls were observed. B cells showed reduced expression of activation molecule CD69 and PD-L1 in 7 and 12-months old $App^{NL\text{-}G\text{-}F}$ mice. Among T cell subsets, the CD4, CD8 and regulatory T (Treg) cell distributions in $App^{NL\text{-}G\text{-}F}$ mice were comparable to control mice in all age groups. However, a rise in follicular T helper (Tfh) cells was observed at 2-month of age only, with altered level of activation molecule ICOS expression on Tfh cells in $App^{NL\text{-}G\text{-}F}$ mice.
Conclusions: These findings in AD mice model show a reduction in B cell and their activation status during aggressive Aβ plaque deposition in brain, suggesting a possible contribution of B-cells in Aβ pathology reinforcing further investigation. Moreover, our data also indicate a possible role of Tfh cells in the early stage of Aβ pathology.

Flow cytometry live cell-based assay for detection anti-aquaporin 4 antibodies (AQP4-IgG)

Raquel Ruiz García[1;2], Laura Naranjo-Rondán[1], Rocío Soledad Couso[1], Maria Antonia Romera[1], Mari Carmen Anton[1], Arnau Trillas[1], Juan Francisco Luchoro[1], Jose María Cabrera[3], Maria Sepúlveda[3], Yolanda Blanco[3], Thais Armangue[2], Eugenia Martinez Hernandez[2;3], Albert Saiz[2], Daniel Lorca-Arce[1]
[1]Immunology Department, Centre Diagnostic Biomèdic CDB, Hospital Clínic de Barcelona, Barcelona, Spain; *[2]Neuroimmunology Program, Fundació de Recerca Clínic Barcelona- Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain*; *[3]Neuroimmunology and Multiple sclerosis Unit, Service of Neurology, Hospital Clinic de Barcelona, and Universitat de Barcelona, Barcelona, Spain*

Purpose: This study aims to comprehensively compare the diagnostic performance of two distinct live cell-based assays, indirect immunofluorescence assay (IFA) and flow cytometry (FACS), for the detection of anti-aquaporin 4 autoantibodies (AQP4-IgG) associated with neuromyelitis optica spectrum disorder (NMOSD)
Method: The presence of AQP4-IgG was assessed in 135 serum samples and 17 cerebrospinal fluid (CSF) samples by both IFA and FACS assays. Samples were obtained from 137 patients (15 paired serum/CSF samples). HEK293 cells were transfected with GFP-tagged cDNA clone with AQP4 (M23 isoform) and incubated with sera (1/20 dilution) or CSF (1/2 dilution). Finally, AQP4-IgG from patients were detected using AF-594-conjugated goat F(ab)2 anti-human IgG (IFA) or AF-647-conjugated goat Fc anti-human IgG (FACS) secondary antibodies. For FACS, the IgG binding index of each sample was calculated as the ratio of the cell population's average MFI: MFI GFP-Positive/MFI GFP-Negative. The mean IgG index value for negative samples tested by both techniques was 2, so we established a conservative cutoff ratio of 2.5.
Results: Out of the 135 sera examined, 123 yielded negative results, while 11 displayed positivity in both assays. Similarly, 17 out of 17 CSF samples were found to be negative. Notably, FACS identified 1 positive serum that remained undetected by IFA. Conversely, no samples were positive only by IFA. Overall, FACS-based determination of AQP4-IgG demonstrated a perfect agreement with IFA (Cohen's kappa = 0.95; 95% CI [0.9-1]).
Conclusion: The findings of this study underscore a remarkable level of concordance between IFA and FACS in the identification of AP4-IgG. Although FACS-based determination seems to be more sensitive than IFA, it remains to be determined whether it is also more specific.

Sex-dependent effects of short-term aerobic exercise on age-related neuroinflammation in the mouse

Joana Augusto[1], Zsuzsanna Barad[1], Áine, M. Kelly[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Modern society is ageing rapidly, posing increased risk of the development of physiological impairments due to age-related inflammation, which plays a role in the development of non-communicable diseases including neurodegeneration. This is occurring in parallel with an increase in sedentary behaviour, which is considered to be one of the leading causes of death worldwide. Extensive evidence has shown the multiple effects of regular exercise to prevent or reverse the detrimental effects of a sedentary lifestyle and to potentially alleviate age-associated low-grade chronic inflammation.
In this study, we investigated the impact of short-term, low-to-moderate intensity treadmill running on age-related neuroinflammation. Male and female C57BL/6J mice, aged between 3 and 18 months old, underwent 7 consecutive days of endurance aerobic exercise, followed by assessment of spatial memory using the novel object location test. Subsequently, gene and protein expression were assessed using an array of different assays to look at potential age-, sex- and activity-related effects. The bioenergetic function of primary microglial cells from both exercising and non-exercising mice was also assessed to investigate their metabolic signature and see whether our exercise regimen had any immunomodulatory impact on these cells.
Findings suggest that some markers of age-related neuroinflammation or cognitive impairment are not impacted by exercise, but that responses to both age and exercise varied widely within experimental groups. Neither sex, age nor prior exercise had an impact on the ability of mice to perform the spatial memory task. Immunohistochemical analysis of microglial markers of inflammation revealed an age-associated effect in both sexes, but with a less exacerbated effect in the aged and exercised male mice when compared with females. Moreover, cytokine expression was not affected by exercise, independently of the mice's sex.
Taken together, these results suggest that male and female mice respond in a physiologically different manner to both ageing and exercise, reinforcing the need to further investigate the underlying molecular mechanisms associated with the observed effects and the potential translational impact of these data. Notably, the broad variation in individual age-related responses to exercise we observed here suggests that a more personalised exercise regimen aimed at attenuating age-associated inflammation.

Unlocking the gut-brain axis: microbiota's impact on neuroinflammation

Emely Elisa Neumaier[1], Lisa-Maria Edrich[1], Mathias Linnerbauer[2], Laura Krumm[3], Thanos Tsaktanis[2], Markus F Neurath[1;4], Beate Winner[3], Veit Rothhammer[2;4], Claudia Günther[1;4]
[1]Department of Internal Medicine I, Uniklinikum Erlangen, Erlangen, Germany; *[2]Neurology, Uniklinikum Erlangen, Erlangen, Germany*; *[3]Department of Stem Cell Biology, Uniklinikum Erlangen, Erlangen, Germany*; *[4]Deutsches Zentrum Immuntherapie (DZI), Erlangen, Germany*

Multiple sclerosis (MS) is one of the most common chronic inflammatory autoimmune diseases of the central nervous system (CNS), typically emerging in young individuals in the most productive period of their lives. Its multifactorial pathogenesis includes genetic and environmental factors such as communication of the gut microbiota with peripheral and central immune cells. Bacterial extracellular vesicles (BEVs) released from the gut microbiota are attracting increased attention for their potential role as biological shuttle system facilitating not only inter-kingdom but also inter-organ communication. Uncovering novel routes of microbiota-brain crosstalk and the effects of gut microbial components on disease-relevant cell types unveil new targets for therapeutic approaches, which are particularly needed for progressive forms of MS.
Bulk RNA sequencing has identified differential gene expression in human induced pluripotent stem cell (hiPSC)-derived microglia upon BEV challenge. Furthermore, *in vitro* stimulation of primary murine glial cells with BEVs induces altered cytokine profiles in response to vesicles derived from various bacterial species. *In vivo* studies in mice injected with BEVs were conducted to examine their effects on the blood brain barrier integrity, immune cell infiltration into the brain, and their impact on CNS-resident cell types, validated through immunohistochemistry and flow cytometry analysis. Additionally, isolation of BEVs from serum samples of MS and inflammatory bowel disease patients also indicates compromised barrier integrity in both inflammatory conditions.
These findings suggest that within an inflammatory environment, gut microbiota-derived extracellular vesicles shuttle along the gut-brain axis to enter the brain, where they interact with CNS-resident glial cells participating in the onset and progression of autoimmune CNS inflammation in MS. Concluding, the study underscores the potential of the role of BEVs in MS pathogenesis, offering avenues for future research and therapeutic interventions.

Intestinal inflammation as a precursor for Parkinson's disease

Luis Eduardo Goncalves[1], Bruno Ghirotto Nunes[2], Vivien Ruder[2], Claudia Günther[3], Beate Winner[2], Markus F Neurath[3]
[1]Department of Medicine 1, Gastroenterology, Pneumology and Endocrinology, Erlangen, Germany; *[2]Department of Stem Cell Biology, Erlangen, Germany*; *[3]Deutsches Zentrum Immuntherapie, Erlangen, Germany*

Ulcerative Colitis (UC) is a chronic inflammatory disease affecting the large intestine by dysregulated immune response, which can modify gut physiology and impact distant organs. Gut-brain axis represents an emerging field that pinpoints the communication between these organs, where the enteric nervous system (ENS) plays an important role. Recently it has been suggested that inflammation may influence the function of the ENS. However, the mechanisms linking UC-associated mucosal to ENS dysfunction and its potential implications for Parkinson's Disease (PD) progression remain poorly elucidated. In this project, our objective is to delineate the relationship between mucosal inflammation and ENS function in the context of UC and connecting mechanisms to PD. Employing *in silico* and immunohistochemistry analyses, we aim to elucidate the involvement of the ENS in inflammatory processes. While the precise triggers driving this inflammation remain elusive, inflammatory cytokines pivotal in UC, such as TNF-α, Type I Interferons, and Th17-related cytokines, emerge as compelling candidates. Furthermore, we have differentiated induced pluripotent stem cells (iPSCs) into enteric neuronal-like cells (ENL) to model human ENL inflammation. Altogether, our work so far investigated initial inflammatory-related triggers that could lead to PD-associated changes in the ENS of UC patients. These results could unravel new mechanisms that connect gut inflammation to the development of PD, offering potential avenues for therapeutic intervention. Funding Support: KFO5024-50553912 (A01, A04 and B01).

Investigating the impact of long-term endurance exercise on brain inflammaging in male and female C57BL/6J mice

Zsuzsanna Barad[1], Joana Augusto[1], Áine, M. Kelly[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Chronic noncommunicable diseases (NCDs), such as diabetes, cancer, cardiovascular disorders, or neurodegenerative conditions are the main cause of morbidity and mortality worldwide. Research suggests that systemic, low-grade inflammation may be a prevailing contributor to the development of NCDs, owing to immunological imbalance which leads to systemic dyshomeostasis. This is further aggravated by heightened inflammation associated with age, often termed 'inflammaging'. Several lines of evidence indicate that modifiable behavioural risk factors, such as physical activity levels, could impact the extent of inflammaging and NCD progression. In this work, we set out to examine the effects of long-term (12+ months), low-intensity endurance exercise on immunological health, and, in particular, on neuroinflammation, which has been implicated in the development of age-related neurodegenerative conditions. C57/BL6J mice of both sexes have been subjected to regular, low-intensity treadmill running beginning in young adulthood. Furthermore, to investigate the potential immunomodulatory effect of specific exercise-related moieties, such as lactate, exercise is combined with pharmacological treatment to prevent lactate uptake into cells. To track potential anti-inflammatory and pro-cognitive effects longitudinally, hippocampus-dependent spatial memory, which is susceptible to inflammation-associated deterioration has been assessed bimonthly using the object displacement paradigm. Results indicate that throughout youth and middle age, the impact of exercise is not significant in either sex. On completion, further behavioural testing will be conducted to assess hippocampus-dependent memory and learning. Subsequently, studies will be conducted to assess peripheral and central inflammatory and activation markers using immunohistochemistry, qPCR, Western blot, and multi-array chemiluminescent immunoassay (MSD) to investigate potential sex-, age-, and activity-dependent effects. Metabolic flexibility and immunometabolic signature of primary microglia, the principal innate immune cell of the central nervous system will also be assessed using Seahorse assay.
Disease burden from NCDs is on the rise globally, and therefore the elucidation of physiological mechanisms and identification of risk reducing strategies are of great importance. Our study will help investigate the potential age-countering impact of long-term, regular, low-intensity endurance exercise on immunological health and the role exercise-associated lactate may play in these effects.

Comparative analysis of brain-derived neurotrophic factor (BDNF) and amphiregulin (Areg) secretion in multiple sclerosis patients: implications for regenerative therapy

Morgane Vermeulen[1], Jasper Van den Bos[1], Hans de Reu[1;2], Barbara Willekens[3], Inez Wens[1], Nathalie Cools[1]
[1]Laboratory of Experimental Hematology, VAXINFECTIO, Faculty of Medicine and Health Sciences, University of Antwerp, Wilrijk, Belgium; *[2]FACSUA - Flow cytometry and cell sorting core facility, University of Antwerp, Wilrijk, Belgium*; *[3]Department of Neurology, Antwerp University Hospital, Edegem, Belgium*

Background: Multiple sclerosis (MS) is an auto-immune disease characterized by inflammation and demyelination. Regulatory T cells (Tregs) and their secreted factors, such as brain-derived neurotrophic factor (BDNF) and amphiregulin (Areg), offer potential for regenerative therapy, besides immunomodulatory potential. BDNF promotes remyelination, axonal plasticity and neuronal cell survival, while Amphiregulin (Areg) aids in tissue repair. This study compares BDNF secretion by Tregs as well as BDNF and Areg secretion in serum between MS patients and healthy controls (HCs).
Material and methods: Peripheral blood mononuclear cells were isolated via density gradient centrifugation, and serum was obtained from serum separation tubes and stored at -80°C. $CD45RA^+$ populations were purified using magnetic activated cell sorting and fluorescence activated cell sorting, followed by 24-hour cell culture and stimulation. Supernatant was collected and stored at -20°C. BDNF and Areg secretion in serum and supernatant were measured using electrochemiluminescence immunoassay.
Results: Sixteen MS patients and 12 HCs were recruited with a mean age of 50 years (IQR: 40 - 58 years) in MS patients and of 53 years (IQR: 31 – 56 years) in HCs. BDNF secretion in serum did not significantly differ between patients (6661 pg/mL; IQR: 5337 – 8299 pg/mL) and HCs (5367 pg/mL; IQR: 3069 – 8266 pg/mL). Among MS patients, those with higher Expanded Disability Status Scale (EDSS) scores showed no significant difference in BDNF levels compared to those with lower scores. Areg levels were uniformly low and showed no significant difference between patients (0.059 pg/mL;, IQR: 0,035 – 0,082 pg/mL) and HCs (0.053 pg/mL; IQR : 0,030- 0,067 pg/mL). Additionally, MS patients exhibited significantly lower amount of $CD45RA^+$ Tregs (56.071, IQR: 42.644 – 133.594 cells/ 100 mL of blood) than their healthy counterparts (190.556, IQR: 76.667 – 232.105 cells/ 100 mL blood).
Conclusion: MS patients demonstrated a significantly lower number of CD45RA+ Tregs compared to HCs. However, BDNF and Areg levels in serum did not significantly differ between MS patients and HCs. Further research is needed to elucidate the regenerative potential of Tregs, BDNF, and Areg in MS.

Cerebrospinal fluid biomarkers soluble CD27 and B-cell maturation antigen in multiple sclerosis and neuroinfection

Malene Bredahl Hansen[1], Helle Bach Søndergaard[1], Helene Mens[2], Anne-Mette Lebech[2], Finn Sellebjerg[1], Jeppe Romme Christensen[1]
[1]Danish Multiple Sclerosis Center, Copenhagen University Hospital, Glostrup, Denmark; *[2]Department of Infectious Diseases, Copenhagen University Hospital, Copenhagen Ø, Denmark*

Purpose: The symptomatic overlaps between multiple sclerosis (MS) and neuroborreliosis (NB) can make them difficult to differentiate clinically. Cerebrospinal fluid (CSF) soluble CD27 (sCD27) is typically considered a marker of T-cell inflammation, but it may also reflect B-cell activation in MS and NB. CSF soluble B-cell maturation antigen (sBCMA) is a biomarker of mature B-cells and plasma cells. Assessment of T- and B-cell activation may help differentiate between these diseases. This study aimed to investigate the potential of CSF sCD27 and sBCMA to differentiate between untreated relapsing remitting MS (RRMS), NB, enteroviral meningitis (EM) and symptomatic controls (SC).
Methods: sCD27 and sBCMA were measured in CSF from age-matched RRMS (n=43), NB (n=67), EM (n=28) and SC (n=38), using electro-chemiluminescence immunoassay. Kruskal-Wallis with Dunn's test post-hoc was used for multiple comparisons, Mann-Whitney for comparing two groups, and Spearman's rank correlation analysis to assess correlations.
Results: The median concentration of sCD27 was 11.92µg/L (Q1=8.26, Q3=24.48) for RRMS, 40.66µg/L (Q1=15.56, Q3=88.04) for NB, 5.20µg/L (Q1=3.24, Q3=10.46) for EM and 2.49µg/L (Q1=1.94, Q3=2.90) for SC. The median concentration of sBCMA was 2.06µg/L (Q1=1.23, Q3=3.32) for RRMS, 3.29µg/L (Q1=1.65, Q3=9.63) for NB, 1.09µg/L (Q1=0.69, Q3=1.50) for EM and 0.9µg/L (Q1=0.76, Q3=1.63) for SC. Using multiple comparison, sCD27 effectively discriminated between all groups ($p \leq 0.01$-0.04). sBCMA was unable to discriminate between the groups of SC and EM, nor RRMS and NB. Comparing individual groups to SC, sCD27 was significantly increased in all groups (all $p<0.01$), while sBCMA was increased in RRMS ($p<0.01$) and NB ($p<0.01$), but not EM ($p=0.18$). Compared to RRMS, sCD27 and sBCMA were higher in NB ($p \leq 0.01$) and lower in EM ($p \leq 0.01$). The levels of sCD27 and BCMA correlated strongly in RRMS ($r_s=0.96$, $p<0.01$) and NB ($r_s=0.93$, $p<0.01$), less in EM ($r_s=0.79$, $p<0.01$) and SC ($r_s=0.44$, $p<0.01$).
Conclusion: The findings highlight sCD27 as a highly sensitive and dynamic inflammatory biomarker in CSF, with discriminatory ability in neuroinflammatory and neuroinfectious conditions of the central nervous system. The strong correlation between CSF sCD27 and sBCMA in RRMS and NB, indicates that sCD27 predominantly reflects B-cell activation in these conditions.

Positivity for anti-NMDAR antibodies exclusively detected by cell-based assay is not associated with clinical presentation and diagnosis of NMDAR encephalitis

Laura Naranjo-Rondán[1], Rocío Soledad Couso[1], Maria Antonia Romera[1], Mari Carmen Anton[1], Arnau Trillas[1], Mar Guasp[2;3], Eugenia Martinez Hernandez[2;3], Francesc Graus[2], Raquel Ruiz García[1;2]
[1]Immunology Department, Hospital Clinic de Barcelona, Barcelona, Spain; *[2]Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain*; *[3]Neurology Department, Hospital Clinic de Barcelona, Barcelona, Spain*

Purpose: The evaluation of anti-NMDAR antibodies (aNMDAR) is commonly performed using solely a commercial indirect immunofluorescence cell-based assay (CBA) in clinical laboratories, while tissue-based assays for screening and/or confirmation are conducted in a few centers. The clinical relevance of aNMDAR exclusively detected by CBA remains uncertain and may lead to misdiagnosis of autoimmune encephalitis.
Methods: We retrospectively examined 157 patients with a positive result for aNMDAR by CBA (Autoimmune Encephalitis Mosaic 6 kit, Euroimmun, Lübeck, Germany) referred to the Immunology Department at Hospital Clinic from March 2018 to March 2024. All samples were also tested by rat brain immunohistochemistry (IHQ). Here, we aimed to evaluate the clinical significance of aNMDAR detected only by CBA (with negative results by IHQ).
Results: Of the total cohort, 137 patients (87.3%) had positive results for aNMDAR by both CBA and IHQ. However, 20 patients (14.6%) presented positive results for aNMDAR only by CBA, with negative results by IHQ. Among these cases, 35 samples were analyzed, including cerebrospinal fluid (CSF)-serum paired samples from 15 patients, serum samples from 4 patients, and a CSF sample from 1 patient. The median age was 43 years (interquartile range: 27-58), and twelve patients were men (60%). Clinical manifestations leading to neurological consultation and antibody evaluation included: CNS inflammatory disorders (6), epilepsy with a non-inflammatory cause (3), primary psychiatric disorders (2), CNS infections (2), encephalopathy with an unknown cause (1), CNS neoplasms (1) and other nonspecific syndromes (4). In patients exhibiting clinical features mimicking autoimmune encephalitis, aNMDAR presence was also not confirmed by indirect immunofluorescence on cultured live hippocampal neurons.
Conclusion: Positive aNMDAR results exclusively identified by CBA are not associated with a well-characterized clinical presentation and diagnosis of NMDAR encephalitis. Positive results for aNMDAR detected by CBA must be confirmed by a tissue-based assay and interpreted within the appropriate clinical context to be considered clinically relevant.

Fas/FasL contributes to HSV-1 brain neuroinflammation and neurodegeneration

Malgorzata Krzyzowska[1], Magdalena Patrycy[1], Kristina Eriksson[2]
[1]*Military Institute of Hygiene and Epidemiology, Warsaw, Poland*; [2]*University of Gothenburg, Gothenburg, Sweden*

The Fas/FasL pathway plays a key role in immune homeostasis and immune surveillance. In the central nervous system (CNS) Fas/FasL is involved in axonal outgrowth and adult neurogenesis. However, little is known about the role of the Fas/FasL pathway in herpes-induced encephalitis, neurodegeneration and memory impairment.
In this study, we used a neuropathogenic clinical strain of herpes simplex virus type 1 (HSV-1) in Fas- and FasL-deficient mice (lpr and gld) to study primary and latent (over 120 days) infection of the brain.
HSV-1 CNS infection induced the infiltration of Fas- FasL-bearing monocytes and T cells in the brain and also to an up-regulation of Fas and FasL expression on resident astrocytes and microglia within infected sites. Upon infection, Fas- and FasL-deficient mice (lpr and gld) were partially protected from encephalitis with a decreased morbidity and mortality compared to WT mice. Fas/FasL deficiency promoted cell-mediated immunity within the CNS, partially due to decreased tightness of the blood-brain barrier. Fas receptor stimulation abrogated HSV-1 induced activation and inflammatory reactions in microglia from WT mice, while lack of Fas or FasL led to a more pronounced activation of monocytes and microglia and also to an enhanced differentiation of these cells into a pro-inflammatory M1 phenotype. Latently infected Fas- and FasL-deficient mice showed increased deaths, with similar viral titers and proinflammatory response as lantently infected WT mice. However, Fas- and FasL-deficient mice showed less neurodegeneration markers (beta-amyloid and tau proteins) and better results in learning (NOR and labirynth tests).
Our data indicate that the Fas/FasL pathway leads to excessive neuroinflammation during HSV-1 infection, which is associated with a diminished anti-viral response and an excessive neuroinflammation further leading to neurodegeneration and memory impairments.

Functional characterization of conditioned media derived from mesenchymal stem cells transfected with anti-mir-29 family using antagomirs on cell lines of neurodegenerative diseases

Violeta Gómez-Vicente[1], Sandra Pascual Garcia[1], Jose Miguel Sempere-Ortells[1], Pascual Martinez-Peinado[1]
[1]*University of Alicante, San Vicente del Raspeig, Spain*

Purpose: The main objective of this work is to analyze the effect of conditioned medium (CM) from human mesenchymal stem cells transfected (tMSC) with antagomir of different components of the miR-29 family in relevant cellular models for studying neurodegenerative diseases generated from cell lines such as SH-SY5Y.
Methods: The study methodology involved characterizing the CM from mesenchymal stem cell (MSC) clones based on their immunomodulatory effect in various assays, including cell proliferation assessment, lymphocyte degranulation, Treg cells promotion, and microglial activation. Subsequently, the effect of tMSC CM with miR-29 in neurodegenerative disease cellular models was analyzed. Proliferation, cellular apoptosis, cell degranulation, neuronal ultrastructure, microglial activation, and cytokine concentration were assessed.
Results: The functional diversity of different mesenchymal stem cell (MSC) clones has been characterized, highlighting their immunomodulatory capacity through inhibition of lymphocyte proliferation, cytotoxic cell degranulation, promotion of Treg cells, along with suppression of microglial activation. Results from the analysis of miRNA levels in MSC clones revealed distinct expression patterns among miR-29 family members before transfection. MSC1 and MSC3 exhibited elevated levels of miR-29a, while miR-29b was downregulated. MSC2 showed a slight increase in miR-29c expression. Evaluating the effect of MSC conditioned media (CM) on apoptosis in SH-SY5Y cell cultures, both under normal conditions and neurodegeneration models induced by H2O2 and 6-hydroxydopamine, revealed a protective effect against apoptosis, particularly evident with untransfected CM. Related to miR-29b-1-5', similar but less pronounced effects were observed with miR-29a-5' in SH-SY5Y cell cultures. Transfecting MSC with antagomir for miR-29a-5' resulted in a modest yet significant reduction in apoptosis. These results highlight the significant roles of miR-29b-1-5' and miR-29a-5' in protecting against apoptosis in neurodegeneration models. These preliminary findings regarding the protective effects of miR-29 family members are undergoing further investigation through ongoing studies to validate and expand upon these observations.
Conclusion: In summary, this study reveals that mesenchymal stem cell (MSC) clones exhibit diverse immunomodulatory capabilities and that MSC conditioned media, especially without transfection (CMt-), have a significant protective effect against apoptosis in neurodegeneration models, suggesting therapeutic potential in neurodegenerative diseases.

Autophagy regulation in peripheral blood mononuclear cells of patients with myasthenia gravis

Emina Milosevic[1], Verica Paunovic[1], Marina Stamenkovic[1], Stojan Peric[2], Ivana Basta[2], Ivo Bozovic[2], Zorica Stevic[2], Vladimir Trajkovic[1]
[1]Institute of Microbiology and Immunology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; *[2]Neurology Clinic, Clinical Center of Serbia, Faculty of Medicine, University of Belgrade, Belgrade, Serbia*

Myasthenia gravis (MG) is chronic autoimmune disease where autoantibodies mediate destruction of the neuro-muscular junction leading to weakness in voluntary muscles. The etiology is still unknown. Autophagy is a major mechanism of cellular homeostasis and it involves degradation of large intracellular cargo, such as damaged organelles or protein aggregates. It is a house-keeping process in the immune cells which regulates their energy balance and survival. Autophagy is influenced by immunological signals and it affects the responses of the immune cells. We analyzed the mRNA expression of autophagy mediators in peripheral blood mononuclear cells of MG patients. The study included 23 MG and 23 age/sex-matched healthy control subjects (HC). Autophagy related 5 (Atg5), Atg12, Microtubule-associated protein 1 light chain 3B (LC3B) and p62 mRNA levels were determined by RT-qPCR. Our results demonstrate upregulation of Atg12, LC3 and p62 in MG. Atg5 mRNA expression was unaltered in MG patients compared to healthy participants. These findings warrant further clarification of the role of autophagy-related mediators in MG pathogenesis.

The study was supported by an unrestricted grant from argenx BV (Ghent, Belgium), Ministry of Education, Science and Technological Development of the Republic of Serbia (Contract No. 451-03-9/2021-14/200110), and Serbian Society for the Peripheral Nervous System.

Modulation of HIV-1 Env antibody responses in mice with rationally designed calcium phosphate nanoparticles.

Dominik Damm[1], Leonardo Rojas Sánchez[2], Kathrin Kostka[2], Christoph Weingärtner[1], Jannik T. Wagner[1], Klaus Überla[1], Matthias Epple[2], Vladimir Temchura[1]
[1]Institute of Clinical and Molecular Virology, University Hospital Erlangen, Erlangen, Germany; *[2]Inorganic Chemistry and Center for Nanointegration Duisburg-Essen, University of Duisburg-Essen, Essen, Germany*

Antigen-functionalized nanoparticles have become a major focus in experimental HIV-1 vaccine research in recent years. Biodegradable calcium phosphate (CaP) nanoparticles offer inherent advantages compared to biological and polymer-based nanoparticles. We evaluated CaP nanoparticles randomly loaded with soluble recombinant Env trimers (rCaP) in different immunization approaches. rCaP themselves induced poor anti-Env antibody responses in mice. However, functionalization of rCaP nanoparticles with a universal T helper epitope of Tetanus Toxoid (TT) enhanced the magnitude of the anti-Env antibody response, indicating an initially suboptimal MHC-II restricted T-cell help. If mice were previously immunized against TT, we were able to recruite pre-existing TT-specific T-helper cells and could further enhance anti-Env humoral immune responses via intrastructural help (ISH). We also substituted the TT peptides in the rCaP nanoparticles with an adjuvant (CpG). The magnitude of anti-Env IgG antibody levels was comparable to the ISH approach, although the anti-Env IgG subtype distribution varied. However, in contrast to CpG-adjuvanted rCaP, the ISH approach did not elicit unfavourable Env-specific IFN-γ secreting CD4 T cell responses. Thus, CaP nanoparticles represent a flexible HIV-1 Env antigen delivery platform that can be adjusted for efficient induction and modulation of humoral immune responses. As a next step, we developed and verified a highly selective, orthogonal bio-conjugation of Env trimers to the surface of CaP nanoparticles (oCaP) via post-translationally introduced aldehyde groups. The resulting oCaP were superior over rCaP in the activation of Env-specific B cells (*in vitro*) and induction of antibody responses (*in vivo*). This method maintains the native-like protein conformation and has a broad potential application in functionalization of nanoparticle platforms with stabilized candidate antigens for both vaccination and diagnostic approaches.

A two-component vaccination strategy based on polyfunctional calcium phosphate nanoparticles

Christoph Weingärtner[1], Kathrin Kostka[2], Dominik Damm[1], Klaus Überla[1], Matthias Epple[2], Vladimir Temchura[1]
[1]Institute of Clinical and Molecular Virology, University Hospital Erlangen, Erlangen, Germany; *[2]Inorganic Chemistry and Center for Nanointegration Duisburg-Essen, University of Duisburg-Essen, Essen, Germany*

Biodegradable calcium phosphate nanoparticles (CaP) offer a customizable vaccination platform. Proteins attached to the surface of CaPs act as an antigen display for B-cell recognition or guide the nanoparticles to target cells. Additionally, small molecules and/or adjuvants can be incorporated into the CaP core to be released under acidic conditions in the lysosomes of target cells.
Since the requirements for recognition of viral antigens differ fundamentally between T- and B-cell responses, we suggest a novel two-component vaccination strategy, in which the T-CaP component is optimized for the induction of T-helper cell responses through the targeting and activation of dendritic cells (DCs). On the other hand, the B-CaP component presents viral glycoproteins in the correct conformation to B-cells. By separating the induction of T-helper cell responses and B-cell responses, we also aim to improve the understanding of the requirements for the induction of long-lived effector antibody responses against the trimeric structures of the HIV-1 envelope protein (Env).
We have developed a highly selective orthogonal bio-conjugation of stabilized native-like Env trimers to the surface of calcium phosphate nanoparticles. This method maintains the trimeric conformation and has broad potential application for other stabilized candidate antigens. Moreover, we demonstrated that B-CaPs displaying orthogonally arranged Env trimers on their surface are superior in activating Env-specific B-cells (in vitro) and inducing Env-specific antibody responses (in vivo) compared to CaPs with randomly oriented Env trimers coupled.
To induce CD4+ T-helper cells, we generated T-CaPs displaying both a CD11c antibody for the targeting of DCs and an isotype non-targeting antibody. Preliminary data demonstrate an increased binding of CD11c-functionalized CaPs to murine DCs in vitro.
The optimized T- and B-CaPs are intended to be explored as a two-component nanoparticle vaccine in a humanized mouse system with regard to their immunogenicity.

Design considerations towards a RIG-I adjuvanted CMV mRNA vaccine

Svenja Dudek[1], Jan Kacprzak[1], Christine Wuebben[1], Thomas Zilliger[1;2], Gunther Hartmann[1]
[1]*Institute of Clinical Chemistry and Clinical Pharmacology, Bonn, Germany*; [2]*Department of Biomedicine, Aarhus University, Aarhus, Denmark*

Cytomegalovirus (CMV) is a prevalent herpes virus that typically causes mild symptoms in healthy individuals but poses significant risks to individuals with weakened immune systems and pregnant women, often resulting in congenital infections with severe birth defects. Consequently, there is an urgent need for CMV vaccines to protect vulnerable populations and newborns from severe complications.
For this purpose, we are developing a novel concept for an mRNA vaccine targeting major CMV antigens, namely the immediate early protein IE1 and the gH/gL/gO trimeric surface complex. In order to maximize the mRNA's translational efficacy and stability, we aim at minimizing the innate immunogenicity of the mRNA itself while adding a RIG-I-based controlled adjuvant activity. By incrementally activating RIG-I, we aim to increase MHC expression and costimulatory cytokines. This will improve vaccine-induced T- and B-cell responses, leading to protective memory.
The effect of RIG-I activation on mRNA translation, stability, and cytokine release is assessed in various cell lines. Subsequently, mice are vaccinated with different mRNA constructs to confirm the beneficial effect of selective RIG-I stimulation on the induction of neutralizing antibodies and on antiviral CD8 T cell responses. By exploring our targets individually or in combination, we hope to determine the best approach for achieving optimal effectiveness against MCMV and advance to HCMV vaccine development.
In summary, our adjuvanted mRNA vaccine provides the ability to control the crucial balance between efficient antigen expression and dosed RIG-I-based innate immune stimulation to boost the adaptive immune response, ensuring effective immunity against CMV. This novel strategy holds great potential for successful vaccination against other infectious diseases and cancer.

Inorganic fullerene-like tungsten disulfide nanoparticles strongly modulate the immune response in vitro

Darinka Popović[1], Snežana Zečević[1], Sergej Tomić[2], Marina Bekić[2], Sara Rakočević[1], Maja Kosanović[2], Dušica Stojanović[3], Petar Uskoković[3], Milan Marković[2], Dejan Bokonjić[1], Miodrag Čolić[1;4]
[1]Medical Faculty Foca, University of East Sarajevo, Foča, Bosnia and Herzegovina; *[2]Institute for the Application of Nuclear Energy, University of Belgrade, Belgrade, Serbia*; *[3]Faculty of Technology and Metallurgy, University of Belgrade, Belgrade, Serbia*; *[4]Serbian Academy of Sciences and Arts, Belgrade, Serbia*

Purpose: Tungsten disulfide (WS_2) nanoparticles have been extensively investigated in the biomedical field as theranostics due to their specific properties, including good biocompatibility. However, almost nothing is known about their effect on the immune system. This study aimed to investigate the effects of inorganic fullerene-like WS_2 (IF- WS_2) nanostructures on the immune response in vitro.
Methods: IF-WS2 nanoparticles, were used in three in vitro culture models: peripheral blood mononuclear cells (PBMCs) stimulated with phytohemagglutinin (PHA); monocyte-derived dendritic cells (MoDCs) co-cultivated with purified T cells; monocyte-derived macrophages (MoMs) and U937 cell line cultivated under M1 or M2 polarizing conditions. Several parameters were analyzed: cytotoxicity; internalization of nanoparticles by immune cells (morphological and flow cytometric analysis); T-cell proliferation of CellTrace Far Red prestained cells; production of cytokines and chemokines in culture supernatants and intracellularly; analysis of cell markers in/on MoDCs, MoMs, and T cells.
Results: IF-WS_2 were non-cytotoxic up to the concentration of 200 µg/mL. However, the concentrations of 25 µg/mL and higher inhibited PHA-stimulated proliferation of PBMC, T cells in co-culture with IF-WS2-treated MoDCs, but not purified T cells stimulated with CD3/CD28 beads. Morphological and flow cytometric data showed a dose- and time-dependent internalization of IF-WS_2 by MoMs and MoDCs but not lymphocytes. IF-WS2 decreased the production of pro-inflammatory cytokines/chemokines (IL-1β, TNF-α, IL-8, MCP-1, and GRO-α) by PHA-stimulated PBMC. The Th1 (IFN-γ), Th17 (IL-17A, IL-17F, and IL-22), and Th21 (IL-21) cytokines were down-regulated, whereas Th2 (IL-4, IL-5, and IL-3), Th9 (IL-9) cytokines and a T regulatory cytokine (IL-10) were up-regulated. These effects were also seen in IF-WS2-MoDC/T-cell cocultures and were correlated with inhibited differentiation, and maturation of MoDCs as well as the induction of their tolerogenic properties as judged by increased expression of tolerogenic markers (ILT4 and IDO-1), decreased production of IL-12 and the increased potency to induce differentiation of Tregs. In addition, IF-WS2 nanoparticles were capable of decreasing M1 and increasing M2 polarizing properties of both MoMs and U937 cells.
Conclusion: IF-WS2 nanoparticles exert a very potent modulation of the immune response in vitro through their action on antigen-presenting cells.

Evaluation of the dose sparing effects of mmCT, dmLT and alum on two different vaccines in a neonatal mouse model

Jenny Lorena Molina Estupinan[1;2], Poorya Foroutan Pajoohian[1;2], Stefanía P. Bjarnarson[1;2], Ingileif Jónsdóttir[1;2], Audur Anna Aradottir Pind[1;2]
[1]University of Iceland, Reykjavík, Iceland; *[2]Department of Immunology, Landspitali, the National University Hospital of Iceland, Reykjavík, Iceland*

Purpose: Childhood vaccinations give long term protection against many infectious diseases, but multiple vaccinations are usually required. In many cases, vaccine demand exceeds production capacity. Adjuvants can enhance magnitude and duration of immune responses and may reduce vaccine dose needed to induce protective immunity, allowing dose sparing and cost savings. Here we assessed dose sparing effects of the adjuvants dmLT, mmCT and alum on neonatal antibody (Ab) response to a pneumococcal conjugate vaccine Pn1-CRM_{197}, and of mmCT and alum to an influenza hemagglutinin (HA) vaccine.
Methods: Neonatal mice were immunized subcutaneously with fractional doses of Pn1-CRM_{197} or HA (2, 1, 0.75, 0.5 and 0.1 µg) with mmCT, dmLT or alum and compared with a full dose of the vaccine (4 µg) without adjuvant. Pn1- or HA-specific IgG antibodies were measured by ELISA in serum collected biweekly up to 8 weeks after immunization, and Pn1- or HA-specific IgG+ antibody secreting cells (ASCs) in bone marrow (BM) were enumerated by ELISpot 8 weeks after immunization.
Results: Ab levels of neonatal mice immunized with a full dose of Pn1-CRM_{197} or HA were low. Inclusion of mmCT or dmLT enhanced Pn1-specific IgG elicited by fractional doses of Pn1-CRM_{197} providing 8- and 5.3-fold dose sparing of the vaccine, respectively, and inducing protective levels against bacteremia (91-75%) and pneumonia (45-50%) in neonatal mice. mmCT also enhanced HA-specific IgG elicited by fractional doses of HA compared with full dose of HA without adjuvant, where inclusion of mmCT provided 8-fold dose sparing of the vaccine. Additionally, mmCT significantly enhanced Pn1- and HA-specific IgG ASCs in the BM 8 weeks after immunization compared with full dose vaccine only. On the contrary, mice immunized with fractional doses of Pn1-CRM_{197} or HA and alum, elicited Pn1- or HA-specific IgG in serum and IgG ASCs in BM comparable with full dose vaccine alone.
Conclusion: The adjuvants dmLT and mmCT are promising candidates for dose sparing and could be used at times when vaccine demand exceeds vaccine production capacity.

Spatial analysis of rhesus macaque lung tissue shows a key role for vaccination or previous SARS-CoV-2 challenge in immune pulmonary status

Cillian Gartlan[1;2], Francisco J Salguero[3], Amy R Cross[4], Peter Todd[1], Megan Bradbury[4], Matthieu Miossec[1], Benjamin Wright[1], Mark Coles[5], Fadi Issa[4], Joanna Hester[4], Stephen Taylor[1], Tom Tipton[1;2], Miles Carroll[1;2]
[1]Centre for Human Genetics, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom; *[2]Pandemic Sciences Institute, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom*; *[3]UK Health Security Agency, Salisbury, United Kingdom*; *[4]Transplantation Research Immunology Group, Nuffield Department of Surgical Sciences, University of Oxford, Oxford, United Kingdom*; *[5]Kennedy Institute of Rheumatology, Nuffield Department of Orthopaedics Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*

Purpose: Much has been learned about how SARS-CoV-2 drives lung immunopathology. However, studies of post-mortem human lung tissue have confounding factors including different viral loads, infection timepoints and treatments. Animal studies allow us to standardise these factors, examine a wider range of pathological states and study the impact of vaccination on protection against or enhancement of lung pathology. We have applied spatial biology techniques to study lung tissue responses to SARS-CoV-2 and propose these methods as novel tools to assess preclinical vaccine efficacy and to determine protective and pathologic mechanisms.
Methods: Using spatial transcriptomics (Nanostring GeoMx) and multiplex immunofluorescence (Leica Cell DIVE), we characterise the immune mechanisms driving pathology and protection in the lung across vaccine and challenge scenarios in rhesus macaques challenged with SARS-CoV-2. Lung tissue from vaccinated (DNA, mRNA, viral vector and formalin-inactivated vaccines), unvaccinated, and re-challenged macaques were analysed. Spatial transcriptomic profiling was carried out on both lesioned and non-lesioned areas of lung tissue from 2 macaques from each group – one with the highest in-group pathology score and one with a low pathology score. Multiplexed imaging was carried out on all of the macaques across the cohorts to examine the cellular profiles and carry out spatial analysis.
Results: Peripheral vaccinations resulted in different vaccine platform-dependent transcriptional profiles and immune infiltrates in the lung following challenge, which is a novel finding. Whole-virus exposure (whether by formalin-inactivated vaccine or previous challenge) strongly induced innate immune pathways and greater antigen presentation in the lung. Viral vector vaccination induced a highly diverse variety of immune pathways.
Conclusion: Adaptive immune cell counts in the lung increase following peripheral SARS-CoV-2 vaccination and challenge compared to challenge alone, suggesting potential recruitment of adaptive immune cells from the periphery. The profile of the resulting immune response differs according to vaccine platform and overall better-protected lung tissue was associated with immune memory, NK cell cytotoxicity, and T cell activation. Pathological responses were associated with greater presence of macrophage markers, while pathways associated with regulation of macrophage responses were upregulated in well-protected tissues. Future vaccines should consider these data to maximise protective efficacy and minimise tissue pathology.

RIG-I ligand adjuvanted mRNA vaccines

Christine Wuebben[1], Thomas Zillinger[1;2], Janos Ludwig[1], Gunther Hartmann[1]
[1]*Institute of Clinical Chemistry and Clinical Pharmacology, University Hospital Bonn, Bonn, Germany*; [2]*Department of Biomedicine, Aarhus, Denmark*

Purpose: mRNA-based vaccines have been proven to be a breakthrough technology with potential for advancing immunotherapies against cancer and infectious diseases. To ensure the vaccination success, several critical factors must be addressed including the optimization of translation of the encoded antigen as well as minimizing the mRNA immunogenicity. However, it has been shown that the adaptive immune responses to *non-mRNA-based vaccines* can be improved by immune adjuvants, originally termed 'dirty little secret of immunologists' to enhance their efficacy. Balancing the immunostimulatory effects of the mRNA vaccine seems to be crucial: while a defined amount of adjuvant can promote controlled innate immune activation beneficial for the resulting adaptive immune response, excessive activation of the innate immune system might suppress mRNA translation and might lead to the degradation of the mRNA. Here, we show a novel concept to introduce controlled adjuvant activity to a non-immunogenic mRNA.
Methods: We focus on the controlled activation of RIG-I, one of the key innate pattern-recognition receptors that sense viral RNA. Our group has identified the ligand of RIG-I to be a short, blunt-ended, double-stranded RNA with a 5'-triphosphate (3p-dsRNA). In this concept, we hybridize specifically designed and chemically modified 3p-dsRNAs to the 3' untranslated region of the mRNA.
Results: We could show *in vitro* that the RIG-I ligand adjuvanted mRNA vaccine induces an innate antiviral type I IFN response while still translating the encoded protein. Moreover, CD11b+ CD11c+ myeloid bone marrow-derived dendritic cells upregulate the expression of activation marker CD69 and CD86, and enhance presentation on MHC I and MHC II compared to a non-adjuvanted mRNA. By controlling the number of 3p-dsRNAs, we can precisely modulate the immunostimulatory properties of the mRNA, achieving an optimal balance between antigen translation and immune activation.
Conclusion: We designed a novel 3p-dsRNA-based adjuvant for an mRNA vaccine. This balanced innate immune activation allowed efficient translation, while enhancing antigen presentation and upregulation of cell surface markers, as well as the expression of co-stimulatory cytokines. Together, this combination should lead to an optimal induction of the adaptive immune response.

Recapitulating memory B cell responses in a lymphoid organ-chip to evaluate mRNA vaccine boosting strategies

Raphaël Jeger-Madiot[1], Delphine Planas[1], Isabelle Staropoli[1], Jérôme Kervevan[1], Héloïse Mary[1], Camilla Collina[1], Barbara F. Fonseca[1], Hippolyte Debarnot[1], Rémy Robinot[1], Stacy Gellenoncourt[1], Olivier Schwartz[1], Lorna Ewart[2], Michael Bscheider[3], Samy Gobaa[1], Lisa Chakrabarti[1]
[1]Institut Pasteur, Paris, France; *[2]Emulate Inc., Boston, United States*; *[3]Roche Pharma Research & Early Development, Basel, Switzerland*

Purpose: Predicting the immunogenicity of candidate vaccines and biologicals in humans based on animal model data remains a challenge. To address this issue, we developed a lymphoid organ-chip (LO chip) model based on a microfluidic chip seeded with human PBMC at high density within a 3D matrix.
Methods: The lower channel of an $S1^R$ chip (Emulate) was seeded with human PBMC at $6x10^8$/mL within a collagen-based extracellular matrix, to mimic the high cellular densities characteristic of lymphoid tissue. The upper chip channel, used as a vascular-like compartment, was continuously perfused with nutrients and antigens for 6 to 14 days.
Results: Perfusion of the SARS-CoV-2 Spike protein mimicked a vaccine boost by inducing a massive amplification of Spike-specific memory B cells, plasmablast differentiation, and Spike-specific antibody secretion. The magnitude of Spike-specific B cell amplification in the LO chip, with a median 32.7x increase at d6, was higher than in 2D and 3D static cultures, highlighting the added value of a dynamically perfused culture. Features typical of lymphoid tissue, including the formation of activated CD4+ T cell/B cell clusters, the induction of ICOS in CD4+ T cells within the clusters, CXCL13 chemokine secretion, and the emigration of matured plasmablasts, were recapitulated in the LO chip. Importantly, myeloid cells were competent at capturing and expressing mRNA vectored by lipid nanoparticles, enabling the assessment of responses to mRNA vaccines perfused in the LO chip. Comparison of responses to Wuhan monovalent and Wuhan/Omicron bivalent mRNA vaccine boosts showed equivalent induction of Omicron neutralizing antibodies, suggestive of immune imprinting, as reported *in vivo*.
Conclusion: We developed a versatile lymph node-on-chip system suitable for the rapid evaluation of B cell recall responses. The model is responsive to protein and mRNA-encoded antigens, highlighting its potential in the preclinical evaluation of vaccine boosting strategies.

Improving paediatric vaccine responses: a neonatal mouse model of pneumococcal vaccination

Kiva Brennan[1], Eleanor Noone[1], Luke Gibbons[1], Rachel Dalton[1], Aline Zoller[1], Ed Lavelle[1], Natalia Muñoz-Wolf[1], Sarah Doyle[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Worldwide, millions of children die every year due to infectious diseases. While vaccinations have saved millions of lives, there remains a significant need to enhance childhood vaccine efficacy. Infants receive vaccinations against dangerous infections but achieve full protection only after several booster vaccinations. This is because their immune systems are not fully mature and do not function in the same way as an adult's immune system, leaving a "window of vulnerability" in a child's life before booster vaccinations can take effect.
To maximise the effectiveness of vaccines, adjuvants can be added to boost the immune response. Most vaccines and adjuvants are developed and tested in adults; thus, effective adjuvants for the paediatric population are often overlooked. Improving current vaccine efficacy could lead to a decrease in the number of booster injections required for full protection. This, along with offering increased protection earlier in life, could impact significantly on children's health globally.
While many adjuvants currently in use are less effective in neonates and young children than in adults, we have identified cytosolic Poly(I:C) (cPIC) as an innovative adjuvant for paediatric vaccines using human cord blood, blood from healthy children, neonatal murine splenocytes and neonatal murine bone marrow derived macrophages. We have subsequently carried out proof-of-concept studies in a neonatal mouse model of pneumococcal vaccination, illustrating that addition of paediatric-relevant adjuvants to current vaccines can improve vaccine responses in early life.
When administered in the neonatal phase of life, inclusion of a RIG-I agonist with PCV13, an alum-containing paediatric vaccine, can improve pneumococcal-specific antibody responses compared to PCV13 alone. cPIC can also significantly increase B cell maturation to plasma cells and increase antigen-specific T cell responses when compared to vaccination with PCV13 alone. The increase in this range of vaccine-induced responses will likely confer increased protection to pneumococcal infection earlier in life. Moreover, these results provide proof-of-principle that inclusion of cPIC into current, alum-containing paediatric vaccines can improve paediatric responses to vaccination.

Investigating SARS-Cov2 antigen cross-reactivity of secreted (monoclonal) antibodies using droplet microfluidic linked deep sequencing

Luca Schlotheuber[1], Klaus Eyer[2]
[1]*ETH Zuerich - Institute for Pharmaceutical Sciences, Zuerich, Switzerland*; [2]*Institute for Biomedicine - University of Aarhus, Aarhus, Denmark*

Introduction: In recent years, the detection and characterization of antibodies from individual cells has made steady progress, allowing for the integration of read-outs, such as quantity, specificity and affinity. In this context, droplet microfluidics are powerful as they confine a cell and its microenvironment permitting a direct link between the cell and its secreted antibody inside individual pico-reactors. The aim of these technologies is not only to characterise the antibody repertoire at single-cell resolution but also to isolate a specific cell of interest for B-cell antibody sequencing. This harnessing of the natural repertoire can then lay the groundwork for developing antibody therapeutics with unique specificity and function. During the SARS-Cov2 pandemic the need for such antibodies, in particular of neutralizing function or cross-reactivity become evident. However, so far developed antibodies were losing effectiveness and were out-performed by the fast evolution of the RNA virus. To address this, powerful modelling techniques from antigen libraries coupled to next-generation sequencing were developed to scan escape mutations and antibody epitopes. While this approach permits for more analysis depths, it is aimed at characterizing antibody-virus binding with known antibodies or polyclonal serum, lacking single-cell resolution and the ability for antibody discovery. Therefore, new technologies are needed which allow to characterize and isolate secreted antibodies with additional information about their potential cross-reactivity.
Methods & Results: Using droplet microfluidics, we report a workflow to encapsulate single-cells into water-in-oil droplets, where secreted antibodies are captured using antibody-capture nanobeads. By further incorporating barcoded T7-phage libraries expressing SARS-Cov2 receptor binding domain (RBD) protein variants at high purity into each droplet, secreted antibodies can be further analysed for antigen specificity. Finally, linking to conventional fluorescent activated (droplet) sorting followed by deep sequencing results in antigen analysis from a single secreted antibody. This workflow allows for mutational profiling of the antigen (RBD), which was first demonstrated in a murine vaccination model, showing both antibodies against common and novel RBD variants. In a next step combined sequencing of antigen variant and antibody-producing cells will allow for the isolation of antibodies binding unique virus variants and discovery of potentially cross-reactive antibodies.

Comprehensive profiling of vaccine-induced tissue response using ex vivo natural human skin modules

Manon Scholaert[1], Mathias Peries[1], Emilie Braun[1], Jeremy Martin[2], Nadine Serhan[2], Alexia Loste[2], Bruner Audrey[2], Lilian Basso[2], Benoit Chaput[3], Eric Merle[4], Pascal Descargues[4], Emeline Pages[1], Nicolas Gaudenzio[2;3]
[1]Genoskin SAS, Toulouse, France; *[2]Infinity, Toulouse, France*; *[3]CHU Toulouse, Toulouse, France*; *[4]Genoskin Inc, Salem, United States*

Purpose: In the rapidly evolving field of vaccine research, there is an urgent need for methodologies that accurately replicate human skin responses prior to clinical trials. Here, we introduce a new approach employing bio-stabilized, injectable *ex vivo* human skin modules (HypoSkin®) to investigate the early onset of tissue response induced by the injection of mRNA vaccines within the skin ecosystem.
Methods: Here we combine multiplex cytokine assays, bulk RNA sequencing, and proteomics analysis, to explore the global skin response following subcutaneous administration of the mRNA-1273 COVID-19 vaccine.
Results: Using our analytical pipeline, we reveal that vaccine injection elicits a distinct release pattern of cytokines and chemokines crucial for T cell and monocyte recruitment, strongly suggesting that immune and/or structural cells naturally present in human skin retain the ability to release immunomodulatory substances in response to vaccine administration within the modules. Additionally, by examining subtle modifications in gene expression, we can discern the precise sequential events occurring between the exogenous substance and the skin's biological processes. These events encompass the recognition and response to a foreign agent, the adjustment of skin homeostasis, the activation of stress responses, and the initiation of immune reactions, providing deeper insights into global modulation of the human skin ecosystem following vaccination.
Conclusion: Our investigation demonstrates that, by combining tissue-level analytic tools with injected HypoSkin®, we can capture the global dynamics of the natural human skin ecosystem response after injection of mRNA vaccine. This comprehensive approach not only enhances our understanding of vaccine efficacy but also provides a versatile platform for evaluating novel vaccination strategies and predicting outcomes in preclinical settings.

An investigation of novel vaccination strategies for inducing gastric mucosal immunity

Nicole O'Sullivan[1], Dorian Dederko[1], Ed Lavelle[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Helicobacter pylori (*H. pylori*) is the most prevalent chronic bacterial infection worldwide, colonising the gastric mucosa of approximately half of the world's population. Indeed, *H. pylori* is the leading cause of gastric cancer, and effective treatment of this infection is hindered by the ongoing rise in antimicrobial resistance. Thus, there is an urgent unmet medical need for novel strategies to prevent *H. pylori* infection.
Previous preclinical and clinical studies indicate that protection against *H. pylori* infection requires local gastric secretory IgA antibodies and mucosal T cell responses, including tissue-resident memory T cells. The development of a safe and efficacious mucosal subunit vaccine against *H. pylori* capable of inducing these responses, represents an easy, affordable solution to confer population-wide protection, but is hampered by the lack of well-tolerated, effective mucosal vaccine adjuvants. Further, incomplete knowledge of the gastric mucosal immune system renders it challenging to specifically tailor vaccination strategies for targeting this mucosal surface. Therefore, currently, the optimal vaccination strategies for inducing gastric cellular and humoral responses are unknown. However, crucial parameters include the route of vaccine administration and the mucosal adjuvants used. Here, we explore these parameters in different systemic prime-mucosal pull and mucosal-prime boost vaccination approaches, to elucidate the most effective vaccination strategies for inducing robust gastric mucosal immunity. Of note, intranasal immunisation of mice with a combination adjuvant formulation consisting of the invariant NK T cell ligand, α-galactosylceramide, and a novel chitin-derived polymer; 'C100', emerged as a promising approach for inducing gastric antigen-specific mucosal immunity.

Cancer patients have been shown to have a dysregulated immune system, leaving them more susceptible to infections and altering their response to vaccines. So far, the molecular and cellular mechanisms underlying these altered responses have not been well understood. To study this, we established a cohort of healthy persons and cancer patients, diagnosed with either multiple myeloma or non-small-cell lung cancer, who received the seasonal influenza vaccine and had blood drawn at different timepoints before and after. We hypothesise that either baseline differences or an altered immune response following vaccination lead to the divergent outcomes observed between the groups. To investigate this, we will assess data generated using high-dimensional cytometry, single-cell epigenomic profiling, cytokine profiling, and transcriptomics. Firstly, we will determine baseline differences between healthy donors and cancer patients using blood samples taken on day 0, before the administration of the vaccine. Secondly, using this data, we will attempt to identify a signature that can predict vaccine success measured by antibody levels and functionality. To do so, correlation and machine learning algorithms will be used. Lastly, samples taken on day 1, 7, and 30 will be used to track the initial immune response to the vaccine. This data will be integrated using MEFISTO and multifactorial response networks (MMRN) and changes over time between groups will be identified. In the long term, the knowledge gained through this study can contribute to the development of immune modulators to improve the vaccine response in cancer patients. Furthermore, vaccines can act as a surrogate for an infection and insights gained from this study can help to stratify individuals based on their risk for severe infection. This, in turn, can help to use limited resources in an optimal way by protecting the most vulnerable persons.

High affinity “non-cognate” ligand proteins as a new strategy for hepatitis C virus vaccine

Petr Kosztyu[1], Lucie Vankova[2], Eliska Kopecna[1], Shiv Bharadwaj[2], Milan Kuchar[2], Veronika Daniel Liskova[2], Hana Petrokova[2], Leona Raskova Kafkova[1], Petr Maly[2], Milan Raska[1]
[1]Department of Immunology, Palacky University Olomouc, Olomouc, Czech Republic; *[2]Institute of Biotechnology of the Czech Academy of Sciences, BIOCEV Research Center, Vestec, Czech Republic*

Purpose: Hepatitis C virus (HCV) is an enveloped, positive-sense, single-stranded RNA virus responsible for hepatitis C infection representing severe global health problem. Most of HCV-infected develop chronic infection. Among them, almost 1/4 may develop liver cirrhosis and 1/4 have chance of developing hepatocellular carcinomas. Number of therapeutic strategies with high efficacy is currently used, including direct-acting antivirals. Nowadays, no efficient HCV vaccine is available, which is caused by many reasons including genetic diversity of virus or shortage of animal models. However, number of promising vaccine candidates, such as mRNA, recombinant viral vectors, peptides, virus-like particles or DNA vaccines, undergo preclinical or clinical testing. Our novel strategy is based on the identification of proteins binding to a paratope of selected broadly neutralizing antibodies (bNAb), that could mimic cognate HCV envelope epitope and thus serve as an immunogen for eliciting neutralizing antibodies.
Methods: We tested this “non-cognate ligand” concept using highly complex combinatorial library derived from human myomesin-1 protein domain. By employing phage display, we identified proteins (binders) binding one of the selected anti-HCV bNAb and thus mimicking nature viral antigen. We immunized experimental mice with selected binders and analyzed immune response by ELISA and neutralization assays using set of HCV pseudotyped viruses of various genotypes (GT1-6) and levels of sensitivity for neutralizing antibodies.
Results: After immunization of experimental mice several binders elicited serum antibodies targeting HCV E2 envelope antigen analyzed by ELISA and neutralizing 5-6 of 15 HCV pseudoviruses, mostly of the genotype 1, 2 and 3 with the highest or medium sensitivity for neutralizing antibodies.
Conclusion: We confirmed that “non-cognate ligand” concept is effective to elicit antibodies neutralizing HCV pseudoviruses. This strategy seems to be a new promising approach in development of HCV and other infection preventing vaccine.

Design and development of a multi-epitope vaccine prototype against SARS-CoV-2

Andrey Tchorbanov[1], Nikola Ralchev[1], Iliyan Manoylov[1], Silviya Bradyanova[1], Nikolina Mihaylova[1], Irini Doytchinova[2], Slavka Tcholakova[3]
[1]Institute Of Microbiology Stephan Angelov, Bulgarian Academy Of Sciences, Sofia, Bulgaria; *[2]Faculty of Pharmacy, Medical University of Sofia, Sofia, Bulgaria*; *[3]Department of Chemical Engineering, Sofia University, Sofia, Bulgaria*

Purpose: SARS-CoV-2 caused COVID-19 pandemic overwhelms global health care. COVID-19 vaccination is crucial for preventing infection and controlling the pandemic. Multiple safe and effective vaccines are available worldwide.
Nanotechnology provides the opportunity for construction of modern transport devices such as nanoparticles for a variety of applications in the field of medicine. A novel experimental protocol for the formation of saponin-cholesterol-phospholipid nanoparticles of vesicular structure has been developed and applied to prepare stable nanoparticles using escin or glycyrrhizin as saponin.
Here, we describe the design and development of a next-generation multi-epitope vaccine for SARS-CoV-2, consisting of epitopes recognizable by T-cells.
Methods: Structure-based and sequence-based immunoinformatics methods were used to derive models for selection of MHC binders specific for the mouse strain used in the study among a set of human SARS-CoV-2 T-cell epitopes identified by convalescent patients with COVID-19. The binders were synthesized and included in a multi-epitope vaccine prototype.
The methods for nanoparticle construction include a sonication, thus forming stable unilamellar vesicles. Tests and assays for cell viability, erythrocyte hemolysis, flow cytometry, and fluorescent microscopy analyses have been performed.
Results: The immunogenicity of the vaccine prototype designed in the present study was tested on humanized-ACE2 transgenic B6.Cg-Tg(K18-ACE2)2Prlmn/J mice by *in vitro*, *in vivo*, and *ex vivo* immunoassays. The animals were immunized with a mix of predicted MHC-I, or MHC-II, or MHC-I/MHC-II peptide epitopes in CFA, and boosted with peptides in IFA. Immunization with SARS-Cov-2 epitopes remodels lymphocyte profile. A weak humoral response and significant production of IL-4 and IFN-γ from T cells were found after vaccination of the animals.
By selecting appropriate component ratios, stable and safe particles were formulated with respect to the tested bio-cells. The versatility of these nanoparticles allows for the encapsulation of various molecules, either within the vesicle interior for water-soluble components or within the vesicle walls for hydrophobic components. These particles are successful included into isolated mouse macrophages.

Conclusion: The multi-epitope vaccine prototype presented in this study demonstrates immunogenicity in mice and shows potential for human vaccine construction.

Development and functional analysis of inducible RNA agonists for spatiotemporal control of RIG-I activation

Sandra Anika Zeidler[1], Vivien Rose McKenney[2], Christine Wuebben[1], Thomas Zilliger[1;3], Janos Ludwig[1], Alexander Heckel[2], Gunther Hartmann[1]
[1]*Institute of Clinical Chemistry and Clinical Pharmacology, University Hospital Bonn, Bonn, Germany*; [2]*Institute of Organic Chemistry and Chemical Biology, Goethe University Frankfurt, Frankfurt am Main, Germany*; [3]*Department of Biomedicine, Aarhus University, Aarhus, Germany*

RIG-I (Retinoic Acid Inducible Gene I) is an intracellular innate immune receptor that detects 5'triphosphorylated blunt end double-stranded viral RNA. Upon activation, RIG-I initiates a type I interferon response, leading to an antiviral state of the cells. Based on the activity to induce an immunogenic cell death in tumor cells, RIG-I agonists are currently developed for cancer immunotherapy. Tumor-targeted delivery of RIG-I agonists is not yet available. Therefore, we aim at inducible targeted activation of systemically administered RIG-I agonists in tumor tissue. Another objective is to use targeted activation of RIG-I to achieve progress in antiviral prevention and therapy.
To investigate the spatiotemporal control of RIG-I activation, we developed synthetic inducible RNA agonists, which were tested in various experimental setups, including primary human immune cells, THP-1 cells, and several cancer cell lines. Additionally, we generated a reporter cell line expressing EGFP under the control of the interferon-beta promoter, enabling non-invasive tracking of RIG-I stimulation at the single-cell level.
We found that activation of our inducible RIG-I agonists within the cells stimulated the production of type I interferon, supporting our concept of inducible RIG-I activation. In the absence of activation, inducible agonists were inactive.
The newly developed inducible ligands allow the targeted activation of RIG-I. Spatiotemporal control of RIG-I activation *in vivo* is expected to improve the therapeutic efficacy of RIG-I agonists while minimizing systemic side effects. Our findings open new avenues for RIG-I-mediated cancer immunotherapy and pave the way for future clinical applications of inducible oligonucleotide agonists of innate immune pathways.

RIG-I like receptor activation by mRNA incorporating modified nucleosides

Katharina I. Maser[1], Katrin Ciupka[1], Bastian Putschli[1], Charlotte Hunkler[1], Martin Schlee[1], Eva Bartok[2], Gunther Hartmann[1], Thomas Zilliger[1]
[1]Institute of Clinical Chemistry and Clinical Pharmacology, University Hospital Bonn, Bonn, Germany; *[2]Institute of Hematology and Transfusion Medicine, University Hospital Bonn, Bonn, Germany*

The remarkable success of nucleoside-modified, *in vitro*-transcribed (IVT) mRNA vaccines against SARS-CoV-2 has brought mRNA technology to the medical mainstream, with more than 12 billion vaccine doses administered worldwide to date. Effective IVT mRNA translation requires the inhibition of innate immune RNA receptors. The co-transcriptional incorporation of modified nucleosides such as N1-methylpseudouridine (m1Ψ) and 5-methylcytosine (5mC) has been utilized to prevent activation of endosomal Toll-like receptors by transfected mRNA. While inhibitory effects on cytosolic RIG-I like receptor (RLR) activation through the reduction of double-stranded IVT byproducts have been suggested, a systematic investigation and direct comparison of nucleoside-modified mRNA sensing by the RLRs RIG-I and MDA5 has not been performed.
Here, we investigate the effects of commonly used modified nucleosides on the activation of MDA5 and RIG-I by IVT mRNA preparations and structurally defined RLR-agonistic RNAs. We quantify mRNA translation as well as activation of the type I interferon response in primary immune cells and gene-edited monocytic cell lines and analyze the differential contribution of MDA5 and RIG-I to the innate immune response against IVT mRNA.
Using this approach, we find that most nucleoside modifications have a less pronounced effect on RLR activation than previously reported, in particular on MDA5 activation. In addition, the effect of modified nucleosides on innate immune activation varies with both length and secondary RNA structure. Our results highlight the importance of rigorous assessment of innate immune stimulation for individual mRNA sequences and nucleoside modifications, with implications for the clinical effectivity of mRNA formulations and their potential inflammatory side effects.

Temperature regulates toll-like receptor signalling in macrophages

Ryan Knight[1], Wei Wang[1], Rebecca Coll[1]
[1]*Wellcome-Wolfson Institute for Experimental Medicine, Queen's University Belfast, Belfast, Northern Ireland*

The innate immune system is the primary response to infection and injury. Innate immune cells express pattern recognition receptors (PRRs), which recognise pathogen- and danger-associated molecular patterns. PRR signalling, such as that of Toll-Like Receptors (TLRs) may induce both local inflammation and systemic fever. Febrile temperatures directly inhibit pathogenic replication and regulate immune function – including lymphocyte recruitment and activation of $CD8^+$ cytotoxic T-cells. Peripheral sites exhibit reduced local temperatures, such as the nasopharynx at ~33°C and trachea at ~35°C, which is reflected in the optimal culture and infection temperature of upper respiratory viruses. However, the role of temperature itself on PRR signalling is poorly understood.
We incubated macrophages for 16 hours at physiologically-relevant temperatures – 34°C (peripheral), 37°C (core) and 39°C (febrile) with TLR-agonists LPS (TLR4), Pam3CSK4 (TLR1/2), R837 (TLR7) or Poly(A:U) (TLR3).
In murine immortalised bone-marrow derived macrophages (iBMDM), TLR-dependent TNF secretion was upregulated at 34°C, and downregulated at 39.5°C. This behaviour was inverted for CCL5, and IL-6 showed minimal variation. Observations were consistent at transcript level (RT-qPCR), and cell viability was unchanged. Of interest at 39.5°C, the inflammasome sensor NLRP3 was also downregulated at protein level. Similar responses were observed in primary human monocyte-derived macrophages (hMDMs).
We also evaluated TLR-induced interferon regulatory factor (IRF) induction using a THP-1 reporter cell line. The IRF response to TLR activation was strongly enhanced at 34°C and suppressed at 39.5°C. Despite this, western blotting demonstrated both free and conjugated ISG15 was downregulated at 34°C and upregulated at 39.5°C, illustrating the complexity of temperature regulation.
Our data demonstrate that subtle, physiological-range changes in temperature have significant effects on TLR signalling. This has substantial implications for our understanding of dysregulated innate immune signalling in autoimmunity. With substantial climate-driven changes in environmental temperature on the horizon, it is critical we understand the interactions between temperature and innate immunity.

Characterization of STING agonist-induced monocyte cell death reveals combination of apoptosis, pyroptosis and caspase 8 activation

Marketa Pimkova Polidarova[1;2], Andrea Brazdova[1;2], Ivan Hirsch[1;2], Klara Grantz Saskova[1;2]
[1]Department of Genetics and Microbiology, Faculty of Science, Charles University, Prague, Czech Republic; *[2]Institute of Organic Chemistry and Biochemistry of the Czech Academy of Sciences, Prague, Czech Republic*

Purpose: The cyclic-GMP-AMP synthase – stimulator of interferon genes (cGAS-STING) pathway senses double-stranded DNA in cytoplasm, a signal of invading pathogens or cell damage. The activation of the cGAS-STING pathway induces secretion of proinflammatory cytokines by immune cells that in turn modulate antiviral and antitumoral responses. Therefore, synthetic activators of the cGAS-STING pathway, such as STING agonists, are of therapeutic interest.
We have recently demonstrated that STING agonists not only trigger cytokine production in peripheral blood mononuclear cells (PBMCs) but also induce cell death of monocytes. Here we investigated the mechanisms of monocyte death in terms of apoptosis, pyroptosis and necroptosis.
Methods: STING agonist-induced monocyte cell death was assayed in PBMCs using multiparametric flow cytometry-based immunophenotyping combined with FAM-FLICA staining of active caspases, or phospho-flow for kinase activation. Additionally, we demonstrated the direct effect in enriched monocytes using reporter-based assays and western blot. We investigated the activation of caspases 3, 7, 1 and 8, along with kinases RIP1, RIP3 and pseudokinase MLKL. The cytokine secretion was analyzed with multiplex assay.
Results: PBMCs secreted a broad cytokine portfolio in response to STING agonist treatment. STING agonists triggered activation of apoptotic caspases 3 and 7 and pyroptotic caspase 1 in monocytes already upon 4-hour treatment. However, phosphorylation of RIP kinases or MLKL pseudokinase was not detected. STING agonists also induced caspase 8 activation and cleavage of RIP1 kinase.
Conclusion: Activation of the cGAS-STING pathway induces proinflammatory cytokine secretion in PBMCs, yet it is linked with a rapid monocyte cell death. STING agonist-induced monocyte cell death combines both apoptotic and pyroptotic processes, while necroptosis is not involved. We propose that necroptosis is blocked by active caspase 8, as RIP1 kinase cleavage fragment was detected upon STING agonist treatment. We suggest that the immunogenic monocyte cell death could be an important immunoregulatory mechanism for inhibition of proinflammatory cytokine secretion, and subsequently activation of secondary innate and adaptive immune processes.

The RIG-I/MAVS pathway promotes Wnt signaling-dependent osteogenic differentiation and calcification of human aortic smooth muscle cells

Madeleine Gräf[1], Paraskevi Vasileiadou[1], Sofia Soler[2], Thomas Zilliger[1], Eva Bartok[2], Gunther Hartmann[1]
[1]Institute of Clinical Chemistry and Clinical Pharmacology, University Hospital Bonn, Bonn, Germany; *[2]Institute for Experimental Haematology and Transfusion Medicine, University Hospital Bonn, Bonn, Germany*

Purpose: It has been already well established that erroneous detection of endogenous nucleic acids by the innate immune system drives pathogenic processes of autoimmunity. Along with that, gain-of function mutations in the innate immune receptor retinoic acid-inducible gene-I (RIG-I) are associated with Singleton-Merten Syndrome (SMS). This rare genetic disorder is characterized by dental and skeletal abnormalities, as well as early and severe aortic calcification. Based on this etiological connection, we aimed to understand the underlying molecular mechanisms connecting RIG-I activation and signaling to aortic calcification.
Methods: To examine the effect of RIG-I activation on interferon (IFN) response and osteoblastic differentiation processes, we stimulated primary human aortic smooth muscle cells (HAoSMC) with a specific RIG-I ligand and performed a qRT-PCR to quantify the relative gene expression. To induce calcification *in vitro*, we cultivated the cells in a pro-calcifying medium (PCM) and visualized the calcium depositions by staining with Alizarin Red.
Results: We found that RIG-I activation in HAoSMC did not only trigger a type I IFN response, but also increased mRNA levels of the osteogenic factors bone morphogenic protein 2 (BMP-2), bone sialoprotein 2 (BSP2) and osteopontin (OPN). Moreover, HAoSMC cultivated in PCM showed production of calcium depositions. Additional RIG-I stimulation in PCM-cultivated cells showed an earlier and stronger process of calcification. Lack of RIG-I or its downstream signaling molecule mitochondrial antiviral-signaling adaptor protein (MAVS) decreased the expression of interferon-stimulated genes and osteogenic factors. Calcification was also reduced in both RIG-I- and MAVS-deficient cells. In addition, we could show that Frizzled-5 (FZD5) and Ras GTPase-activating protein-binding protein 1 (G3BP1), two factors that are connected to the Wnt-signaling pathway, play a major role in these calcification processes, as loss of these molecules resulted in a loss of calcification.
Conclusion: Our results demonstrate that RIG-I and the downstream signaling molecule MAVS are involved in the inflammatory process that drives aortic pathogenesis. In addition, we could show that this pathway is connected to the Wnt-signaling pathway, which seems to have a crucial role in aortic calcification. Further studies are required to identify the underlying molecular mechanisms in greater detail.

Model for the study of drug hypersensitivity based on Bucilamine and the HLA-DRB1*08:02 allele in Colombian Amerindian populations.

Carlos Parga-Lozano[1;2], Nohemí Esther Santodomingo Guerrero[1]
[1]Social Healt IPS, Barranquilla, Colombia; *[2]Fundación Universitaria del Área Andina, Valledupar, Colombia*

Purpose: Allergic diseases and hypersensitivity reactions are common disorders that consist of an extensive genetic component that includes the Major Histocompatibility Complex molecules, which have certain alleles associated with the development of hypersensitivity to medications, among which are the HLA-DRB1*08:02 allele as a predisposing factor for hypersensitivity to Bucillamine; This drug being the starting point for the study of the relationship between hypersensitivity reactions to medications and the expression of certain MHC alleles. Objective: To find the existing relationship between drug hypersensitivity and the expression of the specific allele in Amerindian populations of the Sierra Nevada de Santa Marta and to suggest the application of the proposed methodological model in studies that seek to relate drug allergies with previously identified alleles.
Methods: A systematic search for information was carried out in certain databases such as Sience, ScienceDirect, Elsevier and Pubmed, the frequencies obtained were tabulated and organized according to their expression to later be analyzed using the MEGA7 software.
Results: A significant frequency of the HLA-DRB1*08:02 allele in the Ijka (61.7%), Arhuaco (41.5%), Kogi (17.9%) and Arsario (15%) populations.
Conclusion: Careful management of Bucilamine and drugs molecularly similar to it is recommended in susceptible Amerindian populations. At the same time, the use of the proposed model is suggested for the study of other drugs that can trigger allergic reactions based on the expression of HLA alleles.

Assessing the impact of SERPING1 gene exons 5 and 6 duplications on mRNA expression in type 1- Hereditary Angioedema.

Andrea Ferranti[1], Silvia Romero Chala[1], Esther Vergara Prieto[1], Jose Antonio García Trujillo[1], María Bravo García-Morato[2], Luis Miguel Fernández Pereira[1]
[1]*Complejo Hospitalario Universitario de Caceres, Caceres, Spain*; [2]*Hospital Universitario La Paz, Madrid, Spain*

Objective: This study aimed to evaluate the effect of duplications within exons 5 and 6 of the SERPING1 gene on mRNA expression in a patient diagnosed with Type 1 Hereditary Angioedema (HAE-1).
Introduction: HAE-1 is a rare genetic disorder characterized by recurrent and unpredictable swelling episodes due to aberrations in the C1 inhibitor (C1-INH) protein. The molecular landscape of the disorder encompasses various genetic variants, including missense and nonsense mutations, deletions, duplications, and splice defects in the SERPING1 gene. Approximately 8% of these variants are large deletions or duplications, yet their impact on mRNA expression remains largely unexplored.
Methods: We present the case of a 44-year-old female patient diagnosed with HAE-1. Genomic DNA underwent Sanger sequencing for SERPING1 gene mutations, revealing no pathogenic variants. Subsequent MLPA analysis identified a duplication spanning exons 5 and 6. To delineate the variant boundaries, Reverse-Transcription PCR (RT-PCR) was performed. PBMCs were isolated and stimulated with interferon-gamma to induce C1-INH gene expression. RNA extraction and cDNA synthesis were performed, followed by RT-PCR using SERPING1-specific primers. Quantitative PCR (qPCR) analysis was employed to measure the relative expression of C1-INH mRNA transcripts, normalized to reference genes, enabling comparative analysis between patient and control samples.
Results: Contrary to expectations, RT-PCR analysis only amplified the wild-type allele, indicating potential aberrant mRNA degradation of the duplicated allele. Quantitative analysis revealed that mRNA expression of the patient was significantly reduced (57%) compared to healthy controls (100%), indicating a significant decrease in C1-INH mRNA production and that only mRNA from the wild-type allele was being amplified.
Conclusions: Our findings suggest that genetic duplications in SERPING1 gene may disrupt mRNA integrity, leading to the activation of nonsense-mediated decay (NMD), a mRNA degradation mechanism activated upon detection of premature termination codons (PTC) in transcripts. Therefore, the complete absence of transcripts from the duplicated allele could be attributed to the activation of this degradation mechanism. This hypothesis is based on the observation that genetic duplications often disrupt mRNA integrity, potentially leading to PTC generation and subsequent degradation by NMD, as previously suggested for other genetic variants of the SERPING1 gene (Colobran et al. 2014).

High risk PNPLA3 rs738409 single nucleotide polymorphism is associated with higher concentrations of CCL2 in alcoholic end-stage liver disease

Tomislav Kelava[1;2], Ivan Budimir Bekan[3], Pavao Planinić[4], Dino Šisl[1], Alan Šućur[1;2], Ana Bainrauch[3], Sara Aničić[1;2], Katerina Zrinski Petrović[1;2], Nataša Kovačić[1;2], Danka Grčević[1;2], Vibor Šeša[5], Anna Mrzljak[1;5]
[1]School of Medicine, University of Zagreb, Zagreb, Croatia; *[2]Croatian Institute for Brain Research, Zagreb, Croatia*; *[3]Merkur University Hospital, Zagreb, Croatia, Zagreb, Croatia*; *[4]University of Mostar School of Medicine, Mostar, Bosnia and Herzegovina*; *[5]Croatian Referral Center for Chronic Liver Diseases, University Hospital Center Zagreb, Zagreb, Croatia*

Purpose: PNPLA3 rs738409 single nucleotide polymorphism (G allele) has been pointed out as the most robust genetic predictor of severe metabolic dysfunction-associated steatotic liver disease (MASLD), associated with an increased risk for liver-related events such as decompensation or hepatocellular carcinoma (HCC). In the present research, we have analysed the association between the PNPLA3 genotype and the concentration of 13 proinflammatory cytokines in patients with alcoholic end-stage liver disease (ESLD).
Methods: Upon Ethical approval, DNA was isolated from the whole blood, and patients (106 transplant candidates with alcoholic ESLD, without HCC as determined by explant histology, and sex and age matched control patients) were genotyped for PNPLA3 rs738409 by PCR using the TaqMan assays. Concentrations of 13 selected cytokines (IL-1β, IFN-α2, IFN-γ, TNF-α, CCL2, IL-6, IL-8, IL-10, IL-12p70, IL-17A, IL-18, IL-23, IL-33) were determined in plasma by flow cytometry using the commercially available assay (LEGENDplex™ Human Inflammation Panel 1).
Results: Comparison of patients with ESLD and healthy controls revealed that there is a statistically significant ($p<0.001$, Mann Whitney test) difference in concentration of 11 cytokines (IL-1β, IFN-α2, IFN-γ, TNF-α, CCL2, IL-6, IL-8, IL-10, IL-12p70, IL-23, IL-33). There was no statistically significant difference in the concentration of IL-17 and IL-18. Forty patients with ESLD had CC genotype, 40 were heterozygotes and 26 had GG genotype, there was no difference in sex and age between the genotypes. Patients with the GG genotype had a significantly higher concentration of CCL2 (213 (136 - 265) pg/mL, median with interquartile range) than patients with GC (150 (93 - 238)) and CC genotype (139 (117 - 186)), $p<0.001$ (Kruskal Wallis test followed by Mann Whitney). No significant association was found for the remaining 12 measured cytokines ($p>0.05$ for all analyses).
Conclusion: Higher concentrations of CCL2 are associated with the PNPLA3 GG genotype in patients with alcoholic ESLD. The possible contribution of CCL2 to the development of liver-related events in alcoholic liver disease will be further evaluated. The work was supported by Croatian Science Foundation (IP-2022-10-2285, UIP-2017-05-1965, IP-2020-02-2431, DOK-2021-02-6365).

Follow-up with digital PCR of a patient with VEXAS syndrome treated with azacitidine

Alba Exposito Bey[1], Alicia Jurado Orozco[1], Carmen Morales Garcia[1], Marco Montes Cano[1], María Francisca González Escribano[1], José Raúl García Lozano[1]
[1]*Department of Immunology, Seville, Spain*

VEXAS (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) syndrome is a recently identified, adult-onset, autoinflammatory recessive X-linked disorder. It is caused by somatic mutations in the UBA1 (ubiquitin-like modifier activating enzyme 1) gene in monocytes. This enzyme plays a crucial role in the activation of ubiquitin, a protein involved in intracellular protein degradation and cellular homeostasis. VEXAS syndrome is characterized by rheumatological manifestations such as recurrent fever, skin and lung inflammation, auricular and nasal chondritis, vasculitis, deep vein thrombosis and arthralgia.
Most pathogenic mutations associated with VEXAS syndrome involve substitutions of methionine-41, with c.122T>C (p.Met41Thr) being around half of them. One treatment approach involves targeting and eliminating the UBA1-mutated monocyte population. However, the optimal standard of care for this condition is still undefined. Treatment with azacitidine, a medication that has been reported to maintain a hematological response and provide optimal symptom control, has shown to be promising in this regard.
The purpose of this work was to find a way to measure the levels of UBA1 mutations in patients with VEXAS and to establish whether the treatment with azacitidine reduces that amount. A protocol to use digital PCR (dPCR) has been developed to follow-up the levels of the main UBA1 mutation. Two probes have been designed: one probe targeting the wild-type gene (targeted with VIC probe) and another probe targeting c.122T>C (targeted with FAM probe). With the aim of validate this technique, we elaborated a calibration line using blood cells samples: one from a patient with the mutation and another from a patient with the wild type gene (both genes analyzed with next generation sequencing (NGS), obtaining R^2=0.99 and detection limit of 0.1%).The protocol was used to follow-up a patient who started the treatment with azacitidine, finding out a diminution of the mutated cells level (from 77% to 65% of mutated cells after the first azacitidine dose).
In conclusion, dPCR has been proved to be effective in detecting and monitoring the percentage of UBA1 mutated cells and is thus a way of quantifying the reduction of those mutated cells in patients with VEXAS receiving treatment with azacitidine.

New scenario: interleukin-2 receptor gamma gene mutation as a variant of uncertain significance

Vivian Lizeth Stewart DelCid[1], Ernesto Roldan Santiago[1], Eulalia Rodríguez Martín[1], Elena Manterola Navarro[1], Rafael Rodriguez Ramos[1], José Luis Veiga González[1], Celia Ferrez Hernández[1], Daniel Albert Mendoza Bravo[1], Ivan Garcia De La Torre[1], Alexander Rodero Romero[1], Patricia Fernández San José[1], Ana De Andres Martin[1], Rebeca Perez de Diego[2]
[1]Hospital Universitario Ramon y Cajal, Madrid; *[2]Hospital Universitario La Paz, Madrid, Spain*

Introduction: The interleukin-2 receptor gamma (IL2RG) gene is involved in lymphocyte growth and differentiation. IL2RG mutations are associated with moderate or severe X-linked combined immunodeficiency, characterized by the absence of T and NK lymphocytes. Variants in this gene can be reported as uncertain significance when no validated association with the patient's phenotype is found.
Methods: Genetic study was performed using a Primary Immunodeficiency panel by next-generation sequencing.
Results: We report the case of a 50-year-old patient with a history of recurrent sinusitis. He presented Hodgkin's lymphoma with nodular sclerosis at the age of 28 and diffuse large B cell non-Hodgkin lymphoma associated with Epstein Barr virus at the age of 46, treated with chemotherapy and local radiotherapy, achieving complete remission in both cases. Subsequently, he developed a relapse of diffuse large B-cell lymphoma at the age of 49, treated with chemotherapy and autologous transplantation. In the study of the first lymphoma, the patient presented sustained IgG, IgA and IgM hypogammaglobulinemia, decreased immunoglobulin production in vitro, absence of response to vaccines and decreased memory B lymphocytes. In view of these data, common variable immunodeficiency was suspected and substitutive treatment with intravenous immunoglobulins was started. In addition, CD4/CD8 ratio was inverted with $CD4^+$ T cell lymphocytopenia, requiring prophylactic antibiotics. Maintaining normal values of NK cells. CD132 (common gamma chain) expression in NK, B and CD4-CD8 T lymphocytes showed no alterations compared to a healthy control. The genetic study detected a heterozygous variant in TNFRSF13B gene (exon 4, c.542C>A), with pathogenicity prediction, associated with common variable immunodeficiency type 2, and a hemizygosis variant in IL2RG gene (exon 7, c.918C>A) of uncertain significance.
Conclusion: It is important to report new variants, which require future functional validation studies, to discover new scenarios with less severe forms of the disease. As well as if its association with other mutations could modify the expected phenotype of an immunodeficiency.

HLA polymorphism in *Leishmania infantum* infection

Juan Francisco Gutiérrez-Bautista[1], Maria del Carmen Barrera Aguilera[1], Beatriz Fernandez Perea[1], Lucía Ballesta Alcaraz[1], Ana Marin[1], Mónica Bernal[1], Pilar Jimenez[1], Jose Ramón Vilchez[1], Miguel Ángel López-Nevot[1]
[1]*Hospital Universitario Virgen de las Nieves, Granada, Spain*

Leishmania infantum infection is a zoonotic disease with a high incidence worldwide. The Mediterranean coast of Spain, located in the south of the country, is an endemic area. The infection produces a wide clinical spectrum, ranging from asymptomatic to patients who develop visceral disease or different varieties of cutaneous disease. The life cycle of the parasite is vectored by the female mosquito of the genus Phlebotomus. After the bite, *L. infantum* infects the monocytic-macrophagous series found in the tissues and replicates in them producing the disease. At the immunogenetic level, no genetic association with risk or protection against L. infantum infection has been described. Therefore, we propose a study that recruits four different cohorts to find human leukocyte antigen (HLA) alleles or haplotypes that may be associated with *L. infantum* infection. The cohorts collected were as follows: i) patients with visceral or cutaneous disease (SP), ii) patients with asymptomatic infection (AP), iii) cohabitants of patients with visceral or cutaneous disease (cohabitants), and iv) control group not suffering from the disease (control). After recruitment, we performed HLA typing of each group by high-resolution genotyping of HLA class I (A, B, and C) and II (DRB1 and DQB1). We performed the comparison at the allelic and haplotypic levels. In addition, we compared the frequencies of patients homozygous or heterozygous for the Bw4/Bw6 epitopes, as well as the frequency of the C1 and C2 groups of the HLA-C locus. The results showed that the HLA-B*38 allele (Pc=0.026) was increased in the cohabitant compared to the control group. On the other hand, haplotype 18.3 (HLA-A*02:01 ~B*18:01 ~C*05:01 ~ DRB1* 11:02 ~DQB1*03:01) was more frequent in patients with symptomatic disease than in the control group. The same was true for haplotype 60.3 (HLA-A*02:01 ~ B*40:01 ~C*03:04 ~DRB1* 13:02 ~DQB1*06:04). However, the latter data do not support Bonferroni correction and significance is lost. In conclusion, we show a possible protective role of the HLA-B*38 allele to infection, while haplotypes 18.3 and 60.3 may be related to the risk of developing symptomatic disease. This may help to better understand the disease and the possible development of vaccines.

Impaired reprogramming of the autophagy flux in maturing dendritic cells from Crohn's disease patients with core autophagy gene-related polymorphisms

Gaelle Quiniou [1], Leslie Andromaque [1], Rémi Duclaux-Loras[1], Christophe Viret[1], Stéphane Nancey[2], Mathias Faure[1;3], Aurore Rozieres[3]
[1]CIRI INSERM U1111, Lyon, France; *[2]CIRI INSERM U111, Lyon, France*; *[3]Université Claude Bernard Lyon 1, Lyon, France*

Crohn's disease (CD) is an inflammatory bowel disease whose pathogenesis involves inappropriate immune responses towards gut microbiota on genetically predisposed backgrounds. Notably, CD is associated with single-nucleotide polymorphisms affecting several genes involved in autophagy, the catabolic process that ensures the degradation and recycling of cytosolic components and microorganisms. In a clinical translation perspective, monitoring the autophagic activity of CD patients will require some knowledge on the intrinsic functional status of autophagy. Here, we focused on monocyte-derived dendritic cells (DCs) to characterize the intrinsic quantitative features of the autophagy flux. Starting with DCs from healthy donors, we documented a reprogramming of the steady state flux during the transition from the immature to mature status: both the autophagosome pool size and the flux were diminished at the mature stage while the autophagosome turnover remained stable. At the cohort level, DCs from CD patients were comparable to control in term of autophagy flux reprogramming capacity. However, the homozygous presence of *ATG16L1 rs2241880 A>G* (T300A) and *ULK1 rs12303764 (G/T)* polymorphisms abolished the capacity of CD patient DCs to reprogram their autophagy flux during maturation. This effect was not seen in the case of CD patients heterozygous for these polymorphisms, revealing a gene dose dependency effect. In contrast, the *NOD2 rs2066844 c.2104C>T* (R702W) polymorphism did not alter the flux reprogramming capacity of DCs. The data, opening new clinical translation perspectives, indicate that polymorphisms affecting autophagy-related genes can differentially influence the capacity of DCs to reprogram their steady state autophagy flux when exposed to proinflammatory challenges.

Investigation of the role of the toll-like receptor 3 (TLR3) Leu412Phe (TLR3 L412F) single nucleotide polymorphism in the pathogenesis of long COVID

Thomas J. Butler[1;2], Shane O'Brien[1;2], Luka Moric[1;2], Muireann Carey[1;2], Zara Cunningham[1;2], Seamas Donnelly[1;2], Michelle E. Armstrong[1;2]
[1]Trinity College Dublin, Dublin, Ireland; *[2]Tallaght University Hospital, Tallaght, Ireland*

Purpose: the role of the *TLR3* L412F (rs3775291) single nucleotide polymorphism in the pathogenesis of long COVID has not been reported to date. TLR3 is central to the innate immune response against a number of viruses, including SARS-CoV-2. *TLR3* L412F has previously been shown to reduce cellular TLR3 activity and has been implicated in acute COVID-19 disease severity.
Methods: we carried out a case-control study to investigate the frequency of *TLR3* L412F in long COVID patients (n=183) and healthy controls (n=263). In addition, we investigated the effect of *TLR3* L412F on pulmonary function (% predicted FVC, DLCO, MIP and MEP), serum ACE and vitamin D levels, and olfactory function (SNIFF score) in long COVID patients.
Results: our case-control study observed no significant association between *TLR3* L412F and the development of long COVID. Furthermore, *TLR3* L412F had no significant effect on pulmonary function, serum ACE and vitamin D levels, or olfactory function in long COVID patients.
Conclusion: This is the first study to report the effect of *TLR3* L412F in long COVID patients. This study suggests that *TLR3* L412F does not significantly contribute to long COVID pathogenesis.

The role of NFκB inducing kinase in regulatory T cells and tissue regulatory T cell subtypes

Zeynep Ergün[1], Ari Waisman[1]
[1]*University Medical Center of Johannes Gutenberg University Mainz, Mainz, Germany*

Purpose: Investigating the role of the non-canonical NFκB pathway, particularly NFκB-inducing kinase (NIK), in regulatory T cells (Tregs) and their subtypes across various tissues, with a focus on understanding its impact on Treg function and its involvement in inflammatory conditions.
Methods: Our study employed various approaches, including experimental models and single-cell data analysis. The investigation encompassed the role of NIK in thymically-derived and peripherally induced cells. We conducted assessments of NIK's effect in peripheral tissues and secondary lymphoid organs using experimental animal models. An alternative model of T cell transfer colitis was utilized to investigate NIK's role in inflammatory conditions. Furthermore, single-cell data were generated and analyzed through RNA sequencing and T-cell receptor sequencing.
Results: NIK deletion in all T cells led to a decrease in thymic Treg cell precursor numbers, whereas specific NIK deletion in Tregs didn't produce the same effect. Moreover, NIK was found to play a notable role in maintaining Helios$^+$ Treg subtypes and in modulating the suppressive capacity of Tregs in the periphery. In the colon, NIK signalling appeared to be important for sustaining colonic Helios$^+$ Tregs and facilitating their suppressive function. Additionally, NIK signalling was observed to be involved in the maintenance of ST2$^+$ Tregs in the visceral adipose tissue, which are critical for tissue repair and regeneration. Conversely, NIK overexpression resulted in an increase in specific Treg subtypes in the colon and induced an inflammatory phenotype under steady-state conditions.
Conclusion: Our study highlights the influence of NIK and the non-canonical NFκB pathway on Treg development and function across diverse tissues, emphasizing their crucial roles. Further investigations, including single-cell sequencing analyses and multiparameter flow cytometry, are needed to unravel the intricate mechanisms underlying NIK signalling in Tregs and its therapeutic implications. Integration of T cell transfer colitis model with single-cell data analysis aims to deepen our understanding of NIK's effects on Tregs in vivo. Ongoing investigations into tissue-specific Treg markers such as ST2 and KLRG1 seek to elucidate molecular pathways influenced by NIK signalling. This study contributes significantly to our comprehension of NIK signalling in Tregs and its potential therapeutic implications.

Hybrid SARS-CoV-2 immunity induces durable cellular pan-coronavirus immunity also in the elderly

Lucie Loyal[1;2], Julian Braun[1;2], Andreas Thiel[1;2]
[1]Charité-Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Berlin, Germany; *[2]Si-M / "Der Simulierte Mensch" a science framework of Technische Universität Berlin and Charité - Universitätsmedizin Berlin, Berlin, Germany*

Different vaccines and SARS-CoV-2 variants resulted in highly diverse hybrid immunity in the global population. Age, virus mutations, comorbidities, and other causes of compromised immunity influence the degree of protection in the individuals. Whilst antibody binding is often impaired by escape mutations, T cell responses are less affected and critical for long-term protection. Conserved pan-coronavirus-epitopes might further reduce the risk of T cell escape and provide immunity against potential future coronavirus spillovers. Consequently, monitoring cellular responses is critical to provide the right recommendations regarding vaccination schemes and virus containment measures especially in susceptible individuals. We utilized peptide pools of dominant SARS-CoV-2-specific and dominant pan-coronavirus epitopes with or without spike-specific epitopes to distinguish infection and vaccination status in T cell-based assays and to assess pan-coronavirus immunity. Pan-coronavirus-specific T cells are ubiquitous, boosted especially by combinations of infection and vaccination, and long-living. Their frequencies and TCR avidities are comparable throughout age but display reduced polyfunctionality in the elderly.

Role of co-stimulatory molecules expressed by dendritic cells in formation of immunological synapse

Vincent Gloe[1]
[1]*Biotechnology Institute Thurgau, Kreuzlingen, Switzerland*

Dendritic cells (DCs) play a key role in the adaptive immune response, as they activate T cells by the formation of the immunological synapse and it's well known, that the DC has substantial influence on the executed immune response by varying the presented co-stimulatory receptors and secreted cytokines.
We know that that the arrest of scanning T-cells by DCs is not a "find and stop" scenario. They need multiple transient contacts with target cells prior to forming a stable synapse. The nature of these transient contacts and their duration plays a decisive role in the outcome of T-cell activation. However, to this day, the mechanism behind the arrest of scanning T-cells is still not fully understood.
Interestingly, maturation of DCs is important for the stability of these contacts. This suggests that co-stimulatory molecules, which are induced upon DC maturation, might regulate the formation of the immunological synapse. The fact that arrest and activation does not uniquely relies on adhesive interaction further suggests a potential role for the engagement of co-receptors in this process.
To investigate the influence of different co-receptors and cytokines presented by DCs on the arrest and subsequent synapse formation of scanning T-cells, we developed a quantitative live cell-imaging assay. It relies on the tracking of motile T-cells on a monolayer of CHO cells, which consists of a few cells that express a cognate peptide linked to MHC and co-stimulatory molecules, surrounded by many wild-type cells. This approach allows the quantification of the influence of given co-stimulatory molecules on T cell arrest and synapse formation.
Our data reveal diverse effects of TNFR family members on the propensity of T cells to establish stable contacts with APCs. While CD70 expression had no effect on CD4 or CD8 T cell arrest, CD40 increased the probability of experienced CD4 T cells to form immunological synapses. Conversely, presence of 4-1BB-L on pMHC-I expressing cells appeared to decrease the probability of naïve CD8 T cells to form stable contacts. Altogether, our data suggest that expression of specific TNFRs at the surface of cells presenting antigenic peptides regulates T cell arrest and synapse formation.

Ligand-independent signalling of T cell inhibitory receptors.

Sidrah Naseem[1], Zhengmin Yang[1], Andrea Nunez[1], Jesse Goyette[1]
[1]*The University of New South Wales (UNSW), Sydney, Australia*

Purpose: Cytotoxic CD8+ T cells play a pivotal role in eradicating intracellular pathogens and malignant cells, providing long-term protective immunity. The activation and regulation of these cells are tightly controlled by a delicate balance between activating and inhibitory receptor signalling. Tumor cells exploit inhibitory pathways by overexpressing ligands for inhibitory receptors, evading immune surveillance. A recent study has also unveiled the existence of tonic signalling (also known as ligand-independent signalling) by PD-1. In this study, we extend our understanding of inhibitory receptor signalling by examining tonic signalling in other immunotyrosine based inhibitory motif-containing inhibitory receptors, specifically KIR2D1 and LILRB1 and their effect on early T cell activation. Furthermore, we also compare the potency of ligand-induced inhibitory signalling among all three inhibitory receptors.
Methods: We have used a system that allows us to precisely manipulate the cell surface ligand densities for both activatory and inhibitory receptors on antigen-presenting cells. This enables us to investigate inhibitory receptor signalling in the absence of ligands (tonic signalling) and the level of inhibitory ligands necessary to inhibit different strengths of activation (inhibitory potency).
Results: Our results confirm that PD-1 exhibits ligand-independent tonic signalling, and that this activity is mediated by the cytoplasmic tail. However, we find no evidence of tonic signalling in KIR2D1 and LILRB1, indicating that ligand-independent inhibitory signalling may be specific for PD-1. Furthermore, distinct differences in the ligand-dependent potency of inhibition were observed, with PD-1 demonstrating the highest inhibitory efficacy compared to LILRB1 and KIR2D1. We also employed endogenous PD-1 ligand (PD-L2) to validate receptor signalling while maintaining physiological receptor-ligand binding properties.
Conclusion: In conclusion, the study provides valuable insights into the intricate interplay between activating and inhibitory receptors on T cells which significantly influences the outcome of T cell responses. The knowledge gained can be applied to enhance the efficacy of future T cell-based immune therapies, particularly in the context of cancer treatment.

Histone deacetylases 1 and 2-mediated control of intestinal CD4+ T cell immunity

Phuc Tran Huu[1], Rafael de Freitas e Silva[1], Teresa Preglej[1;2], Moritz Madern[1], Birgit Niederreiter[2], Sara Catarina Da Silva Miranda[3], Caroline Lassnig[3], Birgit Strobl[3], Michael Bonelli[2], Wilfried Ellmeier[1]

Some effector CD4+ T cell subsets display cytotoxic activity, thus breaking the functional dichotomy of CD4+ helper and CD8+ cytotoxic T lymphocytes. However, molecular mechanisms regulating CD4+ cytotoxic T lymphocyte (CD4+ CTL) differentiation are poorly understood. We previously showed that the combined activity of histone deacetylases 1 and 2 (HDAC1 and HDAC2) are crucial for maintaining CD4 lineage integrity and that HDAC1-HDAC2 levels are key determinants of CD4+ CTL differentiation in lymph nodes and spleen. However, it is not known whether HDAC1/HDAC2 are also required for the proper differentiation, regulation and function of intestinal CD4+ CTLs. In order to address this question, we are performing a comprehensive analysis, including flow cytometry, immunohistology and scRNA-seq approaches, of intestinal T cells from mice with a deletion of both Hdac1 and one Hdac2 alleles ($HDAC1^{cKO}$-$HDAC2^{HET}$). We are characterizing CD4 and CD8 subset composition as well as transcription factor and cytokine expression. Our preliminary results indicate alterations in intestinal $CD4^+$ and $CD8^+$ $TCR\alpha\beta^+$ T cells composition within the small intestine intraepithelial lymphocyte (SI-IEL) and lamina propria (SI-LPL) populations at steady-state. These data suggest that $HDAC1^{cKO}$-$HDAC2^{HET}$ mice have a distinct intestinal T cell composition in comparison to wild-type mice that might result in a compromised function of intestinal immunity in homeostasis and during infection with Citobacteria *rodentium*. Data from our ongoing study will be presented.

Two Step Selection for Bias in β Chain V-J Pairing

Yoram Louzoun[1], Reut Levi[1]
[1]*Bar Ilan University, Ramat Gan, Israel*

The β chain rearrangement in T cells is a two-step process where first D_β and J_β bind, and only then V_β is joined to the complex. We here show that the frequency of human and mouse V_β J_β combinations deviates from the one expected based on each gene usage frequency. This bias is observed mainly in functional (F) rearrangements, but also slightly in non-functional (NF) rearrangements. Preferred V_β J_β combinations in F clones are shared between donors and samples, suggesting a common structural mechanism for these biases in addition to any host-specific antigen-induced peripheral selection. The sharing holds even in clones with J_β1 that share the same D_β1 gene. V_β J_β usage is correlated with the Molecular Weight and Isoelectric Point in F clones. The pairing is also observed in the Double Positive cells in mice thymocytes, suggesting that the selection leading to such a pairing occurs before thymic selection. These results suggest an additional structural checkpoint in the beta chain development prior to thymic selection during the T cell receptor expression. Understanding this structural selection is important for the distinction between normal and aberrant T cell development, and crucial for the design of engineered TCRs.

Blockade of PD-1 and costimulation of the CD27 pathway drive the Eomes-dependant proliferation of CD8 T cells with an exhausted phenotype

Solange Dejolier[1], Marie Le Moine[2], Hacene Dreidi[1], Lune Cassart[1], Sébastien Denanglaire[1], Soren Temara[1], Guillaume Oldenhove[1], Stanislas Goriely[1;2], Fabienne Andris[1]
[1]Immunobiology Lab, Institut de Biologie et de Médecine Moléculaires, Université Libre de Bruxelles (ULB), Gosselies, Belgium; *[2]Institute of Medical Immunology, Université Libre de Bruxelles (ULB), Gosselies, Belgium*

Immune checkpoint blockade (ICB) therapies have strikingly advanced the oncological treatments over the past decade. This includes antagonistic and agonistic antibodies that block inhibitory or activate costimulatory receptors, thus modulating effector T cells function. However, it is observed that many cancer patients treated with ICB develop immune-related adverse events (IRAEs) that can force patients to arrest their treatment. A better understanding of the mechanisms underlying IRAEs could help counteracting them and avoiding ICB treatments disruption. Preclinical studies have shown promising results with synergistic blockade of PD-1 and activation of members of the TNF receptor superfamily such as CD27. Our project aims at carefully studying the roles of these two pathways in homeostatic conditions and at understanding the impact of in vivo mAb treatments that target them. We showed that C57BL/6 mice treated with blocking PD-1 mAb develop proliferating T cells expressing exhaustion markers in the liver, which is dependent on the transcription factor Eomes. A scRNA-seq/TCR-seq on PD-1^{KO} mice showed that exhausted T cells induced in the liver are oligoclonal and resident memory T cells (T_{RM})-derived. We also showed that prolonged stimulation of the CD27 signalling pathway reduces the T_{RM} subset differentiation while driving the expansion of an exhausted-like (Tex) population. Interestingly, $CD27^{KO}$ mice expressed more steady-state hepatic T_{RM}, which do not develop into Tex cells upon PD-1 blockade, thus suggesting an interplay between the two signalling pathways for Tex cells development. We also showed that, despite inducing similar exhausted-like populations, individual treatments induced distinct phenotypic profiles among T cells, suggesting that their effects are partly mediated by different factors. Accordingly, combination therapy (PD-1 blockade and agonist anti-CD27 mAbs) resulted in increased exhausted CD8 T cells expansion, compared to individual treatments. Overall, our results suggest a role for PD-1 and CD27 pathways in liver memory T cells homeostasis.

Study of TSLP signaling through dendritic cells in driving skin T cell responses

Marine Guivarch[1], Pierre Meyer[1], Pierre Marschall[1], Thien-Phong Vu Manh[2], Pierre Hener[1], Justine Segaud[1], Beatriz Germán Falcón[1], Marc Dalod[2], Mei Li[1]
[1]Institut de Génétique et de Biologie Moléculaire et Cellulaire (IGBMC), CNRS UMR 7104 – INSERM U 1258 – Université de Strasbourg, Illkirch Graffenstaden, France; *[2]Centre d'Immunologie Marseille-Luminy (CIML), CNRS UMR 7280 – INSERM U 1104 -Aix-Marseille Université UM2, Marseille, France*

Purpose: Atopic dermatitis (AD) is a chronic inflammatory skin disease that affects up to 20% of children and 3-5% of adults worldwide. AD typically presents an aberrant type 2 immune response, shown by skin infiltration of T helper 2 (Th2) cells, eosinophils and basophils, accompanied Tfh cell response and an elevation of blood immunoglobulin E levels. The keratinocyte-derived cytokine TSLP has been recognized to play a key role in AD pathogenesis, but how TSLP signals through its receptor (TSLPR) expressed on dendritic cells (DCs) to drive T cell response remain to be investigated.
Methods: We used a TSLP overexpressing AD model originally established by the lab. We employed DC-selective knock-out mouse lines and gene reporter mouse tools, combined with flow cytometry and single cell transcriptomic analyses, and DC-T cell coculture to investigate TSLP-driven T cell responses.
Results: We demonstrated that TSLP-TSLPR signaling in DCs drives simultaneously Th2 and regulatory T cell (Treg) responses. We showed that TSLP-activated DCs upregulated their expression of the costimulatory molecule OX40L and took use of our newly generated OX40L knockout mice to characterize the implication of OX40L from DC in Th2/Treg responses, as well as OX40L-reporter mice to identify and characterize these DCs from surface marker expression to transcriptomic profiles.
Conclusions: Our results provide insights on how skin TSLP signals through DCs to drive different T cell responses.

Purpose: To avoid viral adaptation to vaccines, it is critical to identify and characterize SARS-CoV-2 (CoV-2)-specific T-cell responses outside the Spike (S) protein. Here, we identify CoV-2 T-cell responses targeting peptides in Nsp3, Membrane (M), and Nucleocapsid (NC) proteins and characterize the functional profile in individuals with hybrid immunity.
Methods: Comprehensive screening using a mega-matrix ELISpot assay identified a total of 27 targeted peptides distributed across the S, Nsp3 (2 peptides), M (3 peptides) and NC (1 peptide) CoV-2 proteins in individuals that received 3-dose mRNA vaccination after CoV-2 infection (n=10). For further characterization, T-cell responses to these targets were analyzed by flow cytometry. PBMCs were stained with T-cell lineage markers (CD4, CD8, CD27, CCR7), activation (CD69) and functional markers (CD107a, IFN-γ, IL-2, TNF-α). We assessed and compared phenotypes and polyfunctionality of responding T cells by SPICE v6.1.
Results: Six individuals presented responses against the S region, while three participants presented responses in Nsp3 and M and one in NC. Concerning S peptides, CoV-2-specific $CD4^+$ and $CD8^+$ T-cell responses produced CD107a, IFN-γ, IL-2, and TNF-α. We observed a trend towards an increase in the frequency of $CD107a^+$ $CD8^+$ (p=0.06) compared to $CD4^+$ T-cells. T-cell responses against Nsp3 and NC peptides expressed all cytokines tested. By contrast, CoV-2 T-cell responses against M peptides were mostly monofunctional, expressing IFN-γ^+. Regarding polyfunctional T-cell responses against S peptides, only a fraction of S-specific $CD4^+$ T-cells expressed IFN-γ^+-$IL2^+$. S-specific $CD8^+$ T-cells were IFN-γ^+CD69^+ and TNF-α^+CD69^+. Most S-specific T-cell responses were associated with CD69 expression without cytokine expression. Interestingly, Nsp3 and NC–specific $CD4^+$ and $CD8^+$ T-cell responses were mostly polyfunctional (IFN-γ^+-$IL\text{-}2^+$, IFN-γ^+-TNF-α^+, $IL\text{-}2^+$-TNF-α^+, IFN-γ^+-$IL\text{-}2^+$-TNF-α^+). The M-specific $CD4^+$ and $CD8^+$ T-cell responses had a monofunctional profile, and a small proportion of $CD4^+$ T-cells expressed IFN-$\gamma^+IL\text{-}2^+TNF\text{-}\alpha^+$.
Conclusion: This study reveals novel and polyfunctional $CD4^+$ and $CD8^+$ T-cell responses in individuals with hybrid immunity targeting peptides of Nsp3, NC, and M CoV-2 regions. These findings may inform future vaccine design.

Next-level efficiency: StraightFrom Spleen Isolation Kits - standardizing isolation of untouched T cells with minimal hands-on time

Amelie Borczewski[1], Sebastian Flade[1], Elina Neufeld[1], Ermanila Dhana[1], Gregor Winkels[1], Anna Baranska[1]
[1]*Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Germany*

Background: Magnetic isolation of T cells from mouse spleen is a widely used technique in immunology and cell biology research. Studies using magnetically isolated T cells contribute to the understanding of the immune system, the development of new vaccines and the advancement of immunotherapy. Therefore, the selection of a reliable cell isolation method is critical for consistent experimental results.
Objectives: Development of gentle isolation strategies for highly purified T cells that preserve cell functionality. These strategies should be compatible with downstream applications and should standardise, simplify and accelerate cell isolation workflows and ensure experimental reproducibility.
Methods: Simultaneous spleen dissociation and labeling of non-target cells with an antibody cocktail was performed using the GentleMACS dissociator. Subsequent automated magnetic labelling of cells and isolation of untouched T cells (CD4, CD8 and Pan T) was performed using the autoMACS NEO Separator. Target cell purity, yield, cell activation status and functionality were assessed.
Results: Utilizing our streamlined StraightFrom Spleen workflow, we efficiently isolated untouched CD4, CD8, or Pan T cells with remarkable purity and yield. Unstimulated cells cultured overnight exhibited no expression of CD25 or CD69. However, upon overnight stimulation with the T cell Activation/Expansion Kit, a notable upregulation of the T cell activation markers was observed. Subsequently, the isolated T cells exhibited successful proliferation in culture, affirming their functional viability. These findings underscore the robustness and efficacy of T cell isolation through the StraightFrom Spleen Isolation Kits.
Conclusion: In summary, we present a novel and expedited cell isolation approach characterized by minimal manual intervention. Our accelerated isolation protocols enable the swift procurement of functional cells with superior purity and yield, offering a compelling alternative to the labor-intensive multi-step procedures commonly employed in both academic and industrial settings.

Oxysterol-mediated inhibition of CD8 T cell metabolism and function

Ella Rogerson[1], Aisling Cameron[1], Aisling McCrudden[1], Sakshi Sankhla[1], David Finlay[1]
[1]*Trinity Biomedical Science Institute, Trinity College Dublin, Dublin, Ireland*

Intermediates of both cholesterol synthesis and cholesterol metabolism can have diverse roles in the control of cellular processes that go beyond the control of cholesterol homeostasis. For example, oxidized forms of cholesterol, called oxysterols, have functions ranging from the control of gene expression, signal transduction and cell migration. This is of particular interest in the context of immunology and immunometabolism where we now know that metabolic processes are key towards shaping the nature of immune responses.
In this study we investigated the impact of two oxysterol species, 25-hydroxycholesterol (25HC) and 27-hydroxycholesterol (27HC), on the metabolism and function of CD8 T cells. 25HC is enzymatically generated by cholesterol 25 hydroxylase (Ch25h) expressed in inflammatory macrophages and tumour associated macrophages. 27HC is generated by Cyp27a1, which is highly expressed in some tumour types including Glioblastoma.
The data show that 25HC and 27HC both potently inhibit the activation of splenic CD8 T cells. In addition, when 25HC and 27HC were applied to fully differentiated cytotoxic T cells an inhibition in proliferation, metabolism and cytotoxicity was observed. This study has also investigated the mechanisms involved and revealed roles for 25HC/27HC-mediated inhibition of Srebp transcription factors and activation of LXR nuclear receptors. In addition, 25HC and 27HC were observed to directly affect the plasma membrane, altering the membrane order.
In conclusion, we show that 25HC and 27HC inhibit the metabolism and function of murine CD8 T cells through multiple mechanisms.

The role of G-protein γ subunit 2 in the pathogenicity of CD4+ T cell in experimental autoimmune uveitis

Suci Cendanawati[1], Benjamin Ede[1], Amy Ward[2], Oliver Bell[2], Dave Copland[2;3], Andrew Dick[2;3], Anne Ridley[1], Lindsay Nicholson[1]
[1]*School of Cellular and Molecular Medicine, Faculty of Life Sciences, University of Bristol, Bristol, United Kingdom*;
[2]*Academic Unit of Ophthalmology, Translational Health Sciences, University of Bristol, UK, Bristol, United Kingdom*;
[3]*NIHR Biomedical Research Centre at Moorfields Eye Hospital and UCL Institute of Ophthalmology, UK, London, United Kingdom*

Autoimmune uveitis, an autoimmune non-infectious inflammatory eye condition, is studied using experimental autoimmune uveitis (EAU) *in vivo*. EAU is driven by T cells, demonstrated by the induction EAU in naïve mice via the transfer of retina antigen specific pathogenic $CD4^+$ T cells (PTCs). The purpose of this study is to understand the mechanism underlying PTCs pathogenicity in EAU. We performed RNA sequencing analysis on C57BL/6 mice comparing PTCs and endogenous $CD4^+$ T cells (ETCs) and found 135 differentially expressed genes (Padj<0.05). Of these, 106 genes were found to have human orthologues and from those genes, 22 gene candidates that were highly associated with human autoimmune diseases were identified. Three genes of interest are: CD226, linked to multiple sclerosis, type 1 diabetes, rheumatoid arthritis, and juvenile idiopathic arthritis; Klrk1/NKG2D, associated with Behçet's disease; and G-protein γ subunit 2 (Gng2), correlated with multiple sclerosis.
Published single-cell RNA sequencing studies of spontaneous uveitis in AIRE-/- knockout mice show that Gng2 expression peaks in Th1 cells, followed by Th17, T regulatory cells, and finally, Th2 $CD4^+$ T cell subtypes. Using quantitative real-time PCR, we found that in OTII transgenic mouse $CD4^+$ T cells and splenocytes, Gng2 mRNA expression increases after stimulation with anti-CD3/28 and is upregulated in retinas during early EAU. Similarly, in human T cell leukaemia cell lines (Jurkat and CCRF-CEM cells) GNG2 mRNA levels were enhanced after TCR stimulation. Using siGNG2 RNAi knockdown and the $G\beta_1\gamma_2$ small molecule inhibitor gallein, we observed that inhibiting Gng2 impedes chemotaxis toward CXCL12 in Jurkat and CCRF-CEM cells, while activation induced upregulation of Gng2 enhances chemotaxis toward CXCL12. Likewise, gallein also inhibited $CD4^+$ T cell chemotaxis towards CXCL12. Gallein also slows proliferation by inhibiting G2/M cell cycle entry in Jurkat and CCRF-CEM cells. In conclusion, targeting Gng2 in $CD4^+$ T cells could be a potential therapeutic strategy to treat autoimmune uveitis.

Exploring Affinity-Dependent Metabolic Imprinting of Anti-Viral T Cell Responses

Hannah Bollons[1], Tracey Haigh[1], Nancy Gudgeon[1], Guillaume Desanti[1], Graham Taylor[1], Sarah Dimeloe[1], Heather Long[1]
[1]*University of Birmingham, Birmingham, United Kingdom*

T cell responses to viral infections are mediated by their recognition of specific viral peptide-MHC complexes by the T cell receptor (TCR). T cell functions are underpinned by changes in metabolism in response to TCR ligation, whereby the metabolic network is reprogrammed to meet the demands of the cell. To date, T cell metabolism studies have been largely based on bulk T cell populations, however each unique T cell can respond differently to a single viral antigen. Therefore, this project uses an antigen-specific approach to focus on how the affinity of a TCR determines T cell function, and how TCR affinity influences T cell metabolism to ultimately drive this response.
Specifically, this project explores antigen-specific T cells in the context of Epstein-Barr Virus (EBV). Primary EBV infection affects over 90% of the worldwide population and in some individuals, is associated with the long-term development of cancer and autoimmunity.
To investigate the immune and metabolic phenotypes of EBV antigen-specific T cells, primary cells were detected *ex vivo* using peptide-MHC tetramers. Tetramer staining was combined with metabolic probes to assess mitochondrial mass and membrane potential, as well as with SCENITH to explore the cells' dependence on glycolysis and oxidative phosphorylation.
Antigen-specific T cell clones were also generated *in vitro* by peptide-MHC tetramer staining and single-cell sorting. T cell clones were assessed for their variable TCR sequences by PCR and functional avidity by IFNɣ ELISA. A range of unique TCRs and distinct functional responses towards the same EBV epitope were identified. T cell clones with different TCR usage and functions will be compared for metabolic differences in response to antigen stimulation by various approaches, including extracellular flux analysis and SCENITH.
Overall, this project aims to explore the fundamental relationship between the TCR affinity, immune function and metabolic phenotypes of EBV antigen-specific T cells, before determining possible underlying mechanistic links. This understanding will enable investigations into differences between affinity-dependent T cell phenotypes in the periphery versus resident-memory populations at the site of EBV infection.

SARM1, a TLR adapter with NADase activity, regulates the differentiation of distinct populations of CD4 T cells and their inflammatory activity

Samuel dos Santos Oliveira[1], José Arimatéa de Oliveira Nery Neto[2], Eloisa Martins[3], Raquel Vieira[2], João Vinícius Honório da Silva[2], Victor Yuji[2], Marcella Cipelli[2], Niels Olsen Saraiva Camara[2]
[1]Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto, Brazil; *[2]Institute of Biomedical Science, São Paulo - SP, Brazil*; *[3]Federal University of São Paulo, São Paulo - SP, Brazil*

During their activation, T cells undergo metabolic reprogramming and glycolysis becomes the main means of generating energy. NAD^+ is a crucial molecule during T cell activation, and high concentrations of this electron acceptor are required. Recently, a domain with the ability to degrade NAD^+ was discovered in the SARM1 protein. Knowing that this protein is expressed in $CD4^+$ T lymphocytes, we hypothesized that SARM1 could control T cell quiescence, activation, differentiation and memory formation by regulating NAD^+ bioavailability. We discovered that in vitro SARM1 can act in the differentiation of distinct populations of lymphocytes, and we also observed that in Th1 polarizing conditions there is a greater number of IFN^+ cells in the absence of SARM1, as well as an increase in the number of FOXP3 positive cells in cells under differentiation medium for Treg and Th17, the latter, in turn, has a reduction in IL-17 production. In vivo, we found that *Sarm1*$^{-/-}$ animals in homeostasis have more activated T lymphocytes, based on CD69 expression, but we observed no difference in the absolute number of T cell subpopulations. We also found that *Rag1*$^{-/-}$ animals transferred with $CD4^+$ T lymphocytes naive animals from *Sarm1*$^{-/-}$ animals develop more severe colitis when compared to those that received naive $CD4^+$ T cells, presenting greater weight loss, splenomegaly, greater shortening of the colon and greater compromise of the intestinal barrier, however we did not observe a difference in the number of T lymphocytes infiltrated the colon after 30 days of transfer. Our data suggest that SARM1 acts in the differentiation of Th1, Treg and Th17 cells, as well as a regulator of lymphocyte-mediated inflammation. Finally, we discovered that circulating $CD4^+$ T cells from patients with colitis have reduced SARM1 expression when compared to healthy donors, which corroborates our hypothesis that SARM1 is an immunoregulatory component of $CD4^+$ T lymphocyte biology.

Polyphosphate regulates T-cell metabolism and differentiation

Benita Kröger[1], Marion Mengel[1], Mandy Malle[1], Reiner Mailer[1]
[1]*University Medical Center Hamburg Eppendorf, Institute of Clinical Chemistry and Laboratory Medicine, Hamurg, Germany*

Purpose: Inorganic polyphosphate (polyP) is a ubiquitous biopolymer, whose functions in mammalian cells have largely remained elusive. PolyP consists of up to several hundred phosphate moieties linked by energy rich phosphoanhydride bonds. As a negatively charged linear polymer, polyP is usually associated with divalent cations, suggesting its role in calcium signalling. Here, we explore the dynamic generation and intracellular function of polyP in murine CD4+ T-cell subsets.
Methods: We performed colorimetric phosphate detection assays, negative DAPI staining in UreaPAGE and used the fluorescently labelled PolyP-binding domain of polyphosphatase (PpxΔ12) to detect the intracellular biopolymer in T cells. To analyse differential PolyP levels in T-cell subsets, we applied in vitro T-cell differentiation assays and inhibitor treatments of isolated CD4+ T cells. To analyse the impact of decreasing polyP levels on CD4+ T cell functions, we performed protein transduction of recombinant exopolyphosphatase 1 from *S. cerevisiae* fused with a cell-permeable peptide (CPP-Ppx1). Efficient transduction of CPP-Ppx1 was assessed by immunoblotting and immunofluorescent microscopy.
Implications of the CPP-Ppx1-mediated degradation of polyP for metabolic rates and calcium mobilisation in T cells was analysed in a seahorse analyser and ratiometric calcium mobilisation assays, respectively.
Results: We found that polyP accumulates in T cells dependent on TCR stimulation strength and calcium mobilisation. Addition of IL-6 further increased, whereas TGF-β treatment decreased polyP levels in stimulated T cells. Consistently, Th17 cells displayed elevated levels of polyP compared to Treg cells. Moreover, the treatment of stimulated T cells with recombinant CPP-Ppx1 effectively transferred the enzyme into subcellular compartments and reduced the amount of polyP. Stimulated T cells treated with CPP-Ppx1 displayed altered ECR/OCR metabolism rates, intracellular calcium levels and T-cell activation. Validating these phenotypic alterations, we also found increased proliferation in T cells that express an inducible Ppx1 transgene, suggesting that polyP acts as a rheostat that restricts calcium signals in stimulated T cells.
Conclusion: Targeting polyP in CD4+ T cells may provide a novel approach to modulate calcium signalling, T-cell metabolism and differentiation.

Distal regulatory elements, e.g., enhancers influence cell identity by regulating transcriptional status of a given cell. Global methylation and acetylation profiling of histone-3 has been used as a marker to identify promoters and enhancers. Here, we utilized ChIP-sequencing to profile the enhancers of differentiating T helper (Th)-17 cells. Using ATAC-sequencing based profiling of differentially accessible Th17-specific chromatin loci, we identified potential enhancers responsible for fate specification of Th17 cells. Our analysis revealed autoimmune diseases associated single nucleotide polymorphisms (SNPs) were enriched near Th17-specific enhancers. We found 24 SNPs overlap with the binding sites of transcription factors active in Th17 cells. Furthermore, we identified an enhancer in the intron of RAR-related orphan receptor alpha (RORA) that was predicted to regulate RORA expression. Functional validation of this proximal RORa enhancer using CRISPR-Cas9-mediated deletion followed by luciferase reporter assay confirmed its role in regulation of RORA expression and thereby Th17 differentiation. These findings provide insights into the potential mechanism by which the RORA enhancer modulates Th17 differentiation. Additionally, they underscore the significance of regulatory SNPs within noncoding regions in conferring resistance or susceptibility to Th17 cell-mediated autoimmune pathologies.

Identification of highly suppressive human regulatory T cells in old age

Lourdes Rocamora Reverte[1], Jonathan Dieringer[1], Birgit Weinberger[1]
[1]*Institute for Biomedical Aging, Innsbruck, Austria*

Purpose: Regulatory T cells (Treg) are the main modulators of immune tolerance and homeostasis and their fitness is crucial to keeping the balance between health and disease. With age, the immune system gets dysregulated and older people become more susceptible to developing different ailments. T lymphocytes ($CD4^+$ and $CD8^+$ cells) are affected by aging processes showing a more pro-inflammatory phenotype and a less reactive status. On the other hand, well-functioning Treg cells express some markers related to aged T cells. It is not clear yet how Treg cells are modified in the course of aging. The aim of our study is to shed some light on the enigmatic field of aging Treg cells, trying to define differences between $CD4^+$ Treg cells from young and older donors.
Methods: The expression of different Treg markers was analysed using flow cytometry by staining freshly isolated human PBMCs. We also performed cell death assays to evaluate Treg susceptibility to the apoptotic stimulus Etoposide. In addition, the suppressive capacity of Treg cells was assessed by co-culturing sorted Treg on proliferating T cells.
Results: While the expression of Treg-related markers stays stable over age, we found that Treg cells from older donors express significant higher levels of the CD28 TCR co-receptor. We analysed some of the most prominent inhibitory molecules on Treg and found that $CD28^{high}$-Treg cells express more PD-1 than $CD28^{low}$-Tregs and this phenomenon increases with age. In addition, $CD28^{hi}$-Treg are mostly $CD45RO^+$ indicating an effector/memory phenotype. Moreover, $CD28^{high}$ expressing Treg suppress proliferating T cells more than their $CD28^{low}$ counterparts.
Conclusion: We have identified a subset of highly suppressive Treg cells that is more abundant in the older population compared to young. Our results propose high CD28 expression by Treg as a potential marker for aged Treg that would partially explain the restrained immune response in the elderly.

Deciphering the impact of preeclampsia on γδ T cells in the decidua

Ziqing Wang[1], Paulina Lukomska[1], Tao Yang[1], Aavani Biju Sindhu[2], Madeleine Wagner[2], Ralf Schild[3], Anke Katharina Bergmann[2], Christine Morfeld[3], Sarina Ravens[1]
[1]Hannover Medical School, Institute of Immunology, Hannover, Germany; *[2]Department of Human Genetics, Hannover Medical School, Hannover, Germany*; *[3]Perinatal Center, Diakovere Henriettenstift, Hannover, Germany*

Preeclampsia, a severe pregnancy complication, is primarily diagnosed by hypertension and proteinuria, with serious risks including intrauterine growth restriction, placental abruption, and stillbirth. Human γδ T cells are enriched at the maternal-fetal interface, while little is known about their functional potential in preeclampsia.
Here, we characterize TCR repertoires, phenotypes and cytokine production of decidual γδ T cells among women with preeclampsia and those with a healthy pregnancy, and compare those to paired maternal and cord blood samples. Decidual γδ T cells show increased TNF-α and IFN-γ production in preeclampsia, suggesting a polarization toward a pro-inflammatory state. Furthermore, TCR repertoire analyses reveal that decidual γδ T cells consist of more adult-like TCR clones, and thus presumably derive from the maternal site.
In conclusion, an enrichment of inflammatory γδ T cells in the decidua during preeclampsia is evident, suggesting that γδ T cells are implicated in the pathogenesis of this pregnancy-related disease.

Histone Deacetylase Class I, Especially HDAC2 Leads to Change of the CD4+ Lineage Genes and Switch the Differentiation to CD4+CD8α+ T Cells

Laurin Braune[1], Hannah R. Spatzier[1], Anne-Marie Glimm[1], Lina E. Werner[1], Kathleen Friedrich[1], Phuong Nguyen[1], Ulf Wagner[1], Kathrin Rothe[1]
[1]*University of Leipzig Medical Center, Rheumatology Unit, Department of Endocrinology, Nephrology, Rheumatology, Leipzig, Germany*

Purpose: Extrathymic $CD4^+CD8^+$ double-positive (DP) T cells in humans were discovered in 1986. In healthy humans, the frequencies of $CD4^+CD8^+$ T cells are very low. However, it has been shown that in certain virus or autoimmune diseases, the percentage of DP T cells in peripheral blood can increase. DP T cells are divided in two subsets: $CD4^+CD8\alpha\alpha^{low}$ and $CD8\alpha\beta^+CD4^{low}$ T cells. The development of DP T cells is still not fully understood, but there are hints of epigenetic factors that favor the expression of CD8 on $CD4^+$ T cells. Hence, we are interested in the expression of class I histone deacetylases (HDAC) in peripheral DP T cells.
Methods: Surface and intracellular expression of peripheral blood T cell markers and transcription factors were analyzed by flow cytometry. Expression of HDAC1, 2, and 3 was investigated in isolated peripheral $CD4^+$ T cells by western blot as well as RT-qPCR. Using an in-vitro assay, naïve $CD4^+$ T cells from peripheral blood of HD (n=5) were activated for 3d under Th0 polarizing conditions and HDAC class I were inhibited for 24h. Afterwards, $CD4^+$ T cells were investigated by flow cytometry.
Results: Our first results demonstrate an increased frequency of $CD4^+CD8\alpha\alpha^{low}$ T cells compared to $CD8\alpha\beta^+CD4^{low}$ T cells in peripheral blood of HD. Furthermore, $CD4^+CD8\alpha\alpha^{low}$ T cells show an increased expression of RunX3 and decreased ThPOK. The inhibition of HDAC class I increases the expression of cytotoxic markers. Coreceptor CD8α is upregulated on the surface of $CD4^+$ T cells. In contrast, ThPOK, CD27, and CD40L are downregulated, which are essential markers for the activation and lineage of $CD4^+$ T cells. The high level of HDAC2 is associated to an increased expression of CD8α and RunX3 and decreased MFI of CD27 on $CD4^+$ T cells. These first suggestions outline possible explanations for the $CD4^+CD8\alpha\alpha^{low}$ T cell lineage.
Conclusion: In summary, the regulation of class I HDAC functionality induces the cytotoxic pathway in peripheral $CD4^+$ T cells. We suggest that especially the role of HDAC2 is essential for the expression and stability of CD4 lineage genes and could be causative for $CD4^+$ T cell dysregulation.

Memory CD8+ T-cell formation and pathogen origin: Investigating the connection

Veronika Cimermanová[1], Eva Šályová[1], Veronika Niederlová[1], Juraj Michálik[1], Ondrej Stepanek[1]
[1]*Institute of Molecular Genetics of the Czech Academy of Sciences, Praha 4, Czech Republic*

Purpose: One of the remarkable features of the adaptive immune system is the creation of immunological memory. Upon recognition of its cognate antigen, CD8+ T cell undergoes phenotypical changes, transforming into short-lived effectors and long-lived memory subsets. Despite extensive exploration into the diversity of memory subpopulations, it is still not clear why and how these diverse memory subsets arise. In our research, we investigate whether the origin of pathogens (type of pathogen, mode of infection) influences the formation of memory subsets, thereby impacting the functional propertiea of the resulting immune memory.
Methods: To address our research question, we utilized established mouse infection models faturing transgenic OT-I mice (TCR recognizing ovalbumin peptide: OVA) and various pathogens expressing the OVA peptide. These pathogens included *Listeria monocytogenes* (Lm-OVA) for bacterial infection, Lymphocytic Choriomeningitis Virus (LCMV OVA) for systemic viral infection, and Influenza strain PR8 (PR8-OVA) for respiratory viral infection. At the peak of infection (day 8 pi.), blood analysis was conducted to observe the phenotype of OT-I effector cells across these diverse infections by flow cytometry. At the memory phase (day 60 pi.), we explored OT-I memory phenotypes in the spleen and lungs using single-cell RNA sequencing. To ensure relevance of our findings in a physiological matter, we further investigated also the endogenous response of polyclonal $CD8^+$ T cells.
Results: Bacterial infection predominantly formed central memory phenotype ($CD62L^+$, $CCR7^+$), systemic viral infection generated mainly effector memory phenotype ($CX3CR1^+$, $KLRG1^+$) and respiratory viral infection produced primarly tissue-resident phenotype ($CD69^+$, $CXCR6^+$) in lungs and another yet undescribed memory phenotype (expressing IFITMs, LGALS3 and ITGA1) in the spleen.
Conclusion: Obtained data suggest that the origin of pathogen influences already the trajectory of the immune response during the infection, and further affects formation of $CD8^+$ T-cell memory subsets.

Human CD8+HLA-DR+CD45RC- T cells as a potential regulatory T cell population

Gabriel Knoll[1], Benedikt Mathies[1], Michael Keller[1], Brigitte Jenewein[1], Birgit Weinberger[1]
[1]*Institute for Biomedical Aging Research, Innsbruck, Austria*

Purpose: Regulatory T cells (Treg) play an essential role in immune homeostasis and medical conditions such as autoimmune diseases and cancer. While their phenotype and functions are extensively described for $CD4^+$ Treg, $CD8^+$ Treg are contradictorily discussed due to a lack of precise markers. In our laboratory, an HLA-DR-expressing $CD8^+$ T cell population with regulatory capacities was described. Other groups proposed $CD122^+$ or $CD45RC^{low/-}$ as $CD8^+$ Treg markers, but none of the currently described $CD8^+$ Treg phenotypes is widely accepted. The suppressive capacity of $CD8^+HLA\text{-}DR^+$ Treg amongst different donors is very variable. These results and the necessity to define *bona fide* $CD8^+$ Treg markers prompted us to characterise these cells in more detail.
Methods: We investigated the expression of inhibitory molecules and the production of various cytokines to identify potential markers for $CD8^+$ Treg candidates. To that purpose, freshly isolated human PBMCs were stimulated with anti-CD3/anti-CD28, and T cells were analysed using flow cytometry.
Results: $CD8^+HLA\text{-}DR^+CD45RC^-$ T cells showed significantly higher percentages of the inhibitory molecules CTLA-4 and PD-1 compared to $CD8^+HLA\text{-}DR^+CD45RC^+$ T cells and $CD8^+HLA\text{-}DR^-CD45RC^-$ T cells. Additionally, IL-10 levels were significantly higher in $CD8^+HLA\text{-}DR^+CD45RC^-$ T cells compared to $CD8^+HLA\text{-}DR^+CD45RC^+$ T cells and $CD8^+HLA\text{-}DR^-CD45RC^-$ T cells, while pro-inflammatory cytokine levels where significantly lower.
Conclusion: Our results propose $CD8^+HLA\text{-}DR^+CD45RC^-$ T cells as a potential Treg population based on their cytokine profile and their expression of inhibitory molecules. The inhibitory phenotype of $CD8^+HLA\text{-}DR^+CD45RC^-$ T cells will be studied in co-culture experiments with sorted cells to analyse the impact of $CD8^+HLA\text{-}DR^+CD45RC^-$ T cells on T cell proliferation and survival.

Purpose: T lymphocytes expressing a mature $TCR_{\alpha\beta}$ are composed by conventional $CD4^+$ and $CD8^+$ T cells and unconventional T cells ($UTC_{\alpha\beta}$), including invariant natural killer T (iNKT) cells, mucosal-associated invariant T (MAIT) cells and intraepithelial lymphocytes (IELs). Recently, our group identified a population of $CD4^-$ $CD8^-$ $UTC_{\alpha\beta}$ that was not recognized by antigen-loaded CD1d and MR1 tetramers, indicating that the cells were not iNKT cells or MAIT cells. Due to the lack of CD4 and CD8 expression and positivity for $TCR_{\alpha\beta}$, we operationally called these cells double negative $TCR_{\alpha\beta}{}^+$ T cells ($DNT_{\alpha\beta}$). The biology and role of $DNT_{\alpha\beta}$ remain poorly understood.
Methods: We employed transcriptomic analyses and multiparametric flow cytometry to characterize $DNT_{\alpha\beta}$ in various tissues. *In vitro* experiments assessed their proliferation, cytokine production, and immune response polarization.
Results: $DNT_{\alpha\beta}$ were present in various tissues of healthy mice at different ages with spleen representing their main reservoir. $DNT_{\alpha\beta}$ were found in CD1d, MR1, β2m, and MHCII- deficient mice, suggesting potential restriction by alternative molecules. Transcriptomic analyses revealed that $DNT_{\alpha\beta}$ expressed a unique gene signature associated with T cell activation and a polyclonal $TCR_{\alpha\beta}$ repertoire. Upon cytokine stimulation, $DNT_{\alpha\beta}$ proliferated and produced effector molecules (IFN-γ, GRZB) at higher levels compared to conventional T cells, reflecting their ability to respond to environmental stimuli. TCR triggering further enhanced their proliferation and activation. We observed the presence of tumor-infiltrating $DNT_{\alpha\beta}$ in different cancer models. Interestingly, the conditioned medium of stimulated $DNT_{\alpha\beta}$ induced increased MHCII expression on macrophages, comparable to that induced by type 1 polarizing stimuli. In contrast, the expression of CD206, associated with type 2 polarization, was not increased, suggesting their capacity to polarize macrophages towards anti-tumor M1-like phenotype.
Finally, $DNT_{\alpha\beta}$ were found in peripheral blood and tissues of healthy donors and cancer patients, with phenotypic similarities to murine $DNT_{\alpha\beta}$.
Conclusion: We revealed the biology and functional properties of a previously poorly known population of $UTC_{\alpha\beta}$, paving the way for their use as therapeutic targets (cell therapy).

High-throughput screening of small molecular compounds targeting FoxP3 identifies MAPK and STAT3 inhibitors as regulatory T cell inhibitors

Elise Solli[1;2], Nuria Garcia Diaz[1;2], Ehsan Hajjar[1], Selma Cornillot-Clément[3], Johannes Landskron[4], Rafi Ahmad[5;6], Qian Wei[1], Kjetil Taskén[1;2]
[1]Department of Cancer Immunology, Institute for Cancer Research, Oslo University Hospital, Oslo, Norway, Oslo, Norway; *[2]Institute of Clinical Medicine, University of Oslo, Oslo, Norway*; *[3]ImmunoConcEpT, Centre National de la Recherche Scientifique, Unité Mixte de Recherche, University of Bordeaux, Bordeaux, France*; *[4]Centre for Molecular Medicine Norway, University of Oslo, Oslo, Norway*; *[5]Department of Biotechnology, Inland Norway University of Applied Sciences, Hamar, Norway*; *[6]Institute of Clinical Medicine, Faculty of Health Sciences, The Arctic University of Norway, Tromsø, Norway*

Purpose: Regulatory T cells (Tregs) have a central role in suppressing antitumor immunity and promoting tumor progression, and the Treg linage-defining transcription factor FoxP3 is key to maintaining the Treg suppressive functions. Thus, targeting FoxP3 expression in Tregs could be a promising anti-tumor approach.
Methods: We have developed a unique, phenotypic, cell-based, high-throughput flow cytometry assay for screening a library of 1522 approved drugs to identify drugs targeting FoxP3 expression.
Results: Here we found drug candidates that downregulate FoxP3 expression in Tregs, show low T cell toxicity, downregulate expression of suppressive Treg markers like LAG-3, PD-1 and ICOS, and inhibit Treg suppressive functions; these drugs converge at inhibiting MAPK and STAT3 signaling. To further characterize these drugs and determine their structure-activity relationship, we built new sub-libraries and searched for analog compound structures by *in silico* prediction. We found that several of these drugs also inhibit Treg suppressive functions in a manner similar to- or better than the original compound.
Conclusion: Although more studies are needed, these drug candidates could serve as probes for studying Treg functions, which could expand the repertoire of anti-tumor therapies. The high-throughput assay will also enable further discovery of drugs regulating Treg functions.

Regulation of T cell homeostasis by extrinsic cell death pathways

Farjana Islam[1], Scott Layzell[1], Benedict Seddon[1]
[1]*Institute of Immunity and Transplantation, University College London, London, United Kingdom*

Purpose: The extrinsic cell death pathway is a critical regulator of activated T cells, responsible for AICD. Our knowledge of how extrinsic cell death pathways influence other stages of T cell development and function is less clear.
Methods: To investigate the role of extrinsic cell death in normal T cell development, we analysed mice with huCD2-driven T cell specific iCre mediated deletion of CASPASE8 from the earlier stages of T cell development, inducible Casp8ΔT^{iCD8} mice for peripheral deletion in $CD8^+$ T cells and mice expressing D138N kinase dead mutant of RIPK1 to explore the mechanism of death.
Results: We found that ablation of CASPASE8 had significant perturbations upon nonconventional thymic NKT cells development, while conventional thymocytes and nonconventional γδ T cells development was unaffected. In the periphery, CASPASE8 expression was crucial for conventional $CD8^+$ T cells and nonconventional γδ T cells survival, but appeared redundant for conventional $CD4^+$ T cells survival. The requirement for CASPASE8 by $CD8^+$ T cells appeared constitutive rather than simply developmental, since inducible deletion in peripheral $CD8^+$ T cells resulted in similar perturbations. We found that in the absence of CASPASE8, $CD4^+$ and $CD8^+$ naïve T cells were completely resistant to FasL-inducing apoptotic and necroptotic cell death, suggesting that naïve T cells are not susceptible to necroptotic cell death. We also observed that kinase dead RIPK1 partially rescued $CD8^+$ VM T cells, NKT cells and completely γδ T cells from cell death in the absence of CASPASE8 in vivo, implicating necroptosis as the mechanism of cell death in these populations.
Conclusion: CASPASE8 deletion from the earlier stages of development revealed that CASPASE8 has multiple roles in different stages of T cell subsets. CASPASE8 plays a crucial role for the survival of $CD8^+$ conventional T cells, although the mechanism of cell death is unclear. Nonconventional γδ T cells, DNNKT cells and $CD8^+$ VM T cells in the absence of CASPASE8 were susceptible to necroptotic cell death.

Pertussis booster vaccination in four age groups reveals different shaping of memory T cell responses related to primary-vaccine background

Jolanda Brummelman[1], Laura van Eijk[1], Jacquenline van Gaans-van den Brink[1], Martien Poelen[1], Cécile van Els[1;2]
[1]Centre for Infectious Disease Control, National Institute for Public Health and the Environment, Bilthoven, Netherlands; *[2]Infectious Diseases & Immunology, Department of Biomolecular Health Sciences, Faculty of Veterinary Medicine, Utrecht University, Utrecht, Netherlands*

Purpose: First and second generation whole-cell (wP) and acellular (aP) pertussis vaccines prevent severe disease and mortality in vulnerable infants. However, aP vaccines are considered less effective in reducing circulation of *Bordetella pertussis* (Bp), supposedly because they shape alternative immune memory. Here, we interrogated differential Bp-specific memory T cell responsiveness after aP booster vaccination in four age groups with wP or aP primary vaccination backgrounds.
Methods: PBMCs were collected before (D0), 28 days (D28) and one year (1yr) after aP booster vaccination from aP-primed children (7-10y, n=16), aP/or wP-primed adolescents (11-15y, n=14/14), wP-primed young adults (20-34y, n=22), and mostly wP- or non-primed older adults (60-70y, n=24) in a phase IV interventional study (Periscope-BERT). T cell responses were characterized by IFNγ/IL-13/IL-17A Triple FluoroSPOT (counting spot-forming cells (SFC)) and supernatant analysis (Th1/Th2/Th17 cytokines) upon stimulation with a peptide pool representing 132 known Bp CD4 T cell epitopes (Bp132), Filamentous Hemagglutinin (FHA), medium or aCD3 (all with aCD28).
Results: Overall, baseline (D0) levels of Bp-specific SFC and secreted cytokines were highest and especially skewed towards a Th2-dominated memory profile in younger aP-primed 7-10y and 11-14y-olds. D28 levels of specific IFNγ/IL-13/IL-17A SFC as well as Th1/Th2/Th17 cytokines were enhanced over D0 in all groups except in aP-primed 7-10y-olds. In this latter group a consistent ‘plunge’ in SFC and cytokine levels was observed on D28 compared to D0, across Th lineages. At 1yr post-booster, a trend towards (still) elevated levels of specific SFC and secreted cytokines over D0 could be seen, in all age (sub)groups.
Conclusions: aP-Primed age cohorts have an alternatively-shaped Bp-vaccine antigen-specific memory T cell compartment compared to wP-primed cohorts, with a Th2-skewed functionality and a differently regulated booster pattern. How this relates to less effective protection against Bp clearance and transmission is to be further elucidated. Generally elevated T cell responses one year post-booster indicate that enhancing immunological memory across differently primed age cohorts is feasible.

Splenic and circulating CD4+ T lymphocyte subsets in autoimmune and malignant hematologic disorders

Sophia Metreveli[1], Nino Nanava[1], Irina Kvachadze[2], Nino Kikodze[1;3], Giorgi Giorgobiani[4], Tinatin Chikovani[1], Nona Janikashvili[1]
[1]Tbilisi State Medical University, Department of Immunology, Tbilisi, Georgia; *[2]Tbilisi State Medical University, Department of Physiology, Tbilisi, Georgia*; *[3]Tbilisi State Medical University, Institute of Medical Biotechnology, Tbilisi, Georgia*; *[4]Tbilisi State Medical University, Department of Surgery, Tbilisi, Georgia*

Purpose: T lymphocytes play a cardinal role in mediating the functions of other immune cells. Therefore, investigations of T lymphocyte counts and functions are critical in autoimmune disease and malignant disorders for elucidating the pathogenesis of such diseases as well as for elaborating management strategy and treatment options. Splenectomy represents the second line therapeutic intervention in many types of hematological disorders. Patients with immune thrombocytopenia (ITP) and hematologic malignancies (HM) undergoing splenectomy were included in this prospective study. We aim to explore the effector and suppressive CD4 T lymphocyte subsets (Th1, Th17 and Treg) in the spleen and blood, as well as to compare splenic and circulating (Th1/Treg, Th1/Th17 and Th17/Treg) cell ratios of patients and control group.
Methods: Mononuclear cells from peripheral blood and dissociated spleen tissue of patients with ITP, hematologic malignancies and controls group were purified and the expressions of the specific transcription factors (Tbet, RORγt and FoxP3) were quantified within the CD4+ compartment of T lymphocytes. Data were acquired on a FacsCalibur flow cytometer and analyzed using FlowJo® v10 software. Statistical analysis was performed using Prism Graph Pad and SPSS software. Mann-Whitney U-test was used to compare different study groups.
Results: Our data suggest no significant differences in the readouts of total CD4+ cells either in spleen or blood samples comparing ITP and HM patients. Frequencies of CD4+ T cell subpopulations: Th1, Th17 and Treg were comparable between the ITP patients and controls both in the spleen and blood samples. Importantly though, the percentages of splenic, but not circulating, FoxP3+CD4+ regulatory T cells were significantly increased in HM patients compared to control subjects and ITP patients. Our findings also showed significant difference in Th1/Treg balance in the spleen of ITP patients compared to patients with hematological malignancies.
Conclusion: Splenic T cell subsets can be considered as biomarkers to assess disease pathogenesis and, respectively, prospective therapeutic targets in patients with hematological disorders undergoing therapeutic splenectomy. The study also emphasize the importance of the biomarkers when they are used as ratios or correlative readouts.

Chronic stress fine-tunes the transcriptomics of ageing T cells in 'dirty' mice

Chinna Susan Philip[1], Uku Haljasorg[1], Igor Filippov[1;2], Pärt Peterson[1]
[1]*University of Tartu, Tartu, Estonia*; [2]*QIAGEN, Aarhus, Denmark*

Purpose: Ageing has deleterious effects on the adaptive immune system, especially T cells. Since chronic stress accelerates ageing, we aim to investigate how stress modulates the transcriptomic profile and function of ageing T cells. Studying ageing T cells from tissues requires an immunologically superior mice model called 'dirty' mice that recapitulates adult 'dirty' human immune system.
Methods: We subjected aged (13-14mo) 'dirty' mice to chronic variable stress over 21 days. Immune cells, including various T cell subsets, were analysed from lymphoid and peripheral tissues by flow cytometry. T cells from different tissues were analysed by single-cell RNA-sequencing (scRNA-seq). Furthermore, T cell functionality under chronic stress was analysed by vaccinating aged mice with COVID-19 mRNA vaccine.
Results: T cell frequencies and absolute numbers in spleen remained quite robust under chronic stress. Further analysis of splenic T cells by scRNA-seq corroborated this finding wherein no significant differences were observed in the proportions of T cell subsets. Interestingly, there was an upregulation in the homeostatic genes under chronic stress. Since these genes are included in the proteostasis network, we vaccinated aged mice to investigate the impact of chronic stress on T cell responses. On stimulation, we observed increase in release of pro-inflammatory cytokines, IFN-γ and TNF-α, in stressed splenocytes but no significant changes in splenic T cell subsets. Additional analysis of immune cells in other lymphoid and peripheral tissues revealed an increase in T cells numbers under chronic stress. However, the proportions of T cell subsets in these tissues remain largely unchanged. Taken together, our data suggests the maintenance of proteostasis in splenic T cells after chronic stress in aged 'dirty' mice.
Conclusion: Loss of proteostasis is one of the hallmarks of T cell ageing. The upregulation of the homeostatic genes under chronic stress highlights a new direction in understanding the ageing T cell proteostasis that needs to be explored further. Comprehending the transcriptional dynamics of ageing T cells is clinically significant for developing effective disease management strategies in stressed individuals.

Breaking barriers: scrutinizing T cells that act at the forefront in people who develop multiple sclerosis

Fabienne van Puijfelik[1], Jasper Rip[1], Sophie Shyfrin[1], Steven Koetzier[1], Annet Wierenga-Wolf[1], Helga de Vries[2], Eric Bindels[1], Jamie van Langelaar[1], Beatrijs Wokke[1], Joost Smolders[1;3], Marvin van Luijn[1]
[1]Erasmus MC, Rotterdam, Netherlands; *[2]Amsterdam UMC, Amsterdam, Netherlands*; *[3]Netherlands Institute for Neuroscience, Amsterdam, Netherlands*

Purpose: $CD4^+$ T-cells likely play a key role in breaching the blood-brain barrier (BBB) in multiple sclerosis (MS). Our previous work revealed that so-called Th17.1 ($CCR6^+CXCR3^+CCR4^{dim/-}$) cells predominate the cerebrospinal fluid (CSF) and accumulate in the blood after natalizumab (anti-VLA-4) treatment in people with MS. Especially Th17.1 cells expressing CCR5 and producing granzyme K (GZMK), may constitute a subset poised to cross the BBB as an early event in MS. Here, we assessed the skewing and effector program of GZMK-producing $CCR5^{high}$ Th17.1 cells as potential instigators of MS development.
Methods: We used a 37-color-based spectral cytometry panel that was designed to profile Th17.1 cells in paired blood and CSF from different MS cohorts. We combined spectral cytometry with bulk and single cell RNA sequencing to analyse Th17.1 cells from pre- and post-natalizumab blood. Th17.1 cells and other $CD4^+$ T-cell subsets were isolated from healthy blood to study *in vitro* induction of Th17.1-associated brain-homing/effector molecules using IL-2, IL-15, IL-12, IL-18 and/or IL-23.
Results: As a GZMK-defining marker, CCR5 co-expressed with CXCR6, IL-18R, CD69, CCR2, CD26 and KLRG1 on the Th17.1, which was hardly seen for Th1 ($CCR6^-CXCR3^+CCR4^-$) and Th17 ($CCR6^+CXCR3^-CCR4^+$). These co-expression profiles for Th17.1 cells were more prominent in MS CSF versus blood, and post- versus pre-natalizumab blood. Single cell RNA-seq analysis showed three clusters within Th17.1 cells with both GZMK (*TRYP2*) and granzyme A (*HFSP*), from which one was characterized by CXCR6 (*TYMSTR*). *Ex vivo* experiments confirmed CCR5 and CXCR6 co-expression in GZMK-producing Th17.1 cells. In the presence of IL-2 and IL-15, we found that Th17.1 cells responded to IL-12 to induce CCR5, CXCR6 and IL-18R surface expression. Only for Th17.1, IL-12 synergized with IL-18 to further upregulate CD69, a known early activation and tissue-residence marker.
Conclusion: This study reveals that GZMK-producing $CCR5^{high}$ Th17.1 cells are enriched for markers that represent pathogenic traits of BBB crossing in MS. These markers likely work together to enable a subset of Th17.1 cells to selectively activate, adhere to and break through the BBB, thereby facilitating the entry of other pathogenic lymphocytes into the MS brain.

NFAT single-deficient T cells as a therapeutic option for anti-leukemia and anti-lymphoma responses

Boutaina El Kenz[1], Snigdha Majumder[2], Isabelle Jugovic[3], Domenica Saul[4], Luisa Bell[3], Nadine Hundhausen[1], Rishav Seal[3], Andreas Beilhack[5], Andreas Rosenwald[3], Dimitrios Mougiakakos[6], Friederike Berberich-Siebelt[3]
[1]1 Institute of Pathology, University of Wuerzburg, Würzburg, Germany; *[2]Institute of Pathology, University of Wuerzburg, wuerzburg, Germany*; *[3]Institute of Pathology, University of Wuerzburg, Würzburg, Germany*; *[4]Department of Internal Medicine 5, Hematology and Oncology, Friedrich-Alexander University (FAU), Erlangen, Germany*; *[5]Department of Medicine II, Center for Interdisciplinary Clinical Research (IZKF), University Hospital Wuerzburg, Würzburg, Germany*; *[6]Comprehensive Cancer Center Mainfranken, Würzburg, Germany*

NFAT plays a pivotal role in transmitting signals during T-cell receptor engagement and activation of T cells. However, prolonged NFAT activation has been associated with abnormal T-cell function, particularly contributing to T-cell exhaustion and cytokine release syndrome (CRS). Besides tissue-specific transgenic mice, CRISPR/Cas9 technology allows the application of sophisticated manipulations of T cells to delete specific NFAT family members. Our protocols demonstrated efficient gene-editing of primary murine and human T cells without virus transduction. Nucleofection only transiently compromised the glycolytic reserve. In both murine and human T cells, cytokines were less expressed upon *Nfatc1* and/or *Nfatc2* knockout, while the cytotoxic activity was unchanged *in vitro*. NFATc1 was identified as crucial for the exhaustion of donor T cells in an allo-HCT model, as mice with *Nfatc1* $^{-/-}$ T cells exhibited significantly decreased exhaustion markers compared to wild type. These results provide valuable insights into the intricate role of NFAT in modulating T cell exhaustion, offering potential avenues for fine-tuning T-cell responses in cancer therapy while addressing challenges associated with prolonged NFAT activation.

Purpose: CAR-T cell immunotherapy relies on the anticancer function of modified T lymphocytes, which is why a thorough understanding of their properties is essential for further optimization. Current research focuses primarily on molecular factors, but CAR-T cells also possess complex physical properties that can significantly influence the efficacy of the therapy, yet their impact remains poorly understood. Our research aims to deepen the understanding of the mechanical properties of T lymphocytes in various environments and thus contribute to the further development of CAR-T therapy.
Methods: We applied deformability cytometry and machine-learning-assisted image analysis to study the mechanical properties of the Jurkat cell line as a standard lymphocyte T model. We aim to elucidate how the deformability of Jurkat cells changes upon their activation, understand how the cytoskeleton governs their mechanics, and investigate the effects of exposure to pharmaceuticals, including lipid emulsions that are part of the intravenously administered nutrition for cancer patients. These emulsions, such as Omegaven (a fish oil emulsion) and SMOFlipid (a mixed oil emulsion), come into direct contact with T lymphocytes and have known immunomodulatory effects, yet their impact on leukocyte mechanics remains unexplored.
Results: Preliminary findings indicate that destabilization of the actin cytoskeleton with cytochalasin D has a milder effect on Jurkat cells compared to adherent epithelial cells, probably due to their small size and large nucleus that is the stiffest cellular component. Additionally, our results show that chemical activation of Jurkat cells by PMA (phorbol myristate acetate) and ionomycin does not affect cell deformability, whereas the more physiological activation with antibodies against CD3 and CD28 increases it. This finding highlights the potential importance of the T cell activation mode in therapeutic contexts. Finally, we demonstrate that the effect of lipid emulsions Omegaven and SMOFlipid on cell mechanics is small. However, Omegaven significantly reduces cell viability, which could be related to its adverse side-effects reported in clinical studies.
Conclusion: Our study represents the first systematic deformability cytometry of Jurkat cells and thus provides a crucial foundation for future research on primary lymphocytes and the optimization of CAR-T therapy.

Expression of cytotoxic T-lymphocyte associated protein 4 in interleukin-17A-producing T cells and regulatory T cells is critical for immune homeostasis: Implications for sarcoidosis pathogenesis

Lieke de Jong[1], Jelle Miedema[1], Ingrid Bergen[1], Jennifer van Hulst[1], Menno van Nimwegen[1], Anne-Marie Mus[2], Erik Lubberts[2], Rudi Hendriks[1], Odilia Corneth[1]
[1]Pulmonary Medicine, Erasmus MC Rotterdam, Rotterdam, Netherlands; *[2]Rheumatology, Erasmus MC Rotterdam, Rotterdam, Netherlands*

Objective: Sarcoidosis is a granulomatous disease of unknown origin that primarily affects the lung. We previously found decreased expression of the co-inhibitory marker cytotoxic T-lymphocyte antigen 4 (CTLA-4) in Th17 cells and regulatory T cells (Tregs) in lung-draining mediastinal lymph nodes (medLN) of patients. However, the effects of low CTLA-4 expression in Th17 cells or Tregs are unknown.
Methods: Using the Cre-LoxP system, we generated mice in which the *Ctla4* gene was specifically targeted in IL-17A-producing cells on one (CTLA-4$^{IL17A\text{-}Hz}$) or both alleles (CTLA-4$^{IL17A\text{-}KO}$), as well as mice haplo-insufficient for CTLA-4 exclusively in Tregs (CTLA-4$^{FoxP3\text{-}Hz}$). The immune status of the mice was evaluated by multicolor flow cytometry at 8 and 30 weeks of age and during an immune response to collagen immunization.
Results: We did not find evidence for immune dysregulation in CTLA-4$^{IL17A\text{-}Hz}$ mice. In contrast, spleen and mesenteric LN of CTLA-4$^{IL17A\text{-}KO}$ mice showed a significant increase in the proportions of CCR6$^+$ T cells. Moreover, increased fractions of cells expressing the ICOS activation marker were found within total CD4$^+$ memory T (Tm) cells, CCR6$^+$ T cells and Tregs. Signs of substantial B cell activation were detected. Nevertheless, these immune alterations did not lead to any histopathological changes in tissues from CTLA-4$^{IL17A\text{-}KO}$ mice. Upon collagen immunization splenic CD4$^+$ T cells exhibited increased ICOS$^+$ cell proportions and cytokine production, but this was not associated with enhanced collagen-induced arthritis symptoms in CTLA-4$^{IL17A\text{-}KO}$ mice. In CTLA-4$^{FoxP3\text{-}Hz}$ mice, Tregs were expanded and, interestingly, the fractions of ICOS$^+$ cells were increased in the Tm, CCR6$^+$ T cell and Treg populations.
Conclusions: This study shows that expression levels of CTLA-4 in Tregs are critical for the maintenance of immune homeostasis. In IL-17A-producing T cells CTLA-4 expression levels appears less critical and only a complete deficiency induces immune dysregulation. We observed a reciprocal influence between CTLA-4 expression levels on Th17 cells and Tregs. This would be consistent with a model in which both Tregs and Th17-like cell subsets with reduced CTLA-4 expression in sarcoidosis patients may support increased T cell activation and inflammation.

Quantitative and functional heterogeneity in CD4+ T cell responses to primary COVID-19 mRNA vaccination in older adults

Yvonne Dogariu[1], Martijn Vos[1], Jacquenline van Gaans-van den Brink[1], Teun Guichelaar[1], Elske Bijvank[1], Josine van Beek[1], Jelle de Wit[1], Patricia Kaaijk[1], Cécile van Els[1;2], Jolanda Brummelman[1]
[1]Centre for Infectious Disease Control, National Institute for Public Health and the Environment, Bilthoven, Netherlands; *[2]Infectious Diseases and Immunology, Department of Biomolecular Health Sciences, Faculty of Veterinary Medicine, Utrecht University, Utrecht, Netherlands*

Purpose: Upon vaccination, older adults generally mount lower and more heterogeneous specific T cell responses. Congruently, we previously observed a greater degree of variability in SARS-CoV-2 Spike-specific cellular responses induced by mRNA-1273 vaccination with older age, as measured by IFNγ ELISpot. More in depth understanding of the quantity, phenotype, and functional capacity of Spike-specific $CD4^+$ T cells in the aging and vulnerable population is crucial to improve (future) vaccination strategies.
Method: Hence, we interrogated the Spike-specific $CD4^+$ T cell responses of adult participants (25-78yrs of age) in the VITAL-Corona study before and 28 days after two-dose mRNA-1273 vaccination. Based on age and degree of Spike-specific cellular responsiveness by IFNγ ELISpot (cut-off 10 spot-forming cells/10^5 PBMCs), three distinct groups were defined; low versus high responding older adults (OA-LR versus OA-HR; 60+yr) and high responding younger adults (YA-HR; 25-45yr) as a control group. The quantity, phenotype and functional capacity of the specific $CD4^+$ T cells were further characterized upon 24h stimulation with a Spike-peptide pool using a combined flowcytometric Activation-Induced Marker (AIM) and Intracellular Cytokine Staining (ICS) assay.
Results: Notably, SARS-CoV-2-specific $CD4^+$ T cells were induced following primary COVID-19 vaccination in all three groups. However, the OA-LR group showed overall lower AIM^+ and/or cytokine-producing $CD4^+$ T cells compared to the OA-HR and YA-HR groups. Although a similar trend was found for any combination of 2 out of 4 tested AIM markers (i.e. CD69, CD134, CD137 and CD154), mainly the $CD69^+CD134^+$ $CD4^+$ T cell subset was impaired in the OA-LR group. Additionally, in the Spike-specific AIM^+ $CD4^+$ T cell compartment, reduced frequencies of IFNγ- and IL-10-producing, but similar levels of TNFα- and IL-2-producing $CD4^+$ T cells were observed in the OA-LR group.
Conclusions: Together, following primary COVID-19 mRNA vaccination, OA-LR mount reduced Spike-specific $CD4^+$ T cell responses based on (mostly $CD69^+CD134^+$) activation marker expression and with distinct functional capacities, as the response is skewed away from IFNγ production. These insights underpin the observed cellular responses measured by IFNγ ELISpot at the cohort level, and suggest that an AIM assay might be more suitable to evaluate T cell responses in older adults.

Contribution of circulating Th2-like Tfr and Th2-like Treg cell subsets to early detection in patients with lung adenocarcinoma

Ziqi Xiong[1], chen liu[1]
[1]*Peking University People's Hospital, Beijing, China*

Objective: This study aims to investigate alterations and clinical implications of circulating Th2-like Tfr and Treg subsets in early-stage lung adenocarcinoma (LUAD) patients.
Methods: Peripheral blood samples from 31 healthy individuals and 34 LUAD patients underwent flow cytometry analysis to identify CD4+ T cell subsets, specifically CCR6-CXCR3- Th2-like regulatory T (Treg) cells and CCR6-CXCR3- Th2-like follicular regulatory T (Tfr) cells. IL-4 secretion in Th2-like Treg/Tfr cells was quantified. Dynamics of Th2-like T cell subsets were monitored in 17 patients both pre- and post-cancer resection. Receiver Operating Characteristic (ROC) curves assessed the diagnostic potential of Th2-like T cell subsets for early-stage LUAD.
Results: LUAD patients exhibited a significant increase in both the percentage and absolute count of Th2-like Treg and Th2-like Tfr cells. Following tumor resection, there was a notable decrease in the absolute count of Th2-like Tfr/Treg cells. Additionally, LUAD patients showed a substantial decrease in IL-4 secretion by Th2-like Treg cells. ROC analysis revealed areas under the curves of 0.8155 and 0.7187 for percentages, and 0.7068 and 0.8321 for absolute numbers of Th2-like Tfr and Th2-like Treg cells, respectively, effectively differentiating early LUAD patients from healthy individuals.
Conclusion: The noticeable upregulation of circulating Th2-like Tfr and Th2-like Treg cell subsets in early-stage LUAD patients suggests their potential involvement in LUAD onset and progression, thereby contributing to its early diagnostic potential.

Development of a CRISPR/Cas9 system for functional studies of transmembrane adaptor protein knockout T cells

Nouria Jantz-Naeem[1], Patricia Gintschel[1], Anja Sammt[1], Camilla Merten[1], Andreas Müller[1;2;3], Sascha Kahlfuß[1;2;3], Burkhart Schraven[1;2;3]
[1]Institute for Molecular and Clinical Immunology, University Hospital Magdeburg, Otto-von-Guericke University, Magdeburg, Germany; *[2]Health Campus Immunology, Infectiology and Inflammation (GCI³), medical faculty, Otto-von-Guericke University, Magdeburg*; *[3]Center for Health and Medical Prevention (CHaMP), Otto-von-Guericke University, Magdeburg*

Background: The bacterial CRISPR/Cas9 defense system targets foreign DNA for destruction via incorporation of copies of this foreign DNA into its CRISPR locus. During subsequent infections with the same pathogen, the pathogenic DNA is recognized and CRISPR-RNA (crRNA) transcribed from the CRISPR locus. Transactivating CRISPR-RNA (tracrRNA) then basepairs with the crRNA and forms a functional unit to act as a scaffold for the Cas nuclease, resulting in a guideRNA (gRNA). Hence, the CRISPR/Cas9 technology can be used for targeted deletion or the knock-in of genes of interest.
Objectives: In this project, we utilize CRISPR/Cas9 to delete **modifiers of TCR-mediated signaling** processes (e.g. the **T**-cell **R**eceptor **I**nteracting **M**olecule (TRIM) and the **S**HP2-**I**nteracting **T**ransmembrane adaptor protein (SIT)), **metabolic key enzymes** and **lineage transcription factors** in murine and human T cells and monocyte populations. Our aim is to dissect the precise immunological functions of these proteins in primary hematopoietic cells. In the long run we aim to use our findings to finely tune innate and adaptive immunity e.g. against tumors and, further, to improve chimeric antigen receptor (CAR) T cell therapy.
Methods: sgRNAs for targets are cloned into a retro-gRNA-eGFP vector, in which we exchanged the eGFP reporter with the Thy1.1 reporter. In addition, we crossed Rosa26-LSL-STOP$^{fl/fl}$-Cas9-EGFP mice with Cre deleter mouse strains (e.g. CD4-Cre), enabling cell type-specific Cas9 expression. By western blotting, FACS-analysis, qPCR- and calcium measurements as well as single cell RNA sequencing, we assess cell functionality, activity and metabolic fitness in wildtype cells and target knockout cells.
Results and conclusion: Our results demonstrate that our *in vitro* transduction system is functional and reproducible. Upon knockout of immune checkpoint proteins and SIT and TRIM target proteins, key cytokines and metabolic targets, activation status, proteins involved in antigen presentation and cytokine profiles are altered.

Impact of Estrogen receptor signaling on Th17 cell polarization: possible contribution to Systemic lupus erythematosus development?

Alisier Malard[1;2], Tobias Alexander[3], Julia K Polansky[1;4]
[1]*BIH Center for Regenerative Therapies (BCRT), Berlin, Germany*; [2]*International Max Planck Research School for Infectious Diseases and Immunology, Berlin, Germany*; [3]*Medizinische Klinik mit Schwerpunkt Rheumatologie und Klinische Immunologie, Berlin, Germany*; [4]*Deutsches Rheuma-Forschungszentrum, Berlin, Germany*

Females tend to mount a more robust immune response, leading to an increased prevalence of many autoimmune conditions. Paradoxically, the female hormone 17-β-estradiol (E2) has been attributed an immunosuppressive role by inhibiting differentiation of healthy mouse naïve CD4 T cells (Tn) into Th17 cells, which promote inflammation in many autoimmune conditions, including Systemic lupus erythematosus (SLE). Therefore, we want to analyze the impact of E2 signaling via the estrogen receptors (ERs) in Th17 polarization in male and female human cells, and assess whether alterations in this pathway may contribute to SLE.
We measured the effect of E2, as well as agonists and antagonists of the two ERs (ERa and ERb), on the polarization of human CD4 Tn cells into Th17 cells *in vitro* by measuring the expression of the Th17-defining transcription factor RORγt and the functional marker CCR6. We observed that an ERα agonist inhibited Th17 polarization in healthy female donors, but not in males. Correspondingly, physiological levels of E2 led to a trend of reduced Th17 cell polarization only in females. Preliminary results suggest that E2/ERα signaling maintained their inhibitory effect on Th17 polarization in SLE. In contrast, signaling via ERβ inhibited CCR6 expression in both healthy female and male donors, even in the absence of E2 – indicating that ligand-independent ERβ signaling inhibits the pro-inflammatory potential of Th17 cells. Preliminary analyses indicate that this immunosuppressive effect by ERβ may be lost in SLE patients.
We have shown a sex-specific effect of ligand-induced ERa signaling on Th17 polarization, as well as an E2-independent effect of ERb on CCR6 expression in healthy females and males. While the role of E2 and ERa signaling appears to be maintained in SLE, preliminary results suggest that the estrogen-independent immunosuppressive effect of ERb may be lost in SLE. Understanding ER signaling in CD4 T cells in SLE will help shed light on the sex bias and pathology of the disease, as well as help inform estrogenic contraceptive choices for SLE patients.

CD25-biased IL-2/anti-IL-2 mAb complexes potently expand antigen-primed CD8+ T cells and overcome Treg cell-mediated suppression of activated CD8+ T cells

Petra Weberova[1], Irfan Baki Kilic[1], Katerina Behalova[1], Bohumil Ptacek[1], Milada Sirova[1], Blanka Rihova[1], Marek Kovar[1]
[1]*Institute of Microbiology of the CAS, v. v. i., Praha, Czech Republic*

Purpose: IL-2 is a critical cytokine for the proliferation, survival, and expression of effector functions in activated T cells, but its therapeutic utility in cancer immunotherapy has been hindered by off-target effects leading to serious toxicity and concomitant expansion and increase in the suppressive activity of T regulatory (Treg) cells. Activated $CD8^+$ T cells are pivotal in cancer immunotherapy due to their cytotoxic activity leading to the elimination of tumor cells. The purpose of this study was to investigate the efficacy of CD25-biased IL-2/anti-IL-2 mAb complexes, formed by rmIL-2 and JES6-1A12 mAb (IL-2/JES6), in expanding antigen-primed $CD8^+$ T cells and inducing their effector functions. Since IL-2/JES6 also potently expands Treg cells, we investigated the possibility whether IL-2/JES6 is capable of overcoming Treg cell-mediated suppression of activated $CD8^+$ T cells.
Methods: We utilized a model of OT-I $CD8^+$ T cell adoptive transfer into congenic B6 mice with subsequent priming with ovalbumin and treatment with CD25-biased IL-2/JES6. Flow cytometry analysis evaluated the expansion of adoptively transferred $CD8^+$ T cells and the expression of activation and effector markers. *In vitro* Treg suppression assays examined the effect of IL-2/JES6 on Treg cell-mediated suppression of activated $CD8^+$ T cell proliferation.
Results: CD25-biased IL-2/JES6 potently expanded antigen-primed OT-I $CD8^+$ T cells as well as Treg cells. IL-2/JES6 promoted the upregulation of CD25, granzyme B, and perforin in expanded $CD8^+$ T cells. We demonstrated that IL-2/JES6 effectively abolished Treg cell-mediated suppression of activated $CD8^+$ T cell proliferation, indicating that IL-2 sequestering is a dominant mechanism in how Treg cells suppress activated $CD8^+$ T cells.
Conclusion: CD25-biased IL-2/JES6 potently and selectively expanded the antigen-primed $CD8^+$ T cells but also Treg cells. However, Treg cells were not able to suppress activated $CD8^+$ T cells in the presence of IL-2/JES6.

Histone Deacetylase 1 as a regulator of CD4+ T cell expansion in skin autoimmunity

Melanie Jensen[1], Alice Taliento[1], Maria Stigler[1], Ludwig Erlmeier[1], Nikolaus Fortelny[2], Wilfried Ellmeier[3], Iris Gratz[2;4;5]
[1]Department of Biosciences and Medical Biology, University of Salzburg (PLUS), Salzburg, Austria; *[2]Department of Biosciences and Medical Biology, Center for Tumor Biology and Immunology (CTBI), University of Salzburg (PLUS), Salzburg, Austria*; *[3]Institute of Immunology, Medical University of Vienna, Vienna, Austria*; *[4]EB House Austria, Department of Dermatology, University Hospital of the Paracelsus Medical University (PMU), Salzburg, Austria*; *[5]Benaroya Research Institute, Seattle, United States*

The skin constitutes the first line of defense against pathogens and toxins derived from the environment. It mounts host-protective responses while maintaining immune homeostasis. These functions are fulfilled by immune cells, including $CD4^+$ T cells. Histone deacetylases (HDACs) regulate the acetylation status of histones and non-histone proteins by removing acetylation marks on lysine residues. Hence, HDACs control several biological processes, such as differentiation and function of $CD4^+$ T cells. However, the exact role of HDAC1 in $CD4^+$ T cells, specifically in skin autoimmune diseases, is not well understood.
To assess the role of HDAC1 in the regulation of cutaneous $CD4^+$ T cells, we utilized a well-established mouse model of experimental skin autoimmune disease (K5/TGO) in which ovalbumin (Ova) is expressed by keratinocytes in a tetracycline-dependent manner. We adoptively transferred HDAC1-WT or HDAC1-deficient (HDAC1-cKO) naïve Ova-specific $CD4^+$ OTII T cells in K5/TGO/TCR$\alpha^{-/-}$ recipient mice. Transferred OTII cells responded to the neo-self-antigen Ova in the skin and elicited inflammation. Recipients of HDAC1-cKO T cells displayed increased skin inflammation. This was in line with a decreased fraction of peripherally induced $Foxp3^+$ Treg in HDAC1-cKO OTII recovered from K5/TGO recipients and with increased numbers of HDAC1-cKO T cells in the skin-draining lymph nodes (sdLNs).
Surprisingly, in a competitive setting of HDAC1-WT and HDAC1-cKO T cells, HDAC1-cKO T cells showed a disadvantage for expansion both in sdLNs and skin as well as reduced activation and skin-homing, which might indicate that HDAC1 impacts the potential of OTII to interact with antigen-presenting cells. To test this, we will study early events of T cell activation and proliferation and chemokine receptor regulation of HDAC1-cKO versus WT $CD4^+$ T cells. With the help of already obtained scRNA-sequencing data, we hope to further understand transcriptional changes and determine HDAC1-dependent regulators of T cell expansion and TCR signaling in skin autoimmunity.

Pro-inflammatory response of human memory CD8 T cells are kept in check by GZMB B regulatory B cells.

Tess Van Meerhaeghe[1;2], Manuel Laslandes[2;3], Nabila Djouadi[2], Richard Danger[2], Gaelle Tilly[2], Sarah Bruneau[2], Christophe Masset[2;3], Alain Le Moine[1], Mai Hoa[2], Sophie Brouard[2], Nicolas Degauque[2]
[1]Hôpital Erasme, Anderlecht, Belgium; *[2]Nantes Université, INSERM, Center for Research in Transplantation and Translational Immunology (CR2TI), UMR 1064, Nantes, France*; *[3]CHU Nantes, Nantes, France*

Purpose: Memory CD8 Tcells are critical mediators of antiviral and antitumor immunity. However, an uncontrolled response can contribute to autoimmune diseases or allograft rejection. Elucidating the mechanisms by which memory CD8 T cells are regulated is important for understanding and treating various disease states. Emerging evidence highlights the role of B cells in the regulation of CD8 function. This study aims to evaluate the proliferation, cytotoxic and inflammatory function of CD8T memory cell subsets after coculture with GZMB regulatory B cells (GZMB Breg).
Methods: Purified CD8T cell subsets (naive CD45RA+CCR7+, effector memory [EM] CD45RA-CCR7- and EM expressing CD45RA [TEMRA] CD45RA+CCR7-) from healthy volunteers were stimulated with aCD3aCD28 beads + IL15 for 3 days with in vitro induced GZMB Breg or resting B cells. Proliferation, expression and production of cytokines and cytotoxic molecules (TNFa, IFNg, GZMB, PERF) were measured by spectral flow cytometry. A redirected cytotoxic assay was used to assess CD8T cell cytotoxicity. The activation of glomerular endothelial cells was assessed by flow cytometry after incubation with coculture supernatant.
Results: The proliferation of memory (TEMRA and EM) CD8T cells and their expression of cytotoxic molecules were inhibited by GZMB Breg compared to CD8T alone. In contrast, resting B cells promoted the inflammatory function of memory CD8T. The cytotoxicity of memory CD8T cells was greatly reduced after coculture with GZMB Breg, especially for TEMRA CD8 T cells. Activation of glomerular endothelial cells was reduced when the supernatant of memory CD8T cells was treated with GZMB Breg compared to CD8T with resting B cells or CD8T alone. Studies in kidney transplant recipients with rejection or stable grafts are ongoing.
Conclusion: We show that the diverse pro-inflammatory functions of human memory CD8T cells are strongly influenced by the B cell, with GZMB Breg inhibiting their function and resting (and potentially activated) B cells promoting their function. The mechanisms by which GZMB Breg cells control CD8 T cell function and the impact of allotransplantation on this regulation are under investigation.

Fast & efficient particle-free isolation of mouse CD304+ natural regulatory T cells

Alistair Chenery[1], Trevor Rogers[1], Allen Eaves[1;2], Sharon Louis[1], Frann Antignano[1]
[1]STEMCELL Technologies Inc., Vancouver, Canada; *[2]Terry Fox Laboratory, BC Cancer, Vancouver, Canada*

CD4+ regulatory T cells (Tregs) (CD25+Foxp3+) are important in immune tolerance and homeostasis because of their role in suppressing effector immune responses. Isolation of Tregs is required for downstream molecular characterization and functional assays. Existing products that isolate mouse Tregs involve a time-consuming two-step protocol where enrichment for CD4+ T cells is followed by positive selection of CD25+ Tregs. These cells are often particle-bound and may impede IL-2 signaling due to antibody blocking of IL-2Rα (CD25), which can impact downstream applications. We have developed a novel, fast, and particle-free Treg isolation strategy that targets the mouse natural Treg marker, CD304 (neuropilin-1), and does not block IL-2Rα signaling. Natural Tregs were isolated from mouse spleen and lymph nodes using the Mouse Release CD304+ Regulatory T Cell Isolation Kit and assessed for purity by flow cytometry. Treg suppression and in vitro IL2-mediated expansion assays were performed to validate the function of isolated Tregs. Using this isolation strategy, Tregs were obtained in under 45 minutes with CD4+CD304+ Treg purities of 90.7 ± 3.0% and 92.1 ± 0.7% for spleen and lymph node, respectively (mean ± SD); the majority (~80%) of isolated cells were CD25hiFoxp3+. CD4+CD304- responder T cells were also obtained in parallel isolations with a purity of 94.1 ± 2.9% (mean ± SD). Further, CD4+CD304+ isolated Tregs exhibited consistent dose-dependent suppressive ability when co-cultured with responder T cells. CD4+CD304+ Tregs also displayed robust in vitro expansion when cultured with IL-2 and soluble Mouse T Cell Activators. In conclusion, this novel isolation strategy enables researchers to efficiently obtain pure and functional mouse natural Tregs.

The Role of Follicular Cytotoxic T Cells Subsets and Their Function in Chronic Lymphocytic Leukemia

Fatih Akboğa[1;2], Fehmi Hindilerden[3], Ipek Yonal Hindilerden[4], Emine Gulturk[3], Gunnur Deniz[2], Metin Yusuf Gelmez[2]
[1]Istanbul University, Institute of Health Sciences, Istanbul, Turkey; *[2]Istanbul University, Aziz Sancar Institute of Experimental Medicine, Department of Immunology, Istanbul, Turkey*; *[3]Istanbul Dr. Sadi Konuk Training and Research Hospital, Department of Internal Medicine, Department of Hematology, Istanbul, Turkey*; *[4]Istanbul University, Istanbul Medical Faculty, Division of Medical Sciences, Department of Internal Medicine, Istanbul, Turkey*

Objectives: The follicular cytotoxic T (T_{FC}) cells are new subset of $CD8^+$T cells, express CXCR5, and eliminate infected or malignant B cells. Recent studies suggested that some T_{FC} subsets may be involved in the regulation of antibody responses by interacting with B cells. The functional differences of different T_{FC} subsets and their roles in B cell differentiation, as well as their frequency and roles in Chronic Lymphocytic Leukemia (CLL), a malignant B cell leukemia was investigated in this study.
Method: Peripheral blood mononuclear cells (PBMCs) were isolated from the whole blood of donors and were stimulated by PMA/ionomycin for 5 hours. After culturing, intracellular levels of IL-4, IL-17, IL-21, IFN-γ, perforin, and granzyme-B in T_{FC} subsets were measured on flow cytometry. $CD40L^+T_{FC}$, $ICOS^+T_{FC}$, and $CD19^+$B cells were sorted. After B-T_{FC} co-culture, plasma cell differentiation was performed by flow cytometry, and IgG responses in supernatants were measured by ELISA.
Results: In healthy subjects, IL-4, IL-17, IL-21, and IFN-γ expressions were higher in $ICOS^+T_{FC}$ than $CD40L^+T_{FC}$ and $ICOS^-CD40L^-$ (DN)T_{FC}. $ICOS^+T_{FC}$ had high levels of perforin and granzyme B, but granzyme B expression in $CD40L^+T_{FC}$ was decreased. $CD40L^+T_{FC}$ induced plasmablast differentiation and IgG production in B lymphocytes more than other subsets.
Total, $ICOS^+$, and $CD40L^+T_{FC}$ of CLL patients were shown to be increased in comparison with healthy controls. IL-4, IL-17, IL-21, and IFN-γ expressions in $ICOS^+$ and $CD40L^+T_{FC}$ of CLL patients were also higher than healthy subjects. In CLL patients, $ICOS^+T_{FC}$ exhibited higher perforin and granzyme B expression compared to other T_{FC} subsets. Additionally, there was a positive correlation between $CD5^+CD19^+$ malign B cells and total T_{FC}.
Conclusions: Our results indicate that $ICOS^+T_{FC}$ exhibits a cytotoxic profile, while $CD40L^+T_{FC}$ is more involved in B cell differentiation. Considering the cytotoxic effect of T_{FC}, an increase in T_{FC} is observed in CLL patients along with an increased tumor burden. Given the involvement of $CD40L^+T_{FC}$ in plasma cell differentiation, it is conceivable that the tumor microenvironment in CLL patients might have a role the differentiation of T_{FC} towards CD40L-expressing cells.

Helios and KLRG1 refine the definition of functionally altered CD8+ T cell subsets that evolve by aging and CMV infection

Tamara Schenk[1;2], Martijn Vos[1], Debbie van Baarle[1;2], Teun Guichelaar[1]
[1]National Institute for Public Health and the Environment, Bilthoven, Netherlands; *[2]University Medical Center Groningen, Groningen, Netherlands*

Throughout life, the $CD8^+$ T-cell population changes due to differentiation, resulting in subsets that exhibit altered responsiveness at old age. Partially driven by chronic infections with viruses such as cytomegalovirus (CMV), this responsiveness shifts from antigen-specific, T-cell receptor (TCR)-dependent signals to innate-like or bystander stimuli, such as inflammatory cytokines. CD45RA re-expression and loss of CD27 and CD28 help define subsets with altered responsiveness, but does not fully explain the heterogeneity observed within currently known subsets. Recent studies revealed novel aging-related markers, such as CD56, KIR, KLRG1, TIGIT, and Helios. We questioned if addition of these molecules could more accurately delineate $CD8^+$ T-cell subsets that show skewing from TCR-dependent to bystander responsiveness driven by aging and CMV infection.
We combined all above-described markers in one flow cytometric panel to phenotypically define new $CD8^+$ T-cell subsets using the clustering algorithm FlowSom. We stimulated human peripheral blood mononuclear cells from CMV^+ and CMV^- blood bank donors aged 20 to 40 years or 50 to 70 years either via TCR (by anti-CD3) or with bystander stimuli (interleukin-2 or TLR7/8-agonist R848) and measured induction of activation markers among the redefined $CD8^+$ T cell subsets.
Expression patterns of CD45RA, KLRG1, and Helios appeared to mark $CD8^+$ T-cells differentially responding to TCR or bystander stimuli more accurately than the combination of CD45RA, CD27, and CD28. Thereby, CD45RA expression marks increased TCR responsiveness, whereas co-expression of KLRG1 expression marks increased bystander responsiveness, and additional expression of Helios marks decreased TCR responsiveness. Moreover, we observed that with age and CMV infection, frequencies of subsets that preferably respond as bystander cells increase, and that the bystander responsiveness of these subsets becomes more pronounced.
Thus, inclusion of novel markers Helios and KLRG1 to the classical combination of CD45RA, CD27 and CD28 refines definition of $CD8^+$ T-cell subsets with different responsiveness that develop by aging or CMV infection. This refinement offers a more comprehensive understanding of the shift from TCR-mediated responsiveness to a less specific bystander responsiveness of T cells, which could improve our comprehension of immunosenescence in older adults.

TCF1 enhances regulatory T cells and is upregulated in SLE via the Wnt-β-catenin pathway.

Chen Liu[1], Xingyue Zeng[1], Ayibaoyta Bahabayi[1], Xiayidan Alimu[1]
[1]*Peking University People's Hospital, Beijing, China*

Purpose: This study aims to elucidate the features of T-cell factor 1 (TCF-1)-associated regulatory T (Treg) cells and their relevance in individuals with systemic lupus erythematosus (SLE).
Methods: We investigated the expression of the Tcf7 gene using multiple sequencing datasets from the NCBI-GEO database. Flow cytometry was utilized to detect TCF1 in peripheral blood T cell subsets. In TCF1-associated Treg subsets, we examined inhibitory molecules and assessed IL-10 secretion through in vitro culture. The involvement of the Wnt-β-catenin pathway was explored using the pathway inhibitor XAV939. Additionally, correlation and ROC curve analyses were conducted to assess the clinical significance of TCF1-associated Treg cells in SLE.
Results: High expression levels of the Tcf7 gene and TCF1 protein were observed in CD4+ T cells and Treg cells. Compared to TCF1-negative Tregs, circulating TCF1-positive Tregs demonstrated elevated expressions of CTLA4 and LAG3, along with increased IL-10 secretion. TCF1-positive Tregs in SLE patients exhibited heightened levels of inhibitory markers. Activation of the Wnt-β-catenin pathway was noted in TCF1-positive Treg cells of SLE patients. Impairment in the expression of inhibitory molecules and IL-10 secretion was observed upon addition of XAV939. Furthermore, TCF1-positive Treg cells showed negative correlations with CRP, ESR, and IL-2 levels. ROC curves illustrated that the abundance of TCF1-positive Treg cells could effectively distinguish SLE patients from healthy controls, as well as individuals with primary Sjogren syndrome and rheumatoid arthritis.
Conclusion: The increased presence of TCF1-positive Tregs in SLE patients suggests a heightened suppressive function regulated by the activated Wnt-β-catenin pathway. The TCF1-positive Treg subset holds promise in screening and aiding in the diagnosis of SLE.

Investigation of Canine T Cell Receptor Beta Chain Constant Gene Variants: Implications for Immunotherapy of T cell malignancies

Marek Pieczka[1;2], Leszek Moniakowski[1;2], Dominika Kubiak-Nowak[1;3], Arkadiusz Miążek[1;2]
[1]Wrocław University of Environmental and Life Sciences, Wrocław, Poland; *[2]Department of Biochemistry and Molecular Biology, Wrocław, Poland*; *[3]Department and Clinic of Surgery, Wrocław, Poland*

Purpose: The pursuit of effective immunotherapies for human T cell malignancies has led to a focus on the mutually exclusive expression of T cell receptor beta chain constant gene variants 1 and 2 (TRBC1 and 2). In this context, dogs, with their comparable clinical and molecular characteristics of T cell malignancies, offer an appealing translational research model. This study aims to analyze the sequence diversity of TRBC1 and 2 in normal leukocytes of various dog breeds, as well as in a collection of canine lymphoma/leukemia cell lines, to identify potential targets for immune intervention.
Methods: cDNA sequences were isolated from six canine hematopoietic cell lines of T, B, and NK cell origin, along with 21 peripheral blood leukocyte samples representing 14 different dog breeds. *TRBC1* and *2* sequence differences were estimated using multiple sequence alignment tools. Additionally, the expression of *TRBC* in canine non-T cell lines was confirmed on the single-cell clones.
Results: Analysis reveals amino acid deletion/substitution in the transmembrane domain of canine *TRBC1* and *2* loci, and no amino acid differences in the extracellular domain. In particular, the canine *TRBC1* variant lacks a conserved transmembrane lysine residue. Similar to humans, canine T cell lines predominantly express *TRBC2* transcripts, however often both transcripts are present. Unexpectedly, *TRBC* expression is also detected in certain B and NK cell lines.
Conclusions: The absolute conservation of amino acids within the extracellular domain of canine TRBC constant chains 1 and 2 complicates the design of differentiating antibodies. The deletion of two amino acids from the transmembrane region of TRBC1, involving a conserved lysine interacting with CD3 chains, predicts functional differences. The presence of *TRBC* transcripts in non-T cell lines of hematopoietic origin suggests a potential mixed B/T or NK/T developmental origin, previously unappreciated. The simultaneous expression of *TRBC1* and *2* transcripts in the CLB70, B cell line, presents an unprecedented opportunity to identify transcriptional elements involved in constant chain usage, pending confirmation at the single-cell level. These findings have implications for both immunotherapy development, canine TCRβ function, and understanding the developmental origins of canine T cell malignancies.

Therapeutic targeting of the cyclic-AMP/prostaglandin E2 pathway in ovarian cancer

Nathaniel Edward Bennett Saidu[1], Katharina Bischof[2], Youxian Li[3], Mentowa Fürst Bright[1], Nora Rojahn Bråthen[3], Kjetil Taskén[3]
[1]*Department of Cancer Immunology, Institute for Cancer Research, Oslo University Hospital, Oslo, Norway*;
[2]*Department of Gynecologic Oncology, Institute of Cancer Research, Oslo University Hospital, Oslo, Norway*;
[3]*Department of Cancer Immunology, Institute of Clinical Medicine, Institute of Cancer Research, University of Oslo, Oslo, Norway*

Prostaglandin E_2 (PGE_2), the most abundant prostanoid in the human body, plays a crucial role in sustaining immune homeostasis. In ovarian cancer, however, PGE_2 signaling promotes an immunosuppressive microenvironment through its cognate receptors EP2 and EP4, primarily via the cyclic AMP (cAMP) signaling pathway. We, therefore, aimed at abrogating the PGE_2/cAMP-mediated suppression of metastatic ovarian cancer effector T cells and restoring immunity in these cells by inhibiting the PGE_2-EP2/EP4 receptors.
Here, we demonstrate that PGE_2 is highly upregulated in the plasma and ascites of metastatic ovarian cancer patients compared to plasma from age- and gender-matched healthy donors. Compared to healthy donors, we could also show that activated T cell subsets from ascites and peripheral T cells from these cancer patients produce low levels of IFNγ, IL-2, and TNFα but express high levels of the T cell exhaustion markers PD-1, TIM-3, HLA-DR, and CD39; all of which could be associated to the observed increased PGE_2 levels.
TPST-1495 is a dual EP2-EP4 antagonist currently undergoing a phase 1a/1b clinical trial for several cancer types (NCT04344795). Antagonism of the EP2/EP4 receptors by TPST-1495 countered PGE_2's immunosuppressive effects on activated T cells. TPST-1495 not only induced cytokine (IFNγ, IL-2 and TNFα) production and decreased the expression of both PD-1 and TIM-3, but also, countered the PGE_2 effect on these exhausted immune cells by enhancing their proliferation. Moreover, previous work in our lab demonstrated that protein kinase A and some of its substrates, including GSK3α, VASP, vimentin, and cAMP response-element–binding protein 1, which are downstream of the adenylyl acylase/cAMP pathway, could all be phosphorylated upon T cell stimulation with PGE_2. Combining fluorescent cell barcoding with phosphoflow cytometry, we could show that pre-stimulating T cells with TPST-1495 before exposure to PGE_2 significantly reduced the phosphorylation of these proteins.
This study underscores the potential of blocking the EP2/EP4 receptors to enhance anti-tumor responses, especially in cancers that show an incomplete response to immune checkpoint inhibitors.

Uncovering molecular mechanisms of rapid protection mediated by memory CD8+ T cells

Eva Šályová[1;2], Ondrej Stepanek[1]
[1]Laboratory of Adaptive Immunity, Institute of Molecular Genetics of the Czech Academy of Sciences, Prague 4, Czech Republic; *[2]Faculty of Science, Department of Cell Biology, Charles University, Prague 2, Czech Republic*

Cytotoxic $CD8^+$ T cells are cells of adaptive immunity protecting against pathogens or tumors. One of their hallmarks is the creation of long-lived memory T cells after a pathogen encounter or vaccination. Antigen-specific memory $CD8^+$ T cells provide rapid protection of the host upon re-infection with their cognate pathogen. It is known that memory T cells are better in the protection against *Listeria monocytogenes* than naive T cells on a per-cell basis, but the molecular mechanisms remain to be explained. Production of effector molecules such as granzyme B and IFNγ, or efficient trafficking into the site of infection via surface Core 2 O-glycosylation mediated by GCNT1 may be involved.
We addressed the importance of these molecules for the rapid protection against *Listeria monocytogenes* expressing model antigen ovalbumin (Lm-OVA) mediated by memory $CD8^+$ T cells. First, we generated OVA-specific memory $CD8^+$ T cells by adoptively transferring T cells from monoclonal OT-I Rag2KO mice or OT-I Rag2KO mice deficient in *Ifng*, *Gzmb*, or *Gcnt1* into a congenic host followed by the infection with Lm-OVA.
After 30-60 days, we adoptively transferred these OVA-specific memory $CD8^+$ T cells again into naive hosts, which were subsequently challenged with a high dose of Lm-OVA, and the bacterial burden was determined in the spleen and liver after four days.
Our results showed that disruption of *Ifng*, *Gzmb*, or *Gcnt1* does not interfere with memory formation following the primary Lm-OVA infection. Moreover, *Gcnt1* is dispensable for rapid Lm-OVA clearance by memory T cells. The experiments with memory T cells deficient in *Infg* and *Gzmb* are ongoing at the moment but will be presented at the conference.

A role for a novel factor in T cell biology

Gonçalo Malpica[1], Silvia Ariotti[1], Himadri Mukhopadhyay[1], Germano Vicente[1], Alea Radcke[1], Marc Veldhoen[1]
[1]*Instituto de Medicina Molecular João Lobo Antunes, Lisbon, Portugal*

Chaperones form complexes with cytoplasmic proteins, such as transcription factors, required for cellular functions. We identified one such factor that appears to be required as part of a signalling pathway downstream of the T cell receptor (TCR), since thymic development in conditional knockout (cKO) mice is compromised from the moment TCR signalling is required. Unpublished data from our lab demonstrates that this factor's conditional deletion results in reduced T but not B cell numbers, with marked naïve T cell lymphopenia. Hence, we aim to dissect the molecular pathways that cause the observed phenotype.

To accomplish this, we performed flow cytometry to characterize the immune populations and signalling cascades, such as calcium flux. Furthermore, mass spectrometry assays suggest that our protein of interest binds to cytoplasmic and mitochondrial proteins, thus we performed quantitative polymerase chain reaction (qPCR) and western blotting to assess the presence of key factors at the messenger ribonucleic acid (mRNA) and protein level and confirmed molecule interactions via reciprocal immune precipitations. Finally, we performed the mito stress test to profile mitochondrial function and, importantly, complemented key experiments with electron and immunofluorescence confocal microscopy.

Despite the relevance of calcium influx downstream of TCR signaling we observed that peripheral T cells from cKO mice display significantly lower amounts of calcium in intracellular stores and influx upon store depletion in comparison to control mice. Critically, we observed that this phenotype is progressive during developmental stages of thymocytes.

Furthermore, we observed that, upon *in vitro* and *in vivo* T cell activation, naïve but not memory T lymphocytes from KO mice display decreased activation and proliferation, which translates into a distinct cellular morphology. Naïve T lymphocytes deficient or our factor of interest also exhibited distinct mitochondrial metabolic profiles. The consequence of an altered immune response in cKO mice could be shown using an *influenza* virus infection, which resulted in increased weight loss.

Altogether, we identified a novel factor involved in T lymphocyte development and activation and hypothesize it acts as a molecular switch in downstream pathways from the TCR, impacting mitochondrial dynamics and calcium homeostasis.

Antigen-specificity determines effector function or regulatory capacity of T cells stimulated by B cells

Chien-Hui Chien[1], Chieh-Hsin Liao[1], Bor-Luen Chiang[2]
[1]National Taiwan University Hospital Hsin-Chu Branch, Hsinchu County, Taiwan; [2]National Taiwan University Hospital, Taipei City, Taiwan

Purpose: It has been found that naive B cells promotes $CD4^+CD25^-$ T cells differentiation into regulatory T (Treg-of-B) cells. Previous studies mostly used wild-type B cells to prepare Treg-of-B cells. Treg-of-B cells express ICOS, LAG3, PD1, and CTLA4, produce higher amount of IL-10, and exhibit inhibitory ability in suppression assay as well as in murine models. We would like to explore whether antigen-specific B induced T cells with regulatory function or effector capacity.
Methods: In this study, spleens from C57BL/6 and OB1 (witch have ovalbumin-specific BCR) mice were employed for the isolation of B cells. Spleens from OTII (witch have ovalbumin-specific TCR) mice were utilized for $CD4^+CD25^-$ T cell isolation. Subsequently, Treg-of-B and T-of-OB1 were cultured for experimental analysis. Treg-of-B and T-of-OB1 cells were characterized by protein expression using flow cytometry, cytokine profiling using ELISA, inhibition using suppression assay and murine model of delayed-type hypersensitivity (DTH).
Results: After OVA stimulation, OB1 splenic B cells increased costimulatory molecules, including CD80, CD86, MHCII, and CD69. In contrast to regulatory Treg-of-B, we found that OVA-activated OB1 B cells induced T-of-OB1 cells witheffector function in *in vitro* suppression assay. In cytokine profiles, higher levels of IL-17, IFN-γ, IL-2, and IL-10 during the generation of T-of-OB1 cells compared with Treg-of-B cells. And activated T-of-OB1 cells secreted higher amounts of IFN-γ than Treg-of-B cells. Furthermore, T-of-OB1 could not inhibit IFN-γ-producing Th1 cells *in vitro* and the swelling in DTH model.
Conclusion: In summary, this study showed that antigen-specific B cells increased costimulatory capacity and induced T cells with effector function but not suppressive functions. These findings provided valuable insights into the mechanisms underlying the interaction between antigen-specific B cells and T cells and pave the way for further researches.

This study was supported by grants from the Ministry of Science and Technology (MOST 109-2320-B-002-059 and NSTC 111-2320-B-002-072).

Increased number of Th1 cells and monocytes is associated with infected non-union in patients with long bone fracture

Pia Fehrenbach[1;2], Ferdinand Weisemann[3], Claudia Siverino[1], Katharina Trenkwalder[4;5], Laura Bürgi[6], Simon Hackl[3], Sebastianus A. J. Zaat[2], Esther de Jong[2], T. Fintan Moriarty[1]
[1]AO Research Institute Davos, Davos, Switzerland; *[2]Amsterdam Institute for Infection and Immunity, Amsterdam UMC, Amsterdam, Netherlands*; *[3]Department of Trauma Surgery, BG Unfallklinik Murnau, Murnau, Germany*; *[4]Institute for Biomechanics, BG Unfallklinik Murnau, Murnau, Germany*; *[5]Institute for Biomechanics, Paracelsus University Salzburg, Salzburg, Austria*; *[6]Swiss Institute of Allergy and Asthma Research, Davos, Switzerland*

Bone fracture non-union is classified as a failure of bone healing at least 6 months after fracture fixation. Confirming infection as the underlying cause is challenging in case of subclinical infection. Preoperative blood testing would be valuable in diagnosing infectious causes and facilitate early initiation of appropriate treatment. The aim of this study was to characterize peripheral blood mononuclear cells (PBMCs) from patients with septic and aseptic non-union and compare with patients with uneventful healing.
Patients were recruited from eight level-one trauma centres in Germany, after appropriate ethical approval. Blood from healed (n=18; HEAL), septic non-union (n=21; S) and aseptic non-union (n=24, AS) patients was taken before surgical revision for routine implant removal or treatment of septic or aseptic non-union respectively. PBMCs were immunophenotyped using high-dimensional mass cytometry with a total of 43 markers. Targeted proteomics was performed on plasma samples using Olink 96-inflammation-panel.
T regulatory cells were increased in both AS (p=0.0118) and S (p=0.0478) compared to HEAL. Furthermore, monocytes and Th1 cells were elevated in S compared to both HEAL (p=0.0004, $p\leq$0.0001) and AS ($p\leq$0.0001; p=0.0023). Activation marker CD38 was decreased in CD4+ T cells in AS compared to HEAL (p=0.0005) and AS (p=0.0332). Exhaustion (PD-1, OX-40 and ICOS) and activation markers (HLA-DR and CD69) showed no significant differences in CD4+ and CD8+ T cells. Proteomics revealed increased IL18 expression in S compared to HEAL (p=0.0090). IL6 was increased in S compared to AS (p=0.0062) and HEAL ($p\leq$0.0001) as well as in AS compared to HEAL (p=0.0014). IL10 abundance was increased in S compared to AS (p=0.0469).
In summary, S patients show an elevated number of monocytes and Th1 cells and a high expression of pro-inflammatory cytokines IL6 and IL18. These findings reflect a state of infection and therefore suggests correlations between protein abundances and elevated cell number in the different groups.
In addition, T helper cell subsets seem to have a fundamental role in non-union patients. These findings bring us one step closer to the final goal of providing distinct biomarkers to distinguishing between non-union patients.

Impact of CD69 on experimental autoimmune encephalomyelitis development

Laura Notario[1], Alicia Ballester[1], Sara Ballester[1], Elena Lorente[1], Pilar Lauzurica[1]
[1]*National Center for Microbiology, Madrid, Spain*

CD69 is a homodimeric membrane type II C-type lectin, expresses in all leukocytes and platelets upon activation in inflammatory, infectious or stressful processes and is not expressed in erythrocytes. CD69 has a pivotal regulatory role in shaping the immune response, facilitating the circulation of lymphocytes through lymphoid organs, retaining memory T cells, and driving the effector differentiation of T cells through cytokine regulation. In addition, our studies have recently described the regulated expression of CD69 in endothelial vessels and its involvement in stroke pathophysiology.
The sphingosine 1-phosphate receptor 1 (S1P1) is known to modulate human Multiple Sclerosis (MS). We propose to study the role of CD69 in experimental autoimmune encephalitis (EAE) using CD69-deficient mice (CD69-/-), CD69 overexpressing mice (CD69_Hi), and treatments with anti-CD69 monoclonal antibodies (Mab).
Using CD69−/− mice we found that they are higher susceptible to EAE than WT mice. This result was similar to that found in WT mice treated with anti-CD69 and in those expressing human-CD69 treated with anti-mouse-CD69 and anti-huCD69 mAb respectively, which block CD69 expression. Conversely, the transgenic mouse that overexpresses CD69, recently developed in our laboratory, did not develop any symptoms related to the induction of the EAE disease. We present results to investigate whether CD69 plays a physiological role in regulating the encephalitogenic T cells.
Using CD69 knockout (CD69−/−) mice, we discovered that they exhibit increased susceptibility to EAE compared to wild-type (WT) mice. This susceptibility was further heightened when WT mice were treated with antibodies against the mouse CD69 molecule and when transgenic mice expressing human CD69 were treated with antibodies against the human CD69 molecule. These antibodies effectively block the expression of CD69 and internalize it. Notably, in contrast, the transgenic mouse overexpressing CD69, recently generated in our laboratory, did not manifest any symptoms related to the induction of EAE disease. We will discuss the results of our investigation on lymphocyte migration to the spinal medulla and cytokine production, focusing on whether CD69, through its role in promoting lymphocyte retention and regulating cytokines, plays a physiological role in the regulation of encephalitogenic T cells.

T cell aging deciphered: a comprehensive study of aging-related adaptations in murine intestinal T cells

Martina Palatella[1], Jana Niemz[1], Ihor Fillipov[2], Stefan Flöß[1], Michael Beckstette[3], Xiaojing Chu[3], Raimo Franke[4], Meina Neumann-Schaal[5], Diego Ortiz[6], Christine Falk[7], Oliver Burton[8], Adrian Liston[8], Mark Broenstrup[4], Leif Schauser[2], Till Strowig[6], Maria Rohm[9], Yang Li[3], Jochen Huehn[1]
[1]Experimental Immunology, Helmholtz Centre for Infection Research, Braunschweig, Germany; *[2]QIAGEN, Aarhus, Denmark*; *[3]Bioinformatics and Individualized Medicine, Centre for Individualised Infection Medicine, Hannover, Germany*; *[4]Chemical Biology, Helmholtz Centre for Infection Research, Braunschweig, Germany*; *[5]Leibniz Institute DSMZ - German Collection of Microorganisms and Cell Cultures, Braunschweig, Germany*; *[6]Microbial Immune Regulation, Helmholtz Centre for Infection Research, Braunschweig, Germany*; *[7]Institute of Transplant Immunology, Medical School Hannover, Hannover, Germany*; *[8]Immunology Programme, Babraham Institute, Babraham Research Campus, Cambridge, United Kingdom*; *[9]Institute for Diabetes and Cancer, German Research Centre for Environmental Health, Helmholtz Centre Munich, Munich, Germany*

Background: In the last century, we have seen a dramatic shift in the global demographic toward older ages, a trend known as grey tsunami. Although it is widely accepted that the aging of the immune system contributes to the elderly frailty, currently it is still not clear whether there is a causal link between age-related changes in the gut microbiota and immune-ageing.
Objectives: In this study, we analysed mice aged under well-defined conditions of genotype, sex, diet and environment, to spotlight age-related adaptations, irrespective of infections or cancer.
Methods&Results: Comparable clinical serum parameters and cytokine levels across all analyzed age groups confirmed good overall health status. Moderate changes in the gut microbiota composition were detected in the metatranscriptomic analysis of feces, which further result in age-related alterations in the microbial metabolic functions. Host serum and fecal metabolome were also affected, since metabolomics analyses revealed changes in some microbiota-derived metabolites, thus suggesting possible links between ageing of the host and gut microbiota. Accumulating evidence highlights T cells as important contributors to the multifaceted phenotype of aging. Indeed, unsupervised high-dimensional flow cytometry analysis showed ageing-related adaptations in the colon lamina propria immune cell subset composition. A special focus on colonic $CD4^+$ T cells unraveled accumulation of tissue-resident $Foxp3^+$ regulatory T (Treg) cells, while old $Foxp3^-$ $CD44^+$ memory T (Tmem) cells acquire a more activated and exhausted phenotype. A deeper profiling of these cell types, via ATAC-seq and EM-seq, revealed that colonic Treg cells show only moderate epigenetic age-related changes, while Tmem cells, in line with the flow cytometry data, show remarkable epigenetic changes.
Outlook: Integration of these multi-layer data together with those from scRNA-seq and scTCR-seq will allow us to better investigate the impact of ageing on gut microbiota and host immunity, and to shed light on age-related adaptations in tissue-resident intestinal T cells.

T helper 17 (Th17) cells play a pivotal role in immune defense against bacterial and fungal infections at mucosal surfaces by producing IL-17A, IL-17F, and IL-22 cytokines. However, dysregulated Th17 responses contribute significantly to the pathogenesis of autoimmune diseases. The differentiation of Th17 cells relies on T cell receptor (TCR) signaling and the presence of cytokines such as TGF-β, IL-6, IL-21, and IL-23, which activate transcription factors promoting Th17 cell differentiation. Endogenous factors, including reactive oxygen species (ROS), affect T cell differentiation and autoimmunity. Oxidative stress is known to threat T cells by driven changes in their differentiation and function. However, the mechanisms by which Th17 cells controls oxidative DNA damage remain elusive. We investigated the involvement of the nucleotide excision repair (NER) pathway, particularly Xeroderma pigmentosum complementation group C (XPC), in controlling oxidative DNA damage and Th17 cell function. Our results demonstrate that Th17 cells upregulate NER genes, including XPC, and accumulate less DNA damage compared to other T helper subsets. XPC deficiency compromises Th17 differentiation and function, leading to increased ROS levels, oxidative DNA damage, and impaired glycolytic capacity. Furthermore, we identified the transcription factor BATF as a regulator of XPC expression in Th17 cells. BATF deficiency results in reduced XPC expression, increased ROS levels, and DNA damage, resembling the phenotype of XPC-deficient Th17 cells. Co-immunoprecipitation experiments confirmed a direct interaction between XPC and BATF, suggesting a functional relationship in DNA repair and genomic integrity maintenance in Th17 cells. These findings highlight the critical role of the NER pathway, particularly XPC, in protecting Th17 cells against oxidative DNA damage and ensuring their differentiation and function. Understanding the molecular mechanisms underlying DNA repair in Th17 cells may offer insights into therapeutic strategies for autoimmune diseases targeting Th17 cell dysregulation.

Unraveling the impact of CD69 modulation on CD8+ T cell responses during viral infection

Elena Lorente[1], Yara Cuesta[1], Ana Pintor-Poveda[1], Laura Cobos-Figueroa[1], Laura Notario[1], Pilar Lauzurica[1]
[1]*National Center for Microbiology, Madrid, Spain*

Understanding the intricate mechanisms governing immune responses against pathogens is pivotal for developing effective therapeutic strategies. CD69, a transmembrane C-type lectin protein expressed in immune cells, including T cells and dendritic cells, has emerged as a key regulator in orchestrating immune reactions. In this study, our aim was to clarify the influence of CD69 modulation on CD8+ T cell responses during vaccinia virus (VACV) infection. VACV serves as a model pathogen, and prior research on immunodominance against it has outlined a diverse repertoire of peptides recognized by CD8+ T cells.

This study delves into the influence of CD69 on antigen processing and CD8+ T cell responses against different MHC-I epitopes during VACV infection, utilizing CD69-deficient, CD69-overexpressing, and wild-type (WT) mice. Interestingly, in secondary lymphoid organs, CD69-overexpressing mice showed a 90% reduction in CD8+ T cells, while CD69-deficient mice exhibited a 30% increase compared to WT mice.

Surprisingly, CD69-overexpressing mice exhibited a remarkable reduction in CD8+ T cell populations in secondary lymphoid organs, while CD69-deficient mice displayed an increase compared to WT counterparts. Despite these alterations in lymphocyte numbers, CD69-overexpressing mice demonstrated heightened IFN-γ responses against immunodominant VACV peptides.

Further investigation into CD8+ T cell clones specific to VACV peptides revealed a consistent proliferation and interferon production, irrespective of the significant differences in lymphocyte counts among the mice groups. A remarkable reduction in granzyme production is observed in CTLs from CD69-overexpressing mice. Additionally, we present detailed findings outlining the impact of this reduction on both the functionality and regulation by CD69.

These findings underscore the multifaceted role of CD69 in shaping CD8+ T cell responses during viral infections, shedding light on its potential as a modulatory molecule in host-pathogen interactions. The observed alterations in cytokine profiles and cytotoxicity emphasize the intricate balance maintained by CD69 in fine-tuning immune responses.

Modelling drug-sensitisation of human T-cells to predict risk of skin rash in the clinic

Paul Thomson[1;2], David Spiciarich[3], Sophie Grice[2], Catherine Betts[1], Dean Naisbitt[2]
[1]Safety Innovation, Clinical Pharmacology & Safety Sciences, AstraZeneca R&D, Cambridge, United Kingdom; *[2]Centre for Drug Safety Science, University of Liverpool, Liverpool, United Kingdom*; *[3]AstraZeneca R&D / Clinical Pharmacology & Safety Sciences, San Francisco, United States*

Purpose: Traditional readouts for T-cell antigenicity in response to drugs are capable of detecting T-cell activation by way of proliferation and secretion of cytokines. However, these lack sensitivity and do not distinguish between mild, moderate and severe skin reactions. This gives rise to the problem that more subtle T-cell responses may be missed by these conventional readouts, leading to a false negative diagnosis. Analysis of global protein repertoires in patient T-cells yields greater sensitivity which ultimately can diagnose the occurrence of a skin reaction but also the severity. Therefore, we aim to identify a panel of biomarkers using PBMC samples from known hypersensitive patients with varying degrees of skin adverse reactions.
Methods: PBMC isolated from a drug hypersensitive patient and a healthy, drug-naive, donor were co-incubated (100,000 cells/well) with an offending and non-offending drug at a range of concentrations for 6 days. Following incubation, cells were washed with PBS then snap frozen using liquid nitrogen. Samples were prepared for mass spectromic analysis with 150ng of peptides injected following tryptic digestion and C18 purification. Samples were searched against a library free spectral library and analysed using MsStats with comparisons made between patient and healthy donor samples.
Results: A large number of significant protein groups were detected in the hypersensitive pateint with the offending drug, when compared to the healthy donor, suggesting a drug specific protein change. Interestingly, a large number of significant proteins were also detected with the patient in the presence of the non-offending drug, compared to the healthy donor, suggesting that the patient may also have underlying susceptibility to the non-offending drug, not detected in prior proliferation experiments, warranting further study and optimisation.
Conclusion: The analysis of global protein changes in cells of hypersensitive patients indicates a significant alteration of the protein repertoire in response to drug treatments suggesting this to bear a greater sensitivity than proliferation as an immunological readout.

Neonatal regulatory T cells persist into adulthood in multiple tissues and are enriched in the skin

Morgane Hilaire[1,2], Léonie Cagnet[1,2], Aristeidis Roubanis[1] and Benoît L Salomon[1,2*]
[1]Sorbonne Université, INSERM U1135, CNRS, Centre d'Immunologie et des Maladies Infectieuses (CIMI-Paris), F-75013, Paris, France : [2]Toulouse Institute for Infectious and Inflammatory Diseases (Infinity), INSERM UMR1291 - CNRS UMR5051 - University Toulouse III, Toulouse, France

Foxp3$^+$ regulatory T-cells (Tregs) are present in lymphoid and non-lymphoid organs to establish immune tolerance and tissue-homeostasis. In mice, Tregs start colonizing these tissues just after birth, participating in long-term immune tolerance. However, the generation kinetics of the adult Treg-pool across different tissues is unknown. Here, we investigated the ontogenesis of Tregs from birth to adulthood in different tissues. In lymphoid organs, the adult Treg-pool is composed of cells generated gradually at different ages. In sharp contrast, in the skin and visceral adipose tissue, a large majority of the adult Treg-pool develops in neonates. The kinetics of Treg development is intermediate in the liver, lungs and colon. Compared to Tregs generated later in life, neonatal Tregs that persist into adulthood have a more activated phenotype, express markers of tissue-Tregs and type 2 immunity. Our study reveals major differences in the Treg-pool generation kinetics between tissues and uncovers a main phenotypic shift between Tregs generated in neonates and afterwards.

Plasmatic extracellular vesicles at the intersection of immune and metabolic dysregulation in obesity and type 2 diabetes

Ilaria Spatocco[1], Giorgia Mele[1], Giovanni Di Lorenzo[2], Davide Nilo[2], Clorinda Fusco[1], Kristyna Ruggiero[1], Giusy De Rosa[1], Claudia Russo[3], Mirjam Hoxha[4], Valentina Bollati[4], Claudio Procaccini[5], Giuseppe Matarese[1], Ferdinando Sasso[2], Paola de Candia[1]
[1]Dipartimento di Medicina Molecolare e Biotecnologie Mediche, Università di Napoli Federico II, Naples, Italy; *[2]Department of Advanced Medical and Surgery Sciences, University of Campania "Vanvitelli", Naples, Italy*; *[3]Azienda Ospedaliera Universitaria Federico II, Naples, Italy*; *[4]Laboratorio di Epidemiologia Molecolare e Epigenetica Ambientale, Dipartimento di Scienze Cliniche e di Comunità, Università di Milano, Milan, Italy*; *[5]Laboratorio di Immunologia, Istituto per l'Endocrinologia e l'Oncologia Sperimentale, Consiglio Nazionale delle Ricerche (IEOS-CNR), Naples, Italy*

Purpose. Understanding the pathological mechanisms involved in the development of type 2 diabetes (T2D) is a pressing priority of biomedical research, considering the high individual burden due to T2D cardiovascular complications. Hence, the identification of the cellular and molecular factors at the node of the association between obesity and chronic inflammation, major drivers of the observed T2D epidemic, is endowed with enormous clinical significance. The aim of this work is to test the hypothesis that plasmatic extracellular vesicles (EVs) may mirror the endogenous dysmetabolic conditions, and consequently hamper the function of $CD4^{+}CD25^{high}$ regulatory T (Treg) cells, key players in the immune tolerance maintenance, hence fueling the inflammatory grade and resulting in increased T2D susceptibility.
Methods. To test the work hypothesis, we have recruited lean healthy subjects (body mass index, BMI<25), and overweight/obese individuals (BMI>25) with i) normal glucose sensitivity, ii) impaired glucose tolerance, and iii) diagnosed T2D. In those subjects, plasmatic EVs were isolated by size-exclusion chromatography and analysed for number, size, and molecular cargo (i.e., protein and microRNA profile); in parallel, peripheral blood circulating Treg cell phenotype and proliferative potential were evaluated by FACS analysis *ex vivo*. Additionally, plasmatic EVs are being tested for their biological effect on Treg cell expression profile, activation, and effector function *in vitro*.
Results. By integrating multiple levels of regulation (metabolic, immunological, and environmental), we are dissecting the specific intersection between the plasmatic EV molecular fingerprint, the cytokine/adipokine signature, and Treg cell fitness in the different groups of overweight/obese subjects compared to controls. We found that plasmatic EVs are significantly affected by the individual metabolic status; specifically, EVs represent a concurrent target during T2D development and, at least in part, they may modulate Treg cell immune suppressive capability in different dysmetabolic conditions and chronic inflammation.
Conclusion. In conclusion, a deeper knowledge of the link between plasmatic EV dysregulation and Treg cell impairment in conditions of obesity and T2D is not only necessary to better stratify patients but also to grasp the very pathological mechanism of T2D disease, thus possibly leading to the development of novel strategies to counteract its development and progression.

An integrated plasma circulating protein-miRNA signature in type 1 diabetes: markers and players of disease progression

Giorgia Mele[1], Ilaria Spatocco[1], Licia Prestagiacomo[2], Clorinda Fusco[1], Kristyna Ruggiero[1], Giusy De Rosa[1], Claudia Russo[3], Alessandra Petrelli[4], Claudio Procaccini[5], Giuseppe Matarese[1], Marco Gaspari[2], Paola de Candia[1]
[1]Dipartimento di Medicina Molecolare e Biotecnologie Mediche, Università di Napoli Federico II, Naples, Italy; *[2]Research Centre for Advanced Biochemistry and Molecular Biology, Department of Experimental and Clinical Medicine, Magna Graecia University of Catanzaro, Catanzaro, Italy*; *[3]Azienda Ospedaliera Universitaria Federico II, Naples, Italy*; *[4]San Raffaele Diabetes Research Institute, IRCCS Ospedale San Raffaele, Milan, Italy*; *[5]Laboratorio di Immunologia, Istituto per l'Endocrinologia e l'Oncologia Sperimentale, Consiglio Nazionale delle Ricerche (IEOS-CNR), Naples, Italy*

Purpose. Type 1 diabetes (T1D) is one of the most common chronic autoimmune diseases of childhood, in which immune cells invade the insulin-producing pancreatic islets, causing inflammation and progressive b-cell destruction. Since the rate of islet loss is associated with diabetes-related complications at later stages, traceable biomarkers predicting the autoimmunity progression and the decline in insulin secretion in T1D children may sensibly improve patient management. Hence, the object of the present work is to identify novel plasmatic molecules able to efficiently anticipate the T1D disease trajectory. Moreover, we aim at evaluating the potential pathological effect of the same molecules on a system of human b-cells *in vitro*.
Methods. We have recruited forty children with T1D, showing either lower insulin-dose adjusted A1c (IDAA1c < 8, n=20) or higher IDAA1c (>10.5, n=20) one year after disease onset. We have purified EVs from the plasma of those subjects retrospectively collected at the time of T1D diagnosis, using size-exclusion chromatography. Isolated EVs are then analyzed for microRNA content by RTqPCR and protein cargo by liquid chromatography-mass spectrometry.
Results. We have previously demonstrated that, at disease onset, the quantity of plasma miR-23~27~24 clusters is significantly higher in T1D patients who will rapidly lose insulin secretion capability, as compared to those mostly preserving it. We are now testing whether plasma EV purification may sensibly augment miR-23~27~24 sensitivity; furthermore, by the integration of miRNA with protein data, we are dissecting a complex EV-molecular signature more efficiently predicting T1D progression. Finally, the *in vitro* functional characterization of T1D plasma circulating EVs on human pancreatic b-cells in terms of glucose responsiveness and overall cell fitness is leading to the identification of the molecular determinants (miR-23~27~24 clusters and associated proteins) potentially linked to the aberrant effect of EVs in accelerating the decline of insulin secretion capability.
Conclusions. In conclusion, the described approach enables to integrate proteomics and miRNA quantitative data for the identification of complex disease-associated signatures. The molecular and functional characterization of a plasma circulating protein-miRNA hallmark, anticipating T1D progression, may possess both a relevant prognostic potential and pinpoint novel pathogenetic components in diabetic children.

Mass cytometry-based immune profiling of human Peyer's patches in crohn's disease

Adrian Huck[1], Yasmina Rodriguez Sillke[2], Christian Bojarski[1], Désirée Kunkel[2], Ulrich Steinhoff[3], Britta Siegmund[1], Rainer Glauben[1]
[1]Charité - Universitätsmedizin Berlin - Department of Gastroenterology, Infectious Diseases and Rheumatology, Berlin, Germany; *[2]BIH Cytometry Core Facility (BIH CCF) Flow & Mass Cytometry, Berlin, Germany*; *[3]Philipps-Universität Marburg Institut für med. Mikrobiologie, Marburg, Germany*

Background: Inflammatory bowel disease (IBDs) like Crohn's disease (CD) is characterized by chronic inflammation of the intestinal tract which has been identified as a potential predisposing factor for the development of colorectal cancer. Peyer's Patches, as specialized lymphoid follicles play a crucial role in the development of oral tolerance due to a constant exposition to environmental factors like microbial or food antigens. Murine data indicate an activation and subsequent apoptosis of food-reactive $CD4^+$ T-cells thus maintaining the healthy balance of the mucosal immune system. In IBD, this homeostasis is disturbed, which could drive the course of the disease and potentially promote tumor formation.
Methods: To study the composition of PP in healthy individuals and CD patients, we collected human biopsies of a respective patient cohort in a prospective manner and performed multiplexed mass and flow cytometry for deep immunophenotyping on single cell suspensions. To evaluate the spatial distribution and cellular interactions of immune cell subsets, we used imaging mass cytometry (IMC) on FFPE samples.
Results: Flow cytometry analysis revealed a reduction of activated B cells and an increase of $CD8^+$ effector memory T Cells in active Crohn's disease. For $CD4^+$ T-cells, total numbers were similar, but CD patients showed an increase of central memory and a reduction of effector memory T-cells. Furthermore, $CD4^+$ T-cells of CD patients in PP revealed a significantly reduced apoptotic rate compared to healthy controls. As the IMC data of lymphoid follicles such as PPs presented several challenges regarding their highly condensed cellular structure, several improvements had to be implemented into our analysis pipeline including cell segmentation, cell type identification and sample integration.
Conclusions: Using an IMC analysis pipeline optimized towards the specific features of lymphoid follicles, we were able to resolve differences in immune cell interactions between lamina propria and Peyer's Patch as well as differences of cell-cell interactions between Crohn's disease patients and healthy controls.

Activation of memory and naïve Th cells distinctively affected by myeloid cells with different co-stimulation capabilities

Sıla Ulutürk[1], Güneş Esendağlı[1]
[1]*Hacettepe University, Ankara, Turkey*

Purpose: To test the costimulatory capacities of distinct types of monocyte-derived myeloid cells and myeloid leukaemia cells on activation, proliferation, and cytokine expression profiles of naïve (T_N), central memory (T_{CM}), and effector memory (T_{EM}) $CD4^+$ T cells, ex vivo.
Methods: T_N, T_{CM} and T_{EM} $CD4^+$ T cells obtained from healthy donors via FACS based on their expression of CD45RA, CD45RO, and CCR7. Peripheral blood CD14+ monocytes were isolated by MACS and differentiated into immature dendritic cells (iDC), mature dendritic cells (mDC), M0, M1, and M2 macrophage subsets. Myeloid leukemia cell lines at distinct differentiation stages were also used as myeloid cell models. T cells were co-cultured with the myeloid cells under anti-CD3 stimulation (first signal) where the costimulatory (second signal) capacities of distinct myeloid cell types were followed at different periods. Multiple activation markers, Th-related cytokine profiles and proliferation of T cells were assayed by flow cytometry and cytometric bead arrays.
Results: Different maturation stages within myeloid cells result in diverse activation and proliferation statuses in T_N, T_{CM}, and T_{EM} cells. As the maturation state of the myeloid cells increased, they induced higher CD69 expression for 24h. However, in contrast to more immature cells, mature myeloid cells did not highly induced CD154 expression. Especially in T memory cells, CD69 and especially CD154 expression was not as drastic as in T_N. Notably, memory cells display distinctive activation states compared to their naive counterparts. Additionally, other activation-related surface markers as CD27, CD28, CD25, and ICOS showed diverse early-expression patterns between $CD4^+$ T cell subsets. Furthermore, myeloid cells at different maturation levels induced distinct proliferation kinetics in naïve and memory T cells with different miyeloid cell ratio.
Conclusion: Our results provide proof-of-concept for differential capacities of naïve and memory T cells receiving plethora of costimulatory signals derived from distinct subtypes of myeloid cells.

Inflammatory cytokine-producing gamma delta T cells are increased in the inflamed skin of hidradenitis suppurativa patients

Andreea Petrasca[1], Conor Smith[1;2], Isla David[1], Orlaith Walsh[1], Emily Pender[3], Siun Murphy[4], Alexandra Zabarowski[5], Des Winter[5], Brian Kirby[2;3], Barry Moran[1], Jean Fletcher[1;6]
[1]School of Biochemistry and Immunology, Trinity Biomedical Sciences Institute, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland; *[2]Charles Institute of Dermatology, University College Dublin, Dublin, Ireland*; *[3]Department of Dermatology, St. Vincent's University Hospital, Dublin, Ireland*; *[4]Department of Plastic Reconstructive and Aesthetic Surgery, Blackrock Clinic, Dublin, Ireland*; *[5]Department of Surgery, St. Michael's Hospital, Dublin, Ireland*; *[6]School of Medicine, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland*

Background: Hidradenitis suppurativa (HS) is a debilitating inflammatory skin disease characterised by painful nodules and abscesses that lead to scarring and disability. Current treatments for the disease, which include biologics, are inadequate for many patients and the development of specific therapies has been hampered by poor understanding of the pathogenesis. Dysregulation of the immune system is known to be involved, with activation of both innate and adaptive immune cells. We have previously identified IL-17-producing T cells as key players in HS pathogenesis. γδ T cells, which are unconventional innate-like T cells which are also capable of producing IL-17. The three main subsets in humans are Vδ1, Vδ2 and Vδ3, with Vδ2 T cells predominantly found in blood, while the other two subsets are primarily found in tissue. To date, no studies have investigated the potential role of γδ T cells in HS, although they are implicated in other skin diseases such as psoriasis.
Aim: This study aimed to analyse the role of γδ T cells in HS pathogenesis by examining the frequency of γδ T cell subsets and cytokine profiles in the blood and skin of HS patients compared to healthy controls.
Methods: We isolated peripheral blood mononuclear cells (PBMC) and isolated cells from skin biopsies from HS patients and healthy volunteers. We labelled these using a panel of cell surface markers and intracellular cytokines to analyse the frequencies of γδ T cell subsets and cytokine production by flow cytometry.
Results: Analysis of γδ T cell subsets in skin revealed an increase in Vδ1 T cells which had increased production of inflammatory cytokines IL-17A and TNF-α compared to healthy controls. Analysis of peripheral blood showed no significant changes between HS and healthy controls.
Conclusion: These results suggest a role for γδ T cells in HS pathogenesis and may present an important source of pathogenic cytokines in HS.

Role of Tiam1 in finetuning intestinal Foxp3+ regulatory T cells

Susanne Herppich[1], Lisa Hoenicke[1], Justine Smout[1], Friederike Kruse[1], Jana Niemz[1], Marina C. Grewelin-Pils[2], Xiaojing Chu[3], Bowen Zhang[3], Yang Li[3], Jochen Huehn[1]
[1]Department Experimental Immunology, Helmholtz Centre for Infection Research, Braunschweig, Germany; *[2]Mouse Pathology Platform, Helmholtz Centre for Infection Research, Braunschweig, Germany*; *[3]Computational Biology for Individualised Medicine, Centre for Individualised Infection Medicine, Hannover, Germany*

Purpose: Foxp3$^+$ regulatory T (Treg) cells are crucial to ensure self-tolerance, maintain immune cell homeostasis and control inflammation. Additionally, Treg cells resident within non-lymphoid tissues (tisTreg cells) are important to promote organ homeostasis and tissue repair. The molecular players regulating the homeostasis and functional properties of tisTreg cells are only incompletely understood. Previously, we had identified the guanine nucleotide exchange factor Tiam1 (T-lymphoma invasion and metastasis 1) as one out of eleven proteins that show diverging signaling patterns between Treg cells and conventional T cells (Tconv) upon TCR-mediated activation. Here, we aimed to explore the so far unknown impact of Tiam1 on the phenotype and function of (tis)Treg cells.
Methods: We characterized the CD4$^+$ T cell compartment in various secondary lymphoid organs and non-lymphoid tissues of Tiam1-deficient mice by high-dimensional flow cytometry under homeostatic conditions.
Results: Under steady-state conditions, we observed significantly increased frequencies of tisTreg cells and effector (e)Treg cells within the colon of Tiam1-deficient when compared to wild-type mice. Single-cell (sc) RNAseq of Treg cells from wild-type mice revealed that *Tiam1* expression is rather homogenously distributed among colonic Treg cell subsets, while it is exclusively expressed in a cluster of splenic Treg cells characterized by the expression of major activation markers.
Conclusion: Together, our study suggests that Tiam1 plays a functional role for the diligent adjustment of the homeostasis and phenotype of intestinal Treg cells.

γδ cells uniquely display traits of innate and adaptive immunity. γδ They are enriched in many extra-lymphoid sites including skin and gut, making critical contributions to tissue homeostasis at steady-state and in the context of stress. Their homing depends on tissue-specific Vγ chains e.g., Vγ5Cγ1$^+$ dendritic epidermal T cells (DETC); Vγ7Cγ1$^+$ intestinal intraepithelial lymphocytes (IEL); and Vγ6Cγ1$^+$ dermal T cells. Such cells can make rapid, responses to tissue challenges, seemingly by deploying innate NK and cytokine receptors. This has fuelled a widely-held view that the primary role of TCRgd is to drive the development of appropriate immunosurveillance compartments, rather than to contribute to real-time innate-like responses to challenge.
To test this idea, we generated an inducible knockout of TCR-Cγ1, used by all tissue-intrinsic γδ cells. Ccrossing to mice with a fluorescent reporter for Cre activity, we can identify erstwhile γδ cells within tissues following TCRgd depletion. By these means, we show that: [1] TCRgd is not needed for the survival of skin γδ cells *in vivo* or *in vitro*; [2] TCRgd loss rapidly leads to multifaceted dysregulation of the signature phenotypes of tissue-intrinsic γδ cells, with real-time impacts on tissue physiology; [3] TCRγδ is absolutely required for cells to make rapid innate-like responses to challenges, including Aldara that induces a γδ-dependent psoriasis-like pathology. Moreover, TCRgd deficiency at steady-state resulted in significantly dysregulated expression of multiple gene-sets.
In sum, there is essential real-time dependence on TCRgd in several settings of innate-like, tissue-intrinsic immunosurveillance, drawing a clear distinction from immunosurveillance by NK and other innate lymphoid cells.
We are now using a gene-editing approach to assess the role of TCRgd in human tissue-resident γδ T cells which are associated with good outcomes in patients with cancer.

Evaluation of the role of mucosal associated invariant T-cells in drug-induced immunotoxicity

Georgia Wells[1], Xiaoli Meng[1], Dean Naisbitt[1]
[1]*University of Liverpool, Liverpool, United Kingdom*

Mucosal associated invariant T (MAIT) cells have emerged as key players in potentiating adaptive immunity and regulating tissue inflammation. They comprise 1-4% of the peripheral blood but up to 40% of the hepatic T-cell population where they are involved within the liver defence systems through ligand presentation *via* major histocompatibility class I related protein (MR1). Natural MR1 ligands are typically related to bacterial and viral infection but recently a more diverse range of ligands have been established including small molecule drugs and drug-metabolites. With a high hepatic prevalence and restriction to MR1 which can bind small molecules, it warrants investigation as to whether the MR1-dependent activation of MAIT cells may play a role in drug-induced hepatotoxicity. Healthy donor peripheral blood and clinical liver isolates were analysed to characterise MAIT cell populations (CD3+/TCRVa7.2+/CD161^{high}) using flow cytometry. Results revealed a distinct population of MAIT cells within the peripheral blood of healthy donors whilst clinical liver samples expressed lower levels of CD161, suggesting a more exhausted phenotype. Thus, peripheral blood mononuclear cells have been used to develop a flow panel incorporating sequential gating for MAIT cells and CD161- populations to interrogate different expression of markers and cytokine secretion in response to drug compounds. MR1 blockade will be incorporated to assess dependency on an MR1-T-cell receptor pathway. Ultimately, this will allow the determination as to whether drug compounds are able to activate MAIT cells within an *in vitro* system. Subsequently if MAIT activation is confirmed for compounds, their involvement within the development of immunotoxicity will be assessed in multi-cellular systems incorporating conventional T-cell subsets and hepatocytes.

Assessment of immunomodulatory effects of compounds on lymphocyte functions in human and rat cell cultures activated with naïve antigens

Patryk Kret[1]
[1]*Immunotoxicology, Pharmaceuticals, Bayer AG, Wuppertal, Germany*

Purpose: Given the rising number of therapies that target the immune system, it is becoming more important to develop *in vitro* experimental approaches which might facilitate a more comprehensive analysis of the pharmacology and safety profiles of potential drug candidates. Additionally, development of *in vitro* assays in toxicological species and human enhances potential translatability. In this context, we have developed a functional assay in which lymphocytes are activated *in vitro* with a naïve antigen and exposed to immunomodulating compounds. The objective of the assay is to identify potential modulation of transcriptome, proliferation and cytokine response upon exposure of cells to different compounds. We use robust model immunogens such as keyhole limpet hemocyanin (KLH) for stimulation of human cells and sheep red blood cells (sRBCs) for rat cell culture.
Methods: Human PBMCs or rat splenic cells were isolated, stained with proliferation tracker and plated. These high-density cell cultures were stimulated with KLH (human) or sRBCs (rat) and treated with compounds for 7 days. Post-treatment, multiplex cytokine readout was performed and cell proliferation was analysed using flow cytometry. RNA was isolated from human cells and analyzed using NanoString nCounter platform.
Results: Both, KLH in human and sRBCs in rat cells induced strong proliferation of CD4 T cells. Stimulation of human PBMCs with KLH upregulated a number of genes related to antigen presentation, cell cycle and interferon response. Both, rat and human assays displayed sensitivity to cyclosporin A. In human cell culture, antibodies targeting PD-1/PD-L1 axis led to an increase in CD4 T cell proliferation and significantly enhanced IFN-gamma release. Surprisingly, ipilimumab targeting CTLA-4 showed inhibitory effect on proliferation.
Conclusion: Developed assays in which rat or human T cells are activated with naïve antigens allow for assessment of compounds immunomodulating potential. As efforts to minimize animal use in preclinical testing intensify, such in vitro tests are becoming increasingly vital to evaluate drug safety and efficacy.

Splicing-aware single-cell RNA-Seq resolution of peripheral blood CD4 T cells

Daniil Lukyanov[1;2], Evgeny Egorov[2;3], Valeriia Kriukova[4], Kristin Ladell[5;6], David A. Price[5;6], Andre Franke[4], Dmitriy Chudakov[7;8;9]
[1]*Skolkovo Institute of Science and Technology, Moscow, Russian Federation*; [2]*Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry RAS, Moscow, Russian Federation*; [3]*Lomonosov Moscow State University, Faculty of Bioengineering and Bioinformatics, Moscow, Russian Federation*; [4]*Institute of Clinical Molecular Biology, Kiel University, Kiel, Germany*; [5]*Division of Infection and Immunity, Cardiff University School of Medicine, University Hospital of Wales, Cardiff, United Kingdom*; [6]*Systems Immunity Research Institute, Cardiff University School of Medicine, University Hospital of Wales, Cardiff, United Kingdom*; [7]*Institute of Translational Medicine, Pirogov Russian National Research Medical University, Moscow, Russian Federation*; [8]*Central European Institute of Technology, Brno, Czech Republic*; [9]*Abu Dhabi Stem Cell Center, Al Muntazah, Abu Dhabi, United Arab Emirates*

Purpose: Existing single-cell RNA-sequencing (scRNA-seq) analytical approaches do not generally differentiate between spliced and unspliced mRNA. However, correct usage of splicing information in scRNA-seq data analysis could reveal multiple functional facets of cell biology. Here we develop a method called SANSARA (Splicing-Aware scrNa-Seq AppRoAch) for the splicing-aware analysis of scRNA-seq data. We apply this approach to resolve the transcriptional landscape of human peripheral blood CD4 T cells in a splicing-informed manner.
Methods: scRNA-seq of sorted CD4 T cells. Splicing-adjusted Gene Expression (saGEX) matrix calculation based on the classical scRNA-Seq bionformatical pipelines (Cellranger, velocyto, veloVI, Seurat): splitting spliced and unspliced UMI counts, feature selection and splicing estimation, saGEX cell-feature matrix calculation. Data integration, clustering and dimensionality reduction of saGEX data. Differential gene expression testing and CD4 T cell subset states annotation.
Results: In SANSARA, we combine algorhytms developed by the Kharchenko and Yosef teams and classical bioinfromatical tools to transform splicing-unaware single-cell gene expression data into a splicing-aware format. It is then used for clustering, dimensional reduction and downstream data analysis. In peripheral blood CD4 T cells, accounting for splicing paints a distinct picture of transcriptional heterogeneity across subsets of helper T cells, often differing from conventional splicing-unaware scRNA-seq. We demonstrate reciprocal splicing interaction between the master transcription factors FoxP3 and Helios in Tregs, along with the exclusive expression of the spliced form of IL10RA in activated and effector Tregs. For Th1/cytotoxic axis of helper T cells, SANSARA shows highly specific splicing-related patterns for a number of subset-specific genes, including NKG7, PRF1, GNLY, GZMA, CCL5, FGFBP2, ETS1 and HOPX.
Conclusions: Splicing-aware scRNA-seq analysis reveals a complex organisation of the intrinsic heterogeneity of regulatory T cells and the Th1/cytotoxic axis of CD4 T cells. Beyond that, SANSARA offers a straightforward way to enhance conventional scRNA-seq data analysis with splicing information, opening up a new dimension to explore the role of splicing regulation in cellular gene expression programs.

Therapeutic Implications of a Herbal supplement: A Study on Alleviating Adjuvant-Induced Rheumatoid Arthritis in Rats

Mehrdad Mosadegh[1], Aref Khalkhali[2], Yasaman Sadeghi[1], Yousef Erfani[1]
[1]Tehran University of Medical Sciences, Tehran, Iran; [2]Islamic Azad University of Mashhad, Mashhad, Iran

Purpose: Nutritional status significantly affect disease activity in rheumatoid arthritis (RA). Assess the effectiveness of the Nutrition Bio-Shield (NBS) supplement in alleviating symptoms and modulating the progression of adjuvant-induced rheumatoid arthritis in a rat model.
Methods: In this experimental investigation, a cohort of twenty-five male Wistar rats was subjected to RA induction via Freud's complete adjuvant. Subsequently, 15 of these rats underwent oral administration of the NBS supplement at varying concentrations (12.5, 25, and 50 mg/kg) over a 30-day period, while the remaining 10 rats constituted the untreated control group. Baseline and terminal blood samples were acquired from all subjects subsequent to the 30-day treatment regimen for the purpose of evaluating serum levels of rheumatoid factor (RF), erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP).
Results: Rats subjected to RA induction exhibited a discernible augmentation in inflammatory markers, namely ESR, CRP, and RF, relative to the control group. However, a one-month administration of the NBS supplement at varying dosages (12.5, 25, and 50 mg/kg) resulted in a statistically significant attenuation of ESR, CRP, and RF levels in the treated rats. Notably, the highest efficacy was noted in the 50 mg/kg dosage group. Rigorous statistical analyses corroborated the substantial disparities in ESR, CRP, and RF levels among the experimental groups, with all NBS supplement dosages exhibiting significantly reduced levels vis-à-vis the untreated control group. Specifically, the mean ESR within the 50 mg/kg cohort demonstrated a marked reduction compared to the 12.5 mg/kg and 25 mg/kg groups. Similarly, the mean CRP in the 25 mg/kg and 50 mg/kg cohorts exhibited a significant decrease relative to the 12.5 mg/kg group. Furthermore, the NBS supplement demonstrated efficacy in restoring RF levels to a normative state across all treated rats, with the most pronounced effects noted at the 50 mg/kg dosage ($p < 0.05$).
Conclusion: The findings posit the potential of the NBS supplement to normalize RF levels and mitigate symptoms associated with RA in animal models. The study advocates for the inclusion of the NBS in the therapeutic paradigm for RA, emphasizing the necessity for further exhaustive analyses to validate its therapeutic efficacy.

Delayed-type hypersensitivity component of mouse trinitrobenzenesulfonic acid-induced colitis and collagen-induced arthritis is suppressed by extracellular vesicle-carried miR-150

Paulina Skalska[1], Martyna Cieślik[1], Angelika Fedor[1], Magdalena Gębicka[1], Angelika Domagała[1], Katarzyna Nazimek[1], Krzysztof Bryniarski[1]
[1]*Jagiellonian University Medical College, Department of Immunology, Krakow, Poland*

Purpose: Despite recent scientific advances the complex pathogenesis of rheumatoid arthritis and Crohn's disease remains incompletely understood. Both diseases are linked by the involvement of Th1 lymphocytes mediating delayed-type hypersensitivity (DTH). Although trinitrobenzenesulfonic acid (TNBSA)-induced colitis in mice is dominated by the autoimmune DTH reaction, its contribution to collagen-induced arthritis (CIA) is unclear. Our previous studies uncovered the immunoregulatory role of suppressor CD8+ T cells releasing extracellular vesicle (EV)-carried miR-150 against effector Th1 lymphocytes in DTH induced by haptens or protein antigens. Therefore, we first attempted to experimentally induce DTH component of CIA and then investigated the immunoregulatory activity of EV-carried miR-150 in both diseases.
Methods: Colitis was induced in CBA mice by rectal administration of TNBSA in 50% ethanol and monitored daily by weighing the mice and scoring diahrrea. Some mice received intraperitoneal injection of EV-carried miR-150 or were transferred with miR-150-treated macrophages. At the endpoint, colons were assessed macroscopically and collected for further analyzes. To induce DTH in CIA, DBA donor mice were injected twice with collagen either in incomplete Freund's adjuvant into tail base skin or in physiological saline into abdominal skin. Twelve or five days later, respectively, DTH effector cells were collected from donor lymph nodes and spleens, partly treated with EV-carried miR-150 and transferred to naive DBA recipients that were intradermally injected with collagen in physiological saline into hind paws, and their swelling was measured 24-72 hours later.
Results: Both, EV-carried miR-150 and miR-150-treated macrophages significantly alleviated active DTH reaction in TNBSA-induced colitis. Moreover, EV-carried miR-150 suppressed adoptively transferred DTH in CIA in both elaborated protocols. These effects were selectively blocked with anti-miR-150.
Conclusion: Currently modified CIA protocol allows for studying DTH reaction induced by adoptive transfer of collagen-induced effector Th1 lymphocytes. Moreover, this reaction is specifically down-regulated by therapeutically-administered miR-150 protected by EVs. Similarly, miR-150 inhibits DTH component of TNBSA-induced colitis and its suppressive activity is greatly increased by macrophages. Altogether, our current findings suggest the possibility of therapeutic use of miR-150 in ameliorating the DTH response in the pathogenesis of various autoimmune diseases.

Characterization of HDM3006, a highly potent and selective leading compound targeting STING for the treatment of Systemic Lupus Erythematosus

Mengting Zhao[1], Chuan He[1], Hao Pan[1], Cancan Cai[1], Yan Huang[1], Liubin Guo[1], Chunhua Jiang[1], Dongzhou Liu[1]
[1]*Global Drug Development Center, Huadong Medicine, Hangzhou, China*

Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disorder with pathogenic autoantibodies and immune complex deposition that lead to severe inflammation and tissue injury. Simulator of interferon genes (STING) plays a critical role in recognizing dsDNA and stimulating immune response in innate immunity. The over activation of STING may cause a range of DNA-driven autoimmune disorders such as SLE. In series of the study of STING modulators, we have characterized a highly potent and selective small-molecule antagonist.
Materials and methods: THP-1 cell line, human and mouse primary cells, two different mouse lupus models were utilized to explore the action of STING antagonist, and its ability to regulate disease development both *in vitro* and *in vivo*. All statistical analyses were calculated through GraphPad Prism.
Results: In our study, HDM3006 showed robust down-stream cytokine inhibition through STING blockage in mouse and human monocytes, and cell potency is nanomole. There was no significant effect on the human ether-à-go-go-related gene (hERG) and cytochrome P450. Importantly, HDM3006 blocks STING activity *in vivo* with good oral bioavailability of 67.3% and ameliorates disease development in two mouse models for lupus, with decreased dsDNA secretion, improved histology infiltration and prolonged mouse survival rate.
Conclusion: The preliminary data of HDM3006, a highly potent and selective small molecule leading compound, has shown the potential for treatment against STING-related autoimmune diseases, especially for SLE.

NK CD45RA+ and CTLs CD62L+ as potential diagnostic biomarkers of Rheumatoid Arthritis, with increased expression of immunosuppressive immune checkpoints following ex vivo cell therapy

Carolina Pujalte-Satorre[1], Jose Miguel Sempere-Ortells[1], Andrés Baeza-Morales[1], Jorge Esteve-Girbés[1], Juan Javaloyes-Anton[1], Ana Belen Lopez-Jaen[1], Pascual Martinez-Peinado[1], Miguel Medina-Garcia[1], Francisco Javier Navarro-Blasco[2], Alicia Navarro-Sempere[1], Cynthia Romera-Lopez[2], Sandra Pascual Garcia[1]
[1]*University of Alicante, San Vicente del Raspeig, Spain*; [2]*General University Hospital of Elche, Elche, Spain*

Purpose: Mesenchymal stem cells (MSCs) are multipotent cells with immunomodulatory and immunosuppressive effect on leukocytes, that have become a potential therapeutic treatment for inflammatory diseases, such as rheumatoid arthritis (RA). RA is a systemic autoimmune disease marked by synovitis resulting in cartilage and bone degradation, diminishing the patients' quality of life. The aim of this study is to analyse variations in the leukocyte expression of different antibodies as potential biomarkers capable of discerning the activity status of RA, and how MSCs could immunomodulate this expression.
Methods: Newly diagnosed RA patients (n=5) and healthy controls (HDs, n=6) were recruited to study their leukocyte phenotype through staining anticoagulated blood samples with different anti-human monoclonal antibodies: CD3, CD4, CD8, CD11a, CD16, CD19, CD28, CD45RA, CD45RO, CD56, CD62L, CD69, CTLA-4 and PD-1 (BD Biosciences) and analysed by spectral flow cytometry (Northern Lights, Cytek). MSCs conditioned medium (CM) was obtained from 10.000 MSCs cultured with DMEM supplemented with 10% FBS, 1% glutamine and 1% antibiotics. After 4 days, the supernatant was frozen at -20ºC. PBMCs from HDs (n=4) and RA patients (n=2) were isolated from anticoagulated blood samples by density gradient centrifugation and cultured in 96-well plates (100.000 cells/well) with different concentrations of MSCs CM (0%, 25%, 50% and 100%). After 5 days of incubation, PBMCs were stained with the previous anti-human monoclonal antibodies and analysed by spectral flow cytometry.
Results: The only statistically significant differences found between HDs and RA were in $CD62L^+$ CTLs ($p<0.01$), $CD45RA^+$ NK cells ($p<0.05$), $CD45RO^+$ granulocytes ($p<0.05$), and $CD45RO^+CD62L^+$ granulocytes ($p<0.0001$). With ROC curve analysis, only $CD62L^+$ CTLs ($p=0.0550$) and $CD45RA^+$ NKs ($p=0.0472$) were able to discern between newly diagnosed patients and HD. On the other hand, the addition of CM from MSCs decreased the expression of $CD62L^+$, $CD69^+$, while increasing CTLA-4^+ and PD-1^+ in RA patients.
Conclusion: In conclusion, the presence of $CD62L^+$ CTLs and $CD45RA^+$ NKs in peripheral blood could be a potential diagnostic biomarker for RA, and MSC-derived CM increases the expression of immunosuppressive immune checkpoints in these patients, favoring a future cellular therapy.

Selective CAR-T cell mediated B cell depletion suppresses interferon signature in systemic lupus erythematosus

Artur Wilhelm[1;2], David Chambers[2], Fabian Müller[2], Aline Bozec[2], Ricardo Grieshaber-Bouyer[2], Thomas Winkler[2], Dimitrios Mougiakakos[3], Andreas Mackensen[2], Georg Schett[2], Gerhard Krönke[1;2]

Autoimmune diseases persist as a significant obstacle for those affected, lacking definitive prospects of a cure. Despite notable advances in comprehending auto-reactivity in recent times, much remains unknown, and new questions continue to emerge. However, the evolution of single-cell sequencing technologies and therapeutic strategies has rendered tackling these questions more feasible. By employing advanced molecular profiling alongside targeted therapies, there exists the potential to unravel the complexities underlying immune-mediated inflammatory disease like systemic lupus erythematosus (SLE) in human subjects. In this study, we utilize a combination of single-cell RNA sequencing and T/B cell repertoire analysis to conduct a thorough examination of molecular alterations in the immune profile following anti-CD19 CAR T cell-induced B cell depletion in SLE patients in a reverse translational manner. The resultant datasets not only validate the targeted resetting of the B cell response by CAR T cells but also unveil concurrent shifts in the transcriptional landscape of monocyte and T cell subsets, manifesting in a notable reduction in type 1 interferon signalling. Consequently, our present findings furnish compelling evidence for a causal link between the B cell response and the heightened interferon signature observed in SLE. Moreover, they underscore the efficacy of integrating targeted therapies with innovative analytical methodologies to decipher the molecular underpinnings of immune-mediated inflammatory diseases in human populations.

Enhanced therapeutic effect of CXCR4/IL10-expressing mesenchymal stromal cells in a preclinical model of inflammatory bowel disease

Mercedes Lopez-Santalla[1], Marta Covadonga Ordoñez-Velasco[1], Miriam Hernando-Rodriguez[1], Maria Fernandez-Garcia[1;2], Juan Antonio Bueren[1], Rosa Maria Yañez[1], Marina Garin[1]
[1]CIEMA/IIS-FJD/CIBERER, Madrid, Spain; *[2]Kiji Therapeutics, Paris, France*

Inflammatory bowel disease (IBD) consists of a chronic inflammatory disorder, which mainly involves the intestinal mucosa of the digestive tract. The aetiology of IBD is not clearly established although many aspects of genetic and environmental factors together with immune responses activated against the epithelium and the commensal flora have been described. Nowadays, no curative treatment for IBD has been discovered. Current treatments of IBD aim to decrease inflammation to prevent recurrence and to prolong periods of remission. Many of them have significant side effects with primary non-response or secondary loss of response. The development of new therapeutic treatments for IBD is urgently required. Mesenchymal stromal cells (MSCs) therapy has emerged as an innovative therapeutic alternative for IBD due to its capacity for modulating inflammatory immune responses. A significant number of preclinical studies in IBD have shown that systemic administration of MSCs can reduce intestinal inflammation without adverse effects. Despite the successful preclinical results in IBD, no consensus on the efficacy of MSCs in IBD clinical trials can be yet drawn. To enhance the therapeutic potential of MSC-based therapy, we have genetically modified adipose tissue-derived MSCs with a lentiviral vector carrying the CXCR4 and interleukin 10 genes aiming to enhance the migration of MSCs with improved anti-inflammatory potential to inflamed tissues. The therapeutic efficacy of CXCR4/IL10-expressing MSCs was tested using the dextran sulphate sodium (DSS)-induced colitis model. Compared with non-genetically modified MSCs, a single intraperitoneal dose of CXCR4/IL10-MSCs on day 5 of a 7-day DSS cycle showed a significant reduction in the disease activity index and the incidence of colitis, preserving the colon structure, both in the short and in the long term. Biodistribution studies by IVIS system indicated that, at 24 h, CXCR4/IL10-MSCs showed decreased signal in peripheral blood whereas an enhanced signal was observed in liver, colon and lungs, with respect to non-modified MSCs. Decreased, inflammatory leukocyte infiltration was observed in colon. These results suggest that CXCR4/IL10-expressing MSCs may represent a targeted and potent MSC-based cell therapy product for the treatment of inflammatory bowel disease.

Recently, several inflammatory and autoimmune diseases, such as multiple sclerosis (MS), have been linked to gut dysbiosis and to an unbalanced diet. Indeed, many research groups have reported differences in the gut microbiota of persons with MS (pwMS) compared to healthy controls. Furthermore, both acute fasting (AF) and caloric restriction (CR) have been shown to be effective and to reduce severity of experimental autoimmune encephalomyelitis (EAE) in animal models. New clinical studies are needed in order to understand if and how diet could supplement MS therapy. The aim of this project is to improve the efficacy of disease-modifying therapies (DMTs) in MS, in influencing the metabolism and immune modulating through CR diet. Patients enrolled in the study were followed for 2 years during which blood for experiments was collected at different timepoints, before the beginning of the therapy, and after 6, 12, 18 and 24 months. Freshly isolated PBMCs from pwMS were stained with different multi-colour flow cytometry panels in order to identify and to characterize the different immune cell populations. Patients were also divided according to the diet in three different cohorts: free diet (FD), caloric restriction (CR) and caloric restriction without gluten and lactose (CRGL). Analyses focused on T lymphocytes phenotype and functionality show the progressive reduction of the absolute numbers of memory T subpopulations and frequencies of pro-inflammatory cytokine (IFN-γ and TNF-α) production during all timepoints in both CR and FD groups. No additional impact was found when a gluten- and lactose-free regimen was followed. Analysis on different immune subsets (B cells and innate immune cells) are still ongoing and may reveal further immune adaptations. Although several dietary regimens have been proposed to provide benefits in pwMS, some of them including the intermittent-fasting diet have been shown to be detrimental in the long run. We propose that a simple diet based on moderate caloric restriction significantly enhances the beneficial effects of a DMT through an additional immunomodulatory effect on inflammatory T cells.

Inflammation is pivotal in relapsing-remitting multiple sclerosis (MS) pathology and involves both T and B cells. Treatment with B cell-depleting monoclonal antibodies is effective in reducing the clinical inflammatory activity of MS, but other drugs with different mechanisms of action also appear to be effective in the treatment of MS. Cladribine is a second-line oral therapy which does not completely deplete all circulating B lymphocytes and impacts mainly memory B cells. However, the exact memory B cell subpopulation involved in disease progression and the most responsive to therapy has not been identified.
We enrolled 40 patients with MS to study how B cell subpopulations change during Cladribine treatment. PBMC were isolated from fresh blood before starting therapy (T0), six months (T1), one (T2), two (T3) and three years later (T4). We monitored B cell reconstitution performing a complete immunophenotyping at baseline and during cladribine treatment with high dimensional flow cytometry. We correlated this dataset with serum neurofilament light-chain dosage, to identify biomarkers of treatment efficacy.
In addition to the reduction of classical memory B cells, changes in atypical subpopulations also emerge. Type 2 Double Negative (DN2) are highly activated unconventional switched (IgD-IgM-) memory B cells peculiarly lacking CD27, associated with chronic immune disorders. Crucially, these cells express the highest levels of HLA-DR among B cell subsets, indicating high potential for antigen-presentation and autoimmune perpetuation through efficient interaction with T cells. Interestingly, MS patients have significantly higher fractions of DN2 at baseline, and we find that these cells are drastically reduced following cladribine treatment. Also IgM+ memory B cells decrease and remain stable for more than two years after treatment.
Meanwhile, naive B cells increase, particularly transitional B cells. The increased presence of transitional B cells, which reach the systemic circulation directly from the bone marrow, compensates for the lack of memory B cells and seem to correlate with a slower progression of the disease.
Our data show a reduction in the circulation of distinct B cell subpopulations together with waves of repopulation by B cells from the bone marrow, which may underlie the efficacy of cladribine in containing neuroinflammation.

Innate immunity under high efficacy disease modifying therapy

Silvia Corbisiero[1], Marta Pirronello[1], Mario Picozza[1], Andrea Misiti[1], Alice Verdiani[1], Silvia D'Orso[1], Gisella Guerrera[1], Manolo Sambucci[1], Beatrice Lista[1], Elena Olivieri[1], Serena Ruggieri[2], Esmeralda Quartuccio[2], Maria Chiara Buscarinu[3], Francesca De Masi[1], Carla Tortorella[2], Marco Salvetti[3], Claudio Gasperini[2], Giovanna Borsellino[1], Luca Battistini[1]

Multiple sclerosis (MS) is a chronic inflammatory disease of the central nervous system (CNS), characterised by the formation of demyelinating lesions in the white and grey matter. While its pathogenesis is still unclear, multiple evidence points towards the role of the neuro-immune crosstalk in determining neuronal damage. Neuroinflammation is mediated by dysregulated pro-inflammatory effector T cells and an involvement of B-cells that induce CNS injury in MS. Cladribine, a high efficacy disease modifying therapy, is a prodrug whose phosphorylated form interferes with DNA synthesis and repair leading to both B and T cell death. To verify the efficacy of this treatment, the serum concentration of neurofilaments was determined, and as we expected, they are higher in persons with MS (pwMS) compared to healthy donors (HD), and their levels in pwMS are reduced under treatment. To better understand how this drug works, it is necessary to expand the view on the spared innate immune cells whose role has not yet been deeply investigated. The function and phenotype of innate immune cells was studied in 40 pwMS and 16 HD. Fresh heparinized blood sample of pwMS was collected before (T0) and after pharmacological treatment at 6, 12, 24 months (respectively T1, T2 and T3) and whole blood was stimulated with LPS and R848 stimuli which mimic bacterial or viral infections, respectively. Thanks to multiparametric flow cytometry analysis, we investigated 10 myeloid subpopulations and their production of 7 different cytokines. Our analysis confirm that Cladribine does not induce a change in the amount of innate immune cells, also in rare innate subpopulations, not previously studied. Before starting therapy, the majority of innate immunity cell populations, including classical, non-classical monocytes and dendritic cells are more reactive in pwMS compared to HD, except for the cDC1 population. During the treatment, this reactivity remains stable, and this ensures a first line protection against infection for pwMS. The preserved cytokine production in pwMS under Cladribine could explain this drug's ability to protect against infection, compared with other immune-depleting drugs which have as main side effect a high risk of infection.

Characterization of immunomodulatory effects of dental pulp stem cells for therapy in rheumatoid arthritis

Alessandro Rossi[1], Veronica Galli[1], Martina Bonacini[1], Ilaria Ferrigno[1;2], Gianluca Carnevale[3], Rosanna Di Tinco[3], Maria Grazia Catanoso[4], Fabio Brandolino[4], Claudio Galluzzo[4], Alessandro Zerbini[1], Carlo Salvarani[3;4], Stefania Croci[1]
[1]Clinical Immunology, Allergy and Advanced Biotechnologies Unit, Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Reggio Emilia, Italy; *[2]PhD Program in Clinical and Experimental Medicine, University of Modena and Reggio Emilia, Modena, Italy*; *[3]Department of Surgery, Medicine Dentistry and Morphological Sciences with Interest in Transplant, University of Modena and Reggio Emilia, Modena, Italy*; *[4]Rheumatology Unit, Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Reggio Emilia, Italy*

Purpose: We aimed to investigate immunomodulatory effects of dental pulp stem cells (DPSCs) on lymphocytes and monocytes from patients with rheumatoid arthritis (RA), a chronic, autoimmune disease that primarily affects joints leading to cartilage and bone damage.
Methods: We evaluated the effects of DPSCs *ex vivo* on lymphocytes and monocytes obtained from peripheral blood of 8 patients with RA non-responders to conventional synthetic disease-modifying antirheumatic drugs. Lymphocytes were activated with anti-CD3/CD28 beads or with CpG ODN 2006, while monocytes were activated with LPS. After 48 hours of co-culture between DPSCs and activated lymphocytes or monocytes, 14 cytokines were quantified in supernatants by a multiplex bead-based assay and the expression of PD-L1, PD-L2, CD155, CD80, CD86 and 4-1BBL immune checkpoints were analyzed by flow-cytometry on DPSCs. Activated lymphocytes and monocytes as well as DPSCs cultured alone were used as comparison.
Results: After co-culture with DPSCs, levels of sIL-6R, MIP1β and TNFα decreased while levels of MCSF, MCP1 and IL-23 increased in supernatants of CD3/CD28 activated lymphocytes. In ODN 2006 treated lymphocytes, levels of IL-6, MCP1 and IL-21 increased in supernatants. Monocytes activated with LPS showed a decrease in IL-6, sIL6R, IFNγ, IL-8, MCP1, TNFα, BAFF, IL-1β, IL-18 levels while an increase in IP-10 levels in supernatants.
DPSCs showed a basal expression on the cell surface of PD-L1, PD-L2, CD155, while they did not express CD80, CD86 and 4-1BBL. Co-culture between DPSCs and CD3/CD28 activated lymphocytes as well as co-culture between DPSCs and LPS activated monocytes from all patients increased PD-L1, PD-L2 and CD155 expression on DPSCs. Instead, the expression of PD-L1, PD-L2 and CD155 on DPSCs following co-culture with ODN 2006 treated lymphocytes resulted heterogeneous among patients. The expression of CD80, CD86 and 4-1BBL were not induced by any of the co-culture conditions.
Conclusions: DPSCs modulated cytokine levels in supernatants from activated lymphocytes and monocytes. In particular, the effects of LPS stimulation on monocytes appeared to be mainly counteracted by DPSCs. Data suggest that the overexpression of inhibitory immune checkpoints by DPSCs could be involved in DPSCs immunomodulatory activities.

Investigating the impact of MSC-EVs on B cell responses

Manon Williams[1], Dessi Malinova[1], Meadhbh Brennan[2], Pamina Contreras Kallens[2]
[1]*Queen's University Belfast, Belfast, United Kingdom*; [2]*University of Galway, Galway, Ireland*

MSCs are multipotent stem cells found in the bone marrow, and there is much interest in their therapeutic potential in the context of tissue regeneration and immunosuppression. MSCs have been shown to induce a regulatory response in some effector immune cells, and have been shown to have immunomodulatory effects on T and dendritic cells. However, their effect on B cell function remains unclear. When these stem cells are exposed to inflammatory conditions mimicking infection or injury, it is thought that their immunomodulatory properties are enhanced. To bypass the risks associated with using cells as therapeutics, we can utilise the MSC secretome, which mainly consists of nanosized extracellular vesicles. We hypothesize that proinflammatory priming of MSCs will increase the immunomodulatory effect of their secreted EVs on B cells, which may offer insight into their use as modifiers of B cell activity in autoimmune disease. To determine this, we are investigating the effects of EVs isolated from resting and primed MSCs on primary murine B cell activation, proliferation, and antigen presenting capabilities.
We isolated EVs from resting and primed MSCs using ultrafiltration and size exclusion chromatography, allowing the collection of a pure fraction of EVs. The EVs were then characterised and co-cultured with primary murine B cells during various cell-based assays including activation and antigen presentation assays, which were analysed using flow cytometry. These experiments have indicated that EVs from primed MSCs enhance B cell activation *in vitro*, even when the cells are not stimulated to induce activation, and potentially promote B cell survival.
Building on this, we are also looking at the effect of MSC-EVs on B cell differentiation and antigen presenting capacity, with a view to replicate these experiments in vivo to advance our understanding of the therapeutic uses of EVs.

Methotrexate hampers induction of antigen-specific CD4 T-cells, while TNF inhibitors impede maintenance of antigen-specific B cells in IMID patients following SARS-CoV-2 mRNA vaccination

Laura Kummer[1;2;3], Laura Fernandez Blanco[1;2;3], Christine Kreher[1;2], Lisan Kuijper[1;2], Veronique Konijn[1;3], Tineke Jorritsma[1;2], Mariël Duurland[1], Maryse Tempert[1;2], Niels Verstegen[1], Koos van Dam[2;3], Eileen Stalman[2;3], Luuk Wieske[3;4], Mathieu Claireaux[3], Marit J. van Gils[2;3], Laura Boekel[5], Gertjan Wolbink[1;5], Geert D'Haens[3], Adriaan Volkers[3], Theo Rispens[1;2], Sander Tas[2;3], Filip Eftimov[2;3], Taco Kuijpers[1;2;3], Anja ten Brinke[1;2], Marieke van Ham[1;2;6]
[1]Sanquin Research and Landsteiner laboratory, Amsterdam, Netherlands; *[2]Amsterdam institute for Immunology and Infectious Diseases, Amsterdam, Netherlands*; *[3]Amsterdam UMC, Amsterdam, Netherlands*; *[4]Antonius Ziekenhuis, Nieuwegein, Netherlands*; *[5]Reade, Amsterdam, Netherlands*; *[6]Swammerdam Institute for Life Sciences, Amsterdam, Netherlands*

Purpose: Immune-mediated inflammatory disease (IMID) patients are often treated with immunosuppressive medication, such as methotrexate (MTX) and TNF inhibitors (TNFi), to dampen inflammatory immune responses. At the same time, these therapies may impact vaccination responses. Post SARS-CoV-2 vaccination, humoral immune responses exhibited slower kinetics in IMID patients using MTX, and reached lower median antibody titers and decreased faster over time in patients using TNFi, compared to controls. B cells and CD4 T-cells are key players in the formation of high-affinity antibodies, yet the effects of MTX and TNFi on cellular vaccine responses remain largely unclear. Understanding the effect of TNFi and MTX on humoral and cellular vaccine responses may help to design optimal vaccination strategies for IMID patients.
Methods: PBMC samples were collected 1 week and 6 months after two SARS-CoV-2 mRNA vaccinations from rheumatoid arthritis (RA) patients using MTX (n=16), inflammatory bowel disease (IBD) patients using TNFi (n=15), RA and IBD controls (n=20) and healthy controls (n=18). An activation-induced marker assay and Spike-specific probes enabled deep phenotyping of vaccine-induced CD4 T- and B-cell responses.
Results: SARS-CoV-2 vaccination induced ~33% lower Spike-specific CD4 T-cell responses in MTX treated patients compared to untreated controls. Moreover, Spike-specific CD4 T-cells highly correlated with vaccine-induced antibody titers, but solely in MTX treated patients, suggesting an association between the antigen-specific CD4 T-cell reduction and slower humoral kinetics in this group. Furthermore, patients treated with MTX generated robust Spike-specific B cell responses, similar to controls. Interestingly, the opposite was observed in TNFi treated patients. Although these patients mounted normal Spike-specific CD4 T-cell responses, B cell induction was ~50% lower compared to controls. The percentage of Spike-specific B cells decreased even more over time, which is consistent with a strong decline in antibody titers previously observed (Wieske et al 2023).
Conclusion: Our data show that MTX and TNFi both affect cellular immune responses following vaccination in IMID patients. This may explain the altered Spike-specific humoral responses observed in these patients. Consequently, strategies to improve vaccine induced immune responses in these patients, such as pausing ISP during vaccination, should be investigated to ensure optimal and durable protective immunity.

Purpose: The importance of the IL-23/IL-17 signaling pathway in the pathogenesis of some chronic inflammatory diseases has been clearly established. Therapies targeting IL-23 show high efficacy for the treatment of psoriasis. This work aims at understanding the impact of IL-23 blockade on local and systemic immune responses by dissecting the immune responses before and after treatment initiation in skin and peripheral blood from psoriasis patients.
Methods: Thirty-five psoriasis patients were recruited for this study. Blood samples of all 35 patients and skin biopsies of 7 patients were obtained before and 12 weeks after initiation of anti-IL-23 therapy. To assess the effects of IL-23 inhibition on systemic immune responses, we performed immunophenotyping of circulating immune cells using spectral flow cytometry, and whole blood stimulation assays. For the analysis of local immune responses, cells were extracted from skin biopsies and analyzed by Cellular Indexing of Transcriptome and Epitopes sequencing (CITE-seq).
Results: Investigation of IL-23R expression by circulating immune cells from psoriasis patients showed that MAIT cells are the population with the highest frequency of IL-23R+ cells, followed by NKT cells, and Vδ2+ γδ T cells. Only a small fraction of CD4+, CD8+ T cells, or NK cells express detectable levels of IL-23R. Comparing before and after initiation of IL-23 therapy, whole blood counts showed a statistically significant increase in lymphocyte counts and a trend for reduction of neutrophil and monocyte counts. We noted a decrease of IL-23R-expressing Th17 cells. Transcriptomic analysis of stimulated whole blood cultures showed a significant decrease in expression of inflammatory cytokines genes following 12 weeks of *in vivo* IL-23 inhibition. Our investigation of local immune responses at the skin tissue level, showed a higher CD45+ cell infiltration in lesional compared to non-lesional skin at baseline. This difference was reduced after 12 weeks of treatment.
Conclusion: IL-23 inhibitors impact both local and systemic immune responses in psoriasis patients. The ongoing single cell analysis of skin infiltrating cells may provide insights into the main cell subsets involved in psoriasis local pathogenesis.

Mesenchymal stem cells expressing anti-inflammatory and anti-fibrotic neuropeptides: a new advanced therapy for autoimmune myocarditis

Ana Blázquez-Caraballo[1], Marta Caro[1], Natividad Martin-Morales[2;3], Francisco O'Valle[2], Jenny Campos-Salinas[1], Mario Delgado[1]
[1]Institute of Parasitology and Biomedicine Lopez Neyra (IPBLN-CSIC), Granada, Spain; *[2]Department of Pathology, School of Medicine, University of Granada, Granada, Spain*; *[3]Biomedical Research Center (CIBM), Granada, Spain*

Myocarditis is a significant inflammatory and autoimmune disorder of the cardiovascular system, often progressing to dilated cardiomyopathy and representing a leading cause of mortality in children/young adults. Evidence indicates that immunomodulatory and anti-fibrotic strategies may be useful for its treatment.
We and others demonstrated the efficacy of neuropeptides, like vasoactive intestinal peptide (VIP) or cortistatin, and of mesenchymal stem cells (MSCs) in reducing autoimmune, inflammatory and fibrotic responses in many experimental models of immune-mediated disorders. However, both approaches face with important limitations for their translation into clinic, including the rapid degradation of neuropeptides in body fluids by endopeptidases, and the difficulty to reach in patients the MSC doses (number/body weight ratio) that were found therapeutically effective in murine models.
To overcome these limitations, we transduced adipose-derived MSCs (ASCs) with lentiviral vectors expressing VIP, cortistatin or a latent-cortistatin form (which is solely released/bioactive in fibrotic/inflammatory environments), as a strategy to potentially increase the efficiency of ASCs by acquiring additional neuropeptide-mediated functions, thus allowing a therapeutic dose reduction. At the same time, transduced-ASCs could act as Trojan horses, protecting neuropeptides of degradation and improving their biodistribution to immune/injured organs. We evaluated their therapeutic efficacy in experimental autoimmune myocarditis (EAM) induced by immunization of Balb/c mice with cardiac alpha-myosin-fragments, a well-established model that mirrors important aspects of human disease, and offers a method to study heart-specific autoimmunity/inflammation (effector phase) and the progression towards dilated cardiomyopathy. Systemic administration of low doses (20% of estimated optimal dose) of ASCs expressing VIP, cortistatin or latent-cortistatin during the effector phase of EAM significantly reduced heart hypertrophy and myocardial inflammatory infiltration (measured by heart-to-body weight, histopathology and flow cytometry). These effects were accompanied by a reduction in self-antigen-specific T-cell responses in spleen. However, at the same doses, empty-lentivirus-transduced ASCs failed to improve all these disease parameters. Importantly, treatment with neuropeptide-transduced ASCs, but not empty-ASCs, ameliorated the subsequent late cardiac remodeling/hypertrophy and fibrosis, as evidenced by echocardiography (normalized ejection fraction and fractional shortening) and by decreased myocardial collagen-fibrotic deposits.
Therefore, the improved version of ASC-v.2 expressing neuropeptides emerges as a new advanced therapy for autoimmune myocarditis.

Targeted modulation of myeloid regulatory cells with prostaglandin E2 ameliorates experimental autoimmune encephalomyelitis and preserves gut microbiota

Marina Bekić[1], Dušan Radojević[2], Nataša Radulović[3], Dušica Stojanović[4], Miroslav Dinić[2], Jelena Đokić[2], Sergej Tomić[1]
[1]University of Belgrade, Institute for the Application of Nuclear Energy, Belgrade, Serbia; *[2]University of Belgrade, Institute of Molecular Genetics and Genetic Engineering, Belgrade, Serbia*; *[3]University of Belgrade, Institute for Biological Research "Siniša Stanković" - National Institute of Republic of Serbia, Belgrade, Serbia*; *[4]University of Belgrade, Faculty of Technology and Metallurgy, Belgrade, Serbia*

Introduction: Autoimmune diseases, such as multiple sclerosis (MS), are impacted by disregulated myeloid cells and disbiosis in gut microbiota. Previously we identified that prostaglandin (PG)E_2 is critical for the activation of myeloid-derived suppressor cells (MDSCs), and their capacity to ammeliorate neuroinflammation in experimental autoimmune encephalomyelitis (EAE). However, it remained unclear how different approaches for the modulation of myeloid cells with PGE2 in EAE associate with gut microbiota composition.
Methods: The therapeutic potential of MDSCs activated with PGE_2 *in vitro*, and a direct delivery of PGE_2/MOG_{35-55} to myeloid cells via gold nanoparticles (GNPs-MOG_{35-55}-PGE_2), was evaluated in C57BL/6 mice EAE model induced with MOG_{35-55}/CFA/PTx. The treatment included intraperitoneal administration of cells or nanoparticles on days 1, 3, and 5 post-immunization, respectively. Extensive immunophenotyping was performed on cells isolated from target organs and microbiota composition was analyzed based on shotgun sequencing of fecal samples collected prior to EAE induction and at the peak of disease.
Results: Both therapeutic approaches led to a delayed onset and mitigated EAE severity over the 45-days monitoring period. At the peak of disease, reduced serum levels of IL-6, IL-12p40, TNF-α, IFN-γ, and IL-17 were followed by a decrease in a proportion of T-helper 1- (Th1) and Th17-polarized effector and memory cell subsets in lymph nodes and spleen, as well as reduced leukocyte infiltrates in the spinal cord and with an increased proportion of IL-10-producing Tregs. MDSC-PGE_2 and GNPs-MOG_{35-55}-PGE_2 treatments also prevented EAE-induced alteration in microbiota composition. Thereby, the treatment with MDSC-PGE_2 led to an increase in the relative abundances of *Muribaculum sp*. and *Duncaniella sp*., while GNP-MOG_{35-55}-PGE_2 treatment promoted the dominance of *Alistipes sp.*, all of which are associated with immunoregulatory properties and improved clinical symptoms in MS patients.
Conclusion: Our study highlights that delivery of PGE_2 into myeloid cell compartment can effectively attenuate neuroinflammation with a significant impact on gut microbiota composition, which deserves to be further explored as a potential strategy for MS treatment.

Generation of regulatory T cells from human memory CD4+T cells by upregulation of NKD2 and downregulation of Wnt-β catenin signaling

Jiajun He[1;2;3], Marcus Maurer[1;2], Stefan Frischbutter[1;2]
[1]*Institute of Allergology, Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin und Humboldt-Universität zu Berlin, Berlin, Germany*; [2]*Fraunhofer Institute for Translational Medicine and Pharmacology ITMP, Immunology and Allergology, Berlin, Germany*; [3]*Department of Dermatology, The Affiliated Hospital of Southwest Medical University, Luzhou, China*

Purpose: Regulatory T cells (Tregs) are indispensable for immune homeostasis and tolerance to self-antigens and allergens whereas the imbalance between immune responses and tolerance causes allergic and autoimmune diseases. A promising therapeutic strategy is to support immune tolerance by converting conventional T cells into suppressive regulatory T cells with small molecular weight compounds, an area which is currently underexplored. To address this unmet need, we aimed to identify small molecule compounds that induce Foxp3 upregulation in $CD4^+$T cells *in vitro*.
Methods: A library of 40,000 small molecules was screened for compounds that significantly upregulated the expression of Foxp3, the master transcription factor of Tregs. One candidate molecule (hereafter referred to as IFA005) was selected and further validated using primary human memory $CD4^+$T cells (Tmem). Dose response studies were performed, long-term toxicity, cell proliferation, and the secretion of pro-inflammatory cytokines was analyzed. Furthermore, the TSDR-methylation status and the suppressive capacity of IFA005-induced Tregs (IFA005-iTregs) towards $CD4^+CD25^-$T cells (Tresp) as well as the transcriptional profiles of IFA005-treated memory $CD4^+$T cells were investigated.
Results: We identified a novel quinoxaline derivative (IFA005) that significantly and dose dependently increased Foxp3 expression in Tmem without impairing cell proliferation or viability. IFA005 significantly upregulated CTLA-4, TIGIT, CD39, and ICOS in Tmem, whereas secretion of IL-4, IL-5, IL-13, and IL-2 were significantly reduced. Furthermore, IFA005-iTregs showed robust suppressive activity towards Tresp but did not show conversion to an epigenetically imprinted phenotype corresponding to that of tTregs. IFA005-treated Tmem showed upregulation of naked cuticle homolog 2 (NKD2) on RNA and protein level, which was associated to enhanced phosphorylation of GSK3β resulting in reduced of β-catenin levels and inhibition of Wnt-β-catenin signaling.
Conclusion: IFA005 could be a promising candidate to induce immune tolerance by converting effector T cells into suppressive Tregs through the inhibition of the Wnt-β-catenin pathway.

B-cell depletion by a novel “2+1” CD19-targeted T-cell Engager (TCE) for the treatment of B-cell related autoimmune diseases

Gang Bian[1], Huiling Liu[1], Tengteng Li[1], Ge Lin[1], Peng Chen[1], Jay Mei[1], Bing Hou[1]
[1]*Antengene Corporation Ltd., Shanghai, China*

Purpose: Autoreactive B cells drives pathogenesis of multiple types of autoimmune diseases, such as systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), Myasthenia Gravis (MG), Neuromyelitis Optica Spectrum Disorder (NMOSD), and multiple sclerosis (MS). The utilization of B cell depletion therapy has great potential as a therapeutic approach in the treatment of autoimmune disorders. The therapeutic efficacy of B-cell-depleting monoclonal antibodies in autoimmune diseases is restricted, primarily attributed to the incomplete B cell depletion and persistence of autoreactive B cells within tissues. In addition, CD19-targeted CAR-T therapies have exhibited promising early clinical efficacy in the treatment of SLE. Here We report a novel "2+1" CD19 x CD3 bispecific T cell engager (TCE), ATG-201, which effectively depletes B cells with minimal risk of CRS and demonstrates potent in vivo efficacy in SLE and MS mouse models.
Methods: ATG-201 was constructed by introducing a high affinity, novel conformational epitope-targeted anti-CD3 single chain fragment variable (scFv) to the hinge region of one of the heavy chains of a CD19 monoclonal antibody. It was evaluated in a series of preclinical studies for binding affinity, T cell activation, T cell dependent cytotoxicity (TDCC), and cytokine release. The *in vivo* efficacies were investigated in a mouse MS model of myelin oligodendrocyte glycoprotein-induced experimental autoimmune encephalomyelitis (MOG-EAE) and a spontaneous SLE mouse model using a mouse surrogate TCE with the same format.
Results: ATG-201 exhibited a single-digit nM binding affinity to CD19 positive cells, and limited binding capability to CD3+ cells before CD19 crosslinking. It activated T cells in the presence of CD19+cell and mediated potent T cell-dependent B cell depletion. Cytokine release is strictly dependent on the presence of CD19+ target cells. The surrogated CD19xCD3 TCE demonstrated enhanced efficacy in suppressing disease progression than CD20xCD3 bispecific antibody, and CD19 or CD20 monoclonal antibody in MOG-EAE mice. In addition, the surrogated CD19xCD3 TCE showed more potent therapeutic benefits in mouse SLE model with higher B cell depletion compared with controls.
Conclusion: ATG-201 demonstrates CD19-dependent T cell binding and activation with low risk of CRS which warrants further study in clinical trials.

Effect of extracellular vesicles derived from licensed and unlicensed MSCs on B cell function and activation

Pamina Contreras Kallens[1], Manon Williams[2], Dessi Malinova[2], Meadhbh Brennan[1]
[1]*University of Galway, Galway, Ireland*; [2]*Queen's University Belfast, Belfast, United Kingdom*

Purpose: Autoimmune diseases (ADs) are characterized by B cell function dysregulation. Novel therapies such as antibody-mediated B cell depletion have significant side effects. Mesenchymal stem cells (MSCs) have been proposed as an alternative therapy for ADs, as these cells bear potent immunomodulatory capacities, particularly when exposed to inflammatory conditions known as 'licensing'. MSCs-derived extracellular vesicles (EVs) have been proposed as safer alternative to MSCs. The aim of this study was to evaluate the effect of EVs derived from licensed and unlicensed MSCs on B cell function and activation
Methods: Bone marrow murine MSCs (BM-MSCs) were cultured on tissue culture plastic until 70% confluency. Cells were then incubated in EV-depleted media with IFN-γ and TNF-α to 'license' them, or in standard conditions, for 48 hours. After this time, the conditioned media was collected, and the MSCs-EVs were isolated by size exclusion chromatography. EVs samples' particle concentrations and protein concentration were measured by NTA and BCA, respectively.
For assessing the effect of EVs on B cells, primary B cells were isolated from an allogeneic strain mouse and activated with CD40L, or CpG. The effect of licensed and unlicensed EVs on the expression of activation surface markers and proliferation of B cells was measured by spectral flow cytometry.
Results: 'Licensed' EVs could modulate the expression activation markers MHCII, CD80, CD69 and CD86 on allogeneic murine B cells activated both by CD40L and CpG, in a dose-dependent manner. This effect was seen regardless of if the EVs were added together with the activation factors or 2 hours after activation. EVs were also capable of modulating B cell proliferation tracked by CellTraceViolet dilution**.**
Conclusion: Our findings demonstrate that BM-MSCs-derived EVs can modulate B cell activation and function *in vitro*. Moreover, our study highlights the influence of MSCs' culture conditions on EV effects, suggesting potential therapeutic versatility in diseases characterized by immune dysregulation, such as autoimmune diseases. Further elucidation of the underlying mechanisms is crucial to fully harness the clinical potential of MSCs-derived EVs as immune therapies.

Protective Properties of Dimethyl Fumarate on Synovial Fibroblast Function

Aenea Brugman[1;2], Dumitru Anton[1;2], Carl Orr[2], Viviana Marzaioli[1;2], Douglas Veale[2], Ursula Fearon[1;2]
[1]Trinity College Dublin, Dublin, Ireland; *[2]EULAR Centre for Arthritis and Rheumatic Diseases, Dublin, Ireland*

Purpose: Dimethyl fumarate (DMF) has been approved for the treatment of psoriasis and multiple sclerosis and has shown a range of anti-inflammatory properties in various tissues or cell types. Its precise effects on synovial fibroblast phenotype and function are yet to be understood.
Methods: PsA and RA patients underwent key-hole joint arthroscopy and synovial biopsies were obtained. PsA and RA synovial fibroblasts (FLS) were isolated and grown to passage 1-8. PsA and RA FLS were pre-treated with DMF (25 μM or 50 μM) for 2 hr before TNF (1 ng/ml) stimulation for 24hr. FLS function was quantified by ELISA/MSD, RTPCR, wound healing assay, network formation and Seahorse metabolic assay.
Results: DMF dampened pro-inflammatory functions of FLS. IL-6 and MCP-1 gene expression and secretion were decreased in a dose-dependent manner, an effect that was more pronounced for PsA than RA FLS. RANTES secretion was also decreased by DMF treatment ($p<0.05$), and no effect was observed on IL-8 secretion. Moreover, DMF treatment led to a decrease in the secretion of chemokines from both PsA/RA FLS, including TARC, MIP-1α, IP-10, MCP-4, and MDC (all $p<0.05$). FLS migratory capacity was also decreased by DMF ($p<0.05$), as measured by the wound healing assay, however no effect was observed on FLS network formation. Furthermore, basal OCR was decreased by DMF ($p<0.01$), with little effect observed on basal ECAR, suggesting a decrease in the utilisation of energy from the oxidative phosphorylation pathway. DMF also decreased maximal respiration, spare respiratory capacity, and ATP production (all $p<0.05$). Interestingly, gene expression of key glycolytic markers GLUT1, LDHA and PKM2 were increased in response to DMF (all $p<0.05$), suggesting that FLS shift their metabolic reliance to glycolysis. Finally, DMF also decreased secretion of the bone mediator OPG ($p<0.05$), suggesting a role in regulating bone remodelling.
Conclusion: Differential effects on FLS were observed in response to DMF treatment. The inflammatory, migratory, and metabolic profiles of FLS were dampened, in addition to a reduction in bone remodelling protein OPG. Overall, DMF demonstrates a specific protective and immunomodulatory role in FLS, with a stronger effect in PsA compared to RA.

Parameters of thrombosis risk and percentage of CD4+Foxp3+ regulatory T cells (Treg) after the first three months of baricitinib treatment of rheumatoid arthritis (RA) patients

Magdalena Massalska[1], Anna Felis-Giemza[2], Paulina Klimek[3], Anna Kornatka[1], Tomasz Burakowski[1], Magdalena Plebanczyk[1], Kornelia Chmurzynska[4], Patrycja Gardias[5], Weronika Kurowska[1], Ewa Kuca-Warnawin[1], Marzena Ciechomska[1], Wlodzimierz Maslinski[1]
[1]Department of Pathophysiology and Immunology; National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland; *[2]Biologic Therapy Center; National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland*; *[3]Central Clinical Laboratory; National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland*; *[4]Department of Connective Tissue Diseases; National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland*; *[5]Faculty of Biology and Biotechnology, Warsaw University of Life Sciences, Warsaw, Poland*

Purpose: Baricitinib is one of two selective oral Janus kinase inhibitors (JAKi), approved for RA treatment. Increased risk of venous thromboembolism (VTE) in RA, expanded by JAKi treatment is well proved, however knowledge about JAKi influence on thrombosis parameters is sparse. In the present work we compared the $CD4^+Foxp3^+$ Treg phenotype and thrombotic parameters in RA patients before and after three months of baricitinib treatment.
Methods: Eighteen RA patients with high disease activity (DAS28 >5.1), the inefficacy of at least one conventional DMARD, and without a history of cardiac event or VTE were qualified for baricitinib therapy. Peripheral blood mononuclear cells (PBMC) were obtained from the citrated blood taken from healthy controls (HCs) and the patients before and after 3 months of baricitinib treatment. Treg cells phenotype was assessed by FACS analysis while thrombotic parameters were evaluated by turbidimetric method. According to EULAR response criteria, patients were termed as good or moderate responders.
Results: In RA patients 3 months of baricitinib treatment resulted in significant percentage decrease of $CD4^+CD25^+$ cells (46.3 ± 1.9 vs 54.4 ± 2.3; p<0.0001), $CD4^+Foxp3^+$ cells (4.6 ± 0.4 vs 5.6 ± 0.4; p=0.01) and $CD4^+Helios^+$ cells (7.4 ± 0.7 vs 8.6 ± 0.5; p=0.049). At baseline, the RA group had higher fibrinogen and d-dimers compared to HC (410.4±29.5 vs 334.9±19.2; p=0.04 and 1472.3±349.2 vs 450.3±54.5, p=0.0002, respectively). After 3 months of baricitinib treatment a significant increase in homocysteine (10.7±0.6 vs 9.1±0.5; p=0.018) and antithrombin III (119.7±2.7 vs 110.4±3.2; p=0.004) was observed, the latter correlated negatively with DAS28 (r=-0.686, p=0.002). Moderate responders had lower antithrombin III (105.3±3.6 vs 115.1±2.7; p=0.043) and higher d-dimers (1639.2 ± 550.5 vs 450.3 ± 54.5; p<0.0001) at baseline as compared with HC, and lower antithrombin III than good responders at month 3 (113.5±3.2 vs 127.5±3.0; p=0.0029).
Conclusions: Three months BARI treatment resulted in restoration of Treg cells balance to that observed in HC. Interestingly, low levels of antithrombin III together with increased d-dimers seem to predispose to moderate response to baricitinib.

Bruton's tyrosine kinase inhibitors tolebrutinib, evobrutinib and fenebrutinib affect neutrophil functions in vitro: implications for treatment of autoimmune disease

Mirre De Bondt[1;2;3], Janne Renders[3], Paloma Petit de Prado[3], Nele Berghmans[3], Noëmie Pörtner[3], Lotte Vanbrabant[3], Gayel Duran[1;2], Paulien Baeten[1;2], Bieke Broux[1;2], Mieke Gouwy[3], Patrick Matthys[4], Niels Hellings[1;2], Sofie Struyf[3]
[1]Neuro Immune Connections & Repair Lab, Department of Immunology and Infection, Biomedical Research Institute, Hasselt University, Diepenbeek, Belgium; *[2]University MS Center, Pelt-Hasselt, Campus Hasselt, Belgium*; *[3]Laboratory of Molecular Immunology, Department of Microbiology, Immunology and Transplantation, Rega Institute for Medical Research, KU Leuven, Leuven, Belgium*; *[4]Laboratory of Immunobiology, Department of Microbiology, Immunology and Transplantation, Rega Institute for Medical Research, KU Leuven, Leuven, Belgium*

Purpose: Multiple sclerosis (MS) is a neurodegenerative, autoimmune disease that is still incurable. Nowadays, a variety of new drugs are being developed to prevent excessive inflammation and halt neurodegeneration. Among these are the inhibitors of Bruton's tyrosine kinase (BTK). Being indispensable for B cells, this enzyme became an appealing therapeutic target for autoimmune disease. Recognizing the emerging importance of BTK in myeloid cells, we investigated the impact of upcoming BTK inhibitors on neutrophil functions. Although adaptive immunity in MS has been thoroughly studied, unanswered questions about the pathogenesis can be addressed by studying the effects of candidate MS drugs on innate immune cells such as neutrophils, previously overlooked in MS.
Methods & results: In this study, we used three BTK inhibitors (evobrutinib, fenebrutinib and tolebrutinib), and found that they reduce neutrophil activation by the bacterial peptide N-formylmethionyl-leucyl-phenylalanine and the chemokine interleukin 8/CXCL8. Furthermore, they diminished the production of reactive oxygen species and release of neutrophil extracellular traps. Additionally, the production of CXCL8 and interleukin-1β in response to inflammatory stimuli was decreased. Inhibitory effects of the drugs on neutrophil activation were not related to toxicity. Instead, BTK inhibitors prolonged neutrophil survival in an inflammatory environment. Finally, treatment with BTK inhibitors decreased neutrophil migration towards CXCL8 in a Boyden chamber assay but not in a transendothelial set-up. Also, in vivo CXCL1-induced migration was unaffected by BTK inhibitors.
Conclusion: Collectively, this study provides novel insights into the impact of BTK inhibitors on neutrophil functions. These findings might have important implications for patients' innate immune responses but can also impact excessive neutrophil activation in chronic inflammatory conditions, such as MS.

Comparison of three assays to quantify serum concentrations of infliximab and adalimumab

Juan López Pérez[1], Mercedes Inda Landaluce[1], Luis Martinez-Lostao[1;2]
[1]*Hospital Clinico Universitario Lozano Blesa, Zaragoza, Spain*; [2]*Instituto de Investigación Sanitaria de Aragón, Zaragoza, Spain*

Purpose: Infliximab and Adalimumab are monoclonal antibodies that work by preventing the action of TNF alpha, which is used to treat several chronic inflammatory and autoimmune illnesses. Adequate monitoring of serum drug concentrations is crucial for optimising drug dosage and identifying potential therapeutic setbacks prior to the onset of clinical signs. Our gold standard monitoring is performed by ELISA, yet it has significant limitations in clinical practice, primarily in relation to the clinician's response time. As a result, new strategies are being developed to speed up response time.
Methods: Chemiluminescence immunoassay (i-Track10®, THERADIAG), fluorescence immunoassay (AFIAS-10, Boditech Med Inc.), and ELISA (Promonitor assays, GRIFOLS) were used to quantify the serum levels in a group of 40 patients who received Infliximab and 35 patients who received Adalimumab.
Results: Measurement ranges for both drugs, when comparing i-Track10 and AFIAS-10 to the ELISA assay showed a correlation above 0.9. The correlation was higher for AFIAS-10 than for i-Track10 (0.979 vs. 0.921 for Infliximab, and 0.972 vs. 0.949 for Adalimumab). The systematic error in the determination of infliximab was lower in the i-Track10 than in the AFIAS-10 (12.56 vs. 13.42). However, the AFIAS-10 device had a lower systematic error for the determination of Adalimumab (14.81 vs. 23.18). Passing Bablok regression was also conducted. The results indicated slopes and y-intercepts as follows: for infliximab, AFIAS-10 yielded a slope of 0.952 and a y-intercept of 0.603, while i-Track10 yielded a slope of 1.201 and a y-intercept of -0.093. For adalimumab, AFIAS-10 produced a slope of 1.189 with a y-intercept of 0.008, whereas i-Track10 resulted in a slope of 1.613 and a y-intercept of -1.2756.
Conclusion: Both methods demonstrated good correlation with the already in use ELISA approach and were valid for determining serum drug levels. While the AFIAS-10 system yielded higher correlation results a priori, the i-Track's smaller detection range (up to 24 μg/mL) may have contributed to selection bias.

Complex immunomodulation by pomegranate-derived ellagitannins

Miodrag Čolić[1;2], Marina Bekić[3], Sergej Tomić[3], Jelena Đokić[4], Dušan Radojević[4], Katarina Šavkin[5], Nataša Miljuš[6], Milan Marković[3], Ranko Škrbić[6]
[1]Medical Faculty Foca, University of East Sarajevo, Foca, Bosnia and Herzegovina; *[2]Serbian Academy of Sciences and Arts, Belgrade, Serbia*; *[3]Department for Immunology and Immunoparasitology, Institute for the Application of Nuclear Energy, University of Belgrade, Belgrade, Serbia*; *[4]Institute for Molecular Genetics and Genetical Engineering, University in Belgrade, Belgrade, Serbia*; *[5]Institute for Medicinal Plant Research "Dr. Josif Pančić", Belgrade, Serbia*; *[6]Faculty of Medicine, University of Banja Luka, Banja Luka, Bosnia and Herzegovina*

Purpose: Pomegranate peel extract (PoPEx) has been shown to have antioxidant and anti-inflammatory properties, but its effect on the adaptive immune system has not been sufficiently investigated. This study aimed to examine the immunomodulatory effects of PoPEx and its main ellagitanin constituents using in vitro models on human immune cells.
Methods: PoPEx was prepared from pomegranate peel powder by using 50% ethanol. The extract was dominantly composed of punicallagin (PG), punicalin (PN), ellagic acid (EA), and gallic acid. The extract and individual ellagitannins were tested in the culture of human peripheral blood mononuclear cells (PBMC) and co-culture of monocyte-derived dendritic cells (MoDCs) and T-cells. Cytotoxicity, autophagy, proliferation, marker expression, and cytokine production were assayed.
Results: The treatment of PBMC with PoPEx (range 6.25-400 μg/mL) resulted in cytotoxicity at concentrations of 100 μg/mL and higher, due to the induction of apoptosis and oxidative stress, whereas autophagy was reduced. Cytotoxicity of ellagitanins was obtained with lower concentrations such that IC50 values (μg/mL) were: EA (7.56), PG (38.52), and PN (69.95). Both PoPEx and ellagitanins inhibited PHA-induced proliferation of PBMC at non-cytotoxic concentrations which was followed by a dose-dependent inhibitory effect on the production of Th1 (IFN-γ), Th17 (IL-17A, IL-17F, and IL-22), Th9 (IL-9), and proinflammatory cytokines (TNF-α and IL-6) in culture supernatants. Lower concentrations of PoPEx upregulated Th2 (IL-5 and IL-13) cytokine production in contrast to ellagitanins. Lower concentrations of PoPEx and EA stimulated the production of IL-10 and increased the frequency of CD4+CD25hiFoxp3+ cells. Both PoPEx and all three ellagitannins inhibited differentiation and maturation of MoDCs, inhibited their potency to induce proliferation of alloreactive T-cells and their Th1 and Th17 polarization properties. All components were able to induce the expression of tolerogenic markers (ILT3, ILT4, and IDO1) on MoDCs upon induction of their maturation with LPS and IFN-γ which was accompanied by an increased frequency of Tregs and Tr1 cells. PG and EA were more potent than PN.
Conclusion: PoPEx exerted potent anti-inflammatory and immunoregulatory effects in vitro. The immunomodulatory effect of the extract is very complex, probably associated with the induction of tolerogenic DCs, and was dominantly attributed to ellagitannins.

Unique abilities of Acr1 protein of Mycobacterium tuberculosis to elicit Tregs and MDSCs and impart protection against experimental autoimmune encephalomyelitis

Taruna Lamba[1], Javed Naim Agrewala[1]
[1]*Indian Institute of Technology, Rupnagar, India*

Purpose: Autoimmune diseases (AID) stem from an immune response that goes awry, targeting the body's own antigens by breaching self-tolerance. Th17 cells play a central role in advancing AID progression, while being counterbalanced by Tregs to some extent. Myeloid derived suppressor cells (MDSC) and Tregs have gained wide impetus in alleviating the inflammation in autoimmune diseases. In a somewhat disparate domain, the latent stage of tuberculosis (LTBI) harbors *Mycobacterium tuberculosis (Mtb)*, which composes an immunosuppressive milieu aided by an array of proteins. Intriguingly, recent research has suggested that *Mtb's* presence / BCG vaccination could mitigate the intensity of autoimmune diseases. Keeping this in view, we aimed to use immunosuppressive proteins of *Mtb* to resolve inflammation in AID. Acr1 is highly expressed in LTBI could generate a suppressive phenotype in both T cells and dendritic cells. So, we were curious whether Acr1 can be used to protect against AID.
Methods: We cultured naïve CD4 T cells and dendritic cells with Acr1 and monitored their phenotype and function. FoxP3-GFP mice were immunized with Acr1 to check the generation of MDSC and Tregs and delineate the mechanistic pathway. Further, we adoptively transferred $MDSC^{Acr1}$ into the mouse EAE model (experimental model for multiple sclerosis) to check whether it can suppress the inflammatory response of AID.
Results: We observed that naïve CD4 T cells and dendritic cells treated with Acr1 were skewed towards Tregs and myeloid-derived suppressor cells ($MDSC^{Acr1}$) respectively. These MDSCs showed elevated expression of suppressive molecules (PDL1, TGF-β, etc.) and could stimulate *in-vitro* generation of Treg and suppress Th17 cells. The RNA-seq data showed differentially expressed genes of granulocytic MDSC. Mice immunized with Acr1 (s.c.) showed elicited Tregs and MDSCs population by activating TLR4. EAE group transferred with $MDSC^{Acr1}$ showed an increased population of Tregs, decreased Th17 population alongwith a significant decline in clinical score.
Conclusion: The results suggest that Acr1 can induce suppressive Tregs and generates TGF- β and IL-10 secreting MDSCs both *in-vitro* and *in-vivo* by activating TLR4, further MDSC leads to Tregs generation and ameliorate EAE symptoms. Conclusively, the study provides new insight into immunotherapeutic strategies for curing AID.

Sialic ac a novel approach to promote FVIII-specific tolerance

Eleonora Nardini[1;2], Brigitte Carole Keumatio[1;2], Katarina Olesek[1], Elko Peterse[1], Hakan Kalay[1], Eveline Li[1;2;3], Ernesto Rodriguez Camejo[1;2], Yvette van Kooyk[1;2;3]

DCs are key orchestrator of the adaptive immune response, instructing the balance between tolerance and activation. They thus represent the elected cells to target to promote/restore FVIII-specific tolerance in Haemophilia A, where the insurgence of anti-FVIII antibodies makes the therapy ineffective. We have previously shown that sialic acid activates a tolerogenic pathway in DCs via Siglecs. Here, we investigate the capability of sialic acid to induce antigen-specific tolerance by employing immunodominant sialylated peptides from FVIII. We first set up a pipeline to identify the best FVIII epitopes to be conjugated to sialic acid based on molecular docking, predicted secondary structure and promiscuity of binding to the most common Caucasian HLA haplotypes. Using these sialylated FVIII sequences (Sia), we tested the effects on monocyte differentiation to DC *in vitro*. We observed a reduced secretion of TNFa, IL-6, IL-12 and the induction of the expression of CD86 and PDL-1. The effects observed are dependent on Siglec-3 and Siglec-9, as demonstrated by knockout of the receptors in primary monocytes from healthy donors, immunophophoblots, and binding/uptake assays in monocytic cell lines genetically engineered to express various combination of Siglecs. Next, we showed that moDCs loaded with Sia were capable to inhibit the proliferation of allogenic naïve $CD4^+$ T cells. We further studied the antigen-specific effects by using a FVIII-$CD4^+$ T cell clone from a severe Haemophilia A patient. When the clone was co-cultured with Sia-loaded HLA-matched moDCs, an anergic-like phenotype with high expression of PD-1, LAG3, CD127 was induced upon second encounter with the antigen. Currently, we are investigating the ability of Sia to suppress the formation of anti-FVIII antibodies *in vivo* in a relevant FVIII-KO mouse model. Our results provide a new strategy to modulate pathogenic CD4+ T cells responses in Haemophilia A by targeting Siglec-3 and Siglec-9 on dendritic cells with sialic acid. This approach could prove useful in other autoimmune diseases to promote/restore antigen-specific tolerance.

Anti-citrullinated histone monoclonal antibody CIT-013 to inhibit eosinophil extracellular trap release.

Eline Zwiers[1], Daphne Montizaan[1], Annemarie Kip[1], Kelsy Waaijenberg[1], Sameer Mathur[2], Paul Fichtinger[2], Paul Vink[1], Renato Chirivi[1], Maarten van der Linden[1], Eric Meldrum[1]
[1]Citryll B.V., Oss, Netherlands; *[2]University of Wisconsin Department of Medicine, Madison, United States*

Purpose: In response to specific stimuli, eosinophils can release decondensed chromatin as eosinophil extracellular traps (EETs) which contain granule contents and citrullinated histones. This programmed form of cell death has been termed cytolysis or EETosis. EETs have been described in various eosinophilic diseases such as eosinophilic esophagitis, eosinophilic granulomatosis with polyangiitis (EGPA) and chronic rhinosinusitis with nasal polyps (CRSwNP). EETs have been described to induce tissue damage and pro-inflammatory cytokine production, resulting in a vicious cycle of inflammation. Currently there are no EET-specific therapies available. We have developed a first-in-class therapeutic monoclonal antibody, CIT-013, specifically targeting citrullinated histone H2A and H4 present in EETs. Previous work has shown CIT-013's inhibitory efficacy for neutrophil extracellular traps. Here, we investigated CIT-013's potency in inhibiting EETosis and as a potential therapy for EET-driven diseases.
Methods: Eosinophils were isolated from healthy volunteers and cultured with disease-relevant stimuli to study EETosis characteristics and underlying pathways. EET release was analyzed with quantitative live imaging immunofluorescent microscopy. High resolution confocal microscopy was used to visualize CIT-013's mechanism of EETosis inhibition.
Results: We have demonstrated that EETosis is associated with PAD4 activity, with high levels of histone citrullination within EETs upon stimulation with A23187, PMA, and platelet activating factor. JBI-589, a specific PAD4 inhibitor, inhibits A23187- and PMA-induced EETosis with an IC50 of 2.7 µM. CIT-013 acts upon the final stage of EETosis, binding to its chromatin epitopes when plasma membrane integrity is compromised and prevents EET release in response to multiple stimuli with an IC_{50} of 2.5 nM. In order to consider CIT-013's safety profile, we show that CIT-013 only binds to eosinophils stimulated to release extracellular traps, not to healthy eosinophils. Furthermore, CIT-013 does not interfere with other eosinophil functions such as IL5-induced EDN degranulation, adhesion, superoxide production and MCP-1 chemokine regulation.
Conclusion: CIT-013 binds to citrullinated H2A and H4 and inhibits pro-inflammatory EET release into the extracellular environment. CIT-013 offers a potential new treatment for patients with eosinophilic diseases high in tissue EETs, such as CRwNP. CIT-013 will enter phase 2 proof-of-concept trials in Reumatoid arthritis and Hidradenitis suppurativa at the end of 2024.

Anti-citrullinated histone antibody CIT-013 is a dual action therapeutic targeting neutrophil extracellular trap-associated pathology in rheumatoid arthritis

Maarten van der Linden[1], Annemarie Kip[1], Sangeeta Kumari[1], Stephanie van Dalen[1], Martyn Foster[2], Tirza Bruurmijn[1], Peter van Zandvoort[1], Leonie Middelink[1], Maarten Kraan[1], Helmuth van Es[1], Eric Meldrum[1], Renato Chirivi[1]
[1]Citryll B.V., Oss, Netherlands; *[2]Experimental Pathology Consultancy, Benfleet, United Kingdom*

Neutrophil extracellular traps (NETs) are pro-inflammatory mediators that drive pathogenesis by inducing osteoclast formation and bone erosion in joints of rheumatoid arthritis (RA) patients. Though NETosis-targeting therapeutics have shown potential as effective treatments, currently there are no NET-specific therapies available. We have developed CIT-013, a first-in-class monoclonal antibody specifically targeting citrullinated histones H2A and H4 in NETs, that has shown efficacy in multiple pre-clinical models of NET-associated inflammation. In this study, we unravel CIT-013's mechanism of action (MoA) and examine CIT-013's target engagement in humans. Additionally, we investigate CIT-013's potential as treatment for RA.

Neutrophils isolated from human blood, were stimulated to induce NETosis and confocal microscopy was used to study CIT-013's MoA. CIT-013's target engagement was examined in healthy volunteers administered with 2 ng/kg LPS to induce low-grade inflammation. A collagen-induced arthritis (CIA) mouse model was used to investigate CIT-013's potential in RA by assessing its distribution, NET-targeting properties, and therapeutic effects on inflammation-induced bone resorption. Subsequently, serum and synovial tissue from RA patients was used to detect presence of CIT-013's epitope.

We here demonstrate that CIT-013 binds to its epitope during the final stage of NETosis when plasma membrane integrity is compromised and prevents NET release with an IC_{50} of 4.6 nM. Monovalent CIT-013 completely lacks the NET-inhibitory capacity. NETting neutrophils and NETs opsonized with CIT-013 are efficiently cleared by macrophages which is Fc domain dependent. LPS nano-dosing in healthy volunteers induces a significant level of circulating NETs which are completely extinguished with 0.3 and 0.9 mg/kg CIT-013 administration. In CIA mice, we demonstrate that CIT-013 distributes specifically to the inflamed joints which correlates with joint arthritis severity (R^2=0.6233, $p<0.0001$). NETs are significantly reduced within these joints upon therapeutic administration of CIT-013 and that interrupts the progression bone/cartilage loss. In serum and tissue of RA patients, we show elevated CIT-013 epitope levels, which correlates with inflammation grade in synovium.

This data demonstrates that CIT-013 has a unique dual NET-targeting MoA, suppressing the pathological consequences of NETs in inflammatory-mediated immune diseases like RA. This reinforces the position of CIT-013 as a drug for NET-associated diseases with unmet therapeutic needs.

Jakinibs effect on subsets of the innate and adaptative immune system

Juan José Fernández Cabero[1], Alejandra Comins-Boo[1;2], Davis San Segundo[1;2], Carmen Lasa-Teja[1;2], Ricardo Blanco[1;2], Marcos Lopez Hoyos[1;2;3]
[1]Instituto de Investigación Marqués de Valdecilla (IDIVAL), Santander, Spain; *[2]Hospital Universitario Marqués de Valdecilla, Santander, Spain*; *[3]Universidad de Cantabria, Facultad de Medicina, Santander, Spain*

Introduction: Rheumatoid arthritis (RA) is a chronic autoimmune disease caused by genetic and environmental factors characterised by joint inflammation. The JAK-STAT inhibitors (jakinibs) are among the therapeutic options.
Aim: To determine the impact of jakinibs in cellular subsets of the immune system in RA patients by flow cytometry.
Materials and methods: Seventy-five patients treated with jakinibs were recruited, 20 healthy donors and, 20 RA patients treated with biological DMARDs, both paired by sex and age with the jakinibs group, were enrolled as controls. Peripheral blood mononuclear cells were isolated and analysed by multiparametric flow cytometry to characterise the immunophenotype of different subsets of the immune system.
Results: Within the jakinib group, 36 (48.00%) patients were treated with baricitinib, 13 (17.33%) tofacitinib, 19 (24.00%) filgotinib and, 8 (10.67%) upadacitinib; in the RA control group 11 patients were treated with tocilizumab and 9 with abatacept. A significant decrease in the percentage of cytotoxic NK Dim (CD56+CD16+) subset was observed in the jakinib group in comparison to the RA group (87.28 vs 92.18, p=0.001). There were significant differences between jakinib group and both healthy and RA patients in the percentage of activated NK Dim expressing Nkp30 (59.51 vs 89.74 and 85.28, respectively; p values: <0.001 and 0.007). In addition, the percentage of intermediate monocytes (CD14+, CD16+) was decreased in jakinib group in comparison with RA and healthy controls (9.84 vs 19.41 and 20.55, p values: <0.001 and 0.001). When comparing the subsets of T helper (Th) cells, the percentage of Th17 (CD3+CD4+CD45RA+CCR6+CXCR3-) and Th1+17 (CD3+CD4+CD45RA+CCR6+CXCR3+) were decreased in the jakinib group in comparison with healthy and RA controls (6.86 vs 9.38 and 10.01, p=0.023 and p=0.012) and (3.43, 10.43 and 8.38, p<0.0001 and p<0.0001).
Discussion: The JAK-STAT inhibition by jakinibs affects innate cells differently than biological DMARDs do. The decrease in both the cytotoxic activated NK and intermediate monocytes could explain some of the side effects caused by these drugs related to intracellular threats such as viral infections or possible neoplasia appearances. Further functional studies should be addressed to better understand the impact of jakinibs.

Which came first, the chicken or the egg? Usefulness of determining total anti-Infliximab antibodies for monitoring biological therapy

Victor Mauricio Bohorquez Cruz[1], Laura Viñas Gimenez[1], Maria Teresa Sanz Martinez[1]
[1]*Hospital Universitari Vall D´Hebron, Barcelona, Spain*

Purpose: Infliximab (IFX) is an Anti-TNF approved for the treatment of inflammatory bowel disease (IBD). It is a humanized chimeric biologic antibody that may be immunogenic. The loss of response due to the presence of anti-drugs antibodies (ADA) in 30-46% of treated patients. There are detection methods for these ADA that detect free antibodies vs. others that detect total antibodies (IFX-complex + free). To date, there is not much evidence regarding the difference or advantage of the determination of total antibodies over free antibodies. The objective of the study is to analyze the difference between the determination of free vs total ADA and their correlation with clinical response.
Methods: We performed a retrospective study with the determination of free and total antibodies in 33 samples of 12 patients with IBD from patients treated with IFX by HUVH gastroenterology unit with loss of response due to serum IFX concentrations < 3ug/ml using Time Resolved Fluorescence Lateral Flow Immunoassay (TRF-LFIA) with europium labeling.
Results: Free antibodies were detected in 9 samples from 6 patients and total antibodies in 15 samples from 8 patients. Of these 8 patients, total antibodies were also detected in 6 samples 1-3 months in advance to the appearance of free antibodies in 4 patients.
It was detected the presence of total but not free antibodies in patients with detectable drug concentrations (between 0,7 and 2,4ug/ml).
Conclusion: The determination of total ADAs can be an important tool in the monitoring of patients with IBD. In our results this determination is useful since it precedes the appearance of free ADAs.
In addition, in case of detecting drug levels below the therapeutic range, free ADAs could take time to appear while total ADAs are detectable 1-3 months earlier.

Advantages of the TRF-LFIA monotest method for monitoring biological drugs in clinical practice.

Victor Mauricio Bohorquez Cruz[1], Laura Viñas Gimenez[1], Maria Teresa Sanz Martinez[1]
[1]*Hospital Universitari Vall D´Hebron, Barcelona, Spain*

Purpose: Infliximab (IFX) and Adalimumab (ADL) are anti-TNF monoclonal antibodies approved for the treatment of inflammatory bowel disease (IBD). Between 13-40% of patients treated with anti-TNF lose response during the maintenance treatment period. This loss of response can be primary or secondary, due to low concentration and/or presence of anti-drug antibodies (ADA) respectively. This makes the therapeutic drug monitoring (TDM) a tool of great interest. The aim of this study is to compare two methods for monitoring drug concentrations.
Methods: We analyzed 43 samples from patients treated with IFX and 21 samples from patients treated with ADL by HUVH gastroenterology unit by chemiluminescence immunoassay method (CLIA) vs single test method of Time Resolved Fluorescence Lateral Flow Immunoassay (TRF-LFIA) with europium labeling. The analysis we performed using the Passing Bablok method. Values ranging from 0.2 to 49.67 ug/ml are obtained for IFX and 2.05 to 16.09 ug/ml for ADL
Results: The results obtained by both methods show a good correlation, to IFX pearson´s r=0,984, passing bablok regression showed the following equation: Y= 1,01x – 1,38. The analysis did not show a proportional difference (slope - 1,384 95% CI, 0.9496 - 1.064), but it showed a constant difference given that the 95% CI of the intercept did not contain 0 (intercept 1,007 95% CI, -2.147 -0.6207). To ADL pearson´s r=0,980, passing bablok regression showed Y=1,39X – 2,32. The analysis showed a proportional difference given that the 95% CI of the slope did not contain 1 (slope 1,389 95% CI, 1,213-1,541). And showed a constant difference given that the 95% CI of the intercept did not contain 0 (intercept -2,319, 95% CI, -3,945 -0,6497).
Conclusion: The correlation of both methods is good for both parameters, although they are not interchangeable. The TRF-LFIA monotest method has several advantages. It has a wide laboratory catalog for minority analyses; it is ideal for optimizing savings and waste in low-volume, multiple-test throughput, and short turnaround routines to support immediate clinical decision-making. In addition, the equipment is easy to use, allowing analysis without the need for a highly trained operator and a high degree of flexibility and ease of use.

Gene expression analyses identify biomarkers that distinguish stable and active multiple sclerosis patients treated with fingolimod

Helle Bach Søndergaard[1], Thor Linnet[1], Annette Oturai[1], Ana I.F. Jensen[1], Melinda Magyari[2], Jeppe Romme Christensen[1], Finn Sellebjerg[1]
[1]Danish Multiple Sclerosis Center, Copenhagen University Hospital – Rigshospitalet, Glostrup, Denmark; *[2]Danish Multiple Sclerosis Registry, Copenhagen University Hospital – Rigshospitalet, Glostrup, Denmark*

Purpose: Fingolimod is a sphingosine 1-phosphate receptor modulator that inhibits the egress of lymphocytes from the lymph nodes into the peripheral circulation and the central nervous system and reduces relapses and MRI activity in relapsing-remitting multiple sclerosis (RRMS). However, some patients continue to experience disease activity while on treatment. The purpose of this study was to identify genes, for use as predictive biomarkers of relapse on fingolimod treatment.
Methods: Gene expression was measured by Affymetrix Gene 2.0 ST array on RNA extracted from whole blood in an explorative cohort of 40 fingolimod-treated RRMS patients of which 20 were stable and 20 had disease activity with at least one relapse during the first year of treatment. Patients were matched on previous treatment, sex, and age. For validation samples from 109 RRMS patients after their six-months of fingolimod-treatment were included and information on clinical and imaging disease relapse activity was obtained from the Danish MS Registry. Real-time qPCR was used for validation of selected targets using TaqMan chemistry and a gene expression index was calculated. Analyses were performed in GenEx, Qlucore, and SPSS on log-transformed data and unadjusted p-values are reported.
Results: In the explorative cohort gene expression differences were observed between stable and active fingolimod-treated patients for 68 genes (±1.2-fold: ANCOVA, $p<0.01$, with adjustment for age, sex, and previous treatment). From these, ten genes were selected for validation - five high expressed genes in unstable patients; *MIR744*, *IL1R1*, *NEAT1*, *FCGR3B*, *TRPM6* and five genes with lower expression; *SBDS*, *KLRAP1*, *LILRB4*, *CYP4F22*, *SAT2*. To investigate their relationship with risk of relapse on treatment, we used cox-regression analysis and showed *MIR744*, together with sex, and previous treatment, could predict the risk of relapse on treatment (3.97 95%CI 1.62-9.76, p=0.003). A negative binomial analysis of total number of relapses confirmed the *MIR744* association (2.65 95%CI 1.15-6.10, p=0.022).
Conclusion: Of the ten differentially expressed genes tested in an independent cohort *MIR744* was able to predict relapses on fingolimod treatment and further tests should clarify its use as a predictive biomarker. Interestingly, its mature form, miR-744, was previously identified increased in MS patients.

Selective suppression of pathogenic B lymphocytes from Hashimoto's thyroiditis patients by chimeric protein molecules

Andrey Tchorbanov[1], Nikola Ralchev[1], Iliyan Manoylov[1], Nikolina Mihaylova[1], Irini Doytchinova[2], Alexander Shinkov[3]
[1]Institute Of Microbiology Stephan Angelov, Bulgarian Academy Of Sciences, Sofia, Bulgaria; *[2]Faculty of Pharmacy, Medical University of Sofia, Sofia, Bulgaria*; *[3]Department of Endocrinology, Medical Faculty, Medical Universiy of Sofia, Sofia, Bulgaria*

Purpose: Hashimoto's thyroiditis is one of the most common endocrine disorders affecting up to 20% of the adult population. No treatment or prevention exists except hormonal substitution of hypothyroidism.
We hypothesize that it may be possible to suppress selectively anti-thyroglobulin (Tg) IgG antibody producing B lymphocytes from HT patients by a chimeric protein molecule containing a monoclonal antibody specific for the human inhibitory receptor CR1, coupled to peptide epitopes derived from Tg protein. We expect that this treatment will down-regulate B cell auto-reactivity by delivering a strong inhibitory signal.
Methods: Three peptides – two epitope-predicted ones derived from Tg and another irrelevant peptide – were synthesized and then coupled with monoclonal anti-human CR1 antibody to construct three chimeric molecules. The binding to CD35 on human B cells and the effects of the chimeric constructs on PBMC and TMC from patients with HT were tested using flow cytometry, ELISpot assay and ELISA methods.
Results: We found that after the chemical conjugation all chimeras retained their receptor-binding capacity and the Tg epitopes could be recognized by anti-Tg autoantibodies in the patients' sera. This treatment down-regulated B cell autoreactivity and cell proliferation, inhibited Tg-specific B cell differentiation to plasmacytes and promoted apoptosis to the targeted cells.
Conclusion: The treatment of PBMCs from HT patients with Tg epitope-carrying chimeric molecules affects the activity of Tg-specific autoreactive B lymphocytes delivering to them a strong suppressive signal.

Treatment of insulin allergy by intranasal Fc-fused preproinsulin

Widad Nefida[1], Grégoire Stym_Popper[1], Claire Deligne[1], Yohan Lorreyte[1], Peter Achenbach[2], Roberto Mallone[1], Sylvaine You[1]
[1]Université Paris Cité, Institut Cochin, CNRS, INSERM, PARIS, France; *[2]Institute of Diabetes Research, Helmholtz Zentrum München, German Research Center for Environmental Health, Munich, Germany*

Insulin allergy (IA) represents a rare yet severe immunological reaction to exogenous insulin treatment, affecting between 0.1% and 3% of patients with type 1 and type 2 diabetes. Symptoms range from type I IgE-mediated or type IV cutaneous reactions, including urticaria to laryngeal angioedema, occasionally escalating to potentially life-threatening anaphylaxis. This condition complicates diabetes management by hampering effective insulin therapy and glucose regulation, with no established cure currently available, often necessitating a shift to an unnecessary insulin pump regimen. Therefore, our goal is to establish a desensitization therapy for this condition.
We have developed a tolerogenic fusion protein that comprises preproinsulin linked to the Fc domain of a human IgG (PPI-Fc). The Fc fragment increases the half-life, bioavailability, and uptake by immune and mucosal epithelial cells by binding to Fc gamma receptors and the neonatal Fc receptor (FcRn).
We evaluated PPI-Fc's effectiveness in treating insulin allergy through non-invasive intranasal delivery. We first verified the expression of FcRn by mouse epithelial cells from the naso-respiratory tract and efficient PPI-Fc transcytosis and bioavailability. Second, we established a mouse model of cutaneous insulin allergy in the Non-Obese Diabetic (NOD) background developing spontaneous type 1 diabetes (T1D), thus simulating the human situation. IA is induced by intradermal sensitizations and revealed by local extravasation, increased IgE titers, insulin-specific Th2 responses, and mast cell degranulation. Third, we demonstrated that PPI-Fc intranasal administrations, after the insulin sensitization phase, significantly decreased the allergic reaction and all associated immune responses, thus providing the first proof-of-concept of the therapeutic efficacy of our strategy.
These encouraging outcomes emphasize the potential of intranasal PPI-Fc as a novel therapy for insulin allergy while also indicating the feasibility of administering Fc fusion proteins through the intranasal route for various allergic conditions. Furthermore, they may open new therapeutic opportunities for T1D treatment as both diseases share the same target insulin antigen.

Immunomodulatory impact of the BanLec-Bet v 1 chimera and its variants on antigen-presenting cells

Isidora Protić Rosić[1;2], Bernhard Kratzer[2], Zorana Lopandić[3], Gordan Blagojević[4], Marija Gavrović-Jankulović[1], Winfried Pickl[2;5]
[1]Faculty of Chemistry, University of Belgrade, Belgrade, Serbia; *[2]Medical University of Vienna, Center for Pathophysiology, Infectiology and Immunology, Institute of Immunology, Vienna, Austria*; *[3]Institute for Chemistry in Medicine, University of Belgrade, Faculty of Medicine, Belgrade, Serbia*; *[4]Institute of Virology, Vaccines and Sera "Torlak", Belgrade, Serbia*; *[5]Karl Landsteiner University of Health Sciences, Krems, Austria*

Employing effective adjuvants and hypoallergenic isoforms is essential for improving the efficacy and safety of allergen-specific immunotherapy (AIT). Banana lectin (BanLec) exhibits immunomodulatory potential, and mutation of histidine at position 84 to threonine ($BanLec_{H84T}$) reduced its mitogenicity. Our study aims to assess the immunomodulatory potential on antigen-presenting cells (APCs) of recombinant chimeras combining the major birch pollen allergen Bet v 1a and its hypoallergenic isoform Bet v 1l with BanLec and $BanLec_{H84T}$. After the production in *Escherichia coli* and purification, chimeras were co-incubated with peripheral blood mononuclear cells (PBMC) from birch pollen-allergic patients. Subsequently, secreted cytokines were analyzed. Antigen uptake was evaluated by co-incubating the treated monocyte-derived dendritic cells (MoDC) or HLA-DR7$^+$ EBV-transformed B cells (EBV-BCL) with T cell receptor (TCR) transgenic (tg) Jurkat reporter cells. The tg TCR recognizes the immunodominant epitope of the Bet v 1, Bet v $1_{142\text{-}153}$ in the context of HLA-DR7 ($Jurkat_{tg}$). MoDC were analyzed for the upregulation of activation marker expression (CD80, CD86, HLA-DR) and secreted cytokines (IL-6, IL-8, IL-10, IL-12p40, IL-23, TNF- α, IFN-γ). Furthermore, chimera's uptake by APCs was modulated by incubation with different uptake pathway inhibitors/enhancers during antigen loading, and co-culture with $Jurkat_{tg}$. We found that the co-incubation of PBMC with Bet v 1a-BanLec prompted the secretion of the anti-inflammatory cytokine IL-10 and augmented the IFN-γ/IL-4 ratio. Co-incubation of chimeras with EBV-BCL or MoDC revealed that all chimeras strongly activated the allergen-specific $Jurkat_{tg}$. Additionally, activation marker expression and secreted cytokines of MoDC co-incubated with the respective chimeras indicated that they led to the activation of these cells. Supplementation of media with low concentrations of glucose stimulated antigen uptake and subsequent $Jurkat_{tg}$ activation. In contrast, antigen uptake was inhibited by sucrose, suggesting interference with the macropinocytotic uptake pathway. Our results highlight the potential of chimeras to modulate allergen-specific immune responses, enhancing anti-inflammatory cytokine secretion and promoting allergen-specific T-cell activation thereby demonstrating their potential in AIT.

Long-term immune changes in patients allergic to bee venom undergoing immunotherapy

Paula Álvarez Romero[1], Raquel Bernardo[1;2], Ana Navas[1;2], Nadine Blanco Toledano[1;2], Aurora Jurado Roger[1;2], Berta Ruiz León[1;2]
[1]Maimonides Biomedical Research Institute of Córdoba (IMIBIC)/ University of Córdoba, Córdoba, Spain; *[2]Reina Sofía University Hospital, Córdoba, Spain*

Purpose: Hymenoptera venom allergy is usually manifested with local symptoms, but systemic reactions, including cardiac or respiratory arrest are not uncommonly described after a bee sting. The only available healing treatment to prevent these potentially life-threatening reactions is venom immunotherapy (IT). The mechanisms which govern the achieving of tolerance are not completely known yet. The aim of this study was to analyse changes in the immune system of patients allergic to bee venom who underwent IT.
Methods: A total of 17 allergic patients to bee venom were recruited at the Reina Sofía University Hospital (Córdoba, Spain). Blood samples were collected before (T0) and after 1 (T1), 3 (T3) and 5 (T5) years of IT, when sting challenges were conducted. Basophil activation test (BAT) was performed using 0.1 and 1 μg/mL of *Apis mellifera* venom extract at each time. Circulating T-cell subpopulations were also analysed by flow cytometry.
Results: The study population included 13 (76%) men and 4 (24%) women (mean age 50 ±13). Sting challenges demonstrated full effectiveness in the 16 tested patients. Regarding BAT, the percentage of degranulated basophils ($CD63^+$) using 1 μg/mL of whole bee venom extract was significantly reduced over the course of IT (T0: 53.3%; T1: 22.1%; T3: 8.7% and T5: 10.2%; $p<0.05$). When considering T-regulatory (Treg) cells, those $CD39^+$ significantly increased in T3 (T0: 25.4% vs. T3: 32.4%; $p<0.05$), whereas those $Ki67^+$ significantly increased throughout the follow-up time (T0: 1.6% vs. T3: 6.8% and T5: 8.8%; $p<0.05$). Furthermore, $CTLA\text{-}4^+$ Tregs significantly decreased at T5 (T0: 10.9% vs. T5: 1.3%; $p<0.05$). No significant differences were found with regard to the remaining studied populations.
Conclusion: IT with bee venom promotes the desensitisation of basophils and changes in the proliferative and tolerogenic properties of Tregs subpopulations, which may be implied in achieving immunotolerance. These cellular biomarkers could be considered as candidate for monitoring the tolerance state.

Influence of the Glutathione S-transferase theta 1 antibodies on renal function rates after kidney transplant

luz cheilly Mosquea Jiménez[1], Sergio Barroso Hernández[1], Maria Begoña Vazquez Araujo[1], Rocio Martínez Gallardo[1], Román Hernández Galledo[1], María Luisa Vargas Pérez[1], Rocío Valencia Pereira[1]
[1]*Hospital Universitario de Badajoz, Badajoz, Spain*

Introduction: The glutathione S-transferase theta 1 *(GSTT1)* is a protein that may function as a minor histocompatibility antigen. Specific antibodies could result an alloimmune reaction in *GSTT1-null* recipients receiving a positive graft. In kidney transplantation, *GSTT1* donor-recipient mismatch is associated with productions of anti-GSTT1 antibodies. *GSTT1* is encoded by a single polymorphic gene with two alleles, *GSTT1* (positive) and *GSTT1*0* (null). The detection of *anti-GSTT1* antibodies is frequent in renal transplant patients with *GSTT1-null* allele who receive organs from donors with the *GSTT1-positive* allele. However, its impact on the evolution of renal grafts is not currently defined.
Purpose: To determine if the presence of *anti-GSTT1* antibodies influence the renal function of the transplanted patient's graft.
Methods: We analyzed the presence of *anti-GSTT1* antibodies in serum, pre- and post-transplant of 42 recipients with the condition *"GSTT1* positive Donors / *GSTT1-null* Receptor". We conducted this analysis using Luminex technology (Anti-no HLA LIFECODES Non-HLA Antibody Kit). To assess the renal function of the graft, CKD-EPI formula was used. The influence of these antibodies was evaluated at the end of the follow-up (median follow-up of 54.3 months post-transplant) by multivariable linear regression. We performed data analysis using the statistical program SPSS 26.0, with the quantification of antibodies measured as median fluorescence intensity (MFI) treated as a quantitative variable.
Results: *anti-GSTT1* antibodies were detected in 16 out of 42 recipients (38%), with a mean MFI of 11,700 (standard deviation 6,360). Among these, 12 (29%) tested positive pre-transplantation and the rest (9%) tested positive at a median follow-up of 34.5 months. Patients with *anti-GSTT1* antibodies exhibiting high MFI values tended to have lower glomerular filtration rates at the end of follow-up compared to those with lower MFI values. However, the results did not reach statistical significance (B: -1.9, 95% confidence interval: -3.9 to 0.0, p=0.054).
Conclusion: There is a negative correlation between MFI values of *anti-GSTT1* antibodies and the glomerular filtration rates of the graft following kidney transplantation. However, further studies with a larger sample size would be necessary to confirm these findings on a greater alteration of renal function.

SLC7A5 deletion in T cells or L-leucine restriction in diet efficiently control acute graft-versus-host disease mouse model

Nieves Fernández-Gallego Anaya[1;2], Susana Luengo-Arias[1;2], Raquel Castillo-González[1;2;3], Amelia Rojas-Gomez[1;2], Blanca Anega[1;2], Marta Ramírez-Huesca[2], Sara Martínez-Martínez[2;4], Maider Bizkarguenaga[5], Rubén Gil-Redondo[5], Oscar Millet[5], Julián Aragonés[4;6], Francisco Sanchez-Madrid[1;2;4], Danay Cibrian[1;2;4]

Background: Acute graft-versus-host disease (aGVHD) remains the principal obstacle to successful allogenic hematopoietic cell transplantation. The disease is triggered by the activation and expansion of donor T cells that recognize the genetically incompatible host as foreign, inducing multiple-organ damage to the transplant recipient. The amino acid transporter SLC7A5 (LAT1), which mediates the uptake of L-Leu in activated T cells as well as in malignant cells, has become an important target in the control of inflammation and cancer. However, its role in aGVHD has not been explored before.
Methods: We assessed the role of SLC7A5 expression in T cells in a mouse model of aGVHD. In addition, we evaluated the effect of dietary L-Leu restriction in mice subjected to aGVHD, to control SLC7A5 function in allogenic T cells. Metabolomic experiments were performed to assess the role of L-Leu in aGVHD.
Results: SLC7A5 deletion in donor T cells completely prevented aGVHD-induced gut inflammation and lethality in mice, thus enhancing the replenishment of non-allogenic T cells. Moreover, SLC7A5 deletion prevented proliferation and promoted apoptosis of activated T cells, reducing T-bet and IFNγ expression. Treg differentiation was increased by the SLC7A5 deficiency. The administration of a L-Leu-free diet prevented allogenic T cell expansion and aGVHD associated mortality in mice, thus resembling the results obtained by deletion of SLC7A5 in T cells. Dietary L-Leu restriction modifies serum amino acid profile and prevents the increase of metabolites derived from tricarboxylic acid cycle, ketogenesis, and urea cycle, induced by aGVHD. Our data identify L-Leu as the preferred substrate oxidized to ketone bodies during aGVHD.
Conclusion: This study demonstrates for the first time that targeting SLC7A5-mediated L-Leu uptake in allogeneic T cells by genetic deletion or amino acid restriction diet effectively prevents allogenic T cell expansion in an experimental model of aGVHD.

Reduced ceramides are associated with acute rejection in liver transplant patients and skin graft and hepatocyte transplant mice, reducing tolerogenic dendritic cells

Nayoung Kim[1]
[1]*Asan Institute for Life Sciences, Asan Medical Center, Seoul, South Korea*

We set up this study to understand the underlying mechanisms of reduced ceramides on immune cells in acute rejection. The concentrations of ceramides and sphingomyelins were measured in the sera from hepatic transplant patients, skin graft mice and hepatocyte transplant mice by LC-MS/MS. Serum concentrations of C24 ceramide, C24:1 ceramide, C16:0 sphingomyelin, and C18:1 sphingomyelin were lower in liver transplant (LT) recipients with than without acute rejection (AR). Comparisons with the results of LT patients with infection and cardiac transplant patients with cardiac allograft vasculopathy in humans and in mouse skin graft and hepatocyte transplant models suggested that the reduced C24 and C24:1 ceramides were specifically involved in AR. A ceramide synthase inhibitor, fumonisin B_1 exacerbated allogeneic immune responses *in vitro* and *in vivo*, and reduced tolerogenic dendritic cells (tDCs), while increased P3-like plasmacytoid DCs (pDCs) in the draining lymph nodes from allogeneic skin graft mice. The results of mixed lymphocyte reactions (MLR) with ceranib-2, an inhibitor of ceramidase, and C24 ceramide also support that increasing ceramide concentrations could benefit transplant recipients with AR. The results suggest increasing ceramides as novel therapeutic target for AR, where reduced ceramides were associated with the changes in DC subsets, in particular tDCs.

Purpose and methods: Early immune reconstitution after autologous hematopoietic stem cell transplantation (autoHSCT) is associated with a better outcome in a variety of cancers. Natural killer (NK) cells have a role in anti-tumoral responses and they are the first lymphocyte subset recovering after autoHSCT. In order to understand the biology and physiopathology of NK cells after autoHSCT, we have studied them by multiparametric flow cytometry and analyzed relevant cytokines in the plasma of adult patients with different hematological cancers before and after autoHSCT (over 6 months). We have also performed in vitro experiments using flow cytometry and scRNA-sequencing in order to better characterize the different NK cell subsets.
Results: Circulating NK cell subsets significantly changed early after autoHSCT. There was a transient acquisition of a decidual-like phenotype, characterized by a significant expansion of CD9+CD151+ cells. Furthermore, plasma levels of some cytokines, such as IL-15 and GDF-15, with relevant roles in NK cell function were significantly increased, while TGF-β levels were unchanged. In vitro flow cytometry and scRNA-sequencing experiments and correlation analysis showed that the combination of IL-15 and TGF-β, among other factors, could explain the acquisition of this distinctive decidual-like phenotype and transcriptome early after autoHSCT. Furthermore, we have observed a correlation between the frequencies of certain NK cell subsets with relapse, which could be used as prognosis biomarkers.
Conclusion: In conclusion, NK cell phenotype and transcriptome are significantly altered early after autoHSCT, resembling NK cells from the decidua. IL-15 and TGF-β may have a significant role in the acquisition of this phenotype.

Purpose: Anti-HLA antibodies are one of the major causes of graft rejection in kidney transplantation. Single Antigen bead (SAB) assays have improved the sensibility of anti-HLA antibodies detection. Nevertheless, some treatments or autoimmune diseases could interfere with this analysis, increasing the background and conducting to a high median fluorescence intensity (MFI) of the negative control bead (NCB) and false positive results. This could extend the time in the waiting list or disabling the opportunity of transplantation for these patients, especially in hypersensitized with elevated cPRA. The aim of this study is to evaluate a protocol of sera pretreatment to eliminate background in sera with SAB with values of MFI >250 in NCB.
Methods: We conducted a prospective study of 21 sera with a NCB >250 MFI or increased background in SAB (1/2/EDTA-pretreated) from patients included in waiting list for kidney and bone marrow transplantation. These sera and negative and positive pools were retested by SAB assay using Luminex after EDTA-0.6%/BSA-5%/PBS pre-treatment at 1/2, 1/4 and 1/8 dilutions.
Results: Negative and positive pools maintained stable after pretreatment at the three dilutions. The MFI value of positive bead control of the 21 pretreated sera remained in correct range for the three dilutions. The MFI value of NCB decreased to correct range for the 21 pretreated sera, but the dilution which reach the correct MFI range vary for each patient. 1/8 dilution was the only one with no NCB over 250 MFI. Before pretreatment, several patients held anti-HLA antibodies against self HLA molecules, but after pretreatment 1/8 no one held them. Four hundred and ninety-one less anti-HLA reactivities in those 21 patients were present (average 23 less). cPRA greatly decreased in the majority of the patients. Ten patients underwent transplantation thanks to this pretreatment without complications in their follow up.
Conclusion: Sera pretreatment with EDTA-0.6%/BSA-5%/PBS at 1/8 dilution is a good option to reduce background and false positive results, increasing transplantation opportunities for those patients with interferences in SAB.

Quantifying HLA mismatches at epitope level in haploidentical hematopoietic stem cell transplnatation: impact in the outcome in strategies using PTCy

Francisco Javier Gil[1], Jairo Eduardo Niño Ramirez[1], Daniel Arroyo-Sánchez[1], Marta Fonseca-Santos[1], Isabel Jimenez[1], Ariadna Vicente Parra[1], Pilar Terradillos Sánchez[1], Miguel Alcoceba[1], Lucía Lopez-Corral[1], Ramon García-Sanz[1], Amalia Tejeda-Velarde[1]
[1]*Department of Hematology, University Hospital of Salamanca, Salamanca, Spain, Salamanca, Spain*

Purpose: Allogenic stem cell transplantation is one of the main curative therapies for haematological malignancies and some immune disorders. The HLA system remains one of the main barriers facing the success of this process. Only 25% of the patients who receive an allogeneic hematopoietic stem cell transplantation (allo-HSCT) from a related donor is HLA identical; thus, new alternative donors like haploidentical HSCT (haplo-HSCT) with post-transplant cyclophosphamide (PTCy) are increasing in clinical practice. The aim of this study is to evaluate the immunogenicity of the HLA mismatches in haplo-HSCT with PTCy accordingly to relapse and GRFS.
Methods: A cohort of 145 haplo-HSCT patients and donors, were retrospectively analysed. HLA-A, -B, -C, -DRB1, -DQB1 and -DPB1 typing of the pairs was performed by PCR-SSOP and/or NGS, when appropriate. HLA compatibility was evaluated by the *Predicted Indirectly Recognizable HLA-Epitopes* (PIRCHE) algorithm and PIRCHE Score (PS).
Results: The median age of the patients was 55 years, enriched in man (55.9%). Acute Myeloid Leukemia (AML) and Myelodysplastic syndromes (MDS) were the main indication for haplo-HSCT (52%). The followed up was 36 months.
PIRCHE algorithm showed that patients with relapse presented an augmented PS in host versus graft (HvG) direction (66, IQR: 50-85 vs 44, IQR: 29-69; p=0.002). ROC curve analysis showed that patients with PS >50 presented relapses earlier (HR: 4.66, p=0.001). The same data was observed analysing incompatible ABO haplo-HSCT (HR: 2.66, p=0.014). In a multivariate analysis both parameters remain as independent risk factors for relapse.
The analysis of PS and GRFS showed that patients with events included in GRFS presented an augmented PS HvG (60, IQR 36-84 vs 43, IQR: 29-56; p=0.001). Patients with PS>49 (calculated by ROC) presented a reduced GRFS (HR: 2.19, p=0.001). Similar results were obtained examining the comorbidity index (HCT-CI)>3 (HR: 1.84, p<0.001). The multivariate analysis demonstrated that both parameters were independent risk factors for a diminished GRFS.
Conclusion: HLA disparities at epitope level calculated accordingly by PIRCHE-algorithm, especially PS-I+II, influence the clinical outcome of haplo-HSCT with PTCy and should be included in the donor selection algorithm.

Pharmacodynamic effect of mTOR inhibition-based immunosuppressive therapy on T and B cell subsets after renal transplantation

Xinyi Wei[1], Sabine Weber[1], Decheng Yin[1], Ida Allabauer[1], Tilman Jobst-Schwan[2], Michael Wiesener[2], Mario Schiffer[2], Diana Dudziak[3;4], Christian H. K. Lehmann[1;4;5], Joachim Wölfle[1;6], Andre Hörning[1;5;6]
[1]Pediatric Gastroenterology and Hepatology, Department of Pediatrics and Adolescent Medicine, University Hospital Erlangen, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany; *[2]Department of Nephrology and Hypertension, University Hospital Erlangen, Friedrich-Alexander University Erlangen-Nuremberg, Erlangen, Germany*; *[3]Institute of Immunology, Friedrich-Schiller University Jena, Jena, Germany*; *[4]Laboratory of Dendritic Cell Biology, Department of Dermatology, University Hospital Erlangen, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany*; *[5]FAU Profile Center Immunomedicine (FAU I-MED), Friedrich-Alexander-Universität (FAU) Erlangen-Nürnberg, Schlossplatz 1, Erlangen, Germany*; *[6]Deutsches Zentrum Immuntherapie (DZI), Friedrich-Alexander-University Erlangen-Nürnberg and Universitätsklinikum Erlangen, Erlangen, Germany*

Objective: Kidney transplantation is currently the best treatment option for terminal kidney failure. After transplantation, a tailored immunosuppression balancing the protection from infections and allograft survival is of utmost importance. Today, the immunosuppression by mTOR inhibitors (mTORi) is solely pharmacokinetically monitored, not necessarily reflecting the efficacy of the blockade of the PI3K-Akt-mTOR pathway which may lead to a potential under- or over-immunosuppression. The close correlation between the mTOR activity and the p70S6 kinase (p70S6K) phosphorylation renders the latter as a promising target to monitor pharmacodynamic effects of mTORi.
Design: In this cross-sectional study, phosphoflow cytometry was used to determine the efficacy of mTOR inhibition in peripheral T and B lymphocyte subsets by assessing p70S6k phosphorylation in renal transplant recipients upon treatment with a combination of either mTORi and calcineurin inhibitors or mTORi with mycophenolic acid. Dialysis patients with end-stage renal disease and healthy age-matched volunteers served as controls.
Results: mTORi-treatment reduced p70S6K phosphorylation in $CD4^+$, $CD8^+$ T and $CD19^+$ B cells compared to healthy controls. An analysis of select subpopulations of $CD4^+$ T cells and B cells revealed a significant reduction of p70S6K phosphorylation levels in helper T cells, transitional B cells, memory B cells, and naive B cells upon mTORi treatment, while regulatory T cells and plasmablasts were not affected. Compared to mTORi+MPA therapy, mTORi+CNI treatment exhibited an even stronger inhibition of p70S6K phosphorylation in helper T cells and cytotoxic $CD8^+$ T cells. However, trough levels of mTORi displayed no correlation with p70S6K phosphorylation.
Conclusion: mTORi selectively inhibited p70S6K phosphorylation in select lymphocyte subtypes. Assessing p70S6K phosphorylation by phosphoflow cytometry may serve as an approach to understand cell subset specific effects of mTOR inhibition and providing detailed pharmacodynamic information for an individual tailoring of the mTORi therapy.

Withaferin A suppresses the activation of CD4+ T cells and the following differentiation of B cells

Gukhui Min[1;2], Green Kim[1], Jung Joo Hong[1;2]
[1]Korea Research Institute of Bioscience and Biotechnology, Cheongju, Chungcheongbuk, South Korea; *[2]Korea University of Science & Technology, Daejeon, South Korea*

The generation of class-switched donor-specific antibodies (DSAs), pivotal in chronic antibody-mediated allograft rejection (AMR), is mediated by a T cell-dependent mechanism, wherein $CD4^+$ T cells promote the differentiation of naive B cells into memory B cells and long-lived plasma cells. Withaferin A (WA), a steroidal lactone from Withania somnifera, recognized for its immunosuppressive properties by inhibiting lymphocyte proliferation and exhibiting anticancer and anti-inflammatory effects, remains unexplored as an immunosuppressant to mitigate AMR by attenuating $CD4^+$ T cell activation and subsequent B cell differentiation. Here, human peripheral blood mononuclear cells (PBMCs) were employed to evaluate whether WA can impede B cell differentiation via the attenuation of helper T ($CD4^+$) cell activation. Our findings indicate that WA effectively suppresses $CD4^+$ T cell proliferation without inducing cell death, evidenced by reduced expression of activation markers (CD25, CD69, CD71, and CD54) and diminished interleukin-2 (IL-2) secretion, critical for T cell proliferation and differentiation into plasma cells (PC). Additionally, WA attenuates B cell activation, as shown by decreased expression of CD80, CD86, and MHC-II, along with reduced interleukin-6 (IL-6) secretion, pivotal for PC progression and high-affinity antibody production. Moreover, WA disrupts the $CD4^+$ T cell-dependent differentiation of B cells, underscoring its potential as an immunomodulatory agent in preventing antibody-mediated responses. In conclusion, WA demonstrates the capability to inhibit B cell activation and differentiation into PCs by suppressing both the proliferation and activation of $CD4^+$ T cells. These findings suggest that WA could serve as a potential therapeutic agent for managing AMR by specifically modulating the interaction between $CD4^+$ T and B cells.

Enhanced Renal Tissue Regeneration and Functional Recovery with IL-15 Treatment in Acute Kidney Injury

Agnes A. Mooslechner[1;2], Konstantin A. Klötzer[2], Hansjörg Habisch[3], Tobias Madl[3], Alexander R. Rosenkranz[2], Thomas Bärnthaler[1], Kathrin Eller[2]
[1]Otto Loewi Research Center, Division of Pharmacology, Medical University of Graz, Graz, Austria; *[2]Clinical Division of Nephrology, Department of Internal Medicine, Medical University of Graz, Graz, Austria*; *[3]Otto Loewi Research Center, Medicinal Chemistry, Medical University of Graz, Graz, Austria*

During transplantation, temporary deprivation of blood supply to the organ followed by reperfusion can lead to ischemia-reperfusion injury (IRI), which negatively impacts graft function and viability. Post-kidney transplantation, IRI can result in acute kidney injury (AKI), a complex clinical condition characterized by a rapid decline in renal function and extensive tubular epithelial cell (TEC) injury. Despite advances in understanding the pathophysiology of AKI, effective therapies to protect the donor organ from IRI remain limited. IL-15 was identified as a survival factor for TECs and $CD8^+$ T cells. This study investigates the potential of low-dose rIL-15 treatment in a mouse model of AKI.
Male C57Bl6/J and $CD8\alpha^{-/-}$ mice, 8 weeks old, received either a low-dose of rIL-15 treatment or vehicle. After 7 days, both groups were subjected to bilateral renal IRI, with their body temperature continuously maintained throughout the 20-minute ischemia period. Following a reperfusion period of 20 hours, the mice were sacrificed for subsequent analysis. IL-15 treatment resulted in improved renal function, as indicated by reduced blood urea nitrogen and creatinine levels in treated wild-type mice post-IRI. Histological assessment showed a comparable level of tubular injury between groups, but the IL-15-treated group exhibited reduced tubular atrophy and a higher presence of recovering TECs. Metabolomic analysis of kidney tissue revealed that IL-15 treatment partially reverted the metabolic phenotype of IRI, with upregulation of metabolites counteracting oxidative stress and improving mitochondrial function and energy regulation. Interestingly, IL-15 treatment increased kidney-infiltrating $CD8^+$ memory T cells expressing regulatory-associated markers CD122 and Ly49. IL-15 treatment failed to protect $CD8\alpha^{-/-}$mice from AKI.
Collectively, our findings suggest that IL-15 pre-treatment enhances the regeneration of renal TECs following IRI and ameliorates AKI, presenting an innovative way we can approach donor organ treatment prior to transplantation. Further research is warranted to unravel the mechanisms underlying IL-15-mediated improvement of AKI and ascertain the potential role played by $CD8^+$ T cells in this process.

Immunosenescent T-lymphocyte subpopulations are greatly expanded in long-term kidney transplant recipients.

Evangelos Memmos[1], Georgios Lioulios[2], Efstratios Kasimatis[2], Aliki Xochelli[3], Lambros Vagiotas[4], Vasiliki Nikolaidou[3], Nikolaos Antoniadis[4], Georgios Tsoulfas[4], Maria Stangou[2], Asimina Fylaktou[3]
[1]Nephrology Department, Papageorgiou General Hospital, Thessaloniki, Greece; *[2]1st Nephrology Department, Aristotle University of Thessaloniki, Hippokration General Hospital, Thessaloniki, Greece*; *[3]National Peripheral Histocompatibility Center and Immunology Department, Hippokration General Hospital, Thessaloniki, Greece*; *[4]Department of Transplant Surgery, Aristotle University of Thessaloniki, Hippokration General Hospital, Thessaloniki, Greece*

Purpose: This ongoing study aims to assess the effect of long-term kidney transplantation (KTx) on the T-lymphocyte series and especially subpopulations with an immunosenescent phenotype.
Methods: The study population consisted of a group of long-term KTx patients (>17 years) and a group of recently transplanted patients (1 year). Peripheral blood samples were examined by flow cytometry and the subpopulations of total lymphocytes, CD4+, CD8+, Natural Killer (NK), CD4+CD28null, CD8+CD28null and CD4+CD25+FOXP3 (Tregs) T-cells were evaluated.
Results: Twenty-five long-term and 38 recently transplanted patients took part in the study. Patient age (p=0,714), sex (p=0,304), eGFR (p=0,153), rejection episodes (p=0,154), compatible HLA antigens (p=0,496 for class I and p=0,334 for class II), DGF episodes (p=0,522) preemptive transplantations (p=0,092) and CMV infection history (p=0,168) did not differ between groups, while long-term KT recipients exhibited a higher ratio of DSAs (4, 6, 6% vs 0, 0% p=0,017) and living donor transplants (16, 64% vs 15, 39,5%, p=0,049), more infection episodes (22, 88% vs 3, 7,9%, p<0,001), as well as a lower percentage of patients treated with basiliximab (11, 57,9% vs. 35, 92,1%, p=0,004) and lower dialysis vintage (30:2-90, vs 75,5:0-156, p=0,028). In the long-term group, a significantly higher number of total lymphocytes (2300: 1245-3900 /μL vs 1600: 800-2900 /μL, p=0,003), CD4+ (1266 ± 591 vs 781 ± 320/μL, p<0,001), CD4+CD28null (125: 26-2232/μL vs 41: 2-254/μL, p<0,001), and CD8+CD28null (441: 55-922/μL vs 241: 34-1601/μL, p=0,021) T-cells, a greater percentage of CD4+ T-cells (52,2 ± 13% vs 44,8 ± 11,6%, p=0,024) and a smaller percentage of Tregs (2,8: 0-7,5% vs 4,2: 1,1-7,8%, p<0,0001) was observed, while there was no significant difference concerning the ratio of total lymphocytes (p=0,183), CD8+ T-cells (p=0,171), NK cells (p=0,174), and the number of NK cells (p=0,653) and Tregs (p=0923).
Conclusions: Long-term KTx is associated with significant alterations in the T-lymphocyte series, mainly due to the expansion of immunosenescent T-cell subpopulations.

QuantiFERON-CMV assay by chemiluminescence immunoassay: Is it more suitable for real-live monitoring of transplant patients?

Raquel Fernandez Moreno[1], Aurora Paez-Vega[1], Diego Rodriguez-Cano[2], Ana Salinas[1], Fernando Rodriguez-Cantalejo[2], Aurora Jurado Roger[3], Julian Torre-Cisneros[4], Sara Cantisán[3]
[1]IMIBIC, CORDOBA, Spain; *[2]Reina Sofía University Hospital, Biochemical Laboratory, CORDOBA, Spain*; *[3]Reina Sofía University Hospital, Immunology Deparment, CORDOBA, Spain*; *[4]Reina Sofía University Hospital, Infectious Diseases Deparment, CORDOBA, Spain*

Purpose: Interferon-gamma release assay is used to monitor CMV-specific cell-mediated immunity (IGRA-CMV) in immunocompromised patients. IGRA-CMV is an *in vitro* diagnostic test that quantifies the interferon-gamma (IFNG) released by CD8+ T cells after stimulation with CMV antigens by the enzyme-linked immunosorbent assay (ELISA). However, ELISA has some disadvantages for clinical implementation such as its slow processing speed. A fully automated chemiluminescent immunoassay (CLIA) detection technique has recently been developed to quantify IFNG to detect latent tuberculosis infection (CLIA-TB). The aim of this work is to compare the results of IGRA-CMV by ELISA with those obtained by CLIA in an automated analyzer using CLIA-TB reagents.
Methods: The IGRA-CMV assay was performed by ELISA in kidney and lung transplant patients between July 2019 and April 2023 on an automated platform at the IMIBIC/Reina Sofía Hospital (Cordoba, Spain). In brief, 1 mL of heparinized whole blood was collected in three collection tubes (nil, CMV peptides and mitogen) and incubated for 16–24 h at 37 °C. Supernatants were analyzed for IFNG by ELISA. Samples were considered "Positive" when the IFNG level ≥0.2 IU/mL. The remaining supernatants were subsequently preserved at -80 °C. For the present study, the IFNG levels in the same samples were determined by CLIA on an automated analyzer and the results were compared.
Results: One hundred and three IGRA-CMV supernatants from kidney (n = 50) and lung (n = 53) transplant patients were selected. An agreement of 87.4% (kappa coefficient 0.788) between CLIA and ELISA was observed. Thirteen (12.6%) discrepant results were detected, mainly in borderline ELISA results. Some borderline Negative results by ELISA (<0.2 IU/mL) were above the 0.2 IU/mL cut-off by CLIA and then were Positive (range 0.21–0.31 IU/mL).
Conclusions: CLIA shows substantial concordance with ELISA and acceptable discrepancies. This, together with some advantages of CLIA, such as full automation, reproducibility, faster processing or its continuous-load system, make it a good alternative for monitoring CMV response in transplant patients in clinical routine. However, the possible higher sensitivity of CLIA returns a higher number of Positive results, which entails potential clinical consequences.

HLA compatibility in renal transplantation: Next Generation Sequencing versus Low/Intermediate resolution methods in our Centre

Ramon Garcia Alaejos[1], Luz Cheilly Mosquea Jiménez[1], Azahara Díaz Lozano[1], Angela Lucas Blanco[1], Maria Begoña Vazquez Araujo[1], Marta Aguilar Criado[1]
[1]*Hospital Universitario de Badajoz, Badajoz, Spain*

Introduction: HLA typing is an essential step in the selection of receptors for kidney transplant. In recent years, Next Generation Sequencing has become a technique present in all histocompatibility laboratories, making high-resolution typing more accessible to all. Histocompatibility of a higher resolution could lead to a more accurate patient selection and a better immunological follow-up after transplant.
Purpose: To compare the HLA compatibility between kidney transplant donors and receptors studied through low resolution techniques versus high resolution in our cohort
Methods: A retrospective observational study comparing HLA compatibility of kidney transplant of 58 patients and their donors, measured through low resolution methods (SSO, qPCR test) with the same compatibility measured with Next Generation Sequencing (NGS) in our centre. Patient data (age, sex, blood type…) was collected from the available clinical records. Panel Reactive Antibody (PRA) was calculated with the results obtained through Luminex testing of patient sera. Compatibility was evaluated using the alleles for HLA-A, HLA-B and HLA-DRB1. All transplants were performed among patients of the same blood type
Results: A total of 39 donors and 58 corresponding receptors were typed. From the evaluated receptors: there were 34 men and 28 women; divided by age groups, 10 patients were under 50 years, while 48 were older than 50 years. Divided by blood type, there were 28 type A patients, 3 type B, 5 type AB and 22 type 0. A total of 4 patients were excluded due to insufficient data. After reevaluating the compatibility with their donors through NGS typing, a total of 32 patients showed worse compatibility than what was initially analysed through low/intermediate resolution testing.
Conclusions: Considering that parameters most frequently used for pairing donor and receptor include blood type, age disparity, immune sensitivity and HLA compatibility, high resolution testing can impact receptor selection and immunological follow-up, as compared to low/intermediate resolution methods.

Assessment of clinical-laboratory parameters in patients with autoimmune renal disease following transplantation

Elisavet Kontou[1], Petros Mantzios[1], Vasiliki Kitsiou[1], Glykeria Tsouka[1], Stella Pomoni[1], Diamanto Kouniaki[1], Katerina Tarassi[1], Vasileios Vougas[1], Maria Darema[1], Alexandra Tsirogianni[1]
[1]*Evangelismos hosp, Athens, Greece*

Background: Rare autoimmune disorders, such as lupus nephritis (LN), granulomatosis with polyangiitis (GPA), and anti-glomerular basement membrane (anti-GBM) disease, can progress to end-stage renal disease (ESRD). Renal transplantation (RT) is the most effective replacement therapy, improving survival and quality of life. Despite the low prevalence of recurring nephritis in allografts, clinical and laboratory surveillance is necessary for successful management of both grafts and patients.
Purpose: The aim of this study was to record and present the data from clinical and laboratory monitoring of patients with autoimmune-mediated kidney diseaseafter RT.
Results: Five patients who had undergone RT due to auto-immune mediated ESRD were included in the present study. Specifically, we enrolled 2 females (aged 50 and 37) with SLE and elevated levels of anti-dsDNA antibodies (Abs), 2 males (aged 40 and 53) with GPA and positive anti-C-ANCA Abs, and 1 male (aged 43) with positive anti-GBM Abs. Immunosuppressive agents, such as tacrolimus, mycophenolic acid, and corticosteroids, were administered to all patients. In the 5-year follow-up period after RT, we recorded good rates of graft survival and no case of antibody or T-cell mediated rejection. Importantly, no recipient has developed donor-specific Abs. There was no documented case of disease recurrence, and Abs followed a downward trend over time until normalization. A single patient passed away five years after transplantation from necrotizing CMV colitis, maintaining normal graft function until the time of death.
Conclusions: Given our small sample size, we acknowledge the limitations of our study. However, it appears that RT is the definitive treatment option for ESRD of autoimmune origin. Despite the low prevalence of post-RT disease recurrence, recipients should be monitored closely, enabling timely diagnosis and early management to prevent transplant rejection.

Kidney transplantation with several and repeatedly positive crossmatch: making a leap into the void

Cristina Torres Durán[1], Primitivo José Buendía Romero[1], Luis Bravo González-Blas[1], Natalia Ridao Cano[1], Jesús Martínez Borra[1], Antonio Lopez Vazquez[1], Jose Ramón Vidal Castiñeira[1]
[1]*Hospital Universitario Central de Asturias, Oviedo, Spain*

Purpose: The aim of this study is to find an explanation for five positive crossmatch results in a year and a half period, from a patient on kidney transplant waiting list, who had been tested for HLA class I and II DSA and MICA antibodies several times, being negative against all the potential donors HLA-alleles. Besides, this patient has not been diagnosed so far with any autoinmune disorder which could lead to a positive crossmatch.
Methods: Anti-HLA class I and II IgG and MICA antibodies and anti-HLA class I and II of the IgM isotype antibodies were examined and came out negative. Taking this into account, and finding no other explanation for the positive crossmatch results, we decided to test 60 different autoantibodies (non HLA related), that could be related to post-trasplantant rejection. The selection of autoantibodies was based on studies of acute accelerated rejection in renal transplantation between HLA identical siblings.
Results: 58 out of 60 non HLA tested autoantibodies were positive. Nevertheless, none of the most positive ones, such as ENO1, HSPB1, FIBRONECTIN1, PLA2R1, MYOSIN, SNRPB2, Thyroglobulin, LPHN1, SNRPN and COLLAGEN III, were associated to a positive crossmatch outcome. Thus, Nephrology and Immunology units decided to transplant the patient at the next opportunity regardless of the crossmatch result. The patient was finally transplantated, sharing one HLA-DR and one HLA-A allele with the donor, with a new positive crossmatch result again, as expected. The surgery was succesfully, with only some post-surgery non-graft related complications. No signs of any type of rejection have been observed until today, in a 6 months follow up period.
Conclusion: In our experience, those patients negative for DSA and MICA specific antibodies, and with a history of positive crossmatches that cannot be explained by any other event/condition, should be considered candidates for kidney transplant as long as they do not show any other clinical contraindications. Thus, we believe that the autoantibodies panel mentioned above, can be helpful to rule out any other posible interferences in the positive crossmatch results, making the complicated decision to transplant patients in a similar situation easier and safer.

Human leucocyte antigen and eplets – A trimolecular docking method for donor selection in renal transplantation

Nidheesh Roy[1], Elyas K K[1], Feroz Aziz[2]
[1]*University of Calicut, Malappuram, India*; [2]*IQRAA International Hospital And Research Center, Calicut, India*

Within the past 5 decades, the studies focusing on human leucocyte antigen (HLA) for identifying a perfect donor for renal transplantaion have found its way to new hieghts. HLA, itself being an antigen and a complex gene set plays a strong role in transplantation. The present study has been focused to ascertain an ideal strategy for selecting unrelated individuals as potential donors for renal transplantation by analyzing the number of eplet mismatches and HLA structural variations, that each individual possesses, thus eliminating the possibility of an undesired immune reaction observed in Indian population.

The study was conducted from a cohort of 1144 transplant patients and donors (n=572 pair) collected from 2 hospitals in India, within a period of 50 months. The mechanism of antigen presentation by class II HLA protein was simulated using the molecular modeling and docking studies. Required structural optimizations on HLA, and other moleclues were carried out with the aid of Schrodinger Maestro. The HLA-antigen interaction studies were carried out by PRODIGY web server. The study is proposed as a new approach, which combines transplantation immunology and immunoinformatics which aided in identifying an appreciable correlation between the acquired clinical data, eplet mismatch analysis and HLA structural information in comparison with the corresponding molecular models. Here, the difference obtained in the $\Delta G/K_d$ values in case of eplet matched and mismatched HLA DRB pairs substantiates the inference. There was an appreciable number of interfacial contacts between the eplet matched HLA DRB structures which were comparable.

The study establishes that class II HLA DRB structures which share same eplets between each other can present an antigen peptide in a similar energy ($\Delta G/K_d$) pattern despite of the peptide involved. The comparison between eplet matched and mismatched class II HLA DR using bi-molecular and tri-molecular protein docking, the results revealed that the HLA-Ag complexes with similar eplets showed same degree of energy in antigen presentation to TCR. The outcome of our study was parallel with those patients who faced graft rejection. Therefore, the study bridges the gap between eplet number and graft survival by structural biological analysis.

Analysis of the relative immunogenicity of mismatched HLA class I eplets in renal transplantation

Javier Galán Picón[1], Alberto Gallardo García[1], Miriam Vilches-Moreno[1], Joel Gutierrez-Serrudo[1], Antonio Nieto[1]
[1]*Hospital Universitario Puerta del Mar, Cádiz, Spain*

Purpose: It is now universally accepted that HLA matching affects transplant outcome and that HLA antibodies are primary causes of transplant rejection. HLA antibodies recognize epitopes, which can be structurally defined by eplets. Understanding the immunogenic potential of HLA epitopes/eplets is increasingly relevant in the field of donor-recipient compatibility as it allows for the identification of acceptable mismatches for sensitized patients and the development of permissible mismatch strategies for non-sensitized patients. The fundamental objective of this study is to analyze differences in the immunogenicity of the HLA eplets described to date in the context of renal transplantation.
Methods: The study population consists of 118 consecutive renal transplant patients who have experienced graft loss and have developed DSA detected through Single Antigen studies performed at least 3 months after complete cessation of immunosuppression. Based on high-resolution typing, mismatched donor eplets were identified using the MatchMaker module of the HLA-Fusion software. The relative immunogenicity of the eplets (I-score) was determined by analyzing the frequencies of antibody response to each of them. All eplets, collected in the HLA Epletregistry database for HLA-A and HLA-B were analyzed; they are categorized into antibody-verified and non-verified. Statistical analysis was performed using SPSS v26 software, and a p-value < 0.05 was considered statistically significant.
Results: Eighty-five verified eplets were observed at least once. Of these, 64 (75%) were observed more than 15 times. The mean I-score was 0.188 [0.026-0.826] Antibody reactivity was not observed against 12 out of the 64 (18.7%).
Regarding non-verified eplets, 106 out of 161 (65.8%)were observed more than 15 times, and 59 of these (55.6%) were found not reactive. The mean I-score was 0.101 [0.032-0.250].Some of the antibody reactivities were explained only by non-verified eplets.
The eplets located in the alpha-2 domain of the molecule showed higher I-score than those located in the alpha-1 domain (0.182 vs 0.108; p=0.05)
Conclusion: The degree of relative immunogenicity of eplets is highly variable. There are eplets with a very low or probably null ability to generate antibodies, so they could be considered as "permissible" incompatibilities. Eplets now categorized as non-verified or theoretical may have clinical relevance.

Donor organ age correlates with NLRP1 inflammasome activation in immune cells in kidney transplantation

Juan Miguel Suárez-Rivero[1], Juan López Pérez[2;2], Antonio Astorga-Gamaza[1], Ines Muela-Zarzuela[1], Raquel de la Varga-Martínez[2], Aurora Aguilera[2], Teresa Garcia[2], Auxiliadora Mazuecos[2], Mario David Cordero[1]
[1]Universidad Pablo de Olavide, Sevilla, Spain; *[2]Hospital Universitario Puerta del Mar, Cadiz, Spain*

Purpose: Inflammation causes a wide range of health disorders. In this process, the formation of inflammasome complexes plays a key role. While inflammasomes have been extensively studied during kidney disease, their role in kidney transplantation has not been fully elucidated. We evaluate the gene and protein expression of several components of the inflammasome pathway before and at several time points after kidney transplantation in a cohort of patients of different ages and receiving an organ from older or younger donors.
Methods: PBMC were extracted from blood samples were collected at various time points: prior to transplantation, as well as at 24 hours, 72 hours, 7 days, 3 months, and 6 months post-transplantation. Expression of NLRP1, NLRP3, ASC and caspase 1 was analysed by quantitative PCR. Mann-Whitney test was used to compare data between 2 groups. All results are expressed as mean ± SD of 3 independent experiments and a p-value<0.05 was considered as statistically significant.
Results: Our results showed that donor age correlated with inflammasome expression levels. Receiving an older kidney increased NLRP1 expression over time, while receiving a younger kidney had the opposite effect. We also checked NLRP3 expression which followed a similar pattern but decreased faster in all groups. Meanwhile, ASC and caspase-1 both increased in the first few days after surgery, but their levels stabilized at later times. For all studied genes, initial expression levels were lower in young patients than in older ones. This difference in starting expression could be due to previous renal failure and/or the inflammaging process. Regardless of that, the presented results suggested the potential activation of the NLRP1 inflammasome in all patients.
Conclusion: Our findings indicate that NLRP1 inflammasome activation is the primary effector in renal transplant, and its level increases gradually in patients who receive an older organ, whereas it has the opposite effect on older patients who receive a younger organ. Despite treatment with immunosuppressants, inflammation persists in some patients. These results suggest that the donor's age is a critical factor in post-transplant inflammasome activation and that specific inflammasome inhibitors should be considered to increase the success of kidney transplantation.

Donor Age Have Effects on Senescence Biomarkers in Kidney-Transplanted Patients

Juan López Pérez[1], Juan Miguel Suárez-Rivero[2], Ines Muela-Zarzuela[2], Raquel de la Varga-Martínez[1], Aurora Aguilera[1], Teresa Garcia[1], Antonio Nieto[1], Auxiliadora Mazuecos[1], Mario David Cordero[2]
[1]Hospital Universitario Puerta del Mar, Cadiz, Spain; [2]Universidad Pablo de Olavide, Sevilla, Spain

Purpose: Young patients who undergo renal transplantation often face a scarcity of kidneys from donors of similar age, resulting in the transplantation of older organs. Young patients who receive older kidneys have a higher chance of graft rejection and various problems compared to older individuals who receive kidneys from donors who are similar in age or younger. This study focuses on studying different senescence biomarkers in donors and patients who received kidneys from various age ranges. Our hypothesis is based on a well-known phenomenon known as the transfer of the senescence phenotype.
Methods: The senescence biomarkers examined include gene expression of P16 and P21, the presence of γH2AX histone. We selected individuals from different age groups and divided them into three categories: older donor than the patient, younger donor than the patient, and similar age.
Results: First, we conducted an immunofluorescence assay on pre-transplant donor kidney biopsies, focusing on the γH2AX histone. Biopsies from donors spanning various age groups were chosen, including individuals aged 23, 43, 57, and 80 years. Our findings demonstrated a gradual elevation in γH2AX expression corresponding to advancing age.
Then, we studied the expression levels of two main genes and proteins associated with senescence and aging in the patients: p16Ink4a and p21. Our findings revealed a correlation between donor age and p16Ink4a expression levels. Young patients who received an older kidney showed an increase in p16 expression over time, while those who received a younger kidney experienced the opposite effect. However, in the final time point, the old donor group exhibited a reduction in p16 gene and protein expression. Moreover, p21 gene expression remained high across all groups and time points, although protein expression increased over time in the Old Donor and Matched groups.
Conclusion: Receiving older organs from young patients induces a pro-senescence state that may cause difficulties later. When older patients receive younger organs, their initial senescent phenotype gradually improves. These results may open new avenues for therapeutic targets, such as senolytics, to reduce the presence of senescent cells and mitigate the complications associated with the transplantation of older organs in young patients.

Identification and characterization of ten novel HLA alleles. Evaluation of their role in optimal donor selection in transplantation

Diamanto Kouniaki[1], Theofilos Athanassiades[1], Vasiliki Kitsiou[1], Katerina Tarassi[1], Alexandra Tsirogianni[1]
[1]*Evangelismos Hosp, Athens, Greece*

HLA mismatch is a critical negative factor in Hematopoietic Stem Cell Transplantation (HSCT) and therefore, finding a suitable donor with an acceptable HLA match is essential for successful transplant outcomes. Although advances in HLA typing have improved transplantation success rates, the search for the ideal matched donor remains a major challenge in daily clinical practice.
Purpose: The objective of this study is to present ten novel HLA alleles and evaluate their significance in the search and selection of the most suitable donor for transplantation.
Methods: In the period 2021-2023 2,340 samples consisting of patients undergoing HSCT and their respective unrelated donors were analyzed. Genotyping at 11 (HLA-A,-B,-C,-DRB1,-DRB3/4/5,-DQA1,-DQB1,-DPA1,-DPB1) or 6 (HLA--A,-B,-C,-DRB1,-DQB1,-DPB1) loci was performed using commercial locus-specific primers supplied by CareDX (AlloSeq Tx17 kit) and GenDx (NGSgo®-MX6-1 kit), respectively. Sequencing was carried out on the MiSeq platform. The raw sequencing data were analyzed by AlloSeq Assign analysis software Tx17.1 v1.0.5 (CareDX) and NGSengine analysis software v.2.31.0 (GenDx) with references from the IPD-IMGT/HLA Database v3.53.0.
Results: During this study, novel HLA allele sequences are deposited into the GenBank database and new HLA allele assignments were obtained from WHO Nomenclature Committee for Factors of the HLA system. Particularly, one 5' UTR variant (HLA-A*02:01:01:243_GenBank accession number OQ357854), four intronic variants (HLA-B*51:01:01:109_OQ357857, HLA-A*02:05:01:23_OP889296, HLA-B*18:01:01:73_OP889297, HLA-A*02:09:01:04_OP795782), one synonymous mutation (HLA-DPB1*02:01:68_OP019279) that had silent base substitution with no change in amino acid sequence when compared with the most similar allele, and four non-synonymous mutations (HLA-C*07:1052_OP889298, HLA-A*24:587_OP654751, HLA-B*51:380_OQ357852, HLA-A*01:426_OP712622) that were single amino acid substitution variants when compared with the most similar allele, were discovered. Variations in amino acids have the potential to influence peptide folding and protein interactions, thereby potentially altering its immunogenic properties.
Conclusion: This study emphasizes the importance of NGS-based HLA typing, where higher resolution HLA typing may elucidate the clinical significance of variation in coding and non-coding regions. By defining novel HLA alleles associated with different ethnicities, our work provides further insight into HLA polymorphism. Moreover, by exploring their potential involvement in allo-recognition and their impact on transplant success, our findings aid in the precise selection of donor-recipient pairs, further optimizing transplant outcomes.

Improving lymphocyte purity in flow cytometric crossmatch assays: a comparison of cell isolation methods

Daniel Marti[1], Alexandra Manchón[1], Nuria Exposito[1], Jose Luis Caro[1], Eduard Palou[1], Juan Torres Canizales[1]
[1]*Department of Immunology, Centre de Diagnòstic Biomèdic, Hospital Clínic de Barcelona, Barcelona, Spain*

Purpose: The flow cytometric crossmatch (FCXM) assay is used to determine whether donor specific HLA antibodies (HLA-DSA) are present in recipient sera. Isolated cell purity is a widely recognized critical factor in the test outcome. For that reason, our goal was to compare the performance of two cell isolation methods in FCXM assays carried out with peripheral blood from living donors for kidney transplant.

Methods: Hematological cell fractions from living donor whole blood samples were evaluated before and after being processed by erythrocyte aggregation and total lymphocyte enrichment through negative magnetic selection (EA&TLE). Results from FCXM assays carried out with EA&TLE and a conventional cell isolation technique by gradient density centrifugation (Ficoll) were compared and correlated with HLA-DSA detection using the Luminex single-antigen bead assay (LSA).
Results: The mean lymphocyte percentage of samples processed using EA&TLE was 94% (95% confidence interval [95% CI] 89% to 97%), with 24 to 50% of the lymphocytes present before isolation retained and a lymphocyte count after enrichment of 3 to 10 million cells/mL. Analysis of 65 FCXM assays performed with EA&TLE and 66 with Ficoll demonstrated that EA&TLE results in higher sensibility (67% EA&TLE vs 43% Ficoll) and higher kappa correlation coefficient (0.61, 95% IC 0.318 to 0.90 EA&TLE vs 0.40, 95% IC 0.01 to 0.82 Ficoll) with HLA-DSA detection by LSA. Furthermore, FCXM assays performed with EA&TLE showed a lower detection threshold for class II HLA-DSA in comparison to FCXM assays performed with Ficoll (lowest mean fluorescence intensity of 5193 for EA&TLE vs 10289 for Ficoll).
Conclusion: Implementation of EA&TLE for cell isolation from whole blood increased lymphocyte purity in the samples, improved FCXM assay sensitivity and resulted in a greater correlation with HLA-DSA identification by LSA. Thus, EA&TLE can increase cell isolation efficiency and cost-effectiveness in FCXM assays.

A novel calculated panel reactive antibody score calculator incorporating HLA-DQB1/DQA1 and DPB1/DPA1 associations: enhancing allocation for organ transplantation in the spanish population

Juan Francisco Luchoro[1], Jose Luis Caro[1], Juan Torres Canizales[1], Montserrat Digon[1], Nuria Exposito[1], Silvia Rica[1], Montserrat Masó[1], Alexandra Manchón[1], Maria Dolores Fernández[1], Nuria Palau[1], Daniel Lorca-Arce[1], Eva González[1], Eduard Palou[1]
[1]*Department of Immunology, Centre de Diagnòstic Biomèdic, Hospital Clínic de Barcelona, Barcelona, Spain*

Purpose: Calculated panel reactive antibody (cPRA) score represents the possibility of encountering an incompatible donor for organ transplant candidates. This study aims to evaluate a novel calculator designed to improve compatibility assessment in the Spanish population and by considering HLA-DQB1/DQA1 or DPB1/DPA1 associations not accounted for in existing calculators.
Methods: A cohort of 1000 deceased donors from Spain was analysed, focusing on HLA-A, B, C, DRB1, DQB1, DQA1, DPB1, DPA1, and DRB345 loci typing. The HLA genotype was compared with Single Antigen Bead (SAB) assay results from 398 patients within the kidney transplant waiting list. A custom computer script written in R language was created for identifying any unacceptable antigen matches between patients and donors. The cPRA represented the percentage of donors with incompatible HLA typing relative to patient serum profiles. Notably, the calculator incorporated distinctions between DQB1/DQA1 and DPB1/DPA1 associations to enhance estimation precision compared to existing calculators.
Results: Our calculator exhibited a high Lin's concordance correlation coefficient (rho = 0.92, 95% CI 0.91-0.93) when compared to the Eurotransplant Reference Laboratory (ERL) calculator. A limit of agreement was established to identify samples requiring further investigation, with 24 samples falling below this threshold. These samples exhibited positive reactions to certain DQ or DP beads but lacked specificity for individual DQB1, DQA1, DPB1, or DPA1 alleles. Mean difference between these samples was –55.39 ($p < 0.001$), so our calculator increased the apparent compatibility in these patients with positivity to single DQB1/DQA1 and DPB1/DPA1 associations.
Conclusions: The novel calculator demonstrates optimised performance in predicting donor-recipient compatibility within the Spanish population, offering additionally improved precision through the consideration of single HLA-DQ or DP associations. Further validation and refinement may enhance its utility in clinical practice, ultimately benefiting organ allocation outcomes.

Mononuclear phagocyte system readily responds to allogeneic platelets in a murine model of platelet transfusion refractoriness

Gabriel Rojas Jiménez[1;2;3], Catherine Angénieux[1;2;3], Blandine Maître[1;2;3]
[1]*Établissement Français du Sang, Grand Est, Strasbourg, France*; [2]*UMR_S 1255, INSERM, Strasbourg, France*; [3]*Université de Strasbourg, Strasbourg, France*

Purpose: Platelet transfusion is a lifesaving procedure to prevent or to stop actual hemorrhage. However, transfusing patients who are immune to HLA-I molecules can result in transfusion failure, known as platelet transfusion refractoriness (PTR). Through mechanisms that are not yet fully understood, alloantibodies cause the rapid clearance of transfused platelets from the bloodstream. Moreover, the variability in transfusion efficacy in immunized patients could be explained by a different immune signature, which may or may not favor PTR.
We aim to analyze the recipient's immune response and the fate of transfused platelets in a mouse model of MHC-I-alloimmune PTR.
Methods: PTR was mimicked by transfusing allogeneic eGFP$^+$-H2^b-platelets into a recipient H2^d-mouse previously immunized against H2^b-platelets. Blood, spleen and liver were sampled 30 min after platelet transfusion. Monocytes, neutrophils, splenic and liver immune cells were analyzed by flow cytometry (FC).The relative importance of spleen and liver was studied *in vivo* by evaluating PTR either in splenectomized/sham mice or in mice treated with asialofetuin/fetuin to block asialoglycoprotein receptors (n=3).
Results: Transfused platelets were eliminated from circulation within the first 30 min only in alloimmune mice, revealing a PTR. At this time point, FC showed a significant decrease ($p<0.05$) of circulating Ly6C^{high} monocytes and an increase in the proportion of CD11b$^+$ cells in the liver of refractory mice, suggesting a recruitment of circulating cells during refractoriness. Analysis of organs revealed that (61.7±7.7)% of hepatic- and (18.7±3.0)% of splenic-F4/80$^+$CD11b$^+$ cells are positive for allogeneic platelets, indicating the involvement of macrophages from both organs in platelet clearance during PTR. However, splenectomized alloimmune mice remained in a refractory state similar to the sham control mice (0.8±0.4)% vs (1.0±1.0)% of total platelets, respectively, indicating that the spleen is dispensable for PTR. Furthermore, treatment with asialofetuin before transfusion did not impact platelet clearance ((0.8±0.4)% vs (0.7±0.4)%) suggesting that the mechanism of platelet internalization is not influenced by desialylation.
Conclusion: Allogeneic platelets are eliminated by hepatic and splenic phagocytic cells during refractoriness. In combination with the compelling shift in Ly6C^{high} circulating monocytes and CD11b+ cells in the liver, these changes point to an overall immunomodulation taking place during PTR.

Purpose: Lung transplantation is the ultimate option for patients suffering from severe end stage lung diseases such as emphysema, pulmonary arterial hypertension or fibrosis. Yet, little is known about the immune cell composition in these diseased lungs that may be critically shaped by the underlying lung disease. Hence, we investigated the immune cell distribution of lung parenchyma obtained from different diseased lungs after explantation in the course of lung transplantation (LTx).
Methods: Explanted lung parenchyma (n=57) of patients that underwent LTx was enzymatically digested and immune cell distribution was determined by flow cytometry. Lung tissue derived from patients with chronic obstructive pulmonary disease (COPD), idiopathic pulmonary fibrosis (IPF) and PAH was compared to immune cell composition of healthy control parenchyma derived from non-tumor lung tissue.
Results: Leukocyte proportions of in lung parenchyma were generally enriched in diseased lungs (with >50% in COPD), indicating their role in these diseases. Lymphocytes constituted the main leukocyte subset in healthy and COPD lungs, while granulocytes represented the majority in IPF and PAH lungs. In all diseases, T cells, primarily tissue-resident memory (TRM), constituted the major lymphocyte population with particularly elevated levels in COPD and lowest levels in PAH and IPF tissue. COPD lungs showed highest proportions of $CD4^+$ T cells translating into highest $CD4^+/CD8^+$ ratio. Regulatory T cells were enriched in IPF lung parenchyma compared to other diseases and lowest in COPD lungs. Subtle differences were found in naïve vs. memory phenotypes of T cells.
Conclusion: Our data conclusively prove that end-stage lung diseases imprint the immune repertoire – and probably vice versa – that populated the lung parenchyma, demonstrating that each lung disorder is characterized by a unique immune cell component. A better understanding of the immune mechanisms involved in these lung disorders will be essential for an adequate management of these diseases in the future.

Selective Deletion of HLA Class I Molecules for Improved Skin Graft Compatibility

Laura Cobos-Figueroa[1;2], Laura Notario[1], Carmen Mir[1], Daniel López[1], Sara Lauzurica[2], Carlos Molpeceres[2], Elena Lorente[1], Pilar Lauzurica[1]
[1]National Center for Microbiology, Madrid, Spain; *[2]Polytechnic University of Madrid, Madrid, Spain*

Treatment for organ failure typically involves transplantation. However, compatibility issues between donors and recipients often arise due to the vast diversity of human leukocyte antigens (HLA) class I molecules, leading to strong immune reactions and organ rejection. To address this, we propose generating skin grafts from cells with selective deletion of HLA class I molecules, except for the prevalent HLA-A allele. We deleted HLA-B and -C genes from cells with a common HLA-A allele using CRISPR technology and also established a humanized murine model to evaluate the feasibility of this approach in vivo. In this study, we developed a humanized skin graft model using mice transgenic for HLA class I, enabling us to closely examine the intricate HLA-mediated immune response in skin transplantation. Mice expressing HLA-A*02:01 allele alone or in combination with HLA-B*07:02 do not reject the skin of mice expressing only HLA-A*02:01 molecule. Additionally, we developed a humanized skin rejection model by transplanting skin fragments from HLA-A02:01/B07:02 mice onto HLA-A*02:01 mice, revealing rejection of incompatible skin and demonstrating HLA-restricted specificity in rejection by specific CD8+ T cells. However, skin from double HLA-A*02:01/B*07:02 transgenic mice transplanted into HLA-A*02:01 mice is rejected and triggers a strong specific CD8+ T cell response against HLA-B*07:02 allele. This mouse model was used to analyze a human lymphoblastoid cell line in which HLA-B and -C genes were knocked out by a one-step CRISPR-Cas9 strategy while retaining expression of the most common HLA class I allele, HLA-A*02:01. Human cell clones lacking HLA-B and -C genes showed hypoimmunogenicity in a skin allograft model, suggesting potential for universal HLA-compatible grafts. In contrast to the parental line, the edited cells did not elicit specific CD8+ T cell response in HLA-A*02:01 transgenic mice transplanted with HLA-A*02:01/B*07:02 skin. This findings demonstrate a promising approach to overcoming the challenges of organ transplantation and improving patient outcomes. We propose a rapid, simple, and scalable HLA-compatible skin graft model that will improve clinical practice in burn units worldwide.

Longitudinal dynamics of SARS-COV-2 specific humoral and cellular immune responses in patients on waiting list and after lung transplantation

Melissa Hübner[1], Jasper Sauer[1], Louisa Ruhl[1], Jenny F. Kuehne[1], Evgeny Chichelnitskiy[1], Kerstin Beushausen[1], Jana Keil[1], Marion Schael[2], Tobias Welte[2;3], Jens Gottlieb[2;3], Ius Fabio[3;4], Mark Greer[2;3], Christine Falk[1;3;5]
[1]*Institute of Transplant Immunology, Hannover Medical School, Hannover*; [2]*Department of Pneumology and Infectiology, Hannover Medical School, Hannover*; [3]*German Center for Lung Research (DZL/BREATH), Hannover*; [4]*Department for Cardiothoracic, Transplantation and Vascular Surgery, Hannover Medical School, Hannover*; [5]*German Center for Infection Research (DZIF), TTU-IICH, Hannover, Germany*

Purpose: Patients with end-stage lung diseases on the MHH waiting list for lung transplantation (WL-LTx) have been vaccinated against the SARS-CoV-2 spike protein with usually three doses of the mRNA vaccine prior to transplantation without the influence of immunosuppression. Therefore, we hypothesized the induction of high spike-specific IgG levels, T cell responses, and protection against SARS-CoV-2 infection and severe COVID-19.
Methods: Peripheral blood samples of pre- (n=100) and matched post-LTx (n=66) of WL-LTx patients were analyzed. Luminex-based multiplex assays were used to quantify SARS-CoV-2-specific IgG antibodies against RBD, S1, S2 domains of spike and N antigens in plasma. Electrochemiluminescence multiplex assays were utilized for surrogate neutralization by antibodies in plasma. Peripheral blood mononuclear cells (PBMC) were used to analyze changes in immune cell components.
Results: 97% of pre- and post-LTx patients mounted spike-specific IgG, but only few patients had neutralizing capacity against wild-type, and even less against omicron variants. Using paired samples pre vs. post-LTx, we observed three different patterns for spike-IgG, with either decreased, stable, or increased levels. Relevant factors for increased IgG levels post-LTx were the absence of infection before Tx, infection or vaccination after Tx and interval between vaccination and Tx of ≤5 months. Immune cell composition at pre- and post-LTx are not likely to have a substantial and direct influence on SARS-CoV2 antibody levels after vaccination.
Conclusion: We demonstrated that LTx patients in the early post-Tx period did benefit from booster SARS-CoV-2 vaccinations, showing even increased IgG levels post- compared to pre-LTx. Based on the poor neutralizing capacity, we propose omicron-adapted vaccination for LTx recipients.

Purpose: Subsequent to lung transplantation (LuTx), the migration of lymphocytes from the transplanted lung into the periphery induces a transient chimerism of donor passenger cells in recipient blood. We characterized the phenotype of donor T/NK cells to investigate whether they might represent tissue-resident memory (TRM) cells.
Methods: Lymphocyte dynamics in recipient blood were determined in n=97 LuTx patients directly (T0), 24 hours (T24) and 3 (wks) weeks after LuTx using flow cytometry. Donor cells were analyzed by HLA class I allele-specific mAb in n=44 LuTx recipients. The same markers were used to determine the phenotype of lymphocytes present in organ storage solution (perfusate, n=111), recipient explanted lung parenchyma (n=28) and donor trachea (n=17). Single cell mRNA sequencing of explant lung parenchyma was conducted (n=16).
Results: In peripheral blood of all recipients, donor-derived T/NK cells were detected at T0, T24 and 3 wks after LuTx and had higher CD69 expression compared to recipient cells, and were mostly $CCR7^-$ memory cells. This phenotype was similar to T/NK cells in corresponding perfusates. In recipient parenchyma and donor trachea, most $CD69^+$ T/NK cells showed coexpression of other tissue residency markers (i.e. CD103, CD49a, PD-1). These markers were not found in circulating donor lymphocytes and perfusates, indicating they represent distinct memory T and NK subsets. Sc-mRNA sequencing confirmed distinct TRM T cell subsets in lung parenchyma. Patients with high frequencies of donor T cells showed a trend towards chronic lung allograft dysfunction- (CLAD-)free survival 2 years post LuTx.
Conclusion: Our results demonstrate that donor T/NK cells found in the periphery of lung transplant recipients are a distinct subset from circulating lymphocytes and TRM cells present in lung tissue, since they express CD69 but lack expression of other classical TRM markers. Donor T cells might be clinically relevant for tolerance induction and long-term survival after transplantation due to their unique features.

Analysis of the relative immunogenicity of mismatched HLA class I eplets in renal transplantation

Javier Galán Picón[1], Alberto Gallardo García[1], Miriam Vilches-Moreno[1], Jorge Mannelli[1], Joel Gutierrez-Serrudo[1], Antonio Nieto[1]
[1]*Hospital Puerta del Mar, Cadiz, Spain*

Purpose: It is now universally accepted that HLA matching affects transplant outcome and that HLA antibodies are primary causes of transplant rejection. HLA antibodies recognize epitopes, which can be structurally defined by eplets. Understanding the immunogenic potential of HLA epitopes/eplets is increasingly relevant in the field of donor-recipient compatibility as it allows for the identification of acceptable mismatches for sensitized patients and the development of permissible mismatch strategies for non-sensitized patients. The fundamental objective of this study is to analyze differences in the immunogenicity of the HLA eplets described to date in the context of renal transplantation.
Methods: The study population consists of 118 consecutive renal transplant patients who have experienced graft loss and have developed DSA detected through Single Antigen studies performed at least 3 months after complete cessation of immunosuppression. Based on high-resolution typing, mismatched donor eplets were identified using the MatchMaker module of the HLA-Fusion software. The relative immunogenicity of the eplets (I-score) was determined by analyzing the frequencies of antibody response to each of them. All eplets, collected in the HLA Epletregistry database for HLA-A and HLA-B were analyzed; they are categorized into antibody-verified and non-verified. Statistical analysis was performed using SPSS v26 software, and a p-value < 0.05 was considered statistically significant.
Results: Eighty-five verified eplets were observed at least once. Of these, 64 (75%) were observed more than 15 times. The mean I-score was 0.188 [0.026-0.826] Antibody reactivity was not observed against 12 out of the 64 (18.7%).
Regarding non-verified eplets, 106 out of 161 (65.8%)were observed more than 15 times, and 59 of these (55.6%) were found not reactive. The mean I-score was 0.101 [0.032-0.250].Some of the antibody reactivities were explained only by non-verified eplets. The eplets located in the alpha-2 domain of the molecule showed higher I-score than those located in the alpha-1 domain (0.182 vs 0.108; p=0.05)
Conclusion: The degree of relative immunogenicity of eplets is highly variable. There are eplets with a very low or probably null ability to generate antibodies, so they could be considered as "permissible" incompatibilities. Eplets now categorized as non-verified or theoretical may have clinical relevance.

Background and Aims: Potential detrimental effect of multiple vaccinations on the immune system aging process has not been proved. The aim of our research was to examine whether response to anti-SARS-CoV-2 vaccination with Tozinameran is associated with immunoscenecence and immunoexhaustion in Kidney Ttransplant recipients (KTRs).
Method: In this prospective, observational study, of 39 adult KTRs on stable immunosuppression, naïve to SARS-CoV-2, CD4+ and CD8+ subpopulations [comprising CD45RA+CCR7+ (naïve), CD45RA-CCR7+ (central memory -CM-), CD45RA-CCR7- (effector memory -EM-) and CD45RA+CCR7- (effector memory re-expressing CD45RA -EMRA-, senescent) CD4+/CD8+, CD28- expressing (CD8+) and CD28-null (CD8-, senescent) CD4+/CD8+ and CD3+PD1+ (exhausted) T-cells] were evaluated at time points: T1 (48 hours prior to the 3rd Tozinameran dose) and T2 (3 weeks after the 3rd Tozinameran dose). Results: CD4-CM and CD8-EM were increased, while naïve CD4+ and CD8+ proportions were reduced in the whole cohort of patients, but particularly in responders at T1 and T2.
At T2, responders compared to non-responders had higher concentrations of CD4+CD28+ and CD8+CD28+ [756.34(368) vs. 446.57(925) and 227.15(166) vs. 131.44(121) cells/μL, p: 0.026 and 0.036 respectively] and reduced proportions of CD4+CD28- [6.1(5.5)% vs. 20.7(25)%, p: 0.04]. There was a negative association between age and naïve CD4+ and CD8+ and CD8+CD28+ concentrations at T1 (p: 0.042, 0.042 and 0.006, r: -0.346, -0.345 and -0.444 respectively) and a positive correlation between exhausted T-cell (CD3+PD1+) numbers prior to the first vaccination and TEM / TEMRA CD4+ concentrations at T1 (p: 0.001 and 0.001, r: 0.558 and 0.578 respectively), as well as TEMRA CD8+ counts at T2 (p: 0.037, p: 0.396).
Conclusion: In KTRs, response to vaccination is not associated with an expansion of senescent and exhausted T-cell concentrations, but rather with a switch from naïve to differentiated-activated T-cell forms. Age, T-cell exhaustion status at baseline and eGFR also to be correlated to the differentiation senescence process.

Calcineurin blockade modifies dendritic cell differentiation and induces a tolerogenic phenotype

Marco Galli[1], Laura Marongiu[1], Stefano Cozzi[1], Giuseppe Rocca[1], Giulia Stucchi[1], Anna Celant[1], Alessia Donato[1], Ilaria Fontana[1], Metello Enzo Innocenti[1], Francesca Granucci[1]
[1]*University of Milano-Bicocca, Milan, Italy*

The Nuclear Factor of Activated T Cells (NFATs) is a family of transcription factors activated by the phosphatase Calcineurin (CN). This pathway holds significant clinical relevance, as drugs inhibiting the CN-NFAT axis exert a potent immunosuppressive effect and are utilized to manage organ transplant rejection reactions. Our research group revealed that NFATs are activated in dendritic cells (DCs), leading to terminal differentiation and apoptosis. Given the immunosuppressive role played by certain types of myeloid cells in pathological contexts, we aim to determine the involvement of the CN-NFAT pathway in early DC differentiation and its potential contribution to the development of an immunosuppressive phenotype in myeloid cells.
To explore this, we transduced a growth factor-dependent splenic dendritic cell (DC) line with a CN inhibitor peptide, generating DC-iCN. To determine the effects of NFATs inhibition in DC-iCN, we conducted proteomic analyses, as well as functional and metabolic assays. The potential immunosuppressive activity of the DC-iCN was determined by Mixed Leukocyte Reaction assay. We analyzed the potential effects of inhibiting NFAT *in vivo* through the intravenous administration of nanoparticles carrying the iCN peptide to investigate whether this would modify the hematopoietic process leading to the formation of DCs.
Blocking the CN-NFAT pathway in DCs increased their growth rate and modified the cell cycle, prolonging the G2/M phase and shortening the G1 phase. Metabolically, NFAT inhibition induced a marked Warburg effect, characteristic of rapidly proliferating cells. Moreover, DC-iCN demonstrated a highly immunosuppressive phenotype, differentiating naïve T cells into FOXP3+ regulatory T cells in MLR assays. Interestingly, inhibiting the CN-NFAT pathway *in vivo* expanded the granulocyte-monocyte progenitor involved in DC ontogeny.
In summary, blocking the CN-NFAT pathway modifies early DC differentiation, resulting in the acquisition of a highly tolerogenic phenotype and traits resembling undifferentiated cells. This sheds light on the potential use of tolerogenic hematopoietic precursors as a cellular therapy for autoimmune diseases and transplant rejection. Further human studies will enhance these findings.

Immune signature profiling in patients with graft-versus-host disease following hematopoietic stem cell transplantation

Leoni Bücken[1], Julika Neumann[1], Adrian Liston[2], Frédéric Baron[3], Stephanie Humblet-Baron[1]
[1]KU Leuven, Leuven, Belgium; *[2]University of Cambridge, Cambridge, United Kingdom*; *[3]CHU of Liège, Liège, Belgium*

Purpose: Allogenic hematopoietic stem cell transplantation (allo-HSCT) is the best treatment option for many patients suffering from an hematological malignancy. However, about 20-70% of allo-HSCT recipients develop a life-threatening complication in the form of chronic graft-versus-host disease (GvHD). GvHD occurs when the donor immune cells contained in the graft identify the host tissues as foreign and trigger an immune response against them. In the current project, we aimed at identifying cell subsets predicting the occurrence of future GvHD onset using a systems immunology approach of high-parameter flow cytometry and machine learning.
Methods: PBMCs prospectively collected 6 months after allo-HSCT in 63 patients, of whom 32 patients developed GvHD in follow-up and 31 patients did not. The adaptive and innate immune system were characterized in detail using high parameter flow cytometry.
Results: Preliminary analyses revealed a higher proportion of naïve CD4+ T cells, CD28+ CD127+ RORgT+ Naïve CD8+ T cells, and classical monocytes in patients who went on to develop GvHD compared to HSCT recipients who remained GvHD-free. In contrast, patients who did not develop GvHD had higher proportions of effector memory CD8+ T cells and higher proportions of non-classical monocytes.
Conclusion: Contrary to what is most often reported in literature, these preliminary results suggest that a higher proportion of naïve T cells are associated with GvHD while higher proportions of effector CD8+ T cells are associated with a GvHD-free state. One potential cause could be attributed to a more extensive immune reconstitution needed if a larger proportion of T cells is naïve, creating more GvHD potential. These first analyses could point towards a specific immune signature that can help to identify patients who might develop GvHD within the first year of follow-up after receiving HSCT. This immune signature could be used as a predictive biomarker in the clinic to identify patients at a high risk of developing GvHD and adjust drug doses preventatively.

Non-killer cell immunoglobulin-like receptor profile following allogeneic stem cell transplantation

Basak Sayinalp Arslan[1;2], Melek Gunindi Korkut[1], Fusun Ozmen[1], Yahya Buyukasik[3]
[1]Hacettepe University Cancer Institute, Ankara, Turkey; *[2]Hacettepe University School of Medicine, Department of Internal Medicine, Ankara, Turkey*; *[3]Hacettepe University School of Medicine, Department of Haematology, Ankara, Turkey*

Purpose: Natural killer (NK) cells are the first lymphocyte subgroup that appear in peripheral blood following allogeneic stem cell transplantation. They have roles in both graft-versus-leukemia effect and prevention of graft-versus-host disease; however, the mechanisms and receptor profiles are not well known. The purpose of this study is to examine the change in non-Killer Cell Immunoglobulin-like Receptor (KIR) NK cell receptor profile following allogeneic stem cell transplantation.
Methods: In this prospective cohort study; peripheral blood samples from patients who were diagnosed with haematological malignancy and underwent allogeneic stem cell transplantation were collected before (Day 0) and after (Day 30, 100, 180) transplantation. Peripheral blood mononuclear cells were isolated and NK cells were identified by flow cytometry. Non-KIR NK cell receptor profiles (NKG2A, NKG2C, NKG3D, NKp30, NKp44, NKp46, ILT-2, ILT-4) were examined by further flow cytometric analyses.
Results: 15 patients (7 acute myeloid leukemia, 5 acute lymphoblastic leukemia, 3 myelodysplastic syndrome) were included in the study. All patients were in remission before transplantation. NKG2A levels decreased over time, statistically significant changes were between days 30 and 100 (p=0,01) and days 30 and 180 (p=0,01). NKG2C levels increased over time, statistically significant change was observed between days 30 and 180 (p=0,040). NKG2D levels decreased over time, statistically significant change was observed between days 100 and 180 (p=0,032). NKp30 levels increased over time, significant change was observed between days 30 and 100 (p=0,042). NKp44 levels decreased over time, changes between days 0 and 100 (p=0,048) and days 0 and 180 (p=0,002) were statistically significant. NKp46 levels and ILT-2 levels decreased over time, however these changes were not statistically significant. ILT-4 levels decreased over time, statistically significant change was observed between days 0 and 180 (p=0,004).
Conclusion: Non-KIR NK cell receptor profile changes after allogeneic stem cell transplantation. According to our study; NKG2C and NKp30 levels increase, while other receptor levels decrease. Further studies are needed to support our findings and determine whether there is an association between the functions of non-KIR receptors and graft-versus-leukemia effect or graft-versus-host disease.

This study was supported by Hacettepe University Scientific Research Projects Coordination Unit (Project Number: 19934).

B cell anti-tumor immune responses in renal cell carcinoma patients

Liat Barak[1], Shayel Bercovich[2], Adva Levy-Barda[3], Avital Sarusi-Portuguez[1], Ronnie Blecher[1], Rabab Naamneh[3], Katharina Imkeller[4], Shay Golan[2], Ziv Shulman[1]
[1]Weizmann Institute, Rehovot, Israel; *[2]Rabin Medical Center-Belinson Hospital and Sackler Faculty of Medicine, Tel-Aviv*; *[3]Rabin Medical Center-Belinson Hospital, Tel-Aviv, Israel*; *[4]7MSNZ/FCI/Edinger Institute, Frankfurt, Germany*

Renal cell carcinoma (RCC) is one of the most prevalent cancer types worldwide, in which clear cell RCC (ccRCC) is the most common subtype that accounts for over 75% of all RCC. The tumor microenvironment of ccRCC is highly infiltrated with multiple subtypes of immune cells, including a minority fraction of B lymphocytes. Notably, high infiltration of B cells is associated with poor prognosis as tumor-educated B cells play a role in promoting renal cancer metastasis. However, the existence of tertiary lymphoid structures (TLSs), enriched with B cells, has shown a positive association with prognosis in various cancer types. Moreover, tumor-infiltrating B cells exhibit the potential to produce tumor-binding antibodies, opening avenues for therapeutic interventions. In this study we aim to detect and analyze the origin, functionality and target specificity of novel tumor-reactive antibodies derived from ccRCC patients. We used single cell RNA sequencing to characterize the specific subsets of B lymphocytes and examine the B cell immunoglobulin repertoire in ccRCC tumors. Based on these transcriptomics, we cloned and generated monoclonal antibodies originating from highly mutated and clonally expanded cells. We found that class-switched plasma cells residing within the tumors can produce antibodies with tumor-binding capabilities. These findings of tumor derived monoclonal antibodies could have the potential to reveal new targets for the therapeutics and treatment of RCC patients.

Oral squamous carcinoma cells differentiate monocytes into immunosuppressive CD25+CD163+CD206+ macrophages

Hector F. Pelaez-Prestel[1], Fernando Gonzalez-Martin[1], Esther M. Lafuente[1], Pedro A. Reche[1]
[1]*Laboratory of Immunomedicine, Department of Immunology, Ophtalmology and ORL, School of Medicine, Complutense University of Madrid, Madrid, Spain*

Introduction: Oral squamous carcinoma (OSC) is one of the top 10 cancers in prevalence and mortality. Tumor-associated macrophages (TAMs) plays an important role regulating OSC progression. Most TAMs derive from circulating monocytes that differentiate *in situ* mostly into M2-like macrophages possessing pro-tumoral functions, enabling immunosuppression, vasculogenesis, tumor progression and metastasis. Understanding how OSC control macrophage differentiation can lead to developing effective anti-tumoral interventions.
Objectives: Study the effect of OSC cells (OSCCs) on macrophage differentiation.
Materials and Methods: We have cultured primary monocytes from healthy donors' peripheral blood for 5 days in the presence of conditioned media derived from two days culture of H413 and TR146 OSCC lines. The phenotype of these monocyte-derived macrophages (moMΦ) was analyzed by flow cytometry. The transcriptomic profile of these conditioned moMΦ was also analyzed by RNAseq. We have studied the stimulation of allogeneic T cells by moMΦ conditioned by OSCC lines.
Results: OSCCs imprint an immunosuppressive phenotype on moMΦ related to M2 macrophages, judged by the lower expression of HLA-DR, CD86, CD11c and increase of CD163 and CD206. In addition, moMΦ differentiated by H143 CM were unable to activate allogeneic T cells, and inhibited T cell activation and proliferation upon CD3/CD28 stimulation.
A signature expression profile involving cytokine and cytokine receptors in the conditioned moMΦ was identified by RNAseq, which surprisingly included *IL2RA* (CD25). We confirmed CD25 expression by flow cytometry in around 20% of $CD163^{+}CD206^{+}$ moMΦ differentiated using H413 CM. We consulted the Single-cell Portal database to identify that approximately the 25% of the TAMs from different tumors express IL2RA. CD25 binds to IL-2, and it is highly express by regulatory T cells, contributing to their immune suppressive functions by sequestering IL-2 required by effector T cells. However, the expression of this marker has been poorly studied before in TAMs.
Conclusion: Our data indicate that OSCCs promote the differentiation of immunosuppressive monocytes into an M2-like moMΦ, which may facilitate tumor progression. Investigating the role of $CD25^{+}$ TAMs *in vivo*, may offer the chance to explore new therapeutic approaches.

Novel human monoclonal antibodies specific to the A33 glycoprotein recognizes prostate cancer

Awatef Ben Jemaa[1;2], Chaima Ben Slimen[2], Ridha Oueslati[2]
[1]*Faculty of Science of Gafsa, Gafsa*; [2]*Faculty of Science of Bizerte, Bizerte, Tunisia*

Purpose: Herein, we aim to evaluate GPA33 protein expression, using two new anti-GPA33 monoclonal antibodies (G72 and G36) produced by the hybridoma technique in normal, benign and cancerous prostate tissue.
Methods: The study was carried out in 4 normal (NP), 11 benign prostatic hyperplastic (BPH) and 18 cancerous human prostates (PC). Immunohistochemical analysis was performed to study the expression of GPA33 using two new anti-GPA33 monoclonal antibodies (G72 and G36). Serum levels of PSA were assayed by an immulite autoanalyzer. Fisher, One way ANOVA and Spearman tests were used for statistical analysis.
Results: Our results show GPA33 protein expression either by the anti-GPA33 monoclonal antibody G72 in the totality of prostate samples analyzed, and by the G36 antibody in the majority of prostate samples analyzed. Taking immunostaining intensity into account, no differences could be shown between assessment of GPA33 expression by monoclonal antibody G72 or by antibody G36 in the three prostate groups. The highest intensity of GPA33 expression detected by G72 or G36 was found in cancer patients. Indeed, the GPA33 immunoreaction detected by both G72 and G36 clones increased gradually from normal to benign to cancerous tissues. This similarity in GPA33 immunoreaction intensity between clones G72 and G36 does not reflect a similarity in intracellular localization. Indeed, a difference in GPA33 localization was revealed if the protein was detected by G72 rather than by G36. Like PSA, GPA33 protein expression increases gradually with Gleason score, whatever the anti-GPA33 antibody used. Interestingly, in cancerous prostate tissue, GPA33 is preferentially localized in the stromal component.
Conclusion: Together, GPA33 expression was demonstrated for the first time in normal, benign and cancerous prostate tissue. Thus, the two monoclonal antibodies, newly produced by the hybridoma technique and previously validated by immunofluorescence and flow cytometry techniques, are applicable for GPA33 detection by immunohistochemistry in prostate tissue. Our work argues in favor of a pro-tumoral role for GPA33 in the prostate tumor process. As a follow-up to this work, it would be important to determine the nature of the immune cells infiltrating the prostate tumor and expressing the GPA33 protein.

Preferential deployment of DNA repair pathways: The Tumor associated macrophages acting as a coordinator in response to cisplatin treatment in ovarian cancer.

Bilash Chatterjee[1;2], Amit Srivastava[1;2]
[1]CSIR-Indian Institute Of Chemical Biology (CSIR–IICB), Kolkata, India; *[2]Academy of Scientific and Innovative Research, Ghaziabad, India*

Introduction- Deeper understanding and analysis of the tumor immune microenvironment ultimately leads to identification of biomarkers and possible cellular and molecular reasons for therapy resistance. Since Tumor Associated Macrophages (TAMs) exhibit dual role in cancer progression, chemoresistance and metastasis. More in-depth investigation is required to reveal the cellular crosstalk with cancer cells and its significance in therapeutic efficacy.
Materials and methods –Western blot, real-time PCR, Cytokine array, flow cytometry, immunocytochemistry, *in-vivo* experiments. All the statistical analysis were performed with GraphPad Prism 8 software.
Results and discussions- *in-vitro* experiments were performed with human ovarian cancer cell lines where cocultured cancer cells with tumor macrophages (THP1 cell line derived) showed elevated expression of Y family DNA polymerases like Polymerase eta (Pol H), REV1 and other TLS (Translesion DNA Synthesis) related genes like RAD18, ubiquityl-PCNA as compared to control. The expression level further increases with cisplatin treatment(20uM). The elevated expression of TLS pathway is known to contribute in DNA lesion bypass, mutagenesis and enhancement of stemness properties which was confirmed by enrichment of CD44+, CD117+ double positive sub-population of cancer cells. On the other hand, there was a downregulation of NER (Nucleotide excision repair) pathway which was confirmed by XPC, XPD, XPA, XPB, XRCC1, XPG expression in cocultured condition. These leads to error prone DNA damage response with downregulated phospho-γH2AX, Cleaved-caspase3 expression and better survival capacity of the cancer cells. Infact, similar experiments were repeated with mice Bone Marrow Derived Macrophages and ID8 mice cell line, which echoed the same differential expression level of both the pathways. With *in-vivo* xenograft tumor model, Immunohistochemistry and Immunofluorescence, flow cytometry analysis of tumor tissues highlighted the similar trend in Pol H, XPC level and related genes of the two pathways. Flow cytometry analysis identified the majority of the TAMs to exhibit M2 phenotype which induces enhanced NFκB expression and IL6 production in cocultured cancer cells which still increases with cisplatin treatment.
Conclusions- TAMs actively modulate the DNA repair pathways of ovarian cancer cells. Which sets a preferential precondition to upregulate TLS pathway and downregulate NER, thus facilitating mutational burden, cancer stemness and chemoresistance.

Purpose: CD8+ resident memory T cells (T_{RM}) represent a heterogeneous T cell memory population that patrols tissues. In the setting of infection or malignancy, TRM harbour cytotoxic functions and recruit other immune effectors to control infection or tumor growth. Although heterogeneity exists, CD8 TRM are identified by the expression of tissue retention markers : CD103, CD69, CD49a, and a reduced expression of migration and tissue egress markers (CCR7, CD62L). CD8 T_{RM} tumor infiltration is correlated with a favorable clinical outcome in cancer patients treated by immunotherapy. However, in preclinical models of lung and head and neck cancer, the efficacy of cancer vaccine is supported by a subset of TRM induced by the mucosal route of immunization. In this work, we aimed to better characterize these different T_{RM} subpopulations in mice and humans and to determine whether these T_{RM} subpopulations play a differential role in predicting response to immunotherapy in patients with non-small cell lung cancer

Results: We identified 2 main T_{RM} subpopulations induced after intra-nasal vaccination in mice, and in tumor infiltrating lymphocytes (TILs) from non-small cell lung cancer patients (NSCLC). One subset co-expresses CD103 and CD49a (DP) and the other only expresses CD49a (MP). Using flow cytometry, immunoassay and single cell analysis, we have shown that the DP population displays greater functionality than the MP population despite higher expression of inhibitory receptors. Analysis of their TCRs and the expression of a stemness marker (TCF1) showed that these 2 populations shared many TCRs and that the MP population appeared to be more progenitor-like. In 2 cohorts of NSCLC treated with anti-PD-1 in 1st or 2nd line, multivariate analysis showed that intratumoral CD8 CD103+CD49a+ was highly predictive of response to immunotherapy whereas CD8 CD49a+ was not irrespective of tumour location.

Conclusions: This study demonstrated that not all CD8 T_{RM} populations are equivalent and need to be distinguished to better define their functional role and value as biomarkers of response to immunotherapy.

Monocytic- and early stage-myeloid derived suppressor cells are expanded in patients with hepatocellular carcinoma and associate with tumor progression

Marta Chivite Lacaba[1], Alberto Utrero Rico[1], Iago Justo[1;2], Cecilia González Cuadrado[1], Oscar Caso[1;2], Patricia Almendro Vázquez[1;3], Carlota Cantonad Ruigomez Martín[1;4], Angel Alfocea Molina[1;4], Esther Mancebo Sierra[1;4], Rocío Laguna Goya[1;4], Manuel J Del Rey Cerros[1;4], Lorena Pascual Palacios[1], Manuel Serrano[1;4], Oscar Cabrera Marante[1;4], Daniel Pleguezuelo[1;4], Edgard Rodríguez de Frías[1;4], Estela Paz Artal[1;3;5]
[1]Instituto de Investigación Sanitaria Hospital 12 de Octubre (imas12), Madrid, Spain; *[2]Department of Surgery and Abdominal Organs Transplantation, Hospital Universitario 12 de Octubre, Madrid, Spain*; *[3]Centro de Investigación Biomédica en Red (CIBER) de Enfermedades Infecciosas (CIBERINFEC - Instituto de Salud Carlos III), Madrid, Spain*; *[4]Department of Immunology, Hospital Universitario 12 de Octubre, Madrid, Spain*; *[5]Department of Immunology, Ophthalmology and ENT, Universidad Complutense de Madrid, Madrid, Spain*

Purpose: Myeloid-derived suppressor cells (MDSC) are a heterogeneous and immature cell population with immunosuppressive capacity, contributing to growth and metastatization of tumoral cells. They associate with poor prognosis. MDSC have been scarcely studied in patients with hepatocellular carcinoma (HCC). Here we assess the myeloid compartment in HCC patients and its association with clinical characteristics.
Methods: Peripheral blood was obtained from 22 HCC patients prior to tumoral resection or liver transplantation and from 18 healthy donors (HD). We characterized four myeloid populations ($CD33^+CD11b^+$) by flow cytometry: monocytes: $CD14^+$HLA-DR^{high}, monocytic MDSC (M-MDSC): $CD15^-CD14^+$HLA-$DR^{-/low}$, polimorphonuclear MDSC (PMN-MDSC): $CD15^+CD14^-$HLA-DR^- and early-stage (eMDSC): $CD15^-CD14^-$HLA-DR^-. We assessed their immunosuppressive function *in vitro* in proliferation assays.
Results: All three proportions of MDSC were significantly increased in HCC patients vs HD: M-MDSC (7.8% vs 0.4%), PMN-MDSC (4.75% vs 1.71%) and eMDSC (6% vs 2.5%) (all $p<0.03$). By contrast, monocytes were significantly decreased in HCC patients (36.4% vs 47.5%, p=0.02). A significant proportion of eMDSC expressed CD25. CD25+ eMDSC were higher in HCC than in HD (73.83% vs 44.4%, p=0.008), and the CD25 *per cell* expression in eMDSC was also significantly augmented in HCC vs HD (MFI 1051.5 vs 832 p=0.02). HCC-myeloid cells ($CD33^+$) showed higher suppression of $CD4^+$ and $CD8^+$ T-cell proliferation than HD-myeloid cells (p=0.001 and p=0.0006 respectively). Inhibition of proliferation directly correlated with the number of nodules and M-MDSC and was inverse with HLA-DR expression on $CD14^+$ cells and CD25 expression in eMDSC. HCC patients with > 2 vs ≤ 2 nodules presented higher eMDSC (7.24% vs 4.2%, p=0.02) and CD25+ eMDSC (4.34% vs 1.65%, p=0.0004). Likewise, when compared with patients with less advanced TNM stages (0/I, T1N0M0), patients with TNM stage II/III (T2N0M0 or T3N0M0) exhibited significant higher M-MDSC (0.44% vs 3.67%, $p<0.0001$), eMDSC (0.58% vs 6.48%, p=0.0001) and CD25+ eMDSC (0.3% vs 3.55%, p=0.003). HCC patients with serum alpha-fetoprotein (aFP) levels above median had higher M-MDSC than those with aFP below median (2.98% vs 0.17%, p=0.03).
Conclusion: HCC patients with more advanced disease had an expansion of M-MDSC and eMDSC. Therapies aimed at depleting of MDSC could favor a better outcome.

To B or not to B in NSCLC: Functional characterisation of tumor infiltrating B cells in NSCLC

Ana Santiso[1], Oliver Kindler[1], Xiaodong Zhu[2], Sofia Raftopoulou[1], Ingeborg Klymiuk[3], Kathrin Maitz[1], Zala Mihalic[1], A. McGarry Houghton[4], Julia Kargl[1]
[1]Otto Loewi Research Center, Medical University of Graz, Graz, Austria; *[2]Fred Hutch Cancer Research Center, Seattle, United States*; *[3]Gottfried Schatz Research Center, Division of Cell Biology, Histology and Embryology, Medical University of Graz, Austria, Graz, Austria*; *[4]Fred Hutchinson Cancer Research Center, Seattle, United States*

Purpose: The study aimed to characterize the phenotypic and functional diversity of tumor-infiltrating B cells within the tumor microenvironment (TME) of non-small cell lung cancer (NSCLC) patients. Understanding the roles of these B cell subpopulations could provide insights into modulating B-cell responses for enhanced anti-tumor immunity.
Methods: Integration of high-dimensional protein and RNA expression data from B cells obtained from lung, blood, and tumor samples was performed. Clinical samples underwent surface marker screening via flow cytometry, with validation of differential protein expression. Single-cell RNA sequencing was conducted on sorted B cells from matched tumor and lung samples. Multiplex immunofluorescence (mIF) was employed to assess spatial B cell localization in tumor and adjacent lung regions of formalin-fixed paraffin-embedded (FFPE) patient samples, focusing on selected protein markers.
Results: Four distinct B cell subtypes were identified within the TME of NSCLC patients: Plasma cells, memory B cells, germinal center (GC) B cells, and naive B cells. Differential expression of 11 markers on TME B cells, including CD55, was successfully detected and validated compared to lung and/or peripheral blood mononuclear cells (PBMCs). Notably, CD55 exhibited differential expression at both mRNA and protein levels, with mIF data indicating increased expression localized around the GC area of tertiary lymphoid structures (TLSs).
Conclusion: The study elucidates the heterogeneity of B cell populations within the TME of NSCLC, providing insights into their phenotypic and functional diversity. These findings contribute to a deeper understanding of the complex interplay between B cells and tumors, highlighting that the B cell phenotypes present are highly dependent of the surrounding TME.

Rafoxanide negatively modulates STAT3 and NF-κB activity and inflammation-associated colon tumorigenesis.

Teresa Pacifico[1], Carmine Stolfi[1], Lorenzo Tomassini[1], Anderson Luiz-Ferreira[2], Eleonora Franzè[1], Angela Ortenzi[1], Alfredo Colantoni[1], Giuseppe S. Sica[1], Manolo Sambucci[3], Ivan Monteleone[3], Giovanni Monteleone[1], Federica Laudisi[1]
[1]University of Rome Tor Vergata, Rome, Italy; *[2]Federal University of Catalão (UFCAT), Catalão, Brazil*; *[3]Santa Lucia Foundation IRCCS, Rome, Italy*

Purpose In the colorectal cancer (CRC) niche, the transcription factors signal transducer and activator of transcription 3 (STAT3) and nuclear factor-κB (NF-κB) are hyperactivated in both malignant cells and tumor-infiltrating leukocytes (TILs) and cooperate to maintain cancer cell proliferation/survival and drive pro-tumor inflammation. Through drug repositioning studies, the anthelmintic drug rafoxanide has recently emerged as a potent and selective antitumor molecule for different types of cancer, including CRC. Here, we investigate whether rafoxanide could negatively modulate STAT3/NF-κB and inflammation-associated CRC.
The antineoplastic effect of rafoxanide was explored in a murine model of CRC resembling colitis-associated disease. Cell proliferation and/or STAT3/NF-κB activation were evaluated in colon tissues taken from mice with colitis-associated CRC, human CRC cells, CRC patient-derived explants and organoids after treatment with rafoxanide. STAT3/NF-κB activation and cytokine production/secretion were assessed in TILs isolated from CRC specimens and treated with rafoxanide. Finally, we investigated the effects of TIL-derived supernatants cultured with or without rafoxanide on CRC cell proliferation and STAT3/NF-κB activation.
Results Rafoxanide restrains STAT3/NF-κB activation and inflammation-associated colon tumorigenesis in vivo without apparent effects on normal intestinal cells. Rafoxanide markedly reduces STAT3/NF-κB activation in cultured CRC cells, CRC-derived explants/organoids, and TILs. Finally, rafoxanide treatment impairs the ability of TILs to produce pro-tumor cytokines and promote CRC cell proliferation.
Conclusions We report the novel observation that rafoxanide negatively affects STAT3/NF-κB oncogenic activity at multiple levels in the CRC microenvironment. Our data suggest that rafoxanide could potentially be deployed as an anti-cancer drug in inflammation-associated CRC.

High frequency of CD16+ ILT2hi monocytes in colorectal cancer: Friend of foe?

Ignacio Juarez[1], Christian Vaquero-Yuste[1], Marta Molina-Alejandre[1], Jose Maria Muguerza-Huguet[2], Cristina Sanchez del Pueblo[2], Maria Suarez-Solis[2], Jose Manuel Martin-Villa[1;3]
[1]Immunology Department. Complutense University School of Medicine, Madrid, Spain; *[2]Servicio de Cirugía General y del Aparato Digestivo. Hospital Clínico San Carlos, Madrid, Spain*; *[3]Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain*

The CD16+ monocyte population is a population of mononuclear cells to which both pro-(angiogenesis, immunosuppression) and anti-tumor functions (metastasis prevention, antibody-mediated cytotoxicity, NKs recruitment) are attributed (Olingy et al. 2019), so it is of particular interest to study this population in the context of cancer.
In this work, we have evaluated the frequency of CD16+ peripheral blood monocytes (PBMo) and the expression of different markers associated with their function by flow cytometry in 23 patients with colorectal cancer (CRC) and 14 healthy donors (HD).
We found an increase in the CD16+ PBMo population (13.8%±6.5) compared to the control population (7.6%±3.6; p=0.0015 t-test), to the detriment of the CD16- population (82.8%±9.2 vs 89.6%±5.0, p=0.0008 t-test), affecting the CD16+/CD16- ratio (0.17±0.11 in CRC vs 0.07±0.04 in HD, p=0.0022 t-test). We determined that CD16+ PBMo have higher ILT2, ligand of class-I HLA molecules, expression (MFI=376.0±174.4) compared to CD16- PBMo (144.6 ± 60.0, p<0.0001, paired and unpaired t-test) in patients with CRC. We also confirmed the presence of CD16+ and ILT2+ cells in CRC tumors by IHC.
The results herein shown describe an increase in the CD16+ PBMo of CRC, which would be equivalent to the non-classical (CD14- CD16+) or intermediate (CD14+ CD16+) monocyte population. Moreover, CD16+ population presents higher levels of the ILT2 receptor, with a suppressor activity, which could imply a high regulation of CD16+ PBMo through ILT2 ligands such as HLA-G and other HLA class I molecules. ILT2 signals through SHP proteins, that have been related to inflammatory properties of macrophages in different contexts. Further research in analyzing the effect of ILT2 signaling in the context of CRC may seed light to the involvement of CD16+ ILT2+ monocytes in this pathology.

Myeloperoxidase alters T cell function and plays an immunosuppressive role in non-small cell lung cancer

Anna Lueger[1], Paulina Valadez-Cosmes[1], Kathrin Maitz[1], Nejra Cosic Mujkanovic[1], Oliver Kindler[1], Marah Runtsch[1], Julia Kargl[1]
[1]*Medical University of Graz, Graz, Austria*

Purpose: The tumor microenvironment (TME) of non-small cell lung cancer (NSCLC) involves high infiltration of immune cells, including neutrophils. These neutrophils contribute to the complexity of the TME by releasing myeloperoxidase (MPO) upon activation and degranulation. In the presence of H_2O_2, MPO generates HOCl, a highly reactive molecule that can cause damage to proteins, lipids and DNA. In this study, we investigated the functional role of MPO in the NSCLC and its effect on T cells within the TME. We hypothesize that MPO in the TME may alter T cell activation and function, ultimately leading to an immunosuppressive TME.
Methods: We studied MPO knock-out mice in a flank tumor mouse model. Additionally, we conducted in vitro experiments using recombinant MPO treatments to analyze the impact of MPO on T cells.
Results: MPO knock-out mice exhibited reduced tumor growth compared to WT controls. This decrease in tumor growth was accompanied by an increase in lymphocyte populations, including natural killer cells (NKs) and $CD8^+$ T cells. Furthermore, MPO knock-out mice demonstrated enhanced expression of IFN-γ by T cells. In vitro experiments also revealed that $CD8^+$ T cells treated with MPO exhibited reduced proliferation and production of IFN-γ.
Conclusion: Our findings indicate that the deletion of MPO promotes an anti-tumorigenic immune environment in a mouse tumor model, characterized by an increase in $CD8^+$ T cells and heightened expression of IFN-γ. Additionally, MPO negatively affects function of anti-tumor T cells, supported by in vitro experiments demonstrating decreased proliferation and IFN-γ expression of $CD8^+$ T cells after MPO treatment. These results suggest that MPO contributes to tumor growth and exhibits an immunosuppressive role in NSCLC. Consequently, MPO might serve as a potential target for lung cancer therapies, aiming to counteract its immunosuppressive effects in NSCLC.

Dysregulated lipid metabolism is a key driver of immunosuppression in ovarian cancer

Karen Slattery[1], Donal Brennan[2], Lydia Lynch[1;3]
[1]*Trinity College Dublin, Dublin, Ireland*; [2]*University College Dublin, Dublin, Ireland*; [3]*Harvard Medical School, Boston, United States*

Ovarian cancer is the most lethal cancer in women worldwide, with over 70% of patients presenting with metastasis upon diagnosis. Build up of ascites fluid in the abdomen promotes metastasis and is associated with relapse and poor survival. Immunotherapy trials to date have failed, and thus there is urgent need to better understand the immunology of ovarian cancer. In this study we analysed the function and metabolism of NK cells from 24 ovarian cancer patients, including samples from up to 6 matched sites of disease. We showed that NK cell dysfunction is evident not only in the primary ovarian tumour, but across all sites of disease, including in secondary tumours and in ascites fluid. Many of the dysfunctional and metabolic features observed in tumour and ascites-infiltrating NK cells were also observed in other lymphocyte subsets, including CD4+ and CD8+ T cells, and innate-like T cells. As ascites plays a key role in promoting the dissemination of ovarian cancer, we developed an *in vitro* model to study the impact of the ascites microenvironment on NK cell metabolism. Using LC-MS based metabolomic and lipidomic analyses, we showed that lipid metabolism is the dominant pathway affected in NK cells exposed to ascites. This was characterised by high uptake of polar lipids and defects in their lipid handling capacity. Treatment with polar lipids *in vitro* recapitulated the phenotype. Importantly, depleting ascites of lipids or blocking the uptake of lipids through FATP2 protected NK cell and T cell anti-tumours functions. Overall, we show that polar lipids are key driver of NK cell dysfunction in ovarian cancer for the first time. These findings have important implications for the design of future immunotherapies for ovarian cancer patients.

Immune checkpoint modulation induced by inflammatory cytokines in colon cancer cells

Ilaria ferrigno[1;2], Martina Bonacini[2], Alessandro Rossi[2], Cecilia Catellani[2], Veronica Buia[1;2], Carlo Salvarani[3;4], Alessandro Zerbini[2], Stefania Croci[2]
[1]PhD Program in Clinical and Experimental Medicine, University of Modena and Reggio Emilia, Modena, Italy, Modena, Italy; *[2]Unit of Clinical Immunology, Allergy and Advanced Biotechnologies, Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Reggio Emilia, Italy*; *[3]Unit of Rheumatology, Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Reggio Emilia, Italy*; *[4]Department of Surgery, Medicine, Dentistry and Morphological Sciences with Interest in Transplant, Oncology and Regenerative Medicine, University of Modena and Reggio Emilia, Modena, Italy*

Purpose: To evaluate the effects of inflammatory cytokines on immune checkpoint expression in colon cancer cells.
Methods: The colon cancer cell lines HT-29 and HCT116 were treated with the following cytokines: IFNγ (10 ng/mL), TNFα (50 ng/mL), IL-1β (50 ng/mL), IL-6 + soluble IL-6R (10 ng/mL + 100 ng/mL), IL-15 (50 ng/mL) and TGFβ (10 ng/mL). The expression of the immune checkpoint PD-L1, PD-L2, Galectin 9 (GAL9), CD155, ICOSL, and 4-1BBL were evaluated after 24 and 48 hours of treatment using flow cytometry. The soluble forms of the same immune checkpoints were quantified in the cell supernatants by multiplex bead-based assays.
Results: Both colon carcinoma cell lines showed a low basal expression of PD-L1, which increased after treatment with IFNγ, TNFα, and IL-1β for 24 and 48 hours, compared to the untreated samples. Intracellular and plasma membrane GAL9 was present in HT-29 and HCT116 cells and increased after treatment with TNFα for 48 hours. On the HT-29 cells, GAL9 also increased after treatment with IFNγ. Both HT-29 and HCT116 cells expressed CD155, but its expression did not change after treatments. HCT116 cells showed a low expression of 4-1BBL which decreased after treatment with TNFα and IL-1β for 24 hours, while HT-29 cells did not express 4-1BBL. PD-L2 and ICOSL were not detected on the cell surface of both cell lines and they were not induced by treatments. IL-6 + soluble IL-6R, IL-15 and TGFβ did not affect the immune checkpoint expression on these cell lines. Low levels of soluble ICOSL were detected in the cell supernatants after treatment with TNFα for 48 hours. The soluble forms of the other investigated immune checkpoints were not detected.
Conclusion: Our findings suggest that the presence of IFNγ, TNFα, and IL-1β in the tumor microenvironment can increase the expression of inhibitory immune checkpoints (PD-L1, GAL9) and decrease the presence of stimulatory ones (4-1BBL), thus favoring immune escape of the colon cancer cells.

Modelling macrophages-glioblastoma cross-talk in tumor microenvironment

Federica Mornata[1;2], Alessandra Maielli[1;2], Haralampos Hatzikirou[3;4], Friedrich Feuerhake[5], Peter Raab[5], Benedetta Savino[1;2], Massimo Locati[1;2]
[1]Department of Medical Biotechnologies and Translational Medicine, University of Milan, Milan, Italy; *[2]IRCCS Humanitas Research Hospital, Rozzano, Milan, Italy*; *[3]Mathematics Department, Khalifa University, Abu Dhabi, United Arab Emirates*; *[4]Technische Univesität Dresden, Center for Information Services and High Performance Computing, Dresden, Germany*; *[5]Department of Neuropathology, Institute of Pathology, Hannover Medical School, Hannover, Germany*

Purpose: Glioblastoma (GBM) is the most common malignant primary brain tumor in adults: treatment relies on surgery, even if its highly infiltrative nature frequently prevents an optimal resection, thus recurrence is inevitable and prognosis remains poor. GBM subsets include isocitratedehydrogenase (IDH)-wild type (Wt), and IDH-mutant tumors, the latter with more favourable prognosis. Among infiltrating immune cells of the tumor microenvironment (TME), tumor-associated macrophages (TAMs) are the most abundant, and their abundance has been shown to correlate with clinical outcomes. Since biological behaviour of residual tumor cells at the GBM resection margin (''edge'') determines the clinical course of the disease a better understanding of the role of macrophages in this context becomes fundamental to drive the second line treatment for the urgent medical need of recurrence.
Methods: We set-up a co-culture system using the U87 GBM cell line, both IDH-Wt and mutants, and monocytes-derived macrophages. In this setting, we also modelled distinguish interactions occurring at the tumor edge *vs* the tumor core by exposing cells to normoxic and hypoxic conditions with different O_2 tension (20% *vs* 1% O_2). Then, $CD45^+$ macrophages were FACS-sorted and their transcriptomic profile were obtained from RNAseq analysis. Responses to hypoxia was assessed by evaluating the expression of selected hypoxia target genes.

Results: Results show that this *in vitro* model is a reliable approach to study the effects of tumor oxygen levels on the interplay between macrophages and tumor cells. In particular, we demonstrate that hypoxia induces its target genes in a cell-specific manner, with significant differences between Wt and IDH-mutant U87 co-cultures. Interestingly, addition of macrophages shapes tumor cells responses to hypoxia. Preliminary results on transcriptomic profiles show that cell interactions are the major driver to shape macrophages phenotype in our system, since we observe a higher number of pathways modulated in comparison to metabolic conditions and IDH status.

Conclusion: Additional studies on macrophages phenotypes in all experimental conditions are in progress to better characterized signature genes/pathways (immunomodulation, angiogenesis, proliferation, matrix remodelling) and to integrate them with mathematical models to elaborate strategies to drive clinical practice.

Profiling the immune populations in paediatric brain tumours: the MIMIC program

Tiago Carvalheiro[1], Joyce I. Meesters-Ensing[1], Raoull Hoogendijk[1], Mariëtte Kranendonk[1], Eelco W. Hoving[1], Friso G. Calkoen[1], Jasper van der Lugt[1], Stefan Nierkens[1;2]
[1]Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands; *[2]Center for Translational Immunology, University Medical Center Utrecht, Utrecht, Netherlands*

Background: Brain tumours are the most common solid cancers in childhood, compromising 25% of the paediatric cancers, and are the leading cause of cancer-related death in children. The combination of aggressive tumours in a delicate environment limits the therapeutic options. Myeloid cells, particularly tumour-associated macrophages (TAMs) in the tumour-microenvironment (TME), exhibit potent immunosuppressive features inhibiting effective anti-tumour T-cell responses. Targeting these cells holds promise to improve outcomes, however the underlying mechanisms of immune dysfunction remain poorly understood.
Aim: This study aims to comprehensively profile the various immune cell populations in paediatric brain tumours (pBT) and investigate their functional phenotypes.
Methods: Spectral-flow cytometry was performed on primary tumour biopsies and tumour fragments obtained via cavitron ultrasonic surgical aspiration (CUSA) from pBT patients (high-grade glioma, ependymoma, medulloblastoma, pilocytic astrocytoma and rosette-forming glioneuronal tumour) enrolled in our immune-monitoring program (MIMIC) at the Princess Máxima Centrum. This allowed the quantification and comprehensive phenotyping of the immune cell populations within the TME.
Results: The pBT TME exhibited a low abundance of immune cells across various tumour types, with myeloid cells comprising the predominant proportion. TAMs were detected in both tumour biopsies and CUSA tumour fragments in similar proportions. However, resident TAMs were enriched in the tumour fragments obtained from CUSA. Additionally, invading TAMs displayed a mixed "M1"/"M2"-like polarization phenotype, with higher expression of the chemokine receptor CCR2 and HLA-DR, as well as the immune-inhibitory receptors SIRP1A/B, CD33, and TIM3, compared to resident TAMs. T-cell infiltration in the TME was relatively low, however $CD8^+$ T-cells retained the capacity to produce Granzyme-B, despite the high expression of the immune-inhibitory receptor PD-1.
Conclusions: The apparent T-cell cytotoxic capacity in the TME indicates their potential to combat the cancer cells, on the other hand invading TAMs in pBT evidence a high expression of immune-inhibitory receptors suggesting an immunosuppressive phenotype, potentially facilitating tumour growth, infiltration and escape to T-cell immunity. Overall, CUSA-derived samples are representative of the TME characteristics observed in tumour biopsies, however a few differences were noted. Understanding the immune dynamics and their functional activity in the TME is crucial for advancing therapeutic efficacy in pBT.

Ferroptosis induces immunogenic cell death and reshapes the tumor microenvironment towards improved immunotherapy in hepatocellular carcinoma

Wiebke Werner[1], Alix Bruneau[1], Johanna Kusnick[1], Katharina Detjen[1], Isabella Lurje[1], Nicola Beindorff[2], Frank Tacke[1], Linda Hammerich[1]
[1]Department of Gastroenterology and Hepatology, Campus Charité Mitte, Campus Virchow Klinikum, Charité-Universitätsmedizin Berlin, Berlin, Germany; *[2]Berlin Experimental Radionuclide Imaging Center, Charité - Universitätsmedizin Berlin, Berlin, Germany*

Purpose: Immune-checkpoint-inhibitor (ICI) therapy has revolutionized cancer treatment but response rates in hepatocellular carcinoma (HCC) are still unsatisfactory. Immunogenic cell death (ICD) has been proposed as a possible way to overcome uninflamed tumor microenvironments (TME) and improve ICI therapy efficacy. Ferroptosis, an iron-dependent programmed cell death characterized by lipid peroxidation, is dysregulated in many cancers and emerging studies indicate that ferroptosis might be immunogenic. Here, we study how ferroptosis influences the TME of HCC and how this can be leveraged to increase efficacy of ICI therapy.
Methods: Mouse and human HCC cell lines were subjected to multiple ferroptosis inducers and the molecular changes analyzed by spectral flow cytometry and multiplex immunofluorescence staining. Primary immune cells were cocultured with ferroptotic cancer cells or their supernatant and characterized for changes in their activation status. HCC tumor-bearing fully immunocompetent mice were treated with buthionine sulfoximine (BSO) to induce ferroptosis and changes in the TME analyzed by spectral flow cytometry and multiplex immunofluorescence staining. Tumor growth was monitored with longitudinal magnetic resonance imaging. Liver sections of HCC patients were stained for markers of ferroptosis and ICD.
Results: Both human and murine HCC cells were sensitive to ferroptosis induction in vitro and displayed a time-dependent translocation of calreticulin to the outer membrane with a downregulation of CD47, both indicating immunogenicity. This was associated with upregulation of PD-L1. Coculture of ferroptotic HCC cells or their supernatant with primary immune cells resulted in activation of both myeloid cells and T cells. Multiplex immunofluorescence revealed that untreated human and murine HCC tumors displayed cold TME with low immune cell infiltration. BSO treatment of HCC-bearing mice resulted in enhanced immune cell infiltration, delayed tumor growth and increased survival compared to untreated mice.
Conclusion: Ferroptosis induction in HCC cells triggers immunogenic cell death and reshapes the TME towards immune cell infiltration and activation. Upregulation of PD-L1 provides a strong rationale that the ferroptosis induction might induce response to ICI therapy and combination therapies should be explored in further studies.

Smoldering inflammation is revealed by the collagen scaffold adaptation and remodeling

Luca Vannucci[1], Dmitry Stakheev[1;2], Pavol Lukac[1;3], Lenka Rajsiglova[1;3], Paolo Tenti[1;3], Daniel Hadraba[4], David Vondrasek[4], Gianluca Mucciolo[5], Paola Cappello[6], Renata Stepankova[7], peter Makovicky[8], Tomas Hudcovic[7], Petr Sima[1], Fabian Caja[1], Daniel Smrz[1;2]
[1]Institute of Microbiology of the CAS, v.v.i., Prague, Czech Republic; *[2]2nd Medical Faculty, Charles University, Prague, Czech Republic*; *[3]Faculty of Science, Charles University, Prague, Czech Republic*; *[4]Institute of Physiology, Prague, Czech Republic*; *[5]Cancer Research UK Cambridge Institute, University of Cambridge, Cambridge, United Kingdom*; *[6]Lab of Tumor Immunology Centro di Biotecnologie Molecolari "Guido Tarone", University of Turin, Turin, Italy*; *[7]Institute of Microbiology of the CAS, v.v.i., Novy Hradek, Czech Republic*; *[8]Medical Faculty of The University of Ostrava, Ostrava, Czech Republic*

Increased deposition and remodeling of collagen in the microenvironment of tissues and tumors depend on chronic inflammation, a leading factor addressing cancer establishment and evolution. However, even minor changes in immune activation inside a tissue can induce structural remodeling if persisting. Reciprocally, collagen accumulation can affect the local immunity e.g. by interaction with LAIR-1 receptor on immune cells. We have shown the gut colonization of germ-free (GF) mice with intestinal microflora from conventional mice (CV) quickly modifies the mucosal scaffold and influences the systemic immunity. In vivo in rat, the induction of either chronic colitis (dextran sodium sulphate – DSS) or colon carcinogenesis (azoxymethane – AOM) resulted to sustain persistent inflammation and remodeling of the collagen scaffold organization, even when the mucosa appears recovered, at one month after acute induction. The collagen scaffold remodeling associated to persistent pro-inflammatory cytokine activities was documented by multi-photon confocal microscopy (second harmonic generation). This was found both after bacterial (GF CV) and chemical (DSS or AOM) stimulations, making the structural changes mirroring the microenvironment immunological activation. These results suggest a mucosal "inflammatory threshold (IT)", i.e. a regulatory limit for tolerating inflammatory signals and maintaining the tissue homeostasis. The collagen scaffold quickly adapts to the immune microenvironment conditions. A dis-balance between pro-inflammatory and regulatory signals can overcome IT even under apparently normal or reduced levels of microenvironmental cytokines, allowing a smoldering inflammation. The scaffold structure alteration can identify either cancer niche or chronic colitis depending on the local cytokine proportions (IL-6, IFN-γ, IL-1, TGF-β). Furthermore, in a mouse pancreatic cancer model different IL-17 expression differently addressed the profibrotic collagen organization. Concluding, cytokine levels and collagen scaffold remodeling measured in the tissue may represent a new diagnostic tool.

Lymphoma B cells express SIRPα and increased SIRPα+ B cells are associated with inferior clinical outcomes in B-cell non-Hodgkin lymphoma

Zhizhang Yang[1], Hyo Jin Kim[1], Xinyi Tang[1], Prithviraj Mukherjee[1], Vaishali Bhardwaj[1], Patrizia Mondello[1], Stephen Ansell[1]
[1]*Mayo Clinic, Rochester, United States*

Purpose: Signal regulatory protein-α (SIRPα) is a key member of the "do-not-eat-me" signaling pathway and expressed on intratumoral monocytes in B-cell non-Hodgkin lymphoma (NHL). In this study, we measured SIRPα expression on lymphoma B cells and determined its biological and clinical significance in B-cell NHL.
Methods: Assays including flow cytometry, PCR, thymidine incorporation, CyTOF, CITE-Seq, and imaging were utilized in this study to measure SIRPα expression, upregulation, and function on B cells.
Results: Using biopsy specimens from follicular (FL) and marginal zone (MZL) lymphoma, we observed that a portion of lymphoma B cells (16.29%, range: 0.2-68%, n=80, FL; 22.8%, range: 0.8-78%, n=30, MZL) expressed SIRPα at a low level. PCR and imaging assays showed that a variety of types of lymphoma B cell lines including diffuse large B-cell lymphoma (SUDHL2, SUDHL6 and OCI-LY3), mantle cell lymphoma (Jeko-1), MZL (Karpas1718), Waldenström's macroglobulinemia (MWCL-1) expressed SIRPα mRNA or protein. Activation with LPS or CpG substantially upregulated SIRPα expression on normal B cells or B cell lines. We observed that SIRPα$^+$ lymphoma B cells exhibited a phenotype similar to plasma cells, as SIRPα$^+$ cells expressed high level of CD38 and CD27 and low level of HLA-DR and IgD. SIRPα$^+$ B cells activated with anti-IgM showed increased proliferation compared to SIRPα$^-$ B cells, as indicated by increased thymidine uptake. Ligation of SIRPα on lymphoma OCI-LY3 B-cells using recombinant human CD47 protein resulted in enhanced BrdU incorporation and increased numbers of cells in S-phase when SIRPα$^+$ OCI-LY3 cells were compared to SIRPα$^-$ cells. The increased proliferation of SIRPα$^+$ cells was associated with increased phosphorylation of SHP-1. Clinically, we observed that a higher number of CD19$^+$SIRPα$^+$ B-cells in the diagnostic tumor biopsies of FL patients was associated with a significantly poorer overall survival.
Conclusion: Our results indicate that a subset of lymphoma B cells express SIRPα, and activation induces SIRPα expression on B-cells. SIRPα$^+$ lymphoma B cells exhibit a plasma cell-like phenotype and are more proliferative in response to activation. Increased numbers of SIRPα$^+$ B-cells in lymphoma patients are associated with a poor prognosis and targeting SIRPα$^+$ B-cells in lymphoma may be a promising therapeutic strategy.

Expression patterns of transforming growth factor beta - related genes in metastatic brain tumours

Boncho Grigorov[1], Antoniya Grirorova[1], Stefan Valkanov[2], Ridvan Yusuf[2], Lyuba Miteva[1]
[1]*Department of Molecular Biology, Immunology and Medical Genetics, Medical Faculty, Trakia University, Stara Zagora, Bulgaria*; [2]*Department of Neurosurgery, Medical Faculty, Trakia University, Stara Zagora, Bulgaria*

Purpose: The main aim of the study was to evaluate the local gene expression at the mRNA level of key TGFβ-related genes among cases with metastatic brain tumours.

Methods: Tissue specimens of metastatic brain tumours were collected from 22 patients with a mean age of 64.9 ± 7.7 years. Brain metastasis (BM) originates from primary lung cancer (n=15 cases); colorectal cancer (n=3); melamome (n=2), breast cancer (n=1), and bladder cancer (n=1). For 7 of these patients, peri-tumour samples were available and used as a calibrator. Gene expression analysis was performed by TaqMan-based assay for qPCR (7500 Real-Time PCR System; Applied Biosystems, Foster City, CA, USA). To quantify the results obtained by qPCR for the target genes *TGFB1*, *TGFBR2*, *FOXP3* and *VEGF* after normalization to reference gene *PPIA*, a relative quantification by comparative Ct method was used. The results are presented as a fold of change of the target genes compared to the calibrator.

Results: All studied target genes were significantly upregulated in the brain metastatic tissue compared to peri-tumoral tissue ($p<0.001$). The *VEGF* mRNA was at the highest level (55.6-fold), followed by *FOXP3* (41.5-fold), *TGFBR2* (40.7-fold), and *TGFB1* (24.2-fold). The *TGFBR2* and *TGFB1* mRNA was up to a 2-fold increase among the majority of BM samples (81.8%; 18 of 22). Similar data were obtained exploring cases of BM originating from lung primary cancer (n=15). Among them, the *VEGF* mRNA was at the highest level (64.9-fold), followed by *FOXP3* (53.2-fold), *TGFBR2* (47.4-fold), and *TGFB1* (29.5-fold). In addition, there was a very strong positive correlation between the mRNA level of *TGFB1* and *TGFBR2* ($r=0.857$; $p<0.001$) and *FOXP3* ($r=0.877$; $p<0.001$) in tumour tissues. Similar relations were detected in peri-tumoral samples. The *VEGF* expression was in strong positive relations with the *FOXP3*, *TGFBR2*, and *TGFB1* expression ($r=0.7$; $p=0.05$) in tumoral tissue in contrast to peri-tumoral tissue ($r<0.2$; $p>0.05$).

Conclusion:
Our findings support the crucial role of TGFβ-related genes (*TGFB1*, *TGFBR2*, and *FOXP3*) in local tumour suppressor activity in brain metastasis. Contrary to tumour-surrounding tissues, the *VEGF* expression strongly correlated to TGFβ-related gene expression in the brain metastasis.

Effect of IFN-gamma on MIF-CD74-Related Immune Pathways in Triple Negative Breast Cancer Cell Lines

Aysenur Kokoglu[1;2], Ali Abdi[1], Esin Cetin[1], Suhendan Ekmekcioglu[3], Gunnur Deniz[1]
[1]Department of Immunology, Aziz Sancar Institute of Experimental Medicine, Istanbul University, Istanbul, Turkey; *[2]Institute of Graduate Studies in Health Sciences, Istanbul University, Istanbul, Turkey*; *[3]Department of Melanoma Medical Oncology - Research, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Istanbul, United States*

IFN-γ is a pleiotropic cytokine involved in inflammation-mediated tumorigenesis processes as well as tumor immune regulation. After stimulation with MIF, CD74 molecule forms complexes with CD44, CXCR2 and CXCR4 molecules and activates signals involved in cancer growth and metastasis such as COX2 and PGE2. In this study, the effect of IFN-γ on MHC-II-mediated or MIF/CD74/CXCR and/or COX2 signaling pathways in cancer cell survival were investigated. MCF-10A and MDA-MB-231 cells were incubated with COX2 inhibitor celecoxib, PGE2 synthetase inhibitor MF63 and MIF antagonist ISO-1 molecules (48 hours, 37°C, 5% CO_2) in the presence or absence of 200 ng/ml INF-γ. After culturing, cells were stained with fluorescently labeled CD74, CD44, HLA-DR2, CXCR2, CXCR4, CXCR7, PDL-1 and PDL-2 monoclonal antibodies and evaluated on a spectral flow cytometry.
Our results showed that IFN-γ stimulation increased the expression of CD74, HLA-DR2, PDL-1 and PDL-2 molecules in MCF-10A and MDA-MB-231 cell lines. Celecoxib and ISO-1 molecules suppressed CD74 expression in both cell lines and MF63 molecule suppressed CD74 expression which increased by IFN-γ in MDA-MB-231 cell line. IFN-γ stimulation decreased CD44 expression in MDA-MB-231 cells, although not significantly compared to the unstimulated condition, while MF63+IFN-γ suppressed it with a synergistic effect. MF63 and ISO-1 molecules in MCF-10A cells and MF63+IFN-γ, celecoxib and celecoxib+IFN-γ conditions in MDA-MB-231 cells decreased PDL-2 expression compared to IFN-γ stimulation. When MCF-10 and MDA-MB-231 cells were compared, it was shown that MDA-MB-231 cells expressed PDL-1, CXCR7, CXCR4, CXCR2 molecules at a higher level. In MCF-10A cells, HLA-DR2 expression was found to be lower in unstimulated condition compared to MDA-MB-231 cells but higher in IFN-γ containing conditions.
Our findings indicates that IFN-γ cytokine promotes tumor cell growth by increasing CD74, PD-L1 and PD-L2 expression. Celecoxib, MF63 and ISO-1 molecules suppress CD74, however PDL-2 expression increased by IFN-γ. In addition, MF63 molecule suppresses CD44 expression when used together with IFN-γ, suggesting that MF63 molecule affects CD74/CD44 complex in two different ways. These findings suggest that celecoxib, MF63 and ISO-1 molecules may be potential agents that may suppress the MIF/CD74-mediated pro-tumoral effect of IFN-γ.

Tumor specific T cells in Acute Myeloid Leukemia (AML) : illusion or reality ?

Lisa Aziez[1], Romain Vazquez[1], Ismael Boussaid[1], Ania Alik[1], Zoé Fremont[1], Kanchanadevi Manasse[1], Chloe Friedrich[1], Marie Templé[1], Justine Decroocq[1], Rudy Birsen[1], Olivier Kosmider[1], Didier Bouscary[1], Michaela Fontenay[1], Nicolas Chapuis[1], Yannick Simoni[1]
[1]*Institut Cochin, Paris, France*

Acute myeloid leukemia (AML) is a heterogeneous group of blood cancer. The standard of care treatment has changed from chemotherapy or hypomethylating agents to the association with Venetoclax or FLT3 or IDH1/2 targeting agents but a large majority of patients still relapse and succumb to the disease, urging the need for better therapeutic approaches. New observations suggest that patients with AML could be good candidates for immunotherapies, but treatment efficacy could be improved by the identification of appropriate therapeutic targets and a better delineation of the patient subgroups. Here, we explore whether tumor-specific T cells response can be identified in AML patients and ultimately determine if a subgroup of patients could be candidates for immunotherapies treatment targeting T cells.
Using mass-cytometry to deeply characterize T cells population in paired blood and bone marrow (BM), we were able to identify a population of $CD8^+$ T cells only present in the BM tissue. These BM-specific cells show the hallmark of activation (i.e. PD-1^+) with a unique cytokine profile. Interestingly, this population is only present in a subgroup of AML patient. Next, we investigated the TCR repertoire of the BM-specific $CD8^+$ T population at the single-cell level to determine whether this population is mono- or polyclonal. Our data indicate the presence of several expanded TCR clonotypes that are specific to this BM cluster and not expressed by other $CD8^+$ T populations.
Taken together, these data highlight that a unique population of $CD8^+$ T cells having the hallmark of activated and expanded T cells is present in AML patient.
Finally, our next step will be to confirm the tumor-specificity of this population. To this end, we will investigate the antigen specificity of these cells using an MHC class I tetramer screening approach for neoantigens derived from splicing variants.

Oral colistin improves the therapeutic response of tumors to anti-PD1 treatment through an IFN-γ-dependent mechanism

Miloslav Kverka[1], Anietie Francis Udoumoh[1], Štěpán Coufal[1], Michal Kraus[1], Zuzana Jacková[1], Tomáš Thon[1], Tomáš Hrnčíř[2]
[1]Institute of Microbiology of the Czech Academy of Sciences, Prague, Czech Republic; *[2]Institute of Microbiology of the Czech Academy of Sciences, Nový Hraádek, Czech Republic*

Gut dysbiosis plays an important role in the response to cancer immunotherapy and antibiotic treatment is associated with a poorer response to immunotherapy. Here, we investigated how narrow-spectrum antibiotic (colistin) affects the outcome of anti-PD1 cancer therapy.
We exposed mice bearing MC-38 tumor and treated with anti-PD1 to colistin. The effect of colistin on the microbiota was analyzed by sequencing, immune cells in the mesenteric lymph nodes and tumors were analyzed by flow cytometry and the significance of specific immune factors was investigated using IFN-γ-deficient mice or IL-17A and CD4 depleting antibodies.
Colistin enhanced rather than impaired the efficacy of anti-PD1 on MC-38 adenocarcinomas. It only slightly altered the composition of the gut microbiota, but it increased tumor infiltration with IFN-γ and IL-17-producing T cells. Depletion of IL-17A did not alter the effect of colistin, but the effect was lost in IFN-γ-deficient mice. Depletion of CD4 further enhanced the antitumor effect of anti-PD1 treatment.
Some antibiotics, such as colistin, enhance the anti-PD1 effect in MC-38 adenocarcinomas by increasing the antitumor response in the tumor microenvironment. This effect is controlled by IFN-γ, but it is not dependent on IL-17A.

Regulatory macrophages in a murine model of lung carcinoma.

Barbara Polese[1], Nicolas Tessandier[1], Gary Dupont[1], Céline Legrand[1], Céline Vanwinge[1], Fabienne Perin[1], Amandine Tytgat Tytgat[1], Laurence Fievez[1], Fabrice Bureau[1], Didier Cataldo[1], Nathalie Jacobs[1]
[1]*University of Liège, Liege, Belgium*

Purpose: Regulatory macrophages (Mreg) play a pivotal role in asthma regulation through interleukin-10 (IL-10) production. However, their significance in tumorigenesis remains poorly understood. Herein, we investigate their involvement in murine lung squamous-cell carcinoma using luciferase-expressing Lewis lung carcinoma (LLC) cells.
Methods and results: Tumor growth was monitored during 28 days via luciferase imaging following intrathecal injection of LLC cells. Our findings reveal significant infiltration of Mreg into the tumor, with a notable increase in CD16.2-expressing Mreg. Interestingly, the phenotypic profile of Mreg shifts within the tumor milieu, characterized by enhanced CD64 expression and diminished MHC-Cl2 expression. We performed single-cell RNA sequencing to delineate a more precise phenotype of myeloid cells within this tumor model. Given Mreg's hallmark secretion of the immunosuppressive cytokine IL-10, we utilized IL-10 reporter mice (ITIB) to confirm a heightened proportion of IL-10-producing Mreg within the tumor microenvironment. Intriguingly, in vitro experiments demonstrated that LLC-conditioned medium augments IL-10 production specifically in Mreg, without affecting monocytes or alveolar macrophages.
Conclusion: In summary, our study sheds light on the dynamic change of Mreg in the context of lung squamous-cell carcinoma. We provide evidence of their increased presence within the tumor microenvironment, coupled with distinct phenotypic alterations with an increased IL-10 production. We will evaluate the influence of Mreg-produced IL-10 on tumor growth by utilizing mice with myeloid cell-specific IL-10 production deficiency.

Prostate cancer (PCa) is the second most common cancer in men worldwide. Recent studies have reported the crucial role of the tumor microenvironment (TME) in each stage of cancer progression, from tumor initiation to advanced disease. Among tumor-infiltrating immune cells, Natural Killer (NK) cells play a crucial role, exerting the ability to directly eliminate cancer cells while also coordinating innate and adaptive immune responses. However, in various cancer types, including PCa, their efficacy is compromised.

In the current project, our objective is to explore the mechanisms underlying the inhibition of NK cells in cancer, with the aim of uncovering innovative therapeutic approaches. We applied single cell RNA sequencing (scRNA-seq) to immune cells infiltrating human advanced PCa that revealed a significant alteration of tumor-infiltrating NK cells (TINKs) in terms of abundance and maturation status, with a decline in the cytotoxic subset. Importantly, TINKs exhibit a profound alteration in the autophagic pathway, as confirmed by FACS analysis in human patients and transplantable and genetic PCa models. To investigate the mechanisms underlying autophagy deregulation, we performed a scRNA-seq analysis to profile $CD45^+$ and $CD45^-$ cells in a transgenic model of PCa ($Pten^{pc-/-}$). The dissection of cellular interactions within the TME by CellPhoneDB and NicheNet algorithms identified the CXCR4/CXCL12 axis among the most significant interactions between tumor and TINKs. FACS analysis confirmed the upregulation of CXCR4 in NK cells in both human and mouse settings. Mechanistically, we demonstrated that the impairment of autophagy in TINKs is mediated by CXCR4 engagement by its ligand, CXCL12. Accordingly, the blockade of CXCR4/CXCL12 pathway determines the recovery of the autophagic defect. Finally, in view of the interconnection between autophagy and NK cell effector functions, inhibition of the axis determines the restoration of NK cell effector functions, which were negatively affected by tumor secretome.

In summary, our findings highlight that the observed autophagy impairment in TINKs is mediated by CXCR4 engagement. Importantly, the inhibition of CXCR4/CXCL12 axis positively regulates autophagy, consequently restoring NK cell anti-tumor functions. These results unveil a novel mechanism underlying NK cell dysfunction that can be targeted to enhance the efficacy of NK cell-based cancer immunotherapy.

Gene electrotransfer of plasmid DNA encoding chemokines CCL5 and CCL17 combined with irradiation induces immunomodulatory effects in murine tumors

Tim Bozic[1], Iva Santek[1;2], Simona Kranjc Brezar[1;2], Gregor Sersa[1;3], Bostjan Markelc[1], Maja Cemazar[1;4]
[1]*Institute of Oncology Ljubljana, Department of Experimental Oncology, Ljubljana, Slovenia*; [2]*University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia*; [3]*University of Ljubljana, Faculty of Health Sciences, Ljubljana, Slovenia*; [4]*University of Primorska, Faculty of Health Sciences, Izola, Slovenia*

Purpose: Chemokines regulate immune cell migration. The degree and the type of immune cells in the tumor affects disease progression and correlates with the efficacy and outcome of immunotherapies. Similarly, beneficial immunomodulatory effects were also observed after irradiation. Therefore, we sought to investigate gene electrotransfer (GET) of proinflammatory chemokines CCL5 or CCL17 in combination with irradiation, as a potential therapeutic strategy for cancer therapy.
Methods: Tumor models were chosen to correspond to an inflamed (CT26 murine colon cancer) or immunosuppressive (4T1 murine breast cancer) immunophenotype. First, chemotactic properties of investigated chemokines were examined *in vitro*. Next, the potential of chemokines to induce the extravasation of fluorescently labelled splenocytes was determined using intravital microscopy of tumors in dorsal window chamber model (DWC). The antitumor effectiveness of combined therapy utilizing GET of chemokines and two irradiation regimes (single dose of 10 Gy and fractionated dose of 3x 5 Gy) was then determined *in vivo*. Lastly, qRT-PCR was used to evaluate gene expression of several cytokines in tumors after the therapies, while changes in the abundance of CD4+, CD8+ cells and vasculature (CD31+ cells) were determined with immunofluorescent staining.
Results: Both CCL5 and CCL17 induced the migration of murine macrophages RAW264.7 *in vitro*. In tumor models, GET of chemokines increased splenocyte retention in DWCs, and combined therapy led to significant delays in CT26 tumor growth and even tumor cures. However, in 4T1 tumors, combined therapy resulted in significant tumor growth delay but not cures. Gene expression analysis revealed increased expression of chemokines post-therapy, along with elevated expression of CXCL9 and CXCL10, potent chemoattractants for cytotoxic CD8+ T lymphocytes. Immunofluorescent staining indicated increased infiltration of CD4+ and CD8+ T lymphocytes post-GET of chemokines, albeit with decreased numbers upon irradiation.
Conclusion: Combining GET of chemokines with irradiation elicited an antitumor immune response in inflamed tumors (CT26) and partially in immunosuppressive tumors (4T1), highlighting the potential of chemokines in cancer immunotherapy.

Spectral cytometry reveals distinct immunological signature discriminating PDAC from HD patients

Teresa Ruckenbrod[1], Hartmann Raifer[1], Magdalena Huber[1]
[1]*Institute of Systems Immunology, Marburg, Germany*

Purpose: PDAC is the deadliest solid malignancy with a 5-year overall survival of about 12%. We have recently described intratumoral $CD8^+ROR\gamma t^+$ T cells which promoted PDAC progression, particularly through IL17A and TNF. Subsequently, we aimed to characterize this cell population more precisely and resolve whether it can be detected in the peripheral blood of PDAC patients. As pancreatitis is a known risk factor for PDAC, we decided to compare PDAC with pancreatitis patients, and healthy donors (HD).
Methods: Blood samples from 22 PDAC, 22 pancreatitis patients, and 20 HD were collected and peripheral blood mononuclear cells (PBMC) were isolated. A panel for characterization of different T cell subpopulations, including 36 markers, was designed for flow cytometric staining of PBMC. Afterward, various subpopulations were characterized using high-dimensional bioinformatic analyses, and differences between the groups were visualized.
Results: For PDAC patients we revealed a decreased MAIT17 frequency in the periphery, while MAIT1 frequency was increased. Moreover, prolonged overall survival was associated with higher MAIT17 frequencies. To assess if MAIT cells are present in PDAC tissue we analyzed scRNA-Seq data obtained from 9 treatment-naïve PDAC patients published previously. Within cells expressing *CD3ε* and *CD8α,* we identified 5 clusters, which we classified as exhausted and pre-exhausted T cells, γδ T cells, and a big cluster of *KLRB1* (CD161) expressing MAIT cells accounting for more than 50% of intratumoral T cells. As MAIT cells are restricted to antigen presentation via monomorphic MHC class I-related protein 1 (MR1), which presents microbial derivatives of the riboflavin synthesis, we investigated the role of MR1. Thereby, we discovered the ability of fibroblasts and pancreatic tumor cells to express MR1, which makes them potential intratumoral activators of MAIT cells. Analysis of public data revealed increased expression of MR1 correlated with shorter survival, higher staging, and increased $CD8^+$ infiltration into the tumor.
Conclusion: Based on this data, we believe that the previously described intratumoral $CD8^+ROR\gamma t^+$ T cells might be MAIT17 cells, immigrating into the tumor due to increased MR1 expression triggered by changed microbial composition in PDAC. By elucidating the interplay of involved cells we aim to develop novel therapy options.

Neutrophil plasticity in the tumor microenvironment is dependent on HPV status in irradiated head and neck cancer

Clara Reichardt[1;2], Lia Mogge[3;4], Devarshi Dadawala[1], Marco Munoz Becerra[1;2], Udo Gaipl[2;3;4], Benjamin Frey[2;3;4], Luis Munoz[1;2]
[1]Department of Internal Medicine 3, Rheumatology and Immunology, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Erlangen, Germany; *[2]Deutsches Zentrum für Immuntherapie (DZI), Friedrich-Alexander-Universität Erlangen-Nürnberg and Universitätsklinikum Erlangen, Erlangen, Germany*; *[3]Translational Radiobiology, Department of Radiation Oncology, Universitätsklinikum Erlangen, FAU Erlangen-Nürnberg, Erlangen*; *[4]Comprehensive Cancer Center Erlangen-EMN, Erlangen, Erlangen, Germany*

Purpose: Neutrophils are the most abundant type of innate immune cell in humans and form the first line of defense against harmful invaders. Due to their short lifespan, they have been largely overlooked in cancer research. However, the presence of neutrophils or neutrophil-derived mediators in the tumor microenvironment has been associated with poor prognosis in several types of solid tumors, including head and neck cancer. Therefore, neutrophils have been reported to be differentially polarized depending on the HPV status of the tumor. However, the effect of cancer therapies such as radiotherapy in combination with HPV status on the tumor microenvironment and neutrophils in particular is not well understood.
Methods: Using an in vitro head and neck cancer model, we aim to analyze the effect of irradiation on HPV+ and HPV- tumor cell survival, immunogenicity and secretome. In addition, we will study the effect of human head and neck cancer secretomes on neutrophils ex vivo to analyze their lifespan, surface molecule expression, effector functions, and ability to migrate out of the bloodstream. We also aim to characterize changes in neutrophil metabolism and gene expression using multiplexed analysis approaches.
Results: Radiation does not differentially affect the viability and cell death modes of HPV+ and HPV- tumor cells. Upregulation of common checkpoint molecules is also independent of HPV status on the head and neck cancer cells tested. Neutrophils, however, show increased survival upon stimulation with the secretome of only irradiated HPV- head and neck cancer cells. Stimulation with secretomes from irradiated and untreated HPV+ head and neck cancer cells does not differentially affect neutrophil survival. Preliminary data also indicate that the effector functions of neutrophils and their ability to migrate are differentially affected by HPV+ and HPV- tumor cells.
Conclusion: We conclude that HPV status does not significantly affect the response of tumor cells to irradiation. Subsequently, however, the secretomes of irradiated HPV+ and HPV- head and neck cancers affect neutrophils differently, potentially affecting the overall anti-tumor immune response. Altered neutrophil migratory behavior may also affect disease outcome by altering the tumor microenvironment.

Spatial immunoprofiling of the tumor tissue in patients with leiomyosarcomas

Iva Benešová[1], Andrej Ozaniak[2], Jan Balko[3], Vira Tovazhnianska[3], Michal Rataj[1], Dominika Galová[2], Jitka Smetanova[1], Robert Lischke[2], Jiřina Bartůňková[1], Zuzana Ozaniak Střížová[1]
[1]Department of Immunology, Second Faculty of Medicine, Charles University and University Hospital Motol, Prague, Czech Republic; *[2]Third Department of Surgery, First Faculty of Medicine, Charles University and University Hospital Motol, Prague, Czech Republic*; *[3]Department of Pathology and Molecular Medicine, Second Faculty of Medicine, Charles University and University Hospital Motol, Prague, Czech Republic*

Leiomyosarcoma (LMS) is an extremely rare cancer with a poor prognosis and very limited treatment options at metastatic stages. While immune checkpoint inhibitors (ICI) showed encouraging results for many cancers, their efficacy varies within LMS. The tumor microenvironment significantly affects patient prognosis and responsiveness to ICI in many solid cancers. Our goal was to gain novel insights into the intratumoral heterogeneity and possible mechanisms of non-responsiveness to ICI in LMS.
Retroperitoneal LMS might exhibit a large size. Therefore, we investigated the intratumoral heterogeneity in four large-scaled treatment-naive tumors (ten samples per tumor). We defined four regions: vital and necrotic centers, organ-adjacent and free margins, where we evaluated immune cells with emphasis on T cells, macrophages and immune checkpoint molecules using flow cytometry and immunohistochemistry. Moreover, we analyzed cytokine secretion after anti-CD3/CD28 stimulation at these tumor regions.
The infiltration of immune cells and the expression of immune checkpoint molecules significantly varied between each patient and also within individual samples. The most profound discrepancy was observed within two distinct areas of the same tumor where $CD8^+TIM\text{-}3^+$ T cells ranged from 7% to 79%. Significantly higher expression of PD-1 and/or LAG-3 on non-T cells and almost significant LAG-3 expression on $CD4^+$ T cells was detected in the free margin in comparison to organ-adjacent margin. In contrast to other analyzed cytokines, the stimulation increased IL-17 secretion in cells isolated from organ-adjacent margin compared to cells from free margin. Following the findings about LAG-3 expression, we tested the cells reactivity to anti-LAG-3 blockade. We have observed decreased cytokine secretion and similar reaction pattern across all analyzed locations. Interestingly, IL-8 secretion was enhanced in necrotic center compared to other locations.
These results highlight the intratumoral heterogeneity of LMS, potentially explaining response to ICI therapy despite low or absent expression of these molecules and vice versa. As the presence of immune checkpoint molecules affects patient's eligibility for ICI administration, our data suggest that multiple biopsies are suitable for analyzing tumor-infiltrating immune cells in large-scaled tumors. This approach may provide higher diagnostic value and better patient selection for the optimal treatment strategy.

Exploring the role of mutant Kras-mediated inflammation in endometriosis development using murine models

Shin-Ting Wu[1], Eing-Mei Tsai[1;2], Jau-Ling Suen[1]
[1]*Graduate Institute of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung City, Taiwan*;
[2]*Department of Obstetrics and Gynecology, Kaohsiung Medical University Hospital, Kaohsiung City, Taiwan*

Purpose: Endometriosis is a common gynecological disease characterized by the presence of ectopic endometrial-like epithelium and stroma outside of the uterine cavity. Previous research has demonstrated that mutated Kirsten rats sarcoma viral oncogene *(KRAS)* can be identified in normal human endometrium and several types of endometrial malignancies. Studies suggest that *KRAS* mutations may foster an immune-suppressive microenvironment in malignancies, hindering effective immune cell infiltration while recruiting suppressive cells. Conversely, mutated *KRAS* has been demonstrated pro-inflammatory effects by upregulating inflammation-related transcription factors and effector cytokines in cancers. Additionally, murine models suggest *KRAS* involvement in endometriosis development, yet mechanisms are unclear. We aimed to explore *KRAS*-mediated inflammation in endometriosis using murine models due to its chronic inflammatory nature.
Methods: We established murine models of endometriosis by surgically transplanting uterine tissues from $Kras^{G12D}$ mice into wild-type recipients, or by injecting these tissues into the peritoneal cavities. The growth of endometriotic lesions was monitored using *in vivo* fluorescence imaging. Upon reaching the endpoint, we recorded the survival rates of lesions, lesion weights, and conducted pathological characterizations. Furthermore, we analyzed the immune cell composition using multi-parametric flow cytometry.
Results: The cystic lesions induced by both methods exhibited typical pathological characteristics, including squamous metaplasia in endometrial glands and heightened inflammation. Mutant Kras protein was expressed prominently in the epithelial region of the lesions. Notably, in our surgically-induced model, the endometriotic lesions showed increased weight and greater infiltration of immune cells in the *Kras*-mutated group. Specifically, we observed a higher number of plasmacytoid dendritic cells (pDCs) within the endometriotic lesions in the *Kras*-mutated group, while the counts of conventional dendritic cells (cDCs) remained unchanged, indicating a shift in dendritic cell subsets in the *Kras*-mutated endometriotic lesions.
Conclusion: Our findings indicate that the expression of mutant *Kras* in uterine epithelial cells likely contributes to the promotion of endometriosis lesion growth. The *Kras*-mediated microenvironment appears to influence the distribution of immune cells, favoring a condition rich in pDCs within the endometriotic lesions. However, the precise mechanism underlying this phenomenon warrants further investigation.

The Role of Extracellular Vesicles In Renal Cell Carcinoma Progression

Aline Seiko Carvalho Tahyra[1], Leandro Colli[2], Martin van Royen[1], Guido Jenster[1], Fausto Almeida[2]
[1]*Erasmus Medical Center, Rotterdam, Netherlands*; [2]*University of Sao Paulo, Ribeirao Preto, Brazil*

Purpose: With approximately 430,000 cases, kidney cancer represents 4.6% of the total number of cancer diagnoses in 2020, according to WHO. Nighty percent of these are Renal Cell Carcinoma (RCC), a neoplasm originating in the nephrons. The 5-year relative survival is related to staging and a drastic rate drop is observed when the tumor is metastasized. Extracellular vesicles (EVs) have emerged as a new paradigm of cell-cell communication supporting cancer progression. As little is known about EVs in RCC, we aim to obtain an EV profiling and address its role in RCC progression.
Methods: Given RCC heterogeneity, the study involves the evaluation of two RCC lines, 786-O and 769-P. HEK293 cells are used as control. It was implemented the 3D culture to mimic the tumor architecture. The lineages used in the 3D model were characterized by molecular and functional assays like western blot (WB), live-dead, wound-healing and transwell assay. Spheroid derived-EVs were isolated by affinity column and characterized by nanoparticle track analysis (NTA), WB, flow cytometry and transmission electron microscopy (TEM). In upcoming experiment, it will be performed co-incubation of EVs with spheroids and WB evaluation of hypoxia and metastasis pathways.
Results: RCC spheroids mimic the architecture of kidney tumor, mainly by consolidating a hypoxic core demonstrated by confocal microscopy images. We demonstrated that 786-O has active HIF-1α and higher levels of vimentin and MMP-2, -3, -8 and -9, pro-tumoral markers. Functionally, we show that 786-O cells migrate faster than 769-P cells. Data from NTA, flow cytometry and TEM from spheroid derived-EVs converged, showing that 786-O-derived EVs have a larger mean size than those derived from 769-P (229nm versus 144nm, respectively) and that tetraspanins CD9 and CD63 are present on the surface of these spheroid derived-EVs.
Conclusion: In summary, the *in vitro* data shows a spectrum of RCC aggressiveness that is related to cellular phenotype. As next steps, we aim to evaluate whether cell phenotype is reflected in its derived EVs via their unique RNA and protein content, which could functionally affect hypoxic-metastatic processes. This could open door for further investigation of therapeutic targets.

LYVE-1+ perivascular macrophages represent a therapeutic target in the tumour microenvironment

Karen T. Feehan[1], Jit Sarkar[1], Tik Shing Cheung[1], Joanne Anstee[1], Meriem Bahri[1], James Rosekilly[1], Cheryl Gillett[1], Pawan Dhami[2], James N. Arnold[1]
[1]School of Cancer and Pharmaceutical Sciences, King's College London, London, United Kingdom; *[2]Genomics Research Platform, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom*

Background: Tumour associated macrophages (TAMs) are a plastic population of immune cells that have been implicated in promoting a variety of pro-tumoral pathways. In a spontaneous murine model of mammary adenocarcinoma (*MMTV-PyMT*), a subset of TAMs co-expressing the lymphatic vessel endothelial hyaluronan receptor-1 (LYVE-1) and the immune-suppressive enzyme heme oxygenase-1 (HO-1) reside proximal to vasculature within the tumour microenvironment (TME). In this current study we aimed to investigate the role of these cells in tumour progression.
Methods: To assess the transcriptomic profile of the perivascular niche, spontaneous *MMTV-PyMT* tumours were analysed using image-guided spatial transcriptomics. Subcutaneous tumours were generated via injection of *PyMT*-derived Py8119 tumour cells into the mammary fat pad of *Csf1r*^{Dtr} *x Lyve1*^{Cre} mice to study the effects of specific LYVE-1$^+$ TAM ablation upon diphtheria toxin (DTx) administration. Spontaneous tumour models were generated when *MMTV-PyMT* mice were crossed with *Csf1r*^{Dtr} *x Lyve1*^{Cre} mice. The role of HO-1 was assessed using *Hmox1*$^{fl/fl}$ x *Lyve1*^{Cre} mice (to genetically inactivate HO-1). Tumour growth was assessed using callipers and immune profiles were analysed via flow cytometry of enzyme-digested tumours.
Results: Transcriptomic analyses of 15 perivascular regions from three tumours reveals regions of high HO-1 expression which coincide with the presence of LYVE-1$^+$ TAMs. These HO-1$^+$ niches have a unique transcriptomic profile enriched for genes associated with a pro-tumoral microenvironment (*Aurka*, *Angplt4*, *Krt14*) along with immune suppression (*Hmox1*, *Ptges*). Hypothesising that areas enriched in LYVE-1$^+$HO-1$^+$ TAMs are pivotal for tumour progression, we proceeded with specific ablation of the LYVE-1$^+$ TAM subset in the TME using DTx in tumours grown in *Csf1r*^{Dtr} *x Lyve1*^{Cre} animals. Ablation of LYVE-1$^+$ TAMs resulted in significant control of tumour growth in spontaneous (*MMTV-PyMT*) and subcutaneously (Py8119) implanted mammary tumours. Interestingly, genetic knockout of HO-1 expression in LYVE-1$^+$ TAMs did not control tumour growth but did improve CD8$^+$ T-cell infiltration to the TME.
Conclusion: This study, and the novel transgenic models generated in it, highlight an unappreciated role for LYVE-1$^+$ macrophages in driving tumour progression, that is independent of their HO-1 expression. Thus, LYVE-1$^+$ TAMs represent a therapeutic target within the TME to control tumour progression.

Immunophenotyping in peripheral blood and bone marrow niche of multiple myeloma: focus on innate CD8+ T lymphocytes

Emma Narbeburu[1], Hélène Gardeney[1;2], Niels Moya[1;2], Arthur Bobin[1;2], Anthony Levy[1;2], Cecile Gruchet[1;2], Xavier Leleu[1;2], André Herbelin[1], Jean-Marc Gombert[1;3], Alice Barbarin[1]
[1]IRMETIST, Université de Poitiers, INSERM U1313, Poitiers, France; *[2]CHU de Poitiers, Service d'Hématologie et thérapie cellulaire, Poitiers, France*; *[3]CHU de Poitiers, Service d'immunologie et inflammation, Poitiers, France*

Purpose: Multiple myeloma (MM) is an incurable malignant hematological disorder characterized by the monoclonal proliferation of transformed plasma cells (PC) in the bone marrow (BM). In addition to the conventional immune system components, cancer immune surveillance involves innate T-cells (ITC), including the newly described innate panKIR(+) NKG2A(+) CD8 T-cells (CD8 ITC). We sought to identify the phenotypic signature of ITC (iNKT, MAIT, γδ-T cells, and CD8 ITC) in the tumoral microenvironment and peripheral blood (PB) of MM.
Methods: Using spectral flow cytometry, we analyzed ITC subsets in PB and BM samples from newly diagnosed MM (NDMM) patients and healthy donors (HD). In BM, we focused our analysis on CD8 ITC, separating them into two subsets based on NKG2A and KIR expression. We also analyzed activation (CD122, CD137) and exhaustion (PD-1, TIM-3) markers, IFN-γ production in response to innate-like stimulation, and their cytotoxic content (Granzyme B).
Results: First, we showed that NDMM patients had a higher proportion of PB CD8 ITC among CD8 T-cells (and not iNKT or γδ-T cells among T-cells), as compared to HD. Moreover, PB CD8 ITC from NDMM patients were functionally impaired, as attested by their reduced IFN-γ production in response to IL-12/IL-18 stimulation, as compared to HD. Secondly, taken as a whole, ITC accounted for 10 to 20% of resident (CD69+) T-cells in BM from HD, a proportion that tended to increase in BM from NDMM patients. Remarkably, this resident (CD69+) T-cell population of NDMM patients co-expressed CD122 and CD137 and was mainly composed of KIR+ CD8 ITC. Moreover, there was no difference in the expression level of exhaustion markers (PD-1 and TIM-3) by CD8 ITC between HD and NDMM. Finally, Granzyme B frequency in KIR+ CD8 ITC patients was increased in NDMM, as compared to HD.
Conclusion: These data show that ITC represent a significant proportion of BM resident cells. Specifically, the co-expression of CD69, CD122 and CD137 in NDMM KIR+ CD8 ITC suggests specific activation by tumor antigens and bystander activity of this cell subset contributing to immune control of the BM MM niche.

Next generation of spatial biology: high-throughput multiplexed Imaging Mass Cytometry™ with whole slide modes

Qanber Raza[1], Thomas Pfister[1], Liang Lim[1], David Howell[2], Nikesh Parsotam[1], David King[2], Christina Loh[1], Dawar Pasha[3], Gloria Martrus Zapater[4]
[1]Standard BioTools, Markham, Canada; *[2]Standard BioTools, South San Francisco, United States*; *[3]Standard BioTools, London, United Kingdom*, *[4]Standard BioTools, Spain*

Purpose: Gaining spatial insights into tumor tissue cellular composition holds great promise for informing clinical and translational researchers about immunotherapy success predictors, disease progression, and etiology. Imaging Mass Cytometry™ (IMC™) facilitates deep characterization of the tumor microenvironment (TME) diversity and complexity. With the ability to simultaneously assess cell phenotype and function using 40-plus metal-tagged antibodies on a single slide, IMC eliminates issues related to fluorescence-based spectral overlap, tissue autofluorescence, and multiple washing and acquisition cycles.
Method and Material: Currently, IMC allows user-defined regions of interest (ROI) in tissues for evaluating cellular and structural composition. To improve the IMC user experience, we introduced two new whole slide imaging (WSI) modes: ultrafast preview mode (PM) and high-throughput tissue mode (TM). PM swiftly samples the entire tissue at predefined intervals to capture a low-resolution image of all markers in the antibody panel, providing quick insights for ROI placement while preserving tissue integrity for higher-resolution imaging. PM and TM seamlessly enable acquisitions on the same slide without extra processing steps. TM rapidly captures whole tissue images at a lower resolution (7 μm pixel size) suitable for quantitative spatial analysis of tissue biology. Tailored for high-throughput applications, TM, along with a new 40-slide loader for the Hyperion XTi™ Imaging System, allows automated and continuous imaging of over 40 large tissue samples (400 mm2 per tissue) per week.
Results and Discussion: We demonstrate the use of WSI modes with the newly developed Maxpar® Human Immuno-Oncology IMC Panel Kit. This 31-marker panel, combined with catalog antibodies, creates a 40-plus-marker panel, enabling comprehensive high-plex tumor and immune cell profiling. Tumor tissue microarrays (TMA) and whole tumor tissue sections were stained with the expanded panel. Single-cell analysis of selected ROIs, guided by PM data, provided quantitative analyses of spatial biology at single-cell resolution. Additionally, TM on whole tumor sections, followed by pixel-based analysis, yielded a spatially resolved quantitative assessment of specific tumor and immune components of the TME.
Conclusion: This work demonstrates the expanded capabilities of IMC and establishes it as a reliable high-plex spatial biology imaging platform with high-throughput imaging capabilities ideally suited for translational and clinical applications.

Novel Whole Slide Imaging Modes for Imaging Mass Cytometry Reveal Cellular and Structural Composition of Mouse Glioblastoma

Qanber Raza[1], Thomas Pfister[1], Nick Zabinyakov[1], Nikesh Parsotam[1], David King[1], Liang Lim[1], Christina Loh[1], Dawar Pasha[2] , Gloria Martrus Zapater[3]
[1]Standard BioTools, Markham, Canada; *[2]Standard BioTools, London, United Kingdom*, *[3]Standard BioTools, Spain*

Introduction: Mouse tumors are valuable models for brain malignancy research, overcoming challenges in studying the human brain. The mouse brain serves as a miniature version of the human brain, facilitating whole tissue visualization for spatial context. Imaging Mass Cytometry™ (IMC™) offers a powerful means to quantitatively analyze protein composition in the brain tumor microenvironment (TME) without autofluorescence or spectral overlap issues. The Hyperion XTi™ Imaging System by Standard BioTools™ employs IMC technology to assess over 40 structural and functional markers simultaneously, shedding light on TME organization and function.
Method and Material: We utilized whole slide imaging (WSI) with a 40-marker panel, combining the Maxpar OnDemand™ Mouse Immuno-Oncology IMC Panel Kit and the Maxpar® Neuro Phenotyping IMC Panel Kit on mouse normal and glioblastoma (GBM) brain tissue. The panel included mouse-specific antibodies highlighting tumor and immune components of the mouse tumor microenvironment (TME). Employing Hyperion™ XTi, we utilized two new features: Ultrafast preview mode (PM) for rapid screening of entire brain sections, guiding selection for region of interest-based IMC analysis and single-cell analysis (SCA); and high-throughput tissue mode (TM) for detailed whole-slide scans, quantified using pixel-based analysis (PBA) to elucidate TME composition.
Results and Discussion: Using TM, we successfully visualized both normal mouse brain and mouse GBM tissue in coronal and sagittal sections. PBA analysis revealed quantitative spatial expression patterns of structural and immune markers throughout the tissue. In normal tissue, we observed well-organized structures including neurons, oligodendrocytes, vascular-adjacent astrocytes, and axonal tracks. In GBM tissue, we detected necrotic cores, areas with high immune infiltration, extracellular matrix deposits, and activated tumor cells. SCA of GBM tissue revealed extensive vascularization, replication of Olig2+ cells, activation of Ras signaling, and abundant infiltrating immune cells.
Conclusion: Overall, we demonstrate the successful application of two novel WSI modes and highlight the power of IMC technology to simultaneously explore dozens of relevant biological outputs to better understand the TME of GBM and other tumors.

Novel whole slide imaging modes for imaging mass cytometry unveil extensive cellular heterogeneity in human gliomas

Nick Zabinyakov[1], Qanber Raza[1], Thomas Pfister[1], Nikesh Parsotam[1], David Howell[1], Liang Lim[1], Christina Loh[1], Dawar Pasha[2] , Gloria Martrus Zapater[3]
[1]Standard BioTools, Markham, Canada; *[2]Standard BioTools, London, United Kingdom*, *[3]Standard BioTools, Spain*

Introduction: Gliomas, particularly glioblastoma (GBM), pose significant diagnostic and therapeutic challenges, with a median survival of just over one year post-diagnosis. GBM can manifest as multi-lesion, remote, or diffuse tumors, often lacking peripheral immune cells in the tumor microenvironment (TME). Notable features include necrosis, hemorrhage, and pseudo palisades, reflecting its high heterogeneity and necessitating deeper exploration. Understanding the cellular and spatial composition of the TME is crucial for interpreting GBM's origin, progression, and informing treatment strategies.
Method and Material: We utilized a 40-plus-marker neuro-oncology Imaging Mass Cytometry™ (IMC™) antibody panel to examine the cellular and structural landscape of the brain tumor microenvironment (TME). This panel was applied to a tissue microarray (TMA) containing numerous human glioma cores, revealing the spatial distribution of over 40 distinct molecular markers. Leveraging the Hyperion XTi™ Imaging System, we employed two new features for whole slide scanning. Ultrafast preview mode enabled swift screening of tumor cores for specific expression signatures related to immuno-oncology processes, guiding targeted imaging and subsequent single-cell analysis. Simultaneously, high-throughput tissue mode conducted a detailed scan of the brain tumor TMA, followed by pixel-based analysis, providing insights into the spatial composition of the TME.
Results and Discussion: Using tissue mode imaging, we effectively mapped cell populations in human gliomas, including neurons, astrocytes, microglia, and oligodendrocytes, across the entire TMA. Various tumor cell phenotypes and immune cell types were detected across all TMA cores. Single-cell analysis provided quantitative assessment of the brain TME's cellular composition. We classified neuronal states and quantified immune cell infiltration across normal, astrocytoma, and GBM tissues. Significant cellular and protein heterogeneity was observed between cores, highlighting IMC's capability for spatial evaluation of high-plex protein composition in the brain TME, without complications like autofluorescence or spectral overlap.
Conclusion: Empowered by the neuro-oncology panel and new whole slide imaging modes, IMC accelerates neurological research and provides insights into the spatial complexity of gliomas and other tumors.

Myeloid-derived suppressor cells (MDSCs) are a heterogeneous family of immune cells including a granulocytic (CD14neg/CD15+/HLA-DRneg) and a monocytic subtypes (CD14+/CD15neg/HLA-DRneg). In the present study, we found a population of CD14+ monocytes expressing the granulocyte marker CD15 that significantly expand in both peripheral blood (PB) and tumoral tissues of patients with colorectal cancer (CRC). Further phenotypical analysis confirmed the granulocytic-like features of this monocyte subpopulation that is associated with an expansion of granulocyte-monocytes precursors (GMPs) in the PB of these patients. Functionally, they secreted large amount of IL-10 and suppressed NK cell activity, crucial for the establishment of antitumor immune response. Mechanistically, this granulocytes-like monocyte population could promote the acquisition of the immune checkpoint inhibitor TIGIT in NK cells and accordingly, increased frequency of dysfunctional TIGIT+ NK cells were found in both peripheral blood and tumoral tissue of CRC patients. Collectively, we provided new mechanistic explanation for tumor immune escape occurring in CRC by showing the expansion of this new class of myeloid suppressor cells in both PB and CRC tissue that significantly impaired the effector function of NK cells thereby representing a potential therapeutic target for cancer immunotherapy.

The impact of ER stress on γδ T cells in the tumor microenvironment

Leonie Schöftner[1], Julia Feiser[1], Amalia Sophianidis[1], Lara Ronacher[1], Oliver Nussbaumer[2], Andrew Hutton[2], Maurizio Zanetti[3], Christof Regl[1], Christina Guttmann-Gruber[4], Stefan Hainzl[4], Iris Gratz[4;5;6], Giorgia Nasi[5]
[1]University of Salzburg, Department of Biosciences and Medical Biology, Salzburg, Austria; *[2]GammaDelta Therapeutics Ltd, London, United Kingdom*; *[3]Moores Cancer Center, Department of Tumor Immunology, University of San Diego, La Jolla, United States*; *[4]EB House Austria, Department of Dermatology and Allergology, University Hospital of the Paracelsus Medical University, Salzburg, Austria*; *[5]University of Salzburg, Department of Biosciences and Medical Biology, Center for Tumor Biology and Immunology (CTBI), Salzburg, Austria*; *[6]Benaroya Research Institute, Seattle, United States*

Gamma delta T cells (γδ T cells) are unconventional T lymphocytes with a role in the immune surveillance of cellular stress. γδ T cells respond to a wide range of tumors and tumor infiltrating γδ are the most significant favorable prognostic immune population among 39 cancer types. However, a suppressive tumor microenvironment (TME) can impair γδ function, and the mechanisms are not fully understood. Thus, we aim to elucidate cellular communication between tumor cells and tissue resident γδ T cells to provide a basis for the development of effective anti-tumor therapies. The TME is often characterized by increased endoplasmic reticulum (ER) stress, a cellular response to an accumulation of un-/misfolded proteins in the ER lumen that can be promoted by several environmental insults (e.g. hypoxia, glucose deprivation). To restore cell homeostasis, the ER activates pathways collectively known as unfolded protein response (UPR), and an enhanced UPR correlates with poor clinical outcomes in cancer patients. Crucially, the UPR can support tumor growth by regulating immune cell function. We hypothesize that ER stress is a mechanism used by tumor cells to dysregulate the activation and function of tumor-infiltrating cutaneous γδ T cells. To this end we induced ER stress pharmacologically in primary human cutaneous squamous cell carcinoma cell lines using thapsigargin and treated cutaneous gd T cells with the conditioned medium of these cells. This induced the upregulation of activation and cytotoxic markers and concomitantly reduced the expression of NK cell receptors (NKRs) and the production of pro-inflammatory cytokines by gd T cells. These findings support the hypothesis that cutaneous γδ T cells respond to ER stress within the TME and this modulates their activation and function. Our findings will provide important new insights into the immune surveillance and anti-tumor function of cutaneous γδ T cells under ER stress and help optimize their future clinical applications for cancer therapies.

Biological investigations require collection of 3D Imaging data for a comprehensive understanding of cellular and molecular spatial distribution. Imaging Mass Cytometry (IMC) reveals cell landscape, abundance and phenotype in tissue. Relevant results were obtained with IMC applied to studies on infiltrating immune cells in tumor. Initial attempts direct at 3D IMC with the aim of expanding measurable parameters, such as assessment of tissue architecture and vasculature, as well as to refine analyses related to cell phenotyping, positioning and their functional interactions. Here, we propose Stereo-IMC, an unprecedented method to advance IMC from conventional 2D to 3D of larger tissue analysis. Alteration in tissue volume resulting from the transition from hydrated to dry, the latter essential in IMC analysis, was addressed through use of antibody-permeant hydrogels. An antibody labelling strategy using both metal and fluorescence, confocal microscopy, IMC and computing corrected the mismatch in cell positioning due to transition of tissue in the different the states (hydrated vs. dry), thus reallocating single cell in volume. Organs of different structure and cell density were used for the purpose, at last challenged in a pancreatic cancer model. Comparative evidence obtained using Stereo-IMC versus conventional 2D IMC raises the method as an expansion towards a 3D multiparametric analysis of single-cell in relationship with tissue microenvironment and for tissue architecture. Results are instrumental in the development of an optimized 3D IMC system to improve investigation of tumor microenvironment.

Purpose: Mast cells (MCs) are tissue-resident immune cells characterized by their cytoplasmic granules containing different proteases and by the surface expression of the high-affinity receptor for IgE (FcεRI) and c-kit (CD117), the receptor for stem cell factor (SCF). Once activated, MCs released several mediators and can orchestrate different immune responses in both physiological and pathological conditions including cancer. In particular, MCs can infiltrate Colorectal Cancer (CRC) but the precise role of mucosal versus connective-like intestinal MC subsets during CRC development is still unclear. The aim of our study is to investigate whether a particular MC subset is involved in CRC progression and to analyse how tumor microenvironment shapes MC plasticity.
Methods: We employed a mouse model of chemical-induced inflammatory colorectal cancer (AOM/DSS) as well as tumor biopsies of CRC patients. We initially performed microscopic and flow cytometric analyses in order to study MC frequency, localization and phenotype. We further investigated by *in vitro* and *in vivo* assays the contribution of soluble factor enriched in tumor microenvironment in shaping murine MC plasticity.
Results: By evaluating the expression of selective proteases within the granules of tumor infiltrating MCs, we demonstrated the prevalence of a connective tissue-like phenotype in both murine and human samples.
Focusing on the tumor microenvironment of AOM/DSS-treated mice, we found a higher concentration of SCF and IL-33 in tumor lesions compared with tumor-free tissue. Moreover, we demonstrated that a sustained *in vitro* stimulation of MC primary cultures with SCF and IL-33 promotes the expansion of a connective-like MC subset. Consequently, trough *in vivo* experiments we observed that SCF-neutralization induce a decrease of the connective tissue-like MC subset accompanied by inhibition of tumor burden.
Conclusion: Our results demonstrate that connective tissue-like MCs accumulate in both murine and human colorectal cancer lesions supporting a role for this subset in the control of tumor progression. Moreover, we underscored the ability of SCF in combination with IL-33 to shape MC phenotype.

Siglec ligand-receptor axis: novel insight into extracellular vesicle mediated immunomodulation in colorectal cancer

Anastasija Walsh[1], Clodagh O'Neill[1], Seyedmohammad Moosavizadeh[2], Ellen Donohoe[2], Lei Lei[1], Roisin Dwyer[3], Aideen Ryan[1]
[1]Discipline of Pharmacology & Therapeutics, School of Medicine, University of Galway, Galway, Ireland; *[2]REMEDI, School of Medicine, University of Galway, Galway, Ireland*; *[3]Discipline of Surgery, School of Medicine, University of Galway, Galway, Ireland*

Colorectal cancer is one of the most prevalent forms of cancer worldwide. A major change in tumour signature is the up-regulation of sialic acids, supporting an immunosuppressive milieu. Sialic acids form Siglec ligands, which interact with immunomodulatory Siglec receptors. Data from our group suggest that cancer associated fibroblast (CAFs) within the colorectal tumour express high levels of Siglec ligands.
Extracellular vesicles (EVs) are key mediators of communication within the tumour microenvironment. This study aims to compare the Siglec ligand profiles of EVs derived from CAFs and CRC cells and investigate their respective effects on NK cell function.
We have optimised a method to analyse Siglec ligands on EVs via single-particle flow cytometry with the Cytek NL2000. Using this method, we will assess the abundance of CD24 (Siglec 10 ligand) on HCT116 cancer cell line and cancer cell secretome conditioned hTERT transduced MSCs (n=3). We will also examine α2,3- & α2,6-sialic acids on EVs from both sources via western blot and compare them with the respective cell membranes.
We examined uptake of CFSE stained HCT116/MSC EV in primary human NK cells via flow cytometry (n=2). Additionally, expression of Siglec 10 post treatment was investigated (n=2). Next, we will look at HCT116 and secretome treated MSC EV ± sialidase treatment on NK Siglec 10 expression (n=3). The ability of NK cells to kill cancer cells post treatment will also be examined.
We anticipate EVs derived from secretome treated MSCs will display unique profiles of Siglec ligands compared HCT116 EVs, in line with our findings revealing heightened Siglec ligand expression in CAFs. Our preliminary results suggest a preference for hTERT MSC EV uptake and a pattern towards downregulation of Siglec 10 expression with treatment with both EV groups. Building upon this observation, our future investigations aim to highlight how the anticipated differences in Siglec ligand composition between CAF-derived and CRC cell-derived EVs could further elucidate their distinct immunomodulatory effects on NK cells.
Investigating the impact of tumour microenvironment-derived EVs on immune cells is crucial for advancing our understanding of tumour immunology and developing EV and sialic acid targeting therapies.

Exercise-induced extracellular vesicles delay tumor growth by igniting inflammation in immunologically 'cold' triple-negative murine breast carcinomas

Agata Mlynska[1;2], Neringa Dobrovolskiene[1], Karolina Suveizde[1], Gabija Lukaseviciute[3], Krizia Sagini[4], Beatriz Martin-Gracia[4], Silvana Romero[4], Alicia Llorente Martinez[4], Beatrice Gudaite[3], Vita Pasukoniene[1;2]
[1]National Cancer Institute, Vilnius, Lithuania; *[2]Vilnius Gediminas Technical University, Vilnius, Lithuania*; *[3]Vilnius University, Vilnius, Lithuania*; *[4]Oslo University Hospital, Oslo, Norway*

Purpose: Preclinical meta-analyses on breast cancer demonstrate that physical activity reduces tumor incidence and growth. Independent studies have also reported exercise effects on the murine breast cancer microenvironment. However, there is a gap in understanding the molecular mechanisms behind the beneficial effects of exercise. Exercise-induced biomolecules can be secreted into the circulation either in soluble form or packaged into carriers such as extracellular vesicles (EVs). This study aims to investigate the effect of exercise-induced plasma EVs, a potential exercise mimetic, on tumor growth and immune microenvironment in two murine models representing triple-negative breast (TNBC) cancer
Methods: Size exclusion chromatography was used to isolate exercise-induced EVs from plasma of healthy Balb/c (n=30) and C56BL/6 (n=30) female mice that underwent 10 sessions of 30-minute treadmill running. The EVs were characterized using electron microscopy, nanoparticle tracking analysis, and dynamic light scattering. Two murine TNBC models were generated by subcutaneously implanting 4T1 cancer cells in Balb/c mice and EO771 cancer cells in C56BL/6 mice (n=60 per strain). Tumor-bearing mice received five doses of 1×10^6 exercise-induced EV particles either prophylactically or therapeutically setting. Extensive immune profiling of the tumor microenvironment was conducted using flow cytometry.
Results: The amount of EVs in the plasma of active mice was higher than in the sedentary group. Both prophylactic and therapeutic administration of exercise-induced EVs delayed tumor growth by 35% in the 4T1 model and by 45% in the EO771 model ($p<0.05$) compared to respective untreated controls. Noticeable differences in the proportions of tumor-infiltrating lymphoid, but not myeloid, cell subpopulations suggested that exercise-induced EVs have immunomodulatory effects. We observed a significant influx of CD8+ lymphocytes in tumors, along with a decrease in the exhaustion marker PD-1, in all groups treated with EVs in both tumor models. Moreover, the level of PD-L1 on tumor cells was reduced, suggesting perturbations in the PD-1/PD-L1 axis upon treatment with EVs.
Conclusion: Our study demonstrates that treatment with exercise-induced EVs triggers a pro-inflammatory antitumor immune response, and converts immune ‘cold' tumors to 'hot', associated with better outcomes. These findings provide rationale for furhter investigations of EVs as potential immunomodulatory exercise mimetics.

Xenografting mouse models to study human cutaneous γδ T cells in health and disease

Giorgia Nasi[1], Leonie Schöftner[1], Oliver Nussbaumer[2], Andrew Hutton[2], Amalia Sophianidis[1], Anshu Sharma[1], Christina Guttmann-Gruber[3], Stefan Hainzl[3], Susanne Kimeswenger[4], Monika Ettinger[4], Iris Gratz[3;5;6]
[1]University of Salzburg, Salzburg, Austria; *[2]GammaDelta Therapeutics Ltd, London, United Kingdom*; *[3]EB Haus Austria, Research Program for Molecular Therapy of Genodermatoses, Department of Dermatology and Allergology, Salzburg, Austria*; *[4]Kepler University Hospital, Department of Dermatology and Venerology, Linz, Austria*; *[5]University of Salzburg, Department of Biosciences and Medical Biology, Center for Tumor Biology and Immunology, Salzburg, Austria*; *[6]4Benaroya Research Institute, Seattle, United States*

Gamma delta (γδ) T cells play important roles in the surveillance of cellular stress, tumors, and infection, that help maintain tissue integrity and modulate adaptive responses to these stimuli. γδ T cells can recognize malignant cells via surface molecules and display killing activity upon activation. γδ T cells respond to a variety of solid and hematological tumors *in vitro* and in *in vivo* xenograft models, and the presence of tumor infiltrating γδ T cells was the most significant favorable prognostic immune population among 39 human cancer types. In clinical trials, adoptive transfer of e*x vivo* expanded γδ T cells lead to temporary tumor regression and increased survival of leukemia patients. Hence, γδ T cells are promising candidates for anti-tumor immune therapeutic approaches. Due to technical difficulties to isolate enough γδ T cells from human skin, most studies on cutaneous γδ T cell biology were focused on murine skin resident γδ T cells. Here we are using novel methodologies to expand functional cutaneous γδ T cells *ex vivo*. Upon adoptive transfer of these cells into mice that have received xenografted engineered human skin or skin tumors, we can study their migration, maintenance, and phenotypic adaptation *in vivo*. Specifically, we have established a squamous cell carcinoma (SCC) xenograft mouse model in which the grafted SCC tissue resembles tumors of patients macroscopically and microscopically. In this model, γδ T cells engrafted in the spleen, healthy skin and the tumor tissue. Crucially, these cells displayed an activated phenotype and function after isolation from the tumor mass. This model enables in depth and mechanistic studies of the biology of cutaneous γδ T cells in the tumor microenvironment. Additionally, the *in vivo* tumor model can be utilized to study the therapeutic potential of γδ T cells in cutaneous carcinomas, paving the way to novel anti-tumor treatments.

Heterotypic 3D Cancer Spheroids as a Controlled Modeling Platform for Studying Tumour Microenvironment

Egle Zymantaite[1;2], Agata Mlynska[1]
[1]*National Cancer Institute of Lithuania, Vilnius, Lithuania*; [2]*Vilnius University, Vilnius, Lithuania*

Purpose: The adoption of 3D cell culture models has greatly improved our understanding of tumour biology as these models closely represent characteristics of *in vivo* tumours, such as cell-cell interactions, hypoxia and pH rate, exposure to nutrients and metabolites, and gene expression profiles. However, 3D models are usually composed of only one cell type and, more often than not, an immortalized cell line. However, they usually lack crucial tumour components like macrophages and fibroblasts. Innovative strategies, including co-culture systems and organoids, address this limitation by integrating diverse cell types, thereby offering a better representations. However, so far there is a lack of 3D controlled *in vitro* models to study tumour and immune cell interactions.
Methods: In our study, we optimized 3D culture conditions for six epithelial ovarian cancer (EOC) cell lines and their co-cultures with fibroblasts or THP1 monocytes. 3D spheroids were measured and observed in different growth conditions and at a different starting point seeding densities. Using qPCR, we compared gene expression profiles focusing on stemness, epithelial-mesenchymal transition, and immune interaction genes. Additionally, flow cytometry analysis was employed for cancer cell, fibroblast and monocyte marker expression evaluation in diferent culture conditions.
Results: We observed that cell lines that were unable to form 3D cell cultures in standard culturing conditions, were able to form spheroids when cultured with fibroblasts. Upon analyzing the gene expression in the 3D cultures and 3D co-cultures with fibroblasts, we found significant differences in the expression of genes such as *SNAI1*, *POU5F1*, *VEGF*, and *FAP*. In addition, flow cytometry analysis showed that the number of monocytes infiltrating the spheroids varied depending on the cancer cell line used in 3D culture model.
Conclusion: Our findings provide input for creating and developing better 3D models that reflect immune-tumor interactions and new *in vitro* models to study and modulate the tumor microenvironment.

Role play by endogenous galectin-1 in an experimental model of melanoma

Javier Gutiérrez[1], Berta Segura-Collar[2], Ricardo Gargini[2], Marina Garin[1]
[1]*CIEMAT / IIS Fundación Jiménez Díaz / CIBER-ER, Madrid, Spain*; [2]*Institute of Biomedical Research I+12, Hospital 12 de Octubre, Madrid, Spain*

Galectin-1 is an endogenous lectin ubiquitously expressed in different tissues and immune cells, as well as by tumor cells. Numerous studies have identified a pivotal tumor promoting role for galectin-1 expressed by the cancer cells. However, the role play by endogenous expression of galectin-1 within the tumor microenvironment remains to be fully dissected. In the present work, the experimental murine model of melanoma using *B16F10* cell line has been used to study the function of endogenous galectin-1 during tumor development. Endogenous galectin-1 expression accelerated tumor burden upon subcutaneous implantation of *B16F10* cells. The endogenous expression of galectin-1 was associated with increased expression of proteins involved in immune checkpoints such as PD-L1 by myeloid cells and CCR8 by intratumoral Treg cells. Taken together, these results underscore the importance of the immunomodulatory role play by the endogenous expression of galectin-1 in the context of melanoma. Our findings identifies galectin-1 as a key regulator of the tumor microenvironment and that strategies to specifically target galectin-1 expression may enhance host's anti-tumor immune responses that could behold great promise for cancer patients, especially when combined with immunotherapy.

Boosting systemic anti-tumour immunity: the effects of electroporation on proteomic output and immune cell polarization in human ex vivo gastrointestinal cancer explant models

Aisling Ui Mhaonaigh[1], Lorraine Smith[1], Matt McElheron[2], Aoibhín Woods[1], Fiona O'Connell[1], Kirstan Murphy[1], Meghana Menon[1], Niamh Hallinan[3], Yasir Bashir[3], Vincent Varley[3], Niamh O'Connor[1], Cian Muldoon[3], Ciara Ryan[3], Brian Mehigan[3], Waqas Butt[3], narayanasamy Ravi[3], Claire Donohoe[3], Noel Donlon[3], John Larkin[3], Paul McCormick[3], Dara Kavanagh[3], Michael Kelly[3], John V. Reynolds[3], Declan Soden[4], Jacintha O'Sullivan[1]
[1]Department of Surgery, Trinity St. James's Cancer Institute, Trinity Translational Medicine Institute, Trinity College Dublin, Dublin, Ireland; *[2]Department of Gerontology, School of Medicine, Trinity Translational Medicine Institute, Trinity College Dublin, Dublin, Ireland*; *[3]St. James's Hospital, James's Street, Dublin 8, Dublin, Ireland*; *[4]Mirai Medical, Oranmore, Galway, Ireland*

Purpose: Electroporation-based antitumor therapies calcium electroporation (CaEP) and irreversible electroporation (IRE), have been shown to be effective on directly treated tumours by altering the tumour microenvironment (TME) and triggering a systemic immune response. We investigated the proteomic secretome following reversible electroporation (rEP), CaEP and IRE in upper and lower gastrointestinal (GI) cancer explants. We analysed the proteomic secretome to further understand the immunological response to EP and investigated the effect of electroporated tumour conditioned media (TCM) on immune cell polarization.
Methods: Following patient consent, *ex-vivo* tumour and matched normal tissue from GI cancer patients were exposed to reversible electroporation with/without 5.0mM $CaCl_2$ and irreversible electroporation using the ePORE electroporator (Mirai Medical, Galway). Treated explants were cultured at 37°C for 24 hours. The resulting supernatants, termed tumour or normal conditioned media, TCM and NCM were analysed via MSD 54plex ELISA to assess secreted factors. The effects of TCM and NCM on dendritic cell and macrophage polarisation was assessed by flow cytometry.
Results: MSD profiling of TCM and NCM from EP treated explants, showed a varied proteome that depends on the treatment delivered and tumour origin. In gastric cancer myeloid cell attractants such as IL-8 and MCP-4 were elevated on EP treatment and not in colorectal cancer (CRC). Normal tissue was less responsive to all treatments than tumour tissue. Inflammatory markers such as IL-1α ($p=0.03$), TNF-α ($p=0.022$) and IL-10 ($p=0.048$) and macrophage released chemokines MIP-1α ($p=0.048$) MIP1-β ($p=0.018$) and MIP-3α ($p=0.0043$) were altered with CaEP. DCs and macrophages were differentially affected by EP treatment at different GI sites. TCM lowers M1 macrophage marker expression in CRC but differentially affects upper GI cancers. TCM from CRC tumour explants alter DC marker expression.
Conclusion: Alterations in the immunomodulatory secretome of tumour tissue after EP affects immune cell function, alters the tumour microenvironment and could illicit an abscopal response. Further interrogation is required to fully elucidate the effects of EP at different sites and could facilitate tailored regimens based on tumour site whilst enhancing a systemic immune response to clear distal metastatic tumours.

Stromal cell-mediated immunosuppression: sialylated ligands as orchestrators of immune evasion in colorectal cancer

Norashikin Zakaria[1], Aoise O'Neill[1], Hannah Egan[1], Oliver Treacy[1], Sean Hynes[2], Aisling Hogan[3], Aideen Ryan[1]
[1]Discipline of Pharmacology and Therapeutics, School of Medicine, College of Medicine, Nursing and Health Science, University of Galway, Galway, Ireland; *[2]Discipline of Pathology, School of Medicine, College of Medicine, Nursing and Health Sciences, University of Galway, Galway, Ireland*; *[3]Department of Colorectal Surgery, Galway University Hospital, Galway, Ireland*

Background: Cancer-associated fibroblasts (CAFs) play a critical role in the tumour microenvironment, often inhibiting the efficacy of cancer immunotherapy. Targeting CAFs directly holds significant potential in improving cancer treatment outcomes. However, the mechanisms underlying CAF-mediated immunosuppression remain poorly understood. Recently, the Siglec-sialic acid axis has emerged as novel mechanism contributing to immune evasion in cancer. This study aims to investigate the involvement of sialic acid in CAF-mediated immunosuppression specifically in colorectal cancer (CRC).
Methods: CAFs and matched normal-associated fibroblasts (NAFs) were isolated from tumour and adjacent non-cancerous tissue, respectively. Expression of fibroblast markers (α-SMA and FAP), sialic acid (SNA-I and MAL-II) and Siglec-7/9 and 10 ligands on NAFs/CAFs were analysed using flow cytometry. Immunosuppressive effects of CAFs on T cells and NK cells were assessed using CAFs-immune cells co-culture and the expression of immune cells immunosuppressive/activation markers, as well as Siglec-7/9 receptor expression were analysed using flow cytometry.
Results: CAFs expressed higher levels of sialic acid and Siglec-7/9 and 10 ligands compared to NAFs and tumour cells. CAFs also induced exhausted immunomodulatory CD8+PD1+ and CD8+Siglec-7/9+ T cell phenotypes. Furthermore, CAFs induced Siglec-7/9 on NK cells and reduced expression of the activating receptor NKG2D, leading to decreased NK cell cytotoxicity. Strikingly, de-sialylation of CAFs reversed these effects.
Conclusion: We show for the first time that CAFs can induce immunosuppressive Siglec receptor expression on T and NK cells. Our study underscores the pivotal role of sialylated ligands on CAFs in immunosuppression. Targeting the Siglec-sialic acid axis on CAFs is a promising strategy to enhance anti-tumour immunity in CRC.

The impact of the STING pathway on the antitumor response of short-term fasting

Raquel Vieira[1], José Arimatéa de Oliveira Nery Neto[1], João Vinícius Honório da Silva[1], Samuel dos Santos Oliveira[2], Eloisa Martins[3], Anthony Gabry[1], Beatriz Leocata[1], Barbara Padovani[1], Niels Olsen Saraiva Camara[1], Rafael Almeida[4]
[1]Institute of Biomedical Sciences, University of São Paulo, São Paulo, Brazil; *[2]Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, Brazil*; *[3]Division of Nephrology, School of Medicine, Federal University of São Paulo, São Paulo, Brazil*; *[4]Heart Institute (Incor), School of Medicine, University of São Paulo, São Paulo, Brazil*

Cutaneous melanoma is the leading cause of death from skin cancer in the world and has relatively high resistance to treatment with radiotherapy and chemotherapy. The partial success achieved with the use of immunotherapy, especially checkpoint inhibitors, therefore, it suggests that immunological interventions are an interesting strategy to be used. Short-term fasting (STF) aims to induce the effect of differential stress resistance, where tumor cells are more compromised than normal cells due to low energy levels during cancer treatment. This occurs because normal cells can better adapt to stress by redirecting energy expenditure towards maintenance and repair, while tumor cells remain focused on proliferation due to mutations in oncogenes and tumor suppressor genes. Considering the importance of the STING signaling pathway in the recognition of DNA released by apoptotic cells and in the subsequent immune response generated, our aim was to investigate the role of STING in the antitumor effect of STF. Mice WT or STING KO were given a subcutaneous injection of B16-F10 cells. When the tumor became palpable, the animals underwent 48 hours of fasting, with free access to water. Our results demonstrated that 48-hour fasting proved to be efficient in controlling tumor growth without negatively affecting the frequency of infiltrated myeloid and lymphoid cells in the tumor. Weight loss during the fasting period was quickly regained when the animals resumed feeding. However, control over tumor growth was maintained until the day of euthanasia. In STING KO animals, there was no statistical difference in tumor weight, suggesting that the STING signaling pathway participates in the antitumor response generated by short-term fasting.

Associations between soluble PD-L1/PD-1 and circulating immune cells for prostate cancer progression

Žilvinas Survila[1], Vita Pašukonienė[2], Margarita Žvirblė[2;3]
[1]1 Institute of Biosciences, Life Sciences Center, Vilnius University, Vilnius, Lithuania, Vilnius, Lithuania; *[2]National Cancer Institute, Vilnius, Lithuania*; *[3]Life Sciences Center, Vilnius University, Vilnius, Lithuania, Vilnius, Lithuania*

Purpose: This study aims to investigate the role of soluble forms of PD-L1 and PD-1 (sPD-L1 and sPD-1) and its potential interaction with circulating immune cells, in influencing prostate cancer (PCa) development and progression, considering specific immunologically cold profile of PCa.
Methods: The study involved 75 patients diagnosed with pT2 and pT3 prostate cancer, along with 41 healthy individuals. The levels of sPD-L1 and sPD-1, as well as specific immune cells: T lymphocytes (CD4+, CD8+), B lymphocytes, regulatory T cells (Tregs), Natural Killer cells (NK), myeloid derived suppressor cells(MDSC), in the peripheral blood of all patients before and three months after radical tumor removal were evaluated. sPD-1 and sPD-L1 were measured in plasma using ELISA method, while immunophenotyping was conducted using flow cytometry technique. The correlations were assessed against the clinicopathological findings of PCa.
Results: Elevated levels of sPD-L1/sPD-1 in the plasma of prostate cancer patients were found compared to healthy controls. Associations between elevated levels of sPD-L1 and sPD-1 and prostate cancer advancement were found. The results indicate the source of low preoperative sPD-L1 might be associated with the secretion of immune cells. High concentrations of sPD-L1 in the blood of prostate cancer patients correlate with Tregs and MDSC as well as with recurrence of cancer. A correlation between sPD-1 and NK cells was observed.
Conclusions: sPD-L1 emerges as a promising prognostic marker in prostate cancer (PCa), potentially influencing disease progression through interactions with Tregs. NK cells could be one of potential sources of sPD-1in PCa.

Specific cellular and humoral response after the third dose of anti-SARS-CoV-2 RNA vaccine in patients with Immune-Mediated Rheumatic Diseases on immunosuppressive therapy

Kauzar Mohamed Mohamed[1], Maria Paula Alvarez Hernandez[2], Carlos Jimenez Garcia[1], Kissy Guevara Hoyer[1], Angela Villegas Mendiola[1], Teresa Guerra Galan[1], Alejandro Pereiro Rodriguez[1], Maria Dolores Mansilla Ruiz[1], Maria Palacios Ortega[1], Juliana Ochoa Grullon[1], Miguel Fernandez Arquero[1], Silvia Sanchez Ramon[1]
[1]Department of Immunology, IML and IdISSC, Hospital Clínico San Carlos, Madrid, Spain; *[2]Rheumatology Department, Hospital Universitario Clínico San Carlos, Madrid, Spain*

Purpose: Data on cellular and humoral immunogenicity after the third dose of anti-SARS-CoV-2 vaccines in patients with immune-mediated rheumatic diseases (IMRDs) are scarce. Herein, we evaluated the adaptive immune response in IMRD patients treated with different immunosuppressive therapies (conventional synthetic disease-modifying antirheumatic drugs [csDMARDs], biological disease-modifying antirheumatic drugs [bDMARDs], and targeted synthetic disease-modifying antirheumatic drugs [tsDMARDs]) after the booster of the anti-SARS-CoV-2 vaccine to determine whether any drug reduced the vaccine's response.
Methods: A single-center prospective study was conducted, including patients presenting with IMRD and healthy controls (HC). Specific anti-SARS-CoV-2 interferon-gamma (IFN-γ) production was evaluated between 8-12 weeks after the third dose of the SARS-CoV-2 vaccine. In addition, anti-Spike IgG antibody titers were also measured.
Results: Samples were obtained from 79 IMRD patients (51 women, 28 men; mean age 57 ± 11.3 years old): 43 rheumatoid arthritis, 10 psoriatic arthritis, 14 ankylosing spondylitis, 10 undifferentiated spondyloarthritis, and 2 inflammatory bowel disease-associated spondyloarthritis (IBD-SpA). In total, 31 HC (mean age 50.9 ± 13.1 years old, 67.7% women) were included in the study. Post-vaccine results displayed positive T-cell immune responses in 68 out of 79 (86.1%) IMRD patients (82.3% of those without prior COVID-19). All HC and IMRDs patients had an antibody response against the SARS-CoV-2 receptor-binding domain; however, the HC response was significantly higher (median of 18,048 AU/mL) than in IMRDs patients (median of 6590.3 AU/mL, $p < 0.001$). MTX and leflunomide were associated with lower titers of IgG and IFN-γ responses. Among bDMARDs, adalimumab, etanercept, and guselkumab are associated with reduced cellular responses.
Conclusion: Our preliminary data show that the majority of our IMRD patients develop cellular and humoral responses after the SARS-CoV-2 booster vaccination, emphasizing the relevance of vaccination in this group. However, the magnitude of specific responses was dependent on the immunosuppressive therapy administered. Specific vaccination protocols and personalized decisions about boosters are essential for these patients.

Assessment of lipid nanoparticle (LNP) uptake and its effects on immune cells in hepatocellular carcinoma (HCC)-burdened versus healthy mice

Yanira Zeyn[1], Paul Schneider[1], Malin Svensson[2], Ignacio Berti[2], German Islan[2], Benedikt Schober[3], Mark Helm[3], Stephan Gehring[2], Leonard Kaps[4], Matthias Bros[1]
[1]Department of Dermatology, University Medical Center Mainz, Mainz, Germany; *[2]Children's Hospital, University Medical Center Mainz, Mainz, Germany*; *[3]Institute of Pharmaceutical and Biomedical Sciences, Johannes Gutenberg-University, Mainz, Germany*; *[4]Department of Medicine II, Saarland University Medical Center, Homburg, Germany*

Purpose: Initial *in vivo* testing of novel lipid nanoparticle (LNP)-based nano-vaccines e.g. for tumor treatment is usually performed in healthy wild type mice. However, considering their intended later application in tumor patients, the biodistribution of the LNPs and the biological activity of their cargo may differ on organ and single-cell level in tumor bearing- versus healthy individuals. For example, tumors establish an immunosuppressive tumor-microenvironment (TME) and induce immunoregulatory cell types, which imprint a tolerogenic status in immune cells. Here, we aimed to identify differences in LNP biodistribution and drug efficacy on organ and single-cell level in healthy versus hepatocellular carcinoma (HCC)-burdened mice.
Methods: HCC cells (Dt81Hepa1-6) were spleen-injected into C57BL/6JRj mice to induce liver tumors. Liver-targeting LNPs containing luciferase-encoding mRNA for *in vivo/ex vivo* detection of transfected cells or Cy5-labeled eGFP mRNA to monitor LNP uptake (Cy5) and eGFP expression on organ and single-cell level were generated using the NanoAssemblr platform. After intravenous LNP injection luciferase activity was monitored *in vivo* (IVIS) and luciferase activities and Cy5 intensities were assessed on organ level. Liver- and spleen- derived single-cell suspensions were subjected to flow cytometry to assess their state of activation. The responsiveness of liver non-parenchyma cells (NPCs) and spleen cells towards immunostimulatory agents was assessed after overnight incubationon by flow cytometry.
Results: Stable LNPs formulations of 100 nm in size with an mRNA encapsulation efficiency >90% were successfully developed. Intraveneously applied LNPs enriched in healthy and HCC-burdened mice in the liver. However, in healthy mice transgene expression occurred in various liver NPC types but in HCC-burdened mice predominantly in tumor-associated macrophages. Furthermore, liver NPC isolated from HCC-burdened mice were refractory to adjuvant stimulation. In a rescue experiment, addition of IL-10 neutralizing antibody overcame this unresponsive state.
Conclusion: LNP biodistribution differs on single-cell level in healthy and tumor-burdened mice, which needs to be considered for nano-vaccine design. Liver NPC from HCC-burdened mice are refractory to adjuvant treatment, yet co-applying agents that inhibit anti-inflammatory mediators and suitable adjuvants may restore responsiveness. Altogether, our study suggests that the efficacy of nano-formulations for therapeutic purposes needs to be tested in representative preclinical models.

Mass cytometry unveils baseline and vaccine-induced cellular correlates of immune response variability to SARS-CoV-2 vaccination in the elderly

Ratnadeep Mukherjee[1], Linn Margrethe Eggesbø[1], Asia-Sophia Wolf[1], Ingrid Fadum Kjønstad[1], Guri Solum[1], Anthony Ravussin[1], Sabin Bhandari[1], Anna Hayman Robertson[1], Per Magnus[1], Lill Trogstad[1], Anja Kristoffersen[1], Unni Nygaard[1], Siri Mjaaland[1]
[1]*Norwegian Institute of Public Health, Oslo, Norway*

Purpose: Vaccine response varies widely among individuals, particularly in vulnerable groups like immunocompromised and elderly, posing a significant concern. In recent years, the utilization of mass cytometry for immune profiling has unveiled inter-individual disparities in immune cellular composition as an important predictor of systemic response to diseases. However, there has been limited exploration into cellular immunity post-SARS-CoV-2 vaccination in the elderly. Therefore, in this study, we performed deep immune cell profiling of phenotype and function to identify cellular factors associated with vaccine responsiveness in low and high responders from a cohort of Norwegian older adults.
Methods: PBMCs obtained before and after second dose of a SARS-CoV-2 vaccine, were stimulated with either spike peptide, Cytostim, or left untreated for 22 hours. Post-stimulation, cells were stained with a cocktail of 40 antibodies targeting phenotypic markers and intracellular cytokines, then analyzed via mass cytometry. Cell type identification was accomplished through unsupervised clustering using FlowSOM, with resulting clusters visualized on UMAP-embedded space. To compare cluster abundances between groups, univariate negative binomial regression models were employed for cell counts of each cluster.
Results: We demonstrate a significant correlation between elevated baseline frequencies of $CD27^{+}IgD^{-}$ class-switched memory B cells and robust vaccine response. Additionally, our study identifies heightened levels of $CD27^{-}CD24^{+}CD38^{+}$ transitional B cells at baseline in individuals with strong vaccine responses. Post-vaccination, high responders had increased frequencies of $IFN\gamma^{+}CD4^{+}$ T cells following activation with spike peptide, coupled with a concurrent reduction in $CCR6^{+}$ Th17 cell subset frequencies. Furthermore, our findings suggest that enhanced vaccine response among the elderly is linked to the presence of a γδ T cell subset characterized by elevated expression of the inhibitory NKG2A receptor.
Conclusions: This study aimed to identify baseline differences in immune cell frequencies and function, alongside qualitative and quantitative changes after two vaccine doses. Utilizing unsupervised clustering and statistical analysis, we identified disparities in immune cell profiles before and after vaccination, linked to vaccine response. These insights provide a valuable guide for refining vaccination strategies for the elderly.

The safety, early lung transcriptional responses and efficacy of differently adjuvanted subunit tuberculosis vaccines after intrapulmonary delivery

Erica Stewart[1;2], Claudio Counoupas[1;2;3], Kia Ferrell[1;2], Taylor Cootes[1;2], Ellis Armitage[2], Matt Johansen[4], Shatarupa Das[4], Philip Hansbro[4], Nikolai Petrovsky[5], Warwick Britton[2], James Triccas[1;3]

Tuberculosis causes approximately 1.3 million deaths annually, and the only vaccine available provides incomplete protection. Mucosal vaccination elicits memory immune responses at the site of infection that respond rapidly to pathogen encounter, making it a promising strategy to achieve optimal tuberculosis vaccine efficacy. Currently, a lack of understanding of adjuvant activity in the respiratory tract hinders the development of mucosal subunit vaccines. We have previously shown that intratracheal (IT) administration of Advax™, a polysaccharide adjuvant, combined with the subunit protein CysVac2, is protective against *Mycobacterium tuberculosis*. Here, we compared CysVac2 with Advax or alum and MPLA to model the clinically approved adjuvant AS04™. IT immunisation of CysVac2 with either adjuvant generated lung Th17 cells and was protective against *M. tuberculosis* challenge. Using lung function measurement techniques, we found there was no significant change in lung function at 7 days or 6 weeks after a full schedule of IT vaccinations, demonstrating the safety of these vaccines.
Whole-lung transcriptional responses to IT immunisation with CysVac2 vaccines were also analysed 4 hours and 7 days after delivery using the Nanostring™ system. At 4 hours post-immunisation, both adjuvants generated a shared immune signature of both pro-inflammatory and immunoregulatory genes, and at 7 days both upregulated genes associated with adaptive immune responses. Interestingly, IT immunisation with CysVac2 and alum/MPLA stimulated inflammasome and type I IFN signalling-associated genes. Contrastingly, IT CysVac2/Advax promoted local upregulation of genes associated with TREM-2 receptor signalling and pulmonary opsonins. Using mice deficient for the T-cell homing receptor CXCR3 we showed that IT CysVac2/AlumMPLA, but not CysVac2/Advax, was partially dependent on CXCR3 for vaccine-specific T cell and total Th17 cell recruitment to the lungs.
In conclusion, our findings confirmed that IT-delivered protein/adjuvant vaccines are safe using novel lung function testing techniques. While alum/MPLA stimulated upregulation of the type I IFN pathway, Advax generated comparable immune responses via non-conventional immune pathways. Ultimately however, both adjuvants generated lung Th17 cells that correlated with protection against *M. tuberculosis* infection.

Boosting Cell-Mediated Immunity to Burkholderia pseudomallei Outer Membrane Protein Antigen with Cationic Nanoparticles

Jeremy Aboagye[1], Jorge Huete-Carrasco[1], Siobhán McClean[2], Julen Tomás Cortázar[2], Thomas Courant[3], Dorothee Neple[3], Ed Lavelle[1]
[1]Trinity College Dublin, Adjuvant Research Group, Dublin, Ireland; *[2]Conway Institute UCD, Dublin, Ireland*; *[3]Vaccine Formulation Institute, Geneva, Switzerland*

Meliodosis, caused by the bacterium *Burkholderia pseudomallei*, is a severe and often fatal infectious disease that is prevalent in tropical regions but is expanding globally due to the rise of anti-microbial resistance. Given its high mortality rate and the challenges associated with diagnosis and treatment, effective vaccines are urgently required. Studies in mice have shown that IFNγ secreting CD4 T cells in mice are critical for protection. We have previously demonstrated the ability of small (50-60nm) biodegradable polymer nanoparticles to enhance antigen-specific cell-mediated immunity. In this study, we evaluated the potential of cationic (DOTAP stabilised) or anionic (no surfactant) poly(lactic-co-glycolic acid) (PLGA) and poly (lactic acid) (PLA) nanoparticles with varying lactide:glycolide ratios as adjuvants when combined with the antigen BpOmpW, a *B.pseudomallei* protein identified by McClean & colleagues as a potential adhesin. Following intramuscular vaccination, BpOmpW-specific T cell frequencies and cytokine secretion was assessed by intracellular staining, while IFNγ, and IL-17 secretion responses were evaluated through ex vivo Fluorospot and ELISA on splenocyte supernatants. Intramuscular vaccination with BpOmpW and cationic PLGA or cationic PLA nanoparticles significantly enhanced the induction of antigen specific IFNγ+ CD4+ T cell response and IgG titres compared to vaccination with antigen alone. In contrast, vaccination with antigen and DOTAP-free nanoparticles induced weaker T cell and antibody responses. These data highlight the potential of cationic PLGA NPs as adjuvants to boost BpOmpW specific cellular immunity and antibody responses and support further evaluation of cationic NP as adjuvants in subunit vaccines against *Burkholderia pseudomallei.*

SphB1 is a potential antigen for inclusion in a pertussis mRNA vaccine to prevent nasal infection with Bordetella pertussis and overcome the challenge of emerging PRN-negative strains

Lisa Borkner[1], Joanne M. O'Hara[2], Brenda Nguyen[2], Kimberly L. Carey[2], Christina Dold[2], Obadiah Plante[2], Andrea Carfi[2], Kingston Mills[1]
[1]Trinity College Dublin, Dublin, Ireland; *[2]Moderna Inc., Cambridge, MA, United States*

Current acellular pertussis (aP) vaccines protect against whooping cough but fail to prevent nasal carriage and transmission of *B. pertussis* (*Bp*). Pertactin (PRN)-deficient *Bp* strains have emerged in countries using aP vaccines. Here we examined the protective efficacy of mRNA-based pertussis vaccines in a mouse model and assessed the role of PRN and the antigen autotransporter subtilisin-like protease (SphB1).
Mice were immunized (i.m.) twice, aerosol-challenged with *Bp*, and CFUs were assessed in lung and nasal tissue. Preliminary data suggest monovalent mRNA pertussis vaccines encoding SphB1 or PRN protected against lung infection and significantly reduced CFUs in the nose. In contrast, a commercial aP vaccine (Adacel) or an mRNA vaccine encoding filamentous hemagglutinin (FHA), pertussis toxin (PT) and fimbrae (FIM) failed to prevent nasal infection. Addition of PRN or SphB1 enhanced protection in the nose and addition of both PRN and SphB1 conferred the highest level of protection against nasal infection.
Assessment of immunogenicity of the pertussis mRNA vaccines demonstrated that they induced potent IgG2c in nasal homogenates and IFN-γ-secreting T cells (Th1 cells) in the spleen. While SphB1 was not a major target for T cells, addition of SphB1 to the vaccine significantly increased FHA- and PRN-specific IFN-γ production assessed by ELISA and flow cytometry.
These studies demonstrate the potential of mRNA-based vaccines in protecting against *Bp* infection of the lung and nose and identified a promising novel autotransporter for inclusion in a pertussis mRNA vaccine to prevent nasal colonization and to address the emergence of mutant strains of *Bp*.

A third Mumps-Measles-Rubella immunization elicits mumps-specific cellular responses in young adults with distinct responses in immune subgroups

Rene Raeven[1], Maarten Emmelot[1], Sara Suarez Hernandez[1], Petra Molenaar[1], Martijn Vos[1], Patricia Kaaijk[1]
[1]*Dutch National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands*

Background: Despite vaccination, mumps outbreaks occur worldwide in young adults indicating waning of vaccine-induced responses. A third Mumps-Measles-Rubella (MMR3) booster immunization may be a solution to increase the level of protection for this specific risk group. We previously demonstrated that such a third MMR immunization could indeed significantly boost mumps neutralizing antibodies but cellular responses remained unexplored.
Objectives: In this study, mumps-specific T and B cell responses were unraveled four weeks and 1 year following a MMR3 immunization in thirty young adults (18-25 years). These responses were compared to Mumps infection-induced responses 1-2 and 7-10 months post infection. Secondarily, correlations were investigated among antigen-specific responses and to *ex vivo* frequencies of cell subsets of the innate, T and B cell compartments.
Methods: *Ex vivo* phenotyping on peripheral blood mononuclear cells (PBMCs) was done using high-dimensional flow cytometry. Mumps-specific T and B cell responses were investigated by measuring activation-induced marker expression (AIM) and by ELISpot assay, respectively.
Results: *Ex vivo* immune cell phenotyping established insight in kinetics of innate, T and B cell responses. MMR3 immunization significantly induced activated mumps-specific $CD4^+$, but not $CD8^+$, T cell responses characterized by expression of one or more activation markers (CD137, CD154, OX40, CD69). Additionally, enhanced mump-specific B cells were observed 1 month post-immunization. Mumps infection, as compared to immunization, induced significantly higher antibody, $CD4^+$ T cell and B cell responses and in addition provided $CD8^+$ T cell responses. While B cell responses correlated positively to IgG and virus neutralization levels, these responses did not correlate to $CD4^+$ T cell responses. Finally, based on pre-existing immunity and kinetics of mumps-specific responses following MMR3 vaccination, participants could be divided in distinct immune subgroups. These subgroups were characterized by different responses to MMR3 immunization with distinct correlations among mumps-specific responses and *ex vivo* immune cell subsets.
Conclusion: A third MMR immunization potentially increases protection of young adults against mumps infections as it provides strong antibody responses and significant mumps-specific T and B cell responses albeit with clear distinct responses in subgroups.

Purpose: Despite older subjects are more at risk of severe COVID-19, especially few months after vaccination, at which extent age and the type of vaccine affect the maintenance of antibody and cellular responses has not been addressed. By this study, we observed spike-specific immune responses elicited by vaccination with two doses of BNT162b2 or ChAdOx1-S and subsequently boosted with a single dose of BNT162b2 or mRNA-1273.
Materials and Method: We enrolled healthy donors with no known history of SARS-CoV-2 infection (n=230) at 6 months on average after the second dose of homologous immunization: 128 subjects were vaccinated with two doses of BNT162b2 vaccine, and 92 subjects were vaccinated with two doses of ChAdOx1-S vaccine. Ninety-nine participants were followed up, and 43 newly enrolled volunteers were recruited, to provide a blood sample at 6 months on average after a mRNA booster dose. The donors were stratified by age as young (*Y*, 18- 40 years), middle-aged (*M*, 41- 65 years), or old (*O*, >65 years).
We evaluated the titers of SARS-CoV-2-spike RBD-specific IgG, and we analyzed the *ex vivo* response with the Human IFNγ ELISpot, the production of cytokines (IFNγ, TNF, CD107, and CD154) in Intracellular Cytokines Staining and the spike-specific expansion and functionality in Tetramer Staining after expanded upon stimulation for 10 days.
Results: Primary vaccination with BNT162b2 ensures better maintenance of spike-specific antibodies than ChAdOx1 vaccination, while both vaccines induce similar memory T cell responses. The booster dose markedly improves the maintenance of both humoral and cellular responses, especially in subjects previously vaccinated with ChAdOx1-S. Aging profoundly affects long-term humoral responses, while the effects on cellular responses are less pronounced, mainly affecting the $CD4^+$ compartment in BNT162b2-recipients. Overall, higher T cell responses are observed in elderly subjects after primary vaccination with ChAdOx1-S and a booster mRNA dose, compared to those vaccinated with 3 mRNA vaccine doses.
Conclusion: In summary, our findings indicate that spike-specific cellular responses elicited by various vaccine formulations persist for up to 6 months post-final vaccination. However, we showed pronounced decline of adaptive responses in older individuals who received mRNA, but not vector vaccines.

Using Human Lymph Node Culture Models to Characterize T cell Activation Dynamics and Early Immune Responses to Vaccines

Alex George[1], Julia Davis-Porada[2], Jenny Huang[1], David Chen[1], Jennifer Hwu[1], Eric Zhang[2], Donna Farber[2], Peter Sims[1]
[1]Columbia University, Department of Systems Biology, New York, United States; *[2]Columbia University, Department of Microbiology and Immunology, New York, United States*

Purpose: Vaccination has long been an effective strategy in reducing morbidity and mortality by safely inducing the formation of immunological memory. T cell activation in memory-forming sites such as the lymph node (LN) is critical in initiating adaptive immunity which facilitates vaccination and ultimately generates a protective immune response. However, early immune responses induced by vaccines are not well characterized in human tissue. We previously utilized our collaborator's well established human tissue resource and demonstrated that T cells from blood, lymphoid, and mucosal sites exhibit conserved transcriptional states during activation in CD4+ cells. However, these T cells were isolated from dissociated tissue, depleting the spatial and signaling contributions of the tissue microenvironment.
Methods: To preserve these effects, we developed a method for culturing intact human LN slices. This culture system overcomes the limitations of liquid culture by preserving tissue architecture, local signaling, and maintaining physiological cell ratios. We utilized α-CD3/28 antibody tetramers, superantigen mimicking antibodies, and vaccines to stimulate both conventional liquid and slice cultures of human LNs up to 24 hours and utilized CITE-seq and flow cytometry to generate datasets.
Results/Conclusions: Stimulating slice and corresponding liquid culture with α-CD3/28 antibody tetramers yield distinct activation patterns and resting cell states with CITE-seq analysis. Antigen independent stimulation in liquid culture produces more robust activation compared to slice culture. However, α-CD3/28 perturbation bypasses physiological cell-cell interactions, while antigen dependent stimulation like superantigens facilitate MHCII/TCR binding and may benefit from the intact microenvironment in slice culture. With superantigen mimicking antibody we observed a discrete T cell metabolic intermediate state and a diverging activation trajectory in slice and liquid culture compared to α-CD3/28 stimulation. The establishment of this robust human LN platform enabled us to assess early immune responses induced by vaccines with single-cell genomics. By profiling these initial cell states, we hope to elucidate mechanisms or signatures which produce long-lasting, durable memory responses to vaccination. Using the methods described above, we have compared LN cultures perturbed with the Measles-Mumps-Rubella (MMR) and COVID-19 mRNA vaccines, revealing dose-responsive and vaccine-specific gene signatures across immune cell subsets.

Effectiveness, immunogenicity and safety of the novel DS-5670 vaccine platform against SARS-CoV-2: evidence from two randomized clinical trials

Shoko Nogusa[1]
[1]*Daiichi Sankyo Co. Ltd., Tokyo, Japan*

Importance: DS-5670 is a vaccine platform comprising the mRNA antigen derived from the spike protein receptor-binding domain (RBD) from SARS-CoV-2 encapsulated in lipid nanoparticles.
Objective To examine the immunogenicity and safety of monovalent DS-5670a (original strain RBD; Study 146) or bivalent DS-5670a/b (original strain and omicron BA.4-5 RBDs; Study 212) as boosters and comparator (BNT162b2 or mRNA-1273)
Design: Randomized, observer-blinded, active-comparator, non-inferiority studies. Enrollment began on January 31, 2022 (Study 146) and May 19, 2023 (Study 212) with 52-week observation and follow-up periods for both studies.
Participants: Study 146: adults (≥18 years) who had completed primary vaccination with monovalent BNT162b2 or mRNA-1273 against the original strain. Study 212: individuals (≥12 years) who had received primary and booster vaccinations with BNT162b2, with the last dose being the bivalent original/BA.4-5 composition.
Main Outcomes and Measures: Study 146: the primary endpoint was geometric mean fold-rise (GMFR) in serum neutralization titers against SARS-CoV-2 (original strain) at day 29; secondary endpoints were geometric mean titer (GMT) of anti-SARS-CoV-2 antibody, and COVID-19 incidence over time. Study 212: co-primary endpoints were GMT and seroresponse rate of anti-SARS-CoV-2 (omicron BA.5 strain) serum neutralization titers at day 29.
Results: Both studies exceeded non-inferiority margins. Study 146 (n=4518): adjusted GMFR ratios for DS-5670a were 1.464 (97.5% CI, 1.112 to 1.927) vs BNT162b2 and 1.772 (97.5% CI, 1.335 to 2.353) vs mRNA-1273. DS-5670a provided high serum neutralization titers and effectively prevented symptomatic COVID-19. Study 212 (n=701): the adjusted GMT ratio of DS-5670a/b to bivalent BNT162b2 was 1.712 (95% CI, 1.509 to 1.944), and the between-group difference in seroresponse was 21.4% (95% CI, 13.8 to 28.6). There were no serious AEs associated with DS-5670 in either study.
Conclusions and Relevance: Monovalent and bivalent compositions of DS-5670 were effective against symptomatic COVID-19 and well-tolerated, with broad neutralization activity across omicron sub-lineages. This platform can be utilized to produce new vaccines against future SARS-CoV-2 variants.

Effectiveness, Immunogenicity and Safety of the Novel DS-5670 Vaccine Platform Against SARS-CoV-2: Evidence From Two Randomized Clinical Trials

Fumihiko Takeshita[1], Shoko Nogusa[1]
[1]*Daiichi Sankyo Co. Ltd., Tokyo, Japan*

Importance: DS-5670 is a vaccine platform comprising the mRNA antigen derived from the spike protein receptor-binding domain (RBD) from SARS-CoV-2 encapsulated in lipid nanoparticles.
Objective: To examine the immunogenicity and safety of monovalent DS-5670a (original strain RBD; Study 146) or bivalent DS-5670a/b (original strain and omicron BA.4-5 RBDs; Study 212) as boosters.
Design: Randomized, observer-blinded, active-comparator, non-inferiority studies. Enrollment began on January 31, 2022 (Study 146) and May 19, 2023 (Study 212) with 52-week observation and follow-up periods for both studies.
Setting: Hospitals and clinics across Japan.
Participants: Study 146: adults (≥18 years) who had completed primary vaccination with monovalent BNT162b2 or mRNA-1273 against the original strain. Study 212: individuals (≥12 years) who had received primary and booster vaccinations with BNT162b2, with the last dose being the bivalent original/BA.4-5 composition.
Interventions: Study 146: monovalent booster dose of DS-5670a or comparator (BNT162b2 or mRNA-1273). Study 212: bivalent booster dose of DS-5670a/b or BNT162b2.
Main Outcomes and Measures: Study 146: the primary endpoint was geometric mean fold-rise (GMFR) in serum neutralization titers against SARS-CoV-2 (original strain) at day 29; secondary endpoints were geometric mean titer (GMT) of anti-SARS-CoV-2 antibody, and COVID-19 incidence over time. Study 212: co-primary endpoints were GMT and seroresponse rate of anti-SARS-CoV-2 (omicron BA.5 strain) serum neutralization titers at day 29.
Results: Both studies exceeded non-inferiority margins. Study 146 (n=4518): adjusted GMFR ratios for DS-5670a were 1.464 (97.5% CI, 1.112 to 1.927) vs BNT162b2 and 1.772 (97.5% CI, 1.335 to 2.353) vs mRNA-1273. DS-5670a provided high serum neutralization titers and effectively prevented symptomatic COVID-19. Study 212 (n=701): the adjusted GMT ratio of DS-5670a/b to bivalent BNT162b2 was 1.712 (95% CI, 1.509 to 1.944), and the between-group difference in seroresponse was 21.4% (95% CI, 13.8 to 28.6). There were no serious AEs associated with DS-5670 in either study.
Conclusions and Relevance: Monovalent and bivalent compositions of DS-5670 were effective against symptomatic COVID-19 and well-tolerated, with broad neutralization activity across omicron sub-lineages. This platform can be utilized to produce new vaccines against future SARS-CoV-2 variants.

Clonotypic analysis of T cell responses reveals long-term vaccine efficacy

Xiuyuan Lu[1], Sho Yamasaki[1;2]
[1]*Laboratory of Molecular Immunology, Immunology Frontier Research Center, Osaka University, Suita, Osaka, Japan*; [2]*Department of Molecular Immunology, Research Institute for Microbial Diseases, Osaka University, Suita, Osaka, Japan*

As a fundamental component of the immune system, adaptive immunity is crucial in defending against viral infections. Cellular immunity works in controlling the infection as well as promoting humoral immunity; however, antigen-specific T cells were less investigated and less considered in the designing of SARS-CoV-2 vaccines. To characterize the T cell responses in SARS-CoV-2 vaccinees on a clonotype level, we traced the dynamics of spike (S)-specific T cells before and after the vaccination, and determined their epitopes and restricting human leukocyte antigen (HLA) alleles. We observed that the dominant follicular helper T (Tfh) clonotypes induced by vaccination were associated with the diverse humoral immune response, and can be used as an indicator of antigen-specific antibody longevity. In contrast, pre-existing S-responsive T cells were contracted post-vaccination and thus were unlikely to contribute to the protection established by vaccination. These findings suggest the pivotal role of T cell immunity in defending against SARS-CoV-2 infection, and could be helpful for the vaccine design in the future.

Background: Cytomegaloviruses (CMV) elicit a lasting immune response with remarkably large populations of antigen-specific $CD8^+$ T cells for life. Therefore, CMV has been proposed and investigated as a novel vaccine vector. Strict species specificity of CMV has compelled vaccine developers to use HCMV in clinical trials. We propose that non-human CMVs used in cross-species settings may overcome several limitations of HCMV vectors and be superior in terms of safety and immunogenicity. On one hand, such constructs are naturally unable to replicate in human cells, omitting the need to generate recombinant single-cycle CMV vectors grown on complementing cell lines. On the other, immune evasion genes are host-specific and do not affect responses in species discordant settings. A recombinant murine CMV (MCMV) vaccine vector expressing the spike protein of SARS-CoV-2 ($MCMV^S$) showed a robust and long-lasting protection against distinct SARS-CoV-2 variants in the mouse model. We show in this study the immunogenicity and efficacy of our MCMV-based vector vaccine in the non-cognate hamster host.
Methods: We immunized hamsters with $MCMV^S$ and longitudinally quantified humoral and cellular immunogenicity following different immunization routes. At ten months post immunization, immunized hamsters were challenged with SARS-CoV-2 including the Omicron BA.5 variant.
Results: Hamsters tolerated $MCMV^S$ well. They developed neutralizing antibodies and antigen-specific T cell responses which expanded in size and breadth over time. Comparing intramuscular, subcutaneous, intranasal and intraperitoneal application routes, we found that robust humoral and cellular immune responses to spike antigens were elicited after all infection routes, but in particular after intramuscular injection. All immunized animals fully controlled productive SARS-CoV-2 infection upon challenge with the vaccine seed strain or with the antigenically distinct BA.5 variant at ten months post-immunization.
Conclusion: Our data suggest that a single-dose vaccination with an MCMV-based vector vaccine elicits exceptionally long-lasting and broad protection in a non-cognate host species. Hence, this technology might be a promising platform for the development of broadly reactive and long-lasting immune responses and has the potential for use in clinical settings.

Micronutrient supplementation supports immune response to seasonal influenza vaccine in mice

Biljana Bufan[1], Nevena Arsenović-Ranin[1], Irena Živković[2], Ivana Ćuruvija[2], Veljko Blagojević[2], Jelena Kotur-Stevuljević[3], Gordana Leposavić[4]
[1]*Department of Microbiology and Immunology, University of Belgrade – Faculty of Pharmacy, Belgrade, Serbia*; [2]*Department of Research and Development, Institute for Virusology, Vaccines and Sera "Torlak", Belgrade, Serbia*; [3]*Department of Medical Biochemistry, University of Belgrade - Faculty of Pharmacy, Belgrade, Serbia*; [4]*Department of Pathobiology, University of Belgrade – Faculty of Pharmacy, Belgrade, Serbia*

Purpose: Although nutritional gaps are prevalent in several micronutrients reported to support immune function, the significance of their deficits/supplementation for efficacy of vaccines, particularly those with low efficacy, as it is seasonal influenza vaccine, has not been fully investigated, yet. The present study examined influence of supplementation combining vitamins C and D, oligoelements zinc, selenium and manganese, and N-acetyl-cysteine on germinal centre (GC) and serum IgG responses to seasonal quadrivalent influenza vaccine (QIV) in mice.

Methods: Study encompas female BALB/c mice that were given QIV in two doses (28 days apart). The supplementation started five days before the first injection. Phenotypic and functional characteristics of cells from secondary lymphoid organs (SLOs) (draining lymph nodes and spleens) were analyzed by flow cytometry, whereas serum IgG response to QIV and levels of cytokines from SLO cell cultures were determined by ELISA. Redox status parameters were evaluated in spleens by spectrophotometric methods.

Results: The supplementation increased the magnitude of serum IgG response 28 days post the first QIV dose, through stimulation of GC reaction in SLOs, as indicated by increase in the frequency of GC B cells and follicular CD4+ T helper (Th) cells, and Th cell IL-21 production. Additionally, 14 days following the second QIV dose the supplementation supported more favorable (viz. more effective in the context of virus infection clearance) IgG2a response through favoring Th1 response. This could be ascribed not only to its indirect action related to antioxidant properties (confirmed by redox status analyses), but also to direct action on Th cell differentiation, as indicating by the ratio in production levels of Th1 (INF-γ) /Th2 (IL-4) signature cytokine ratio upon QIV restimulation in SLO cell cultures.
Conclusion: Thus, the study forms solid base for further studies aimed at repurposing use this safe and inexpensive micronutrient preparation as an adjuvant for virus influenza vaccine and possible some other virus vaccines.

BpOmpW antigen administered with CAF01 adjuvant stimulates comparable T cell responses to Sigma adjuvant system

Julen Tomás Cortázar[1;2], Conor Quinn[1;2], Niamh Corcoran[2], Alfonso Blanco[1], Dennis Christensen[3], Siobhán McClean[1;2]
[1]UCD Conway Institute, University College Dublin, Dublin, Ireland; *[2]School of Biomolecular and Biomedical Science, University College Dublin, Dublin, Ireland*; *[3]Center for Vaccine Research, Statens Serum Institut, Copenhagen, Denmark*

Purpose: There are no licensed vaccines to protect vulnerable populations from the potentially fatal tropical infection, melioidosis, despite its causative agent, Burkholderia pseudomallei, being endemic in tropical and subtropical regions. A promising vaccine candidate, BpOmpW protected mice from melioidosis infection for up to 81 days and stimulated robust interferon-gamma responses in $CD4^+$, $CD8^+$, NK and NKT cells. In order to progress to human studies, the selection of an adjuvant as CAF01 with an acceptable human safety profile that stimulates appropriate correlates of protection is essential.
Methods: The T-cell responses were characterised by flow cytometry using a 15-multicolour antibody panel after re-stimulating splenocytes from BpOmpW-immunized mice. Cytexpert and Cytobank software were used for the analysis of the cytometry data.
Results: Here we demonstrate that the CAF01 vaccine adjuvant elicits optimal immune correlates of protection when administered with our BpOmpW vaccine. Specifically, we demonstrate that CAF01 administered with BpOmpW elicits robust Th1 responses, with potent IFN-γ responses in $CD4^+$ and $CD8^+$ T cells and NKT cells, in addition to Th17 and Th2 responses comparable to Sigma Adjuvant System
Conclusion: This formulation BpOmpW/CAF01 will be particularly effective in protecting susceptible populations including people with type 2 diabetes from melioidosis.

Development of a new selection model for selection vaccine candidates against multidrug resistant *Staphylococcus aureus*

Brenda Vieira[1], Giulia Destro[1], Maria Eduarda Souza Guerra[1], Karina Cruz Melo[1], Anders Hakansson[2], Michelle Darrieux[1], Thiago Rojas Converso[1]
[1]*Laboratório de Biologia Molecular de Microrganismos, Universidade São Francisco, Bragança Paulista, Brazil*;
[2]*Division of Experimental Infection Medicine, Department of Translational Medicine, Lund University, Lund, Sweden*

Staphylococcus aureus is a bacterium of great interest being responsible for high levels of hospital and community acquired infections, it is responsible for the rapid increasing of multidrug resistant bacteria. The infections are initiated by the host's asymptomatic colonization, where this bacterium forms biofilms, a complex structure composed by bacteria and extracellular matrix, from biofilms, the bacterium can spread to other tissues causing several diseases. A recent report from WHO pointed that *S. aureus* is one of the most important bacteria for the development of prophylactic and therapeutics strategies. Even tough several vaccine candidates have been proposed, until now there is no vaccine approved against these pathogen. Therefore, we propose the development of a new selection and validation model for vaccine candidates against *S. aureus*, our model combines bioinformatic, transcriptomic and proteomic analysis of the bacteria in two stages: from colonizing biofilms and biofilm-dispersed, virulent bacteria. For that, we used a cell substrate biofilm formation protocol, which allow the bacterium to form biofilm in a physiological model using lung epithelial cells for 48 h at 34ºC and 5% CO2 (simulating the nasopharynx condition), after this time, the biofilm was treated for 3 h at 38.5ºC (simulating fever), as control a 34ºC treated plate was also prepared. After the 3 h, the bacterium was plated on blood agar plates for CFU count, a scanning electron microscopy (SEM) was also performed to evaluate biofilm formation.: The results showed that fever simulation works triggering the bacterial dispersion form biofilms, two S. aureus strains were tested and for both the heat treatment provided 4 times more dispersion in relation to the control, SEM showed that the cells formed viable, well-structured biofilms, the samples were prepared for transcriptomic and proteomic analysis. As conclusion, we were able to develop a protocol that simulates a real curse of infection by S. aureus trigged by fever, this result will be used to analyze the bacterium profile during colonization and infection phases.

Evaluation of fimbrial subunits as vaccine candidates against Klebsiella pneumoniae infection in a mouse model of pneumonia

Lucas Assoni[1], Isabelle B. Ciaparin[1], Ana Julia M. Couto[1], Gabriel R. Silva[1], Vitoria Valim[1], Thiago Rojas Converso[1], Michelle Darrieux[1]
[1]*Molecular Microbiology Department, São Francisco University, Bragança Paulista, Brazil*

Klebsiella pneumoniae infections pose a great burden worldwide, causing high morbidity and mortality, which is worsened by the increase in multidrug resistant strains. New therapeutic/prophylactic strategies are urgently needed to overcome antibiotic resistance and reduce the health and economic impacts of diseases caused by this pathogen. Fimbriae are important virulence factors involved in biofilm formation and adhesion to host cells. Their exposed location and conservation among clinical isolates make them interesting candidates for inclusion in protein-based vaccines. Therefore, the present work investigated the immunological potential type 1 and 3 fimbriae subunits in a murine model of *K. pneumoniae* lung infection. The genes encoding fimbriae subunits FimA and MrkA were cloned in procaryotic vector systems, expressed in *Escherichia coli* and purified by affinity chromatography. Subcutaneous immunization with the recombinant proteins using Alum as adjuvant induced specific IgG production, mainly of the IgG1 subclass; the antibodies efficiently recognized the native proteins at the bacterial surface and reduced biofilm formation *in vitro*. Furthermore, mice vaccinated with the co administered proteins, but not the individual antigens, showed reduced bacterial loads in the lungs after intranasal challenge with a virulent *K. pneumoniae* clinical strain. Overall, the results suggest that both type I and type III fimbriae subunits contribute to protection against *K. pneumoniae* lung infection, possibly by inducing antibodies that can bind to the bacteria and favor clearance by the host.

Can Lacticaseibacillus rhamnosus modulate the immune response to inactivated Influenza vaccine in young and old rats?

Marija Petrušić[1], Veljko Blagojević[1], Ivana Anđelović[1], Marko Vasić[1], Luka Dragačević[2], Irena Živković[1]
[1]*Institute of Virology, Vaccines and Sera Torlak, Department for Preclinical Research and Immunology, Belgrade, Serbia*; [2]*Institute of Virology, Vaccines and Sera Torlak, Belgrade, Serbia*

Purpose: The senescence of the immune system bears the burden of poor response to vaccination. The Influenza virus is a common etiological factor that humans encounter every year. The elderly are at greater risk of undesirable outcomes, even when vaccinated, since the vaccine response rate is 45-65%. To address the poor immunological response to vaccination in the elderly, we sought a non-invasive and comfortable "adjuvant" in the form of probiotic Lacticaseibacillus rhamnosus that could boost the immune response and affect the vaccination outcomes.
Methods: Young (3) and old (24 months) Dark Agouti female rats were set into four experimental groups (n=6). One from each group of young and old rats received L.rhamnosus supplemented to the water (~$1x10^9$ CFU per day) 7 days before the vaccination and during the next 3 weeks after it (L.rhamnosus+vaccinated). The control groups drank tap water *ad libitum* (control+vaccinated). All 4 groups were vaccinated with the seasonal Influenza vaccine (inactivated, fragmented virus). Three weeks after the vaccination, the experiment was ended and the thymuses and blood were retrieved for flow cytometry, qPCR, and ELISA analysis.
Results: Our results indicated that supplementation with L.rhamnosus induced a significant increase ($p<0.05$) in the frequency of Foxp3+CD25+CD4+TCRαβ+ cells in the blood of young, but not old vaccinated rats. Also, their thymuses were significantly ($p<0.05$) larger compared to the control vaccinated group of the same age. Following this was the significantly lower ($p<0.05$) frequency of memory CD90-CD45RC-CD4+ T cells in the blood of the young L.rhamnosus+vaccinated group and CD28nullCD8+ T cells ($p<0.05$) in both young and old L.rhamnosus+vaccinated groups compared to the control group. Interestingly, the concentration of proinflammatory IFNγ was significantly lower ($p<0.01$) in sera retrieved from both young and old vaccinated rats that received L.rhamnosus supplementation.
Conclusion: The immunomodulatory effect of L.rhamnosus is complex and affects both primary and secondary lymphoid systems. Our preliminary results suggest that L.rhamnosus supplementation: can be beneficial to vaccination outcomes for both young and old but is guided by different mechanisms; it could potentially affect slower thymus involution and take part in postponing the immunosenescence. Future experiments should provide us with additional answers.

The IL33/ST2 axis negatively regulates vaccine adjuvant induced cell-mediated immunity in a sex-dependent manner

Lorena Garcia del Rio[1], Jorge Huete-Carrasco[1], Jeremy Aboagye[1], Dorian Dederko[1], Kate Roche[1], Ed Lavelle[1]
[1]*Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland*

Introduction and Purpose: Cell mediated immune responses, particularly antigen specific $CD8^+$ T cells and Th1 cells are vital in prophylactic and therapeutic interventions for cancer and intracellular pathogens. It has been demonstrated that IL-33 is a negative regulator of vaccine-induced antigen-specific cellular immunity in mice, however, the role of biological sex in those immune responses has not been addressed. Therefore, the main purpose of this work is to elucidate the impact of biological sex on IL33/ST2 axis regulation of vaccine induced cell-mediated immune responses.**Methods:** Female and male C57BL/6 mice were vaccinated on days 1 and 14 in both leg flanks with ovalbumin and 50nm polymeric nanoparticles as adjuvant. Wild type mice (WT) and mice lacking the cytokine IL-33 (RD8) or its receptor ST2 (ST2) were employed. Antigen-specific $CD8^+$ and $CD4^+$ T cell responses were determined by tetramer staining and intracellular cytokine staining and secretion of IFN-γ by restimulated splenocytes was assessed by ELISA. Antigen-specific serum antibody titres were determined by ELISA. **Results:** Vaccination with antigen (ovalbumin) and adjuvant nanoparticles enhanced antigen-specific $CD8^+$ and $CD4^+$ T cell responses compared to vaccination with antigen alone. These responses were higher in female than male mice. Vaccine induced T cell responses were negatively regulated by IL-33 and ST2 but this effect was most marked in female mice. Specifically, the number of antigen specific $CD8^+$ T cells assessed by tetramer staining and percentage of antigen specific IFN-γ producing CD4 and CD8 cells was elevated in female IL-33 and ST2 deficient female mice. Vaccine induced antigen-specific antibody responses were also higher in female than in male mice, but this effect was independent of the IL-33/ST2 axis.**Conclusion:** IL33 and ST2 negatively regulated the ability of adjuvant nanoparticles to promote antigen specific T cell responses. The adjuvant more effectively induced T cell and antibody responses in females than in males and the immunomodulatory effect of IL-33 and ST2 was most marked in females. This indicates that biological sex should be considered when pursuing immunomodulatory strategies concerning the IL-33/ST2 axis.

Tuberculosis remains one of the deadliest infectious diseases worldwide. Despite the heterologous BCG vaccine, which shows a limited protection, a *Mycobacterium tuberculosis* (Mtb)-based homologous vaccine is not available to date. We found earlier that double immunizations with heat-killed Mtb massively induced monocytic myeloid-derived suppressor cells (M-MDSC) in mice. Our new results indicated that induction of M-MDSC is not an exclusive feature of Mtb, but Mtb appears quantitatively superior over other bacteria, including *Mycobacterium bovis, Mycobacterium smegmatis, Listeria monocytogenes*. In contrast, BCG vaccination did not generate M-MDSC or other myeloid cell types under any condition tested. We also investigated how Mtb and BCG vaccines affect subsequent live BCG infection in mice. Infection of Mtb-immunized mice with heterologous BCG resulted in increased effector neutrophil, macrophage, and DC generation specially in the lung, despite elevated M-MDSC frequencies. Thus, the balance between suppressive and effector immune responses tipped towards increased DC maturation and T cell activation, leading to a protective phenotype with lower bacterial loads. Remarkably, BCG-immunized mice infected with homologous BCG showed higher overall bacterial loads, with no induction of effector cell frequency and function. These results offer new insights into the relationship between M-MDSC induction, T cell response, and protection from disease following homologous versus heterologous challenges. Our findings may impact Mtb-based TB vaccine development to achieve a robust protection against Mtb.

Immune stimulating properties of lipid nanoparticle formulations containing a polyethylene-glycol alternative

Raphaela Semper [1], Dwain van Zyl[1], Livia Palmerston Mendes[1], Christine Rueckert[1], Patrick Baumhof[1]
[1]*CureVac SE, Tübingen, Germany*

Purpose: Lipid nanoparticles (LNPs) are an established platform for mRNA delivery. Currently approved LNPs comprise four components: an ionizable lipid, cholesterol, a phospholipid, and a polyethylene-glycol (PEG)-conjugated lipid. PEG is a key component since it prevents aggregation and ensures particle stability but also influences LNP behaviors in biological systems. There is evidence that PEG is immunogenic and contributes to rare adverse reactions to mRNA-LNP vaccines. PEG-specific antibodies can accelerate blood clearance of nanomaterials. Thus, we explored the hydrophilic polymer Poly(2-methyl-2-oxazoline) (PMOZ) as an alternative to PEG lipids in mRNA therapeutics.
Methods: SM-102-based LNPs containing different percentages of PMOZ were prepared using the microfluidics mixing technique, and physicochemical characteristics were evaluated by dynamic light scattering. Transfection efficiency was evaluated in different cell lines and primary human PBMCs by quantifying GFP expression by flow cytometry. The immunostimulatory profile of the LNPs was determined by evaluating expression of co-stimulation and activation markers by means of flow cytometry and by quantification of cytokines and chemokines in cell culture supernatants of PBMCs using a cytokine bead array. Toxicity was evaluated by staining cells with a viability dye. Immune stimulatory properties *in vivo* were addressed in mice after intramuscular injection.
Results: Cells exposed to LNPs with higher amounts of PMOZ responded with reduced percentage of GFP expressing cells and reduced upregulation of surface CD80, CD83 or CD86 on innate immune cells than cells exposed to LNPs with lower amounts of PMOZ. Furthermore, there was an inverse correlation of percentages of PMOZ in LNPs and induced cytokine and chemokine responses in supernatants of transfected PBMCs. The stronger immunostimulatory properties of LNPs containing lower percentages of PMOZ was also observed *in vivo* in LNP-injected mice.
Conclusion: PMOZ shows the potential to be used in LNPs for mRNA vaccine delivery as an alternative to PEG. Transfection efficiency and immunostimulatory potential of LNPs can be modulated by altering the amount of PMOZ.

Delivering SARS-CoV-2 mutated RBD antigens to the CD40 receptor: A strategy for inducing long-term antibody responses

Marwa El Hajj[1], Mathieu Surénaud[1], Florence Picard[1], Guillaume Hypolite[1], Amandine Sansoni[2], Manon Fabregue[2], Sarah Sharkaui[2], Camille Pierrini[2], Sylvain Cardinaud[1], Mireille Centlivre[1], Bernard Malissen[2], Gerard Zurawski[1;3], Ana Zarubica[2], Sandra Zurawski[1;3], Yves Lévy[1], Véronique Godot[1]
[1]VRI / INSERM-U955 / UPEC, Créteil, France; *[2]Centre d'Immunophénomique (CIPHE) / Aix Marseille Université / INSERM, Marseille, France*; *[3]Baylor Scott and White Research Institute, Dallas TX, United States*

Purpose: The rapid availability of SARS-CoV-2 vaccines was pivotal during the COVID-19 pandemic. However, the emergence of variants (VOCs/VOIs) evading antibody (Ab) neutralization has reduced vaccine efficacy. Urgent needs are to develop new vaccines/strategies: i) targeting VOCs/VOIs; ii) inducing long-lasting Ab responses.
Methods: CD40.Pan.CoV is a Dendritic Cell (DC) targeting vaccine consisting of a mAb specific to human (h)CD40 fused with RBD harbouring K417N, L452R, T478K, E484Q, N501Y mutations common to VOCs and a Nucleocapsid sequence, (>95% conserved across Sarbecoviruses). Immunogenicity and viral protection were tested in hCD40 and hCD40/K18-hACE2 transgenic mice, respectively. Animals were immunized at days 0/21 with the CD40.Pan.CoV vaccine (10µg) plus poly-ICLC (50µg, i.p.) or the mRNA BNT162b2 vaccine (1µg, i.m.) and either sacrificed (n=5-10/Group) 14 days post-boost or infected (Wuhan strain; n=6-11/Group) 7 days post-boost. Control mice received poly-ICLC or PBS. In another set of experiments, mice primed with two doses of BNT162b2 were boosted at month (M) 8 with either BNT162b2 or CD40.Pan.CoV+ poly-ICLC (n=4-5/Group) and serum was collected monthly till M16. The levels of binding and neutralizing RBD-IgG were assessed with MSD tests. Splenic B cells were analysed by flow cytometry.
Results: The rate of protection reached 100% in CD40.Pan.CoV and BNT162b2 vaccine groups with no animals exhibiting clinical symptoms or viral replication in the lungs unlike mock animals. CD40.Pan.CoV induced IgG-specific RBD responses as potent as the BNT162b2 vaccine but with a broader range of cross-reactivity and neutralization against δ/ε/γ/κ VOC and higher frequency of germinal centre B cells. In BNT162b2-pre-immunized animals, BNT162b2 or CD40.Pan.CoV boost (M8) increased IgG-specific RBD responses. However, post-boost dynamics revealed different decreasing slopes of binding and neutralizing Ab responses with CD40.Pan.CoV maintaining long-lasting responses.
Conclusion: Our study presents the proof of concept of the efficacy and immunogenicity of a vaccine targeting a mutated-RBD and a conserved nucleocapsid region (Npep) to the CD40 receptor. The CD40.Pan.CoV vaccine induced humoral and B cell responses against VOC/VOIs, complete protection against SARS-CoV-2 with potentially superior immune outcomes than BNT162b2, and specifically antibody longevity when used as a boost. CD40.Pan.Cov vaccine will be moved to a phase I/II clinical trial in 2024.

Functional in vitro B cell assay for Tetanus and Diphtheria containing vaccine batch release using memory B cells from healthy donors

Olga Ticha[1], Isabell Franz[1], Svitlana Skoroplyas[1], Isabelle Bekeredjian-Ding[1]
[1]*Paul-Ehrlich-Institut, Langen, Germany*

Objectives: Vaccines containing inactivated toxins (toxoids) provide protection by eliciting a neutralizing antibody response against bacterial toxins such as tetanus and diphtheria. Release testing of vaccines ensures that efficacy and safety of the vaccine product are maintained in all batches. Currently, release of tetanus toxoid (TT) and diphtheria toxoid (DT)-containing vaccines relies on *in vivo* experiments mimicking the vaccine response.
Results: Here, we developed an *in vitro* assay based on the stimulation of switched memory B cells containing TT/DT antigen-specific B cells isolated from buffy coats. Exposure of TT/DT-specific memory B cells within the memory B cell fraction to vaccine antigen induced differentiation into IgG TT- and DT-specific antibody-secreting cells detected by ELISpot. The results further demonstrate that the protocol elicits a specific response to the target TT/DT antigens. Importantly, the assay provides robust and reproducible data on the immunogenicity of TT and DT vaccine components regardless of the presence of adjuvants, other antigens or excipients contained in the final vaccine formulation. Additionally, use of vaccine samples containing heat-treated TT displayed a decreased TT-specific response, indicating that the B cell assay is sensitive to alteration of vaccine antigen and its epitopes, an important prerequisite for batch release testing.
Conclusions: Our cell-based test system can serve to prove the functional integrity of the vaccine antigens and it might offer a potential alternative to animal experiments currently used for batch testing of vaccines containing TT and DT components by complementing biochemical assays.

Staphylococcus aureus-specific TIGIT+ Treg are present in the blood of healthy subjects – a hurdle for vaccination?

Elisabetta Soldaini[1], Jonah Clegg[1;2], Malgorzata Ewa Mnich[1;3], Alberto Carignano[1], Giovanni Cova[1], Simona Tavarini[1], Chiara Sammicheli[1], Bruna Clemente[1], Megan Smith[1;2], Emilio Siena[1], Monia Bardelli[1], Michela Brazzoli[1], Fabio Bagnoli[1], Rachel McLoughlin[2]
[1]GSK, Siena, Italy; *[2]Trinity College, Dublin, Ireland*; *[3]Pasteur Institute, Paris, France*

Staphylococcus aureus poses an enormous burden of morbidity and mortality worldwide. Making an efficacious vaccine has however proven extremely challenging. Due to colonizing interactions, pre-existing *S. aureus*-specific $CD4^+$ T cells are often found in the human population and yet a detailed characterization of their phenotypes and how they might in turn impact vaccine efficacy are thus far unknown. Using an activation induced marker assay to select for *S. aureus*-specific $CD4^+$ T cells in an effector function-independent manner, phenotypical analysis was carried out via single-cell RNA sequencing. *S. aureus*-specific $CD4^+$ T cells consisted not only of effector (Teff) but also of regulatory (Treg) phenotypes. As compared to polyclonally activated $CD4^+$ T cells, Teff showed an enrichment for the expression of Th17-associated cytokine genes, which was further elevated in skin-tropic (cutaneous lymphocyte antigen, CLA, positive) cells. The vast majority of *S. aureus*-specific Treg was found to highly express the co-inhibitory receptor TIGIT. Remarkably, an antagonistic anti-TIGIT monoclonal antibody was shown to increase IL-1b production in response to *S. aureus*. Therefore, our results uncover the presence of *S. aureus*-specific $TIGIT^+$ Treg in the blood of healthy subjects suggesting that these cells could be responsible for blunting the response to re-infection and vaccination and indicate TIGIT as a potential targetable biomarker to overcome pre-exposure-induced immunosuppression.

Vaccination with BrpA, Biofilm Regulator Protein A, induce antibodies that affect biofilm formation in Streptococcus mutans

Giulia Destro[1], Brenda Vieira[1], Maria Eduarda Souza Guerra[1], Karina Cruz Melo[1], Michelle Darrieux[1], Thiago Rojas Converso[1]
[1]*Laboratório de Biologia Molecular de Microrganismos, Universidade São Francisco, Bragança Paulista, Brazil*

Streptococcus mutans plays an important role in caries development due to its ability to produce and tolerate an acidic environment, as well as its capacity to form biofilms on the tooth surface. Many proteins have been investigated as vaccine candidates against *S. mutans*, particularly those involved in bacterial adhesion and biofilm formation. Biofilm regulator protein A (BrpA) is a virulence factor necessary for biofilm accumulation and maintenance of envelope integrity. Bioinformatics analysis suggests that BrpA is a transmembrane protein; however, the cellular location of BrpA has not been experimentally investigated. The present study aimed to determine the cellular location of BrpA, along with other traits associated with its potential inclusion in a vaccine against *S. mutans*, such as immunogenicity, prevalence among clinical isolates, accessibility to interact with antibodies, and the ability of these antibodies to block biofilm formation *in vitro*.The results indicate that mouse immunization with BrpA can produce a high amount of IgG antibodies. Western blot analysis showed that BrpA is present in 75% of the analyzed strains. Flow cytometry analysis revealed that BrpA is a membrane-exposed protein, making it accessible to interact with antibodies generated against the recombinant protein. Lastly, we tested the ability of these antibodies to block native BrpA, impairing biofilm formation by the bacterium. The strains pre-incubated with the antibodies formed less biofilm than the control. Together, these results suggest that BrpA stands out as a promising vaccine candidate against *S. mutans*.

A T cell inducing prime-boost vaccine for elephant endotheliotropic herpesvirus (EEHV)

Tanja Maehr[1;2;3], Javier Lopez[2], Gabby Drake[2], Federico Ferreira[4], Richard Fraser[2], Susan L Walker[2], Rebecca McKown[2], Helder Nakaya[5], Falko Steinbach[1;3]
[1]School of Veterinary Medicine, FHMS, Univ of Surrey, Guildford, United Kingdom; *[2]Chester Zoo, Chester, United Kingdom*; *[3]Animal and Plant Health Agency, Weybridge, United Kingdom*; *[4]Infectious Disease Pathology Laboratory, University of Sao Paulo, Sao Paulo, Brazil*; *[5]Hospital Israelita Albert Einstein, Sao Paulo, Brazil*

Purpose: Elephant endotheliotropic herpesviruses are a major threat to juvenile Asian elephants where losses due to EEHV induced haemorrhagic disease (EEHV-HD) remain high. There are no efficacious antiviral therapies or vaccines yet. Notably, the target cells for EEHV *in vivo* are unclear and monocytes/macrophages have been proposed as such.
Since immunity against herpesviruses particularly relies on cellular responses, we aimed to devise a T cell-inducing vaccine. Accordingly, we applied reverse vaccinology techniques aiming to design an EEHV vaccine that prevents death and severe disease not using external (glycoprotein) antigens.
Methods: We used a modified vaccinia Ankara (MVA) viral vector as priming vaccine and an adjuvanted protein formulation each containing two antigens as boost, creating a heterologous prime-boost vaccine against EEHV-HD.
In a first-in-elephant proof-of-concept trial, this prototype vaccine was tested for safety (and immunogenicity) in three adult elephants. We used a modified IFN-g release point-of-care, vaccine-specific whole blood stimulation assay as a way to determine immune responses with RT-qPCR as readout first as described for HCMV not least. This was necessary to overcome limitations of sample transport times from the zoo to the laboratory. RNA from preserved stimulated whole blood was used to determine the immune reaction via RNA Sequencing and assessment of differential gene expression pre- vs. post-vaccination using systems immunology approaches.
Results: A complete lack of adverse reactions post-vaccination strongly suggests that this heterologous prime-boost vaccine can be safely used in elephants. Recall IFN-g responses to our candidate antigens were observed against a background of reactions caused by the latent infection that exists in all elephants. Of diagnostic value for the immune reaction were Abs that could be detected against the candidate antigens using Western blot.
Over representation gene analysis (ORA) demonstrated that the vaccine induced a $CD8^+$ and $CD4^+$ T cell-based immune cell composition. Further ORA and GSEA as well a review of DEG demonstrated the Th1 bias of the antigen-specific immune response.
Conclusion: These results support a further evaluation of this prototype vaccine in young elephants as the target population for vaccination against EEHV-HD.

The M2SR intranasal H3N2 single replication live influenza virus vaccine induces more potent and broad mucosal secretory IgA response in older adults than the high-dose inactivated FluzoneHD vaccine

Lilach M. Friedman[1], Shelly Shriker[1], Amos Guetta[1], David Marshall[2], Renee Herber[2], Pamuk Bilsel[2], Tomer Hertz[1;3]
[1]Department of Microbiology, Immunology and Genetics, and the National Institute for Biotechnology in the Negev, Ben-Gurion University of the Negev, Beer-Sheva, Israel; *[2]FluGen, Inc, Madison, Wisconsin, United States*; *[3]Vaccine and Infectious Disease Division, Fred Hutch Caner Research Center, Seattle, WA, United States*

The M2-deficient single replication (M2SR) H3N2 intranasal influenza vaccine was shown to protect from a drifted H3N2 virus in a phase 2a challenge human trial, inducing cross-reactive neutralizing antibodies, as well as IgA and secretory IgA (sIgA) antibodies. Here we compared the vaccine induced responses of M2SR to the licensed quadrivalent inactivated Fluzone High Dose (FluzoneHD) vaccine in a phase 1b trial of 305 older adults (65-85 years). Participants were randomized to receive placebo, FluzoneHD, M2SR or MS2R+FluzoneHD co-administration. Antigen microarrays spotted with 90 recombinant hemagglutinin (HA) and neuraminidase (NA) proteins of 58 influenza strains were used to profile the magnitude and breadth of serum IgG and IgA, and mucosal IgG and sIgA antibody responses at enrollment and 28 days post-vaccination.

While both FluzoneHD and M2SR induced significant serum IgG and IgA responses to influenza HA proteins ($p<0.001$), only M2SR induced nasal sIgA responses. Significant antibody responses to NA proteins were not detectable with any vaccine, except for FluzoneHD induced serum IgG response to B NA. Interestingly, although M2SR included only an H3N2 strain, it induced broad serum sIgA responses to H1 and B HA proteins as well, while in the nasal swabs the sIgA response was specific to H3 proteins only. The combination of M2SR and FluzoneHD was synergistic in inducing serum IgG to the conserved HA2 subunit and swab sIgA to H3N2 HA proteins. We compared the effects of both vaccines on individuals in the lowest quartile when ranked based on baseline H3 sIgA magnitude. M2SR induced significantly higher mucosal IgG and sIgA H3N2 responses in this group compared with FluzoneHD.

Overall, the H3N2 M2SR vaccine induced a significant mucosal sIgA response to H3 proteins in older adults, while FluzoneHD did not affect their sIgA levels. This effect was particularly significant for individuals with pre-vaccination low H3N2 mucosal antibody responses. M2SR also induced a heterologous serum IgG responses to influenza subtypes that were not included in the vaccine. These results suggest that M2SR vaccines may be used in populations with a limited response to the traditional influenza vaccines and may induce more broader protection from multiple influenza subtypes.

Leishmania extracellular vesicles mediate protection against cutaneous leishmaniasis

İbrahim Tokmak[1;2], İsmail Cem Yilmaz[1], Muzaffer Yildirim[1], Volkan Yazar[3], Bekir Salih[4], Ülkü Güler[4], İhsan Gürsel[1], Mayda Gürsel[1]

Purpose: Leishmaniasis is a group of vector-borne diseases caused by several species of *Leishmania* protozoan parasites. The disease manifests as cutaneous, mucocutaneous, or visceral leishmaniasis depending on the infecting *Leishmania* species and the nature of the host response. As a neglected tropical disease, leishmaniasis is a serious global health problem that necessitates the development of new disease prevention measures to limit its spread. In this study, we sought to evaluate the immunogenicity of *L. major*-derived extracellular vesicles in the BALB/c mouse model of cutaneous leishmaniasis.
Materials and methods: *L. major*-derived extracellular vesicles (EVs) were purified under GMP-adaptable conditions from axenic cultures of late-log phase metacyclic promastigotes via multimodal chromatography and tangential flow filtration. EVs were characterized by proteomics, tunable-resistive pulse sensing, and scanning electron and atomic force microscopy. 6-8-week-old naive female BALB/c mice were immunized twice (2 weeks apart) with 3 or 10 µg of EVs as such or combined with different vaccine adjuvants. Cellular and humoral immune responses were evaluated 2 weeks after booster injection and immune protection after live parasite challenge was followed longitudinally.
Results and conclusions: GMP-adaptable EV purification protocol allowed consistent and reproducible isolation of extracellular vesicles enriched in several *Leishmania*-specific antigens (proteomics) with the expected vesicular structure and size (microscopy). EVs generated humoral and cellular immunity and provided protection against live parasite challenge. In conclusion, our data suggest the feasibility of utilizing parasite-derived vesicles as candidate vaccines against *Leishmania major*-induced cutaneous leishmaniasis.

Saponin-based adjuvants: deciphering the molecular mechanism of QS-21

Alba Mosteiro-Couso[1], Adrián Plata[1], Abhijit Saha[1], Nagore Sacristán[1], Juan Anguita[1;2], Alberto Fernández-Tejada[1;2]
[1]Asociación Centro de Investigación Cooperativa en Biociencias CIC bioGUNE, Derio, Spain; [2]Ikerbasque, Basque Foundation for Science, Bilbao, Spain

Purpose: Adjuvants are key immune activators added to vaccine formulations that prolong the immunogenicity of the antigen and stimulate a strong long-lasting immune response. However, toxicity problems, among others, restrict the use of many of them in humans. Traditionally, aluminum-based salts have been used as adjuvants in the clinic, but more recently the saponin-based family of adjuvant formulations have gained relevance due to their efficiency. Nonetheless, their molecular mechanism is yet unknown and scant mechanistic studies have been performed to date. Therefore, our work seeks to decipher the molecular target responsible for their activity.
Methods: Synthetic saponin variants were chemically developed deriving from QS-21's structure, in order to obtain a simplified and less toxic molecule, but with the same effector capacity. Moreover, a photoaffinity probe consisting of a light-activatable group and a biotin tag was added to the structure of our saponin probe, enabling subsequent photo-crosslinking and detection with streptavidin. Western blotting and proteomics assays were performed to detect the molecular target of our saponin. Once some hits were discovered, validation assays were carried out, both microscopy and in vitro inhibition of the target, to ensure the results' accuracy. Last, an in vivo experiment was performed to check the antibody responses against our saponin in presence and absence of an inhibitor.
Results: Western blot results showed some lysosomal proteins as potential targets, which were also upregulated compared to the results obtained by the proteomics. Furthermore, binding assays were performed and checked by confocal microscopy showing the co-localization of the target with our saponin. Moreover, a commercial inhibitor was used to assess the veracity of the target, which validated our previous results. Last, in vivo results show less antibody titers in the neutralized mice.
Conclusion: Qs-21 appears to have a lysosomal protein as its intracellular target, provoking the lysosomal disruption and the subsequent cross-presentation to the MHC-I molecules of the immune system.

Purpose: COVID-19 booster vaccination is currently advised to subpopulations at high-risk of severe COVID-19. In autumn 2022, bivalent vaccines encoding both Spike protein from SARS-CoV-2 Original and Omicron BA.1 variants (Original/BA.1) were rolled out to enhance protection against infection with emerging Omicron variants. Hereby, we study the vaccine-induced variant-specific anti-Spike T cell and serological response across the general Dutch population (including non-risk groups), with special focus on the booster´s benefit in cross-reactivity across different adult age groups.
Methods: In a long-term follow-up, PBMCs and serum from 24-89 years old (y.o.) participants (n=86) of three COVID-19 vaccination longitudinal studies were collected before and after receiving the Original/BA.1 booster (Comirnaty or Spikevax). An IFNy-ELISpot served to study the Spike-specific T cell response towards the S1 and S2 subunits of the Original, Omicron-BA.1, and -BA.4/-BA.5 strains; the latter to study vaccine-induced cross-reactivity towards the then most prominent circulating variant. Additionally, we measured anti-S1 IgG concentrations in serum for the Original and Omicron-BA.1 variants. Nucleocapsid serology determined SARS-CoV-2 infection.
Results: Booster vaccination with Original/BA.1 increased the Original- and Omicron-BA.1 Spike-specific IFNy-T cell response only among older adults (≥70 y.o.), while IgG concentrations were increased across all age groups. Notably, the pre- and post-booster Spike-specific IFNy-T cell response towards both vaccine strains was similar; and showed additional cross-reactivity towards Omicron-BA.4/-BA.5. By contrast, at both timepoints, anti-S1 IgG concentrations were higher for the Original strain compared to Omicron-BA.1; and interestingly, the fold-change ratio between IgG concentrations at both timepoints was higher for Omicron-BA.1 compared to the Original strain. These findings were similar among participants with or without previous SARS-CoV-2 infection, which showed comparable fold-change ratios of both the IFNy-T cell response and IgG concentrations.
Conclusion: Firstly, our results demonstrate that the Original and Omicron-BA.1 cellular response in ≥70 y.o. adults can be increased with booster vaccination. Secondly, boosting with the bivalent Original/BA.1 vaccine induces IgG concentrations across all adult age groups, with a more significant change of Omicron-BA.1 specific antibodies. Overall, the higher cross-reactive capacity of T cells compared to antibodies supports the importance of vaccine-induced cellular immunity for protection against emerging variants.

Monitoring of the immune response against SARS-CoV-2 in patients with common variable immunodeficiency vaccinated with mRNA vaccines

Juan Francisco Gutiérrez-Bautista[1], Beatriz Fernandez Perea[1], Lucía Ballesta Alcaraz[1], Maria del Carmen Barrera Aguilera[1], Mónica Bernal[1], Ana Marin[1], Pilar Jimenez[1], Jose Ramón Vilchez[1], Miguel Ángel López-Nevot[1]
[1]*Hospital Universitario Virgen de las Nieves, Granada, Spain*

Common variable immunodeficiency (CVID) is a disorder characterized by B cell dysfunction and impaired immunoglobulin production. Individuals with CVID typically exhibit reduced levels of immunoglobulin G (IgG) and IgA, often accompanied by low IgM levels. Additionally, they may display diminished switched memory B cells and a poor response to vaccinations. Therefore, it is crucial to closely monitor the vaccination status of these patients to assess their vaccine response. Following the SARS-CoV-2 pandemic, the emergence and deployment of mRNA vaccines have become a critical issue for the general population, with even greater significance for individuals with immunodeficiencies such as CVID. Consequently, it is imperative to evaluate and track both the cellular and humoral responses to mRNA vaccines in CVID patients. To address this, we enrolled 26 CVID patients alongside a healthy control group and monitored their response to five doses of mRNA vaccines, comprising four doses of mRNA-1273 and one dose of the BNT162b2 bivalent vaccine. The humoral response was assessed by measuring serum IgG anti-spike protein (anti-S) antibodies and their neutralizing activity against prevalent variants. Meanwhile, the cellular response was quantified by IFN-γ production specific to SARS-CoV-2. Our findings revealed that CVID patients initially exhibited lower anti-S IgG levels compared to controls, although subsequent vaccine doses led to an increase in anti-S IgG levels, albeit with individual variability. Some patients required up to three doses to seroconvert. Moreover, cellular response levels increased with each vaccine dose, and patients demonstrating a cellular response also exhibited higher anti-S IgG levels. Furthermore, successive vaccine doses enhanced neutralization against the wild-type strain but did not improve neutralization against emerging variants, even with the use of the bivalent vaccine. In conclusion, monitoring vaccine response in CVID patients enables the identification of non-responders, facilitating appropriate precautionary measures. Our results underscore the heterogeneous response among CVID patients, with some requiring multiple doses to achieve seroconversion. While successive doses bolster humoral and cellular responses, their efficacy is limited to strains included in the vaccine formulation, emphasizing the importance of tailoring vaccinations to prevalent strains, akin to strategies employed for influenza virus vaccination.

T cell responses to the replication-complex of SARS-CoV-2 remain subdominant in the current landscape of SARS-CoV-2 immunity

Ruairi McErlean[1], Selin Cankat[1], Daniel Brown Romero[1], Gloryanne Aidoo-Micah[1], Anandita Mathur[1], Mariana Diniz[1], Laura McCoy[1], Leo Swadling[1], Mala K Maini[1]
[1]*University College London, London, United Kingdom*

Purpose: During the first wave of the COVID-19 pandemic, a subset of highly exposed healthcare workers remained seronegative despite blood biomarker evidence of exposure and longitudinal expansion of SARS-CoV-2-specific T cells, indicating 'abortive' infections. In this cohort, T cells preferentially targeted the replication transcription complex (RTC) of SARS-CoV-2, a non-structural protein complex essential for the replication of the virus. In contrast, in individuals with detectable infections (seropositive, PCR+) with Wuhan-Hu-1 virus, RTC-specific responses were subdominant to structural-specific T cell responses. However, it is unclear what impact repeated exposure to SARS-CoV-2 variants and vaccine breakthrough infections would have on the RTC-specific T cell compartment. Here, we investigate the prevalence of RTC-specific T cell responses in a 'contemporary' (Sept2023-May2024) London-based cohort of healthy donors, after vaccination and likely exposure to SARS-CoV-2 Omicron variants.
Methods: PBMC from healthy donors were collected and T cell assays (IFN**γ** ELISpot, Intracellular cytokine staining, Activation induced marker assay) were performed to quantify the prevalence of T cell responses to structural and RTC proteins of SARS-CoV-2. These data were compared to existing data on pre-pandemic responses, responses induced by detectable Wuhan-Hu-1 infection and responses induced by abortive infection.
Results: RTC-specific responses remain subdominant in the 'contemporary' cohort despite potential repeated exposure to SARS-CoV-2, with comparable magnitude to the RTC-specific responses observed pre-pandemic. Further, these responses are lower in magnitude than RTC-specific responses induced by abortive infection. Structural-specific T cell responses, including those to antigens not included in vaccines, are expanded above levels seen pre-pandemic.
Conclusions: Repeated exposure to Omicron variants has not boosted RTC-specific T cell responses. Further, the preferential targeting of structural proteins beyond spike in the 'contemporary' cohort suggests repeated exposure to SARS-CoV-2 variants has boosted this immunity. Together, these data suggest boosting RTC-specific T cell responses, shown to correlate with abortive infection, with an RTC-based vaccine may offer a further layer of protection against infection with current and future SARS-CoV-2 variants than is currently seen in exposed vaccinated cohorts.

An investigation of immune interference following sequential platform vaccinations in a guinea pig filovirus infection model

Courtney Cohen[1], Darrell Wetzel[1], Andrew Herbert[1]
[1]*USAMRIID, Frederick, United States*

Filoviridae are a family of negative-strand RNA viruses that include several important human pathogens, including Ebola virus (EBOV), Sudan virus (SUDV) and Marburg virus (MARV). Recent deadly EBOV outbreaks in Western Africa highlight the potential for these emerging viruses to have a devastating global impact. Several EBOV vaccine platforms are currently progressing through clinical trials in the US and abroad, including a live-attenuated, replication-competent recombinant vesicular stomatitis virus (rVSV)-vectored vaccine (ERVEBO®) and a live-attenuated, replication-incompetent chimpanzee adenovirus type 3 (ChAd3)-vectored vaccine, both expressing the immunogenic EBOV glycoprotein (GP). While the plug-and-play nature of vectored vaccines have many advantages (ease of production, path to licensure, etc), concerns remain around immune interference obstructing the use of platform technology for subsequent vaccinations. Here, we investigated whether pre-existing antigen- or vector-specific vaccine-induced responses impact the immunogenicity or efficacy of anti-filovirus vaccines. Groups of n=12 female Hartley guinea pigs (gpigs) were vaccinated intramuscularly in a prime-boost regimen four weeks apart, with one vaccine containing homologous rVSV-SUDV-GP, and the other a heterologous EBOV or MARV GP expressed by either an rVSV or ChAd3 vector. Sera was collected pre-vaccination and 14 days post-prime and post-boost for evaluation by ELISA and microneutralization assay. Four weeks post-boost, gpigs were challenged with 10,000 plaque forming units of guinea-pig adapted SUDV (GPA-SUDV) via intraperitoneal injection. Sera was collected at 6 days post-infection to evaluate viremia, and any gpigs surviving to 28 days post-infection were considered protected and euthanized. Sera ELISAs (using recombinant SUDV GP) and microneutralization assays against authentic SUDV demonstrated significant immunogenicity post-vaccination compared to unvaccinated controls. All vaccinated gpig groups, regardless of timing of homologous antigen, or combination of antigens and vectors, demonstrated 100% survival following GPA-SUDV infection, a significant difference from unvaccinated gpigs (83% lethality). Further, vaccination prevented significant weight loss, temperature elevation, clinical signs of disease and viremia post-infection in comparison to controls. This experiment suggests that there is little to no significant vaccine-associated immune interference as a result of heterologous, sequential vaccinations with vector platforms currently in clinical development.

Complete cross strain protection against congenital cytomegalovirus by vaccine targeting key components of the virus life cycle that induces antibody and T cell immunity

Alistair McGregor[1], Nadia El-Hamdi[1], K.Yeon Choi[1]
[1]*Texas A&M University Health Science Center, College Station, United States*

Purpose: Congenital cytomegalovirus (cCMV) is a leading cause of hearing loss/cognitive impairment in newborns. A vaccine is complicated by existence of multiple CMV strains enabling reinfection. Consequently, a vaccine must exceed convalescent natural immunity. The guinea pig is the only small animal model for cCMV but requires guinea pig CMV (GPCMV). Viral glycoprotein complexes (gB, gM/gN, gH/gL/gO and pentamer complex/PC) are important for cellular virus tropism. The fusogenic gB glycoprotein is essential for entry into all cell types by all routes. A GPCMV non-replication competent DISC vaccine strain demonstrated the importance of neutralizing antibodies to viral glycoproteins for protection in this model but failed to provide cross strain protection against a new clinical strain of GPCMV evading antibodies by being closely cell associated rather than cell free virus. Consequently, the T-cell response against CMV is equally important to target cell associated virus.
Methods: GPCMV antibody (viral glycoproteins) and T-cell (IE1/pp65) target antigens were evaluated as recombinant defective adenovirus (Ad5/35) based vaccines against horizontal and vertical challenge models with multiple strains of wild type GPCMV.
Results: A trimeric gB complex based Ad vaccine (AdgB) induced potent neutralizing antibodies, unlike gB monomer. However, cell associated virus was able to disseminate and similar results were obtained for gH/gL vaccines. GPCMV encodes functional homologs of IE1 and pp65 (GP83) pathogenicity factors targeting PML bodies and IFI16/cGAS-STING pathway respectively. Ad vaccines (AdIE1/AdGP83) induced T-cell responses in animals and reduced viral load in target organs against horizontal challenege but were not fully protective with AdIE1 exceeding AdGP83. A combination strategy of AdgB and AdIE1 (targeting humoral and cell-mediated responses) against mixed wild type strains of GPCMV in a congenital protection study was evaluated. 4 groups of female animals (N=10/group) were vaccinated with either AdgB, AdIE1, AdgB+AdIE1, or unvaccinated before mating. During 2nd trimester, animals were challenged with GPCMV. Pup cCMV transmission in unvaccinated was 91% but the AdgB+AdIE1 group had no detectable virus in pup tissues unlike single antigen vaccines.
Conclusion: Results demonstrate the importance of combined immune responses to antibody (gB) and T-cell (IE1) antigens for potent cross strain protection against cCMV.

Evaluation of the protective efficacy of novel vaccine candidates against *Acinetobacter baumannii* and *Pseudomonas aeruginosa* pathogens

Nouran Rezk[1], Julen Tomás Cortázar[1], Chaoying Ma[1], Irene Jurado-Martín[1], Siobhán McClean[1]
[1]*School of Biomolecular and Biomedical Sciences and Conway Institute of Biomolecular and Biomedical Research, University College Dublin, Dublin, Ireland*

Acinetobacter baumannii and *Pseudomonas aeruginosa* are highly multidrug-resistant bacteria and major contributors to nosocomial infections. They are classified by the World Health Organization as critical priority pathogens that require immediate action to develop novel antibiotics. However, no approved vaccines for these pathogens are currently available. We have identified several proteins involved in cell attachment of *P. aeruginosa* and *A. baumannii* to lung epithelial cells, some of which are homologous between *P. aeruginosa* and *A. baumannii.* Therefore, the aim of this project is to compare the protective efficacy and cross-reactivity of these homologous antigens (AgN) against *A. baumannii* and *P. aeruginosa. A. baumannii* AgN possesses seven, and *P. aeruginosa* AgN possesses nine predicted CD4 T cell epitopes, suggesting the potential of these antigens to induce cellular immune responses, and are of interest because Th1 and Th17 responses may contribute to protection against these pathogens. Mice immunised with recombinant *A. baumannii* AgN or *P. aeruginosa* AgN (with Sigma Adjuvant System (SAS) as adjuvant) expressed significantly more IFN-γ compared to the SAS adjuvant-only group (4-fold increase, p=0.0035 for *A. baumannii* AgN and 6.4-fold increase, p=0.007 for *P. aeruginosa* AgN), indicating strong T cell stimulation. However, IL17 expression was only significantly increased in the *P. aeruginosa* AgN-immunised mice (9.2-fold increase, p< 0.0001)
Mice immunised with SAS-adjuvanted *A. baumannii* AgN and subsequently challenged in an acute pneumonia model showed reduced bacterial lung colonisation (0.74-$\log_{10}$, p<0.0102) and spleen dissemination (0.9-$\log_{10}$, p<0.0426), highlighting its potential as a vaccine. Mice also showed robust IgG titres prior to the challenge. Although challenge studies on *P. aeruginosa* AgN are ongoing, its ability to stimulate more robust IFN-y and IL-17 responses, suggests it is a promising vaccine candidate.
Overall, these novel vaccine candidates against these two pathogens contribute to the urgent need for effective vaccines against antibiotic-resistant infections.

Cellular immunity against SARS-CoV-2 after different vaccination regimens

Emina Milosevic[1], Vladimir Perovic[1], Dusan Popadic[1], Ljiljana Markovic-Denic[2], Verica Jovanovic[3]
[1]Institute of Microbiology and Immunology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; *[2]Institute of Epidemiology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia*; *[3]Institute of Public Health of Serbia "Dr Milan Jovanović Batut", Belgrade, Serbia*

We longitudinally explored cellular immune response to SARS-CoV-2 in four COVID-19 vaccines regimens.
Venous blood was obtained from healthy volunteers at three time-points: before the third dose of the vaccine, 21 days and 6 months after. COVId-19 infection during the follow up was an exclusion criterion. A total of 21 persons completed the follow-up. BNT162b2 was administered as a booster in 7 persons after BNT162b2 primary series, in 7 after BBIBP-CorV, and 3 after ChAdOx1 nCoV-19. In 4 persons BBIBP-CorV was used as a booster after BBIBP-CorV primary series. Cellular immune response to SARS-CoV-2 was assessed by interferon (IFN)-γ release assay and flow cytometric in vitro proliferative response to S-protein, along with unstimulated and pokeweed-stimulated blood as negative and positive control, respectfully. Total lymphocytes, T, B and NK cell were counted in a population of lymphocyte blasts after 7 days of antigen stimulation as absolute numbers, using absolute counting tubes. In addition to antigen specific analyses, samples were assessed for the T, B and NK cell counts before incubation.
There were not any statistically significant differences in total lymphocytes, T, B and NK cell counts between the groups and time-wise. Statistically significant increase in IFN-γ levels for all stimulations (Ag1, Ag2, Ag3) was observed 21 days after the third dose in regimens where BNT162b2 was administered as a booster after the same vaccine or BBIBP-CorV primary series. Higher IFN-γ levels after booster were measures in samples in other groups without statistically significant difference. After 6 months, IFN-γ release upon Ag1, Ag2 and Ag3 stimulations was comparable to the level before the booster. In vitro incubation with S-protein did not reveal any differences in T, B and NK cell blast numbers among vaccination regimens.
Small number of participants is a major limitation of the study. However, longitudinal alterations after vaccination warrant further assessment.

The study was supported by unrestricted grants from the Government of the Republic of Serbia and Betamed doo.

Lynch syndrome-related neoantigens prediction and validation for a dendritic-cell based cancer prevention vaccine

Cristina Bayó Llorens[1;2], Giancarlo Castellano[2], Teresa Ocaña[2;3], Rebeca Moreira[2;3], Joaquin Castillo[2;3], Maria Pellisé[2;3], Liseth Rivero[2;3], Maria Daca[2;3], Oswaldo Ortiz[2;3], Manel Juan Otero[1], Daniel Benitez-Ribas[1;2], Francesc Balaguer[2;3]
[1]Hospital Clinic of Barcelona, Immunotherapy, Barcelona, Spain; *[2]IDIBAPS, Barcelona, Spain*; *[3]Hospital Clinic of Barcelona, Gastroenterology, CIBEREHD, Barcelona, Spain*

Purpose: Lynch syndrome (LS), caused by germline mutations on DNA mismatch-repair genes (MMR) predisposes to colorectal and endometrial cancer (CRC, EC) amongst other tumors. Although CRC prevention is effective, no strategies exist for most LS-related tumors. Ex-vivo generated and tumor-antigen-loaded dendritic cell (DC) vaccines have been used as cancer immunotherapy; however, their full potential would likely be as a preventive approach in high-risk cancer patients. LS is a paradigmatic model for its limited and predictive mutational spectrum in repetitive DNA sequences (microsatellites, MS). We aimed to Identify and validate LS-related frameshift-derived neopeptides (FSDN) to develop a cancer preventive DC-based vaccine.
Methods: Search of LS-related coding MS (cMS) mutations and prediction of neoantigens with high coverage on common HLA-I and II alleles (pVACbind; pVACtools v2.0.1). Sequencing and analysis of FSDN-mutations presence on colorectal adenomas (CrAD), EC and CRC samples from LS patients, non-LS tumor sequences and RNA and DNA sequences from tumoral cell-lines. In-vitro FSDN immunogenicity analysis on tissue infiltrating lymphocytes (TILs) from LS CrADs, CRCs and normal mucosa by IFN-y ELISPOTs, flow cytometry. Detection, expansion, and characterization of neoantigen-specific CD8+ T-cells (Dextramers, IFNy+ magnetic selection, flow cytometry).
Results: 98 neoepitopes from 53 coding-MS-containing genes were prioritized. In silico analysis showed that ≥1 neoantigen-related mutations are found in all analyzed CrADs (31), EC (8) and CRC (52) LS samples and in 18-84% non-LS MSI tumors. FSDN mutations were found in DNA (66% cMS) and cDNA (69.8%) from MSI tumoral cell lines. In-vitro analysis showed that 71% FSDN gave a positive IFNy response in ≥1 LS patient (n=9). FSDN-specific TILs were detected and isolated from CrAD and normal colonic mucosa from 7 LS samples (n=12, 58%). Based on the results we prioritized a set of 24 FSDN for the vaccine.
Conclusion: Our predicted neoepitope set has optimal coverage among LS patients (HLA alleles, associated cancers and prevalence) and is capable of inducing IFNy inflammatory responses in LS-derived TILs. A phase Ib clinical trial will start on 2024 to determine the safety and efficacy of the autologous DC-based vaccine in LS-individuals.

Purpose: *Pseudomonas aeruginosa* (PA), known for causing severe acute nosocomial infections and chronic lung infections, exhibits extensive intrinsic and extrinsic resistance mechanisms. Pathogenesis of PA involves various virulence factors, including secreted proteases. Among these, elastase B (LasB), a highly potent exoprotease with broad substrate specificity capable of dissolving connective tissue and inactivating host defence proteins, emerges as a pivotal virulence factor and a promising target for antivirulence therapies. Although the immunogenicity of LasB in humans has been recognized for decades, a comprehensive analysis of the humoral immune response is lacking.
Methods: In this study, we investigate the humoral immune response to LasB in humans by screening a cohort of individuals with cystic fibrosis (CF), mostly with detectable or recurrent PA infections, followed by single B cell analysis of selected donors. Monoclonal antibodies (mAbs) derived from patients were produced based on B cell receptor repertoire analysis of LasB-specific B cells and characterized *in vitro* and *in vivo*.
Results: Among 102 individuals with CF, six donors were selected for single cell analysis of LasB-specific B cells. B cell receptor repertoire analyses revealed a polyclonal antibody response with evidence of clonally related B cells within each donor. Produced mAbs, originating from various clonal groups and donors, exhibited varying binding epitopes and neutralizing potency against LasB, including evidence of mAbs with superior activity. These mAbs completely inhibited cytolytic LasB activity and protected against LasB-induced loss of cell integrity and cell death. Notably, broadly neutralizing mAbs were identified with activity against several LasB variants, without detection of mutations leading to a loss-of-function of neutralizing antibodies.
Conclusion: Our findings offer novel insights into the intricate host-pathogen interactions involved in chronic PA infections by elucidating the humoral immune response to LasB. Patient-derived anti-LasB mAbs represent an innovative antivirulence therapeutic approach aimed at disarming PA during invasive infections. Leveraging the long half-life of human IgG, this approach holds promise for extending to passive immunization strategies for individuals at high risk of PA infections.

Epigenetic Inhibitors Together With TLR9 Agonist elevated IFN response and Th1 immunity

Havva Homak[1], Banu Bayyurt Kocabas[1]
[1]*Middle East Technical University, Ankara, Turkey*

Purpose: Cancer immunotherapy is a successful treatment that triggers person's own immune system during fight against cancer. However, some patients might show immunotherapy resistance, or worse, cancer hyper-progression. Therefore, immunotherapy is preferred as combinational therapy. Another novel cancer treatment is epigenetic therapy which solves dysregulations of cancer cells in terms of epigenetic modifications. They can prevent relapsing of cancer by repairing of abnormal gene expressions. Additionally, some have an influence on immune cells which can resolve suppressive environment of tumor. In this study, we aim to combine both immunotherapy and epigenetic inhibitors which FDA has been already approved to use against cancer to elevate the effectiveness of both therapies and limit their possible side effects. We used nucleic acid-based adjuvants and ovalbumin as a cancer vaccine and epigenetic inhibitors including DNA methylation and histone deacetylation inhibitors.
Methods: Splenocytes were stimulated with unmethylated CpG-containing oligonucleotides (CpG-ODNs) as a TLR9 agonist together with epigenetic inhibitors. We have checked production of cytokines using ELISA assay and reporter cell lines. After selecting the combination with highest Th-1 biased immune response, we have applied the combinational therapy to established melanoma tumor using B16-OVA cell line on C57BL/6 mice as a treatment. We have followed tumor growth, survival rate and antigen specific immune responses.
Results: We have shown that combination of K-type CpG-ODNs with Zebularine elevated Th1-biased immune responses by increasing type-I and II IFN production, in addition, up-regulation of co-stimulatory molecules (CD86 and CD40) and down-regulation inhibitory signals (PDL1) was observed *in vitro* splenocyte. *In vivo* experiments revealed that antigen specific production of type II IFN increased, however; IgG2c/IgG1 ratio remained unchanged after the novel combination.
Conclusion: We have found that DNMT inhibitor Zebularine showed coadjuvancy with K-type CpG-ODN against murine melanoma. Next, we will apply loading the combination into nanovesicles like liposomes to increase the delivery efficiency to tumor side.

Grants: HH and BBK supported by TUBITAK #121C122 project, and the study is part of TUBITAK #223S846 project.

mRNA-Encoded SFTSV Neutralizing Antibodies: Evaluation of Therapeutic Potential

Hyo-Jung Park[1;2], Soo-Yeon Lee[1;2], Yebeen Lee[3], Eun Yong Oh[4], Jae-Yong Kim[5], Yoo-Jin Bang[5], Sang-In Park[5], Eun-Jin Choi[1;2], Jisun Lee[1], Dahyeon Ha[1;2], Ayoung Oh[1;2], Seonghyun Lee[1;2], Sue Bean Youn[1;2], Jeong Soo Park[6], Hye Won Kwak[5], Daegeun Kim[5], Sang-Myeong Lee[4], Nam-Hyok Cho[3], Jae-Hwan Nam[1;2;5]
[1]The Catholic University of Korea, bucheon-si; *[2]BK21 plus Department of Biotechnology, bucheon-si*; *[3]Department of Biomedical Sciences, Seoul National University College of Medicine, Seoul*; *[4]Chungbuk National University, Cheongju, South Korea*; *[5]SML Biopharm, Gwangmyeong*; *[6]PanGen Biotech Inc., Suwon*

Purpose: Severe fever with thrombocytopenia syndrome (SFTS) was first discovered in 2009 as the causative agent of SFTS virus (SFTSV), an infectious disease caused by the SFTSV that is primarily transmitted through tick bites, localized to Korea and China. Despite its potential threat to public health because of high fatality rate, no effective prophylactic vaccine or therapeutic antibody are yet available. Recently, mRNA has been in the spotlight as a preventive and therapeutic vaccine or antibody. The advantage of mRNA is that it can be produced quickly and easily for the desired antigen gene.
Methods: In this study, we developed a promising mRNA-based therapeutic antibody candidates against SFTSV Gn in vitro and in vivo.
Results: In this study, we developed a promising mRNA-based therapeutic antibody candidates against SFTSV Gn. Administration of varied lipid nanoparticle-encapsulated mRNA-based therapeutic antibody candidates successfully elicited high neutralizing antibody titers in vitro. The mRNA-based therapeutic antibody candidates expressed anti-Gn antibodies dose dependently. We found that mRNA -based therapeutic antibody treatment significantly improved survival compared to the control group and protected against a lethal SFTS virus challenge in both vaccinated wild-type mouse and IFNAR-1 KO mouse in vivo
Conclusion: This study suggests that this mRNA-based therapeutic antibody candidates may be potential as an effective SFTSV therapeutic antibody.

Purpose: Worldwide, over 200 million individuals suffer from allergy to cats. Allergen-specific immunotherapy (AIT) is a highly effective allergen-specific treatment, but current allergen extract-based vaccines can induce severe adverse reactions, are not effective against all cat allergen molecules and require multiple and cumbersome administrations.
We report the engineering and characterization of a cat allergy vaccine based on a recombinant fusion protein consisting of hypoallergenic peptides derived from the three most important cat allergens Fel d 1, Fel d 4 and Fel d 7 fused with the PreS-surface antigen from hepatitis B virus as an immunological carrier protein.
Methods: Five recombinant fusion protein variants containing differently arranged allergen-derived peptides, (designated SuperCat 1-5) were produced, characterized and investigated regarding their allergenic activity (i.e., IgE-reactivity and induction of basophil degranulation), T-cell reactivity and cytokine release in cat allergic patients' samples. Their ability of inducing protective IgG responses was evaluated by immunization of rabbits in comparison with registered extract-based vaccines.
Results: SuperCats 1-5 lacked relevant IgE-reactivity and did not induce basophil activation demonstrating lack of allergenic activity. Allergen-specific IgG antibodies induced with only two injections in rabbits with SuperCat 1 and 5, but not with registered extract-based vaccines, blocked cat allergic patients' IgE binding to Fel d 1, Fel d 4 and Fel d 7 and allergen-induced basophil activation. Even induction of cross-protective IgG antibodies to cross-reactive major dog and horse allergens was observed. Furthermore, SuperCats 1 and 5 induced the production of the tolerogenic cytokine IL-10 in cultured PBMCs from allergic patients.
Conclusion: The in vitro data suggest that SuperCats are safe AIT vaccines capable of inducing protective IgG antibodies preventing allergen-induced basophil activation in cat allergic patients. In particular Supercats 1 and 5 are highly promising antigens for AIT of cat allergy.

Study of Mycobacterium indicus pranii and human beta defensin-2 as a combinatorial therapy against Mycobacterium tuberculosis

Deepak Vats[1], Faisal Shah[1], Vidushi Sharma[1], Archana Singh[1]
[1]*All India Institute of Medical Sciences, New Delhi, India*

Purpose: To reduce the host damage and enhance the elimination of mycobacteria, host directed therapeutics (HDT) can modulate specific host responses related to inflammation. Some HDTs have the potential to complement the existing Tuberculosis treatment by targeting both the bacteria and the host immune system. Among them, *Mycobacterium indicus pranii* (MIP) and human beta defensin-2 (hBD-2) have emerged as promising candidates for the treatment of various infectious diseases, including tuberculosis (TB). They have the ability to directly kill *Mtb* bacilli and also induce a cell-mediated immune response, which is lacking in conventional antitubercular drugs. In this study, we used MIP and hBD-2 as novel adjuvants to evaluate their effects on bacterial clearance and Th1 immune response in THP-1 cell line infected with an avirulent strain of *Mtb*.
Methods: THP-1 cells were differentiated into macrophages by using PMA. PBMCs were isolated using Ficoll Hypaqe Density Gradient method from the whole blood and monocytes were differentiated into macrophages. Cultured macrophages were infected with avirulent strain of *Mycobacteria.* Then, infected cells were treated with MIP, hBD-2 or both. Pro-inflammatory response was measured using gene expression of pro-inflammatory cytokines by qPCR. Bacterial clearance was assessed using CFU assays and Pyroptosis was checked using flow cytometry.
Results: When cells were treated with MIP and hBD-2 together, a strong pro-inflammatory response was observed. This signifies a robust Th1 immune response, which further reduced the bacterial count in the CFU assays. Flow cytometry expression of Caspase-1 showed the enhanced pyroptosis of infected cells after treated with combined MIP and hBD-2.
Conclusion: The current findings support the use of these powerful immunomodulators as adjuvants against mycobacterial infection as an effective strategy of therapy. However, the current findings must be verified in an appropriate animal model.

Advancing rheumatoid arthritis therapy by tolerogenic peptide-based vaccines

Laura Romero Castillo[1], Rajan Kumar Pandey[1], Kejsi Zeqiraj[1], Christian Beusch[2], Ana Coelho[1], Carolin Svensson[1], Bingze Xu[1], Vilma Urbonaviciute[1], Roman Zubarev[1], Rikard Holmdahl[1]
[1]*Karolinska Institute, Stockholm, Sweden*; [2]*Uppasala University, Uppsala, Sweden*

Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disorder, characterized by peripheral joint inflammation and bone destruction. Interestingly, around the onset of the disease, autoantibodies against citrullinated proteins cross-react with joint proteins, such as type II collagen (COL2). Currently, the medical treatment of established RA is the neutralization of inflammatory mediators such as TNFα. However, these treatments remain problematic, largely because of their lack of immune specificity and side effects. Therefore, there is a need for the development of more specific, safer, and more effective therapeutic interventions, targeting the initiation immune mechanisms. The genetic association of RA with certain MHC class II (MHCII) alleles indicated T cells as central players and, consequently, an important target for therapeutic intervention in the disease. We propose a tolerogenic peptide-based vaccination as a new therapeutic option for the treatment of early/established disease.
Methods: This process involves the expression of MHCII-$COL2_{peptides}$ complexes in eukaryotic cells, utilizing HEK cells. Collagen-induced arthritis (CIA) model is used to test our vaccine candidates in new unique physiologically accurate mouse strains. These strains were made by knock-in technology replacing the extracellular domains of HLA-DRA, HLA-DRB1*04:01 and CD74 in C57BL/6N mice, surpassing the limitations observerd in transgenic approaches. Fluorescently labeled MHCII-peptide tetramers aid in detecting COL2-specific T cells, while flow cytometry assesses T cell phenotype post-vaccination. ELIspot, ELISA, qPCR, and proteomic analysis provide deeper insights into antigen-specific T cell phenotypes.
Results: Among various COL2 peptide modifications, the AL179 peptide emerges as the most promising vaccine candidate. Vaccination with MHCII-AL179 complexes demonstrates potent suppressive effects and protects against arthritis in mice. Notably, the therapeutic effect can be transferred using T cells from vaccinated mice into COL2-immunized mice. Furthermore, the immune checkpoint inhibitor molecule VISTA, appears to play a significant role in the vaccination's efficacy.
Conclusion: We describe a vaccine that directly targets COL2-specific T cells, mediating a suppresive and tissue-specific effect on inflammation and the development of arthritis in peripheral joints. Leverageing our unique humanized mouse strains, we present promising avenues for developing an effective RA vaccine for human use.

Dendritic cells (DCs) are pivotal orchestrators of immune responses, crucially involved in fostering IFN-γ-producing CD8+ cytotoxic T lymphocytes (CTLs) and CD4+ T helper 1 (Th1) cells, pivotal for combating viral infections and optimizing vaccination efficacy. Moreover, lamin A/C, a nuclear envelope protein, has emerged as a key player in T cell immunity. However, the intricate dynamics between innate and adaptive immunity during viral infections, particularly the impact of lamin A/C on DC function in this context, remain elusive.
Herein, we unveil that mice lacking lamin A/C in myeloid LysM promoter-expressing cells exhibit diminished capacity to elicit Th1 and CD8 CTL responses, culminating in impaired clearance of acute primary VACV infection. Intriguingly, in vitro-generated GM-CSF BMDCs display elevated levels of lamin A/C. Notably, lamin A/C deficiency in GM-CSF BMDCs does not alter the expression of surface costimulatory molecules but profoundly impairs their ability to form immunological synapses with naïve CD4 T cells. This impairment correlates with perturbations in NFκB nuclear translocation, thereby modulating NFκB-dependent transcription. Furthermore, lamin A/C ablation induces epigenetic alterations in BMDCs, predisposing these cells to mount a suboptimal antiviral response upon TLR stimulation.
Our findings underscore the indispensable role of DCs in orchestrating interactions with CD4 T cells during antiviral responses, elucidating the intricate molecular mechanisms through which lamin A/C governs DC function via epigenetic and transcriptional regulation.

HIV control status is associated with functional changes in memory natural killer cells

Alisa Huber[1], Groenendijk Albert[1;2], dos Santos Jéssica[1], Adriana Navas[1], Aysel Gurbanova[1], Marien de Jonge[1], Annelies Verbon[2], Mihai Netea[1;3], Jan van Lunzen[1], Leo Joosten[1;4], Andre van der Ven[1]
[1]RadboudUMC, Nijmegen, Netherlands; *[2]ErasmusMC, Rotterdam, Netherlands*; *[3]University of Bonn, Bonn, Germany*; *[4]Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania*

Purpose: HIV controllers (HIC) are a unique subset of people living with HIV (PLHIV) who spontaneously control HIV. We aimed to characterize functional alterations in Natural Killer (NK) cells prior and post HIV infections in HIC and non-controllers (non-HIC). 1st-degree family members (FAM) of HIC and non-HIC were used to infer NK-cell functionality prior HIV infection.
Methods: General NK-cell markers (CD56 and CD16) were assessed by flow cytometry on whole blood samples from 1315 PLHIV (105 HIC vs. 1213 non-HIC) and 43 HIV-negative FAM of PLHIV of the 2000HIV-study (NTC03994835). 10 activating and inhibitory NK-cell receptors were measured on MACS-sorted NK-cells of 27 PLHIV (15 HIC vs. 12 non-HIC) and 21 FAM of the 2000HIV-TRAINED-study (NCT04968717). Functional NK-cell markers were assessed using supervised and unsupervised analysis, integrating UMAP and FlowSOM metaclusters (MT). NK-cell functionality was evaluated by co-culturing PBMCs with K562 cells and measuring IFNγ, granzyme B, and perforin via flow cytometry.
Results: HIC exhibited increased $CD56^{bright}$ NK-cells compared to non-HIC and a higher expression of DNAM, NKp30, and NKp46 in HIC. Unsupervised analysis of CD56-sorted cells comparing PLHIV with FAM identified the expansion of an HIV-specific NK-cell MT. Increased NKG2C and ILT2 and decreased KIR2DL2/3 expression (MFI) within the HIV-specific MT was seen in HIC compared to non-HIC. Because NKG2C is a memory receptor in cytomegalovirus (CMV)-induced NK-cells, we stratified the FAM according to their CMV serostatus, who are 50% CMV seronegative. We identified KIR2DL2/3 expression as a differentiating receptor between HIV- and CMV-specific MT because it was expressed lower in HIV-induced NK-cells. NKG2C+ NK cells from HIC produced greater amounts of IFNγ than non-HIC, while no differences in granzyme B and perforin were observed.
Conclusion: An HIV-specific NK-cell population was identified in PLHIV that differed from CMV-induced NK-cells. NK-cells in HIC are more functionally competent and characterized by increased NKG2C, ILT2 and decreased KIR2DL2/3 expression. These HIC-specific NK-cells with a memory phenotype produce IFNγ, which may contribute to HIV control.

Funding: The 2000HIV-study was funded by ViiV Healthcare, which did not have any role in data quality control, statistical analysis, and final interpretation of the data.

Purpose: It has been suggested that individuals experiencing severe COVID-19 develop a distinctive SARS-CoV-2-specific humoral response, which is associated with disease progression. Here, we evaluated whether SARS-CoV-2 antibodies contribute to disease exacerbation in unvaccinated individuals infected with SARS-CoV-2.
Methods: We quantified IgG, IgA, and IgM levels against the SARS-CoV-2 Spike, Nucleocapsid, and Envelope proteins, as well as S2 and RBD Spike domains, in plasma obtained from individuals with severe (Group S, n=74) and mild (Group M, n=25) COVID-19 up to 31 days post-symptoms onset. We measured SARS-CoV-2-specific IgG and IgA avidity, neutralizing activity, and antibody-dependent cellular phagocytosis (ADCP) and cytotoxicity (ADCC).
Results: Group S had higher levels of anti-Spike IgA (p=0.0109), and anti-S2 IgA and IgG than Group M (p=0.0019 and 0.0076, respectively). No differences in neutralizing activity or avidity were detected between groups. Additionally, Group S exhibited greater ADCP and ADCC activities against RBD and S2 than Group M (ADCP-RBD: p=0.0167, ADCP-S2: p=0.0096, ADCC-S2: p=0.0244). After adjusting for IgG levels, Group S exhibited a slight reduction in ADCC (ADCC-S2/IgG: p=0.0594) and a modest increase of ADCP activity compared to Group M (ADCP-RBD/IgG: p=0.0563). However, Group S exhibited significantly lower ADCP activity than Group M (ADCP-S2/IgA: p=0.0164), when corrected by IgA levels. These results indicate that S2-specific humoral responses are distinct between those SARS-CoV-2-infected individuals that progress to either severe or mild COVID-19.
Conclusion: Our results demonstrate that individuals experiencing severe COVID-19 develop higher anti-S2 IgG and IgA titers, which are functionally distinct to those with milder COVID-19. Further work should deepen into the role of these antibodies in triggering the proinflammatory cytokine storm linked to the severity of COVID-19.

B cell expression of the complement receptor 2 (CR2/CD21) constitutes a novel biomarker for COVID-19 severity

Ana Marcos-Jiménez[1], Pablo Delgado-Wicke[1], Paula Díaz-Fernández[1;2], Nuria Montes[3], Iris Fernández-Lázaro[3], Rosa M. Andreu-Martínez[1], Noelia López[1], Carlos Cuesta–Mateos[1], Cecilia Muñoz-Calleja[1;2]
[1]Department of Immunology, Biomedical Research Institute La Princesa Hospital (IIS-IP), Madrid; *[2]Universidad Autónoma de Madrid, Madrid, Spain*; *[3]Biomedical Research Institute La Princesa Hospital (IIS-IP), Madrid, Spain*

Purpose: We previously detected a decrease in immunoglobulin (Ig) and complement levels in severe COVID-19 patients, suggesting an unbalanced Ig and complement consumption (Marcos-Jiménez et al.*Eur J Immunol*,2021). As part of the B lymphocyte co-receptor, complement receptor 2 (CR2/CD21) plays an essential role in B-cells function, linking the innate and adaptive humoral immunity. We therefore aimed to study the role of CD21 on B cells as a bridge between complement activation and the early humoral B-cells response in COVID-19 pathogenesis and clinical course.
Methods: Clinical and laboratory parameters of 162 subjects (aged 18-80 years) were collected during the second and third waves of the pandemic in Madrid (Spain), along with complement activation products and the serum Igs profile. Among them, we also immunophenotyped B-cells and plasmablasts from healthy donors (n=17) and patients who achieved a mild (n=16), moderate (n=18) or severe/critical/fatal (n=15) outcome, according to the WHO ordinal clinical severity scale.
Results: B-cells immunophenotyping revealed that their CD21 expression is lower in patients than in healthy donors. By performing ROC analysis, we established a cut-off point that distinguishes mild from moderate/severe patients. Multivariate analysis confirmed that CD21 expression at admission predicts disease severity (OR 0.059, p=0.003) and length of hospitalization (OR 0.0520, p=0.007). The significant variables in each multivariate model were considered to calculate the predicted probabilities of final outcome and hospitalization length, which showed that patients in the $CD21^{high}$ group are more likely to have milder disease and a hospitalization period of ≤ 7 days. In addition, in comparison with mild patients, moderate and severe/critical patients failed to increase the proportion of $IgG1^{+}$-plasmablasts after 5 days of hospitalization. Accordingly, specific α-RBD Ig levels on day 10 were lower in severe/critical patients than in milder/discharged ones.
Conclusion: Our results support the determination of CD21 expression on B-cells as an early prognostic biomarker for worse clinical course and a longer hospitalization period. From a practical point of view, this could represent a new tool for hospital management optimization. We are currently validating the results in other respiratory infections and investigating whether CD21 low expression associates with less effective humoral responses.

Interleukin-36γ is causative for liver damage upon infection with Rift Valley fever virus in type I interferon receptor-deficient mice

Martina Anzaghe[1], Marc A. Niles[1], Eugenia Korotkova[1], Dominguez Monica[1], Stefanie Kronhart[1], Ingo Bechmann[2], Malte Bachmann[3], Heiko Mühl[3], Georg Kochs[4], Zoe Waibler[1]
[1]Division of Immunology, *Paul-Ehrlich-Institut, Langen, Germany*; [2]*University Leipzig, Medical Faculty, Institute for Anatomy, Leipzig, Germany*; [3]*Pharmazentrum Frankfurt/ZAFES, University Hospital Frankfurt, Frankfurt, Germany*; [4]*Institute of Virology, Medical Center – University of Freiburg, Faculty of Medicine, Freiburg, Germany*

Objectives: Type I interferons (IFN) are pro-inflammatory cytokines which can also exert anti-inflammatory effects via the regulation of interleukin (IL)-1 family members. Several studies showed that interferon receptor (IFNAR)-deficient mice develop severe liver damage upon treatment with artificial agonists such as acetaminophen or polyinosinic:polycytidylic acid.
In order to investigate if these mechanisms also play a role in an acute viral infection, experiments with the *Bunyaviridae* family member Rift Valley fever virus (RVFV) were performed.
Methods and Results: Upon RVFV clone (cl)13 infection, IFNAR-deficient mice develop a severe liver injury as indicated by high activity of serum alanine aminotransferase (ALT) and histological analyses. Infected IFNAR$^{-/-}$ mice expressed high amounts of IL-36γ within the liver, which was not observed in infected wildtype (WT) animals. In line with this, treatment of WT mice with recombinant IL-36γ induced ALT activity. Furthermore, administration of an IL-36 receptor antagonist prior to infection prevented the formation of liver injury in IFNAR$^{-/-}$ mice, indicating that IL-36γ is causative for the observed liver damage. Mice deficient for adaptor molecules of certain pattern recognition receptors indicated that IL-36γ induction was dependent on mitochondrial antiviral-signaling protein and the retinoic acid-inducible gene-I-like receptor. Consequently, cell type-specific IFNAR knockouts revealed that type I IFN signaling in myeloid cells is critical in order to prevent IL-36γ expression and liver injury upon viral infection.
Conclusions: Our data demonstrate an anti-inflammatory role of type I IFN in a model for virus-induced hepatitis by preventing the expression of the novel IL-1 family member IL-36γ.

Anti SARS-CoV2 properties of quinacrine and its analogues identified from Treg regulators screening

Qian Wei[1], Håvard Foyn[1], Saskia Meyer[1;2], Rafi Ahmad[3], Jo Klaveness[4], Johanna Olweus[1;2], Gunnveig Grødeland[2;5], Kjetil Taskén[1;2]
[1]Department of Cancer Immunology, Institute for Cancer Research, Oslo University Hospital, Oslo, Norway; *[2]Institute of Clinical Medicine, University of Oslo, Oslo, Norway*; *[3]Department of Biotechnology, Inland Norway University of Applied Sciences, Hamar, Norway*; *[4]School of Pharmacy, University of Oslo, Oslo, Norway*; *[5]Department of Immunology, Oslo University Hospital, Oslo, Norway*

The COVID-19 pandemic caused by SARS-CoV2 infection resulted in disrupted immune responses in many patients, presenting as increased inflammation and acute respiratory distress syndrome. Regulatory T cells (Tregs) are a subset of CD4 T cells that maintain immune response homeostasis in the body by suppressing effector T cells, which could also inhibit anti-viral immune responses. However, conflicting observations were reported with respect to function and proportions of Tregs relative to severity of COVID-19 infection. In a high-throughput screen to identify small molecules targeting FoxP3$^+$ Tregs in primary T cells, we found that the anti-malaria and anti-inflammatory drug quinacrine could down-regulate FoxP3 and inhibit Treg suppressive function. With a structure related to, yet distinct from, chloroquine and hydroxychloroquine that were evaluated as re-purposing drug during pandemic, we observed that quinacrine also harbored an inhibitory effect on SARS-CoV2 replication in cell-based assays. By checking analogs of quinacrine that were identified by *in silico* prediction, we found that compounds with comparable effects on anti-SARS-CoV2 activity as quinacrine also showed down-regulation on FoxP3. This suggested a shared anti-viral function based on a quinacrine-like compound structure. In contrast, chloroquine and hydroxychloroquine did not affect FoxP3 levels. Next, we examined the effect of a potent quinacrine analog MP4 in Golden Syrian hamsters infected with SARS-CoV2 virus, which demonstrated lower total viral loads in throat swabs and significant lower overall symptoms than the control group. By analyzing the lung samples from SARS-CoV2 infected hamsters, we observed lower FoxP3 levels in the MP4-treated group after 6 days of infection, together with reduced production of IL-4, GM-CSF and IFN-γ. However, after 10 days of treatment, lower IL-10 and higher TNFα were observed, implying recovery of the immune response. Furthermore, we investigated effects of quinacrine and its analog on virus antigen specific T cell responses. Our preliminary data showed that CMV-antigen specific CD8 responses were enhanced by quinacrine and its analog, represented as higher IFN-γ and TNF-α productions. We are investigating effects of our compounds on anti-SARS-CoV2 antigen specific T cell responses in ongoing experiments.

The impact of infection dose on CD8 T cell diversity and differentiation in acute viral infection

Ioana Sandu[1], Natalia Ramirez Comet[1], Wenning Zheng[1], Carmen Gerlach[1]
[1]*Department of Medicine Solna (MedS), Division of Rheumatology, Center for Molecular Medicine (CMM), Karolinska Institutet, Solna, Sweden*

Cytotoxic CD8 T cells are essential in fighting pathogens by differentiating into subsets with specialized functions: short-lived highly cytotoxic effectors, and memory cells with poor effector functions, but with high proliferation and differentiation potentials. While CD8 T cell responses upon infection are very robust at the population level, they are very variable at the clonal level, even for naïve cells expressing the same T cell receptor (TCR).
At the population level, T cell fate (response size and functional state) is influenced by factors such as infection dose, antigen affinity, and the amount of antigen and inflammation. Generally, larger T cell responses are associated with more extensive differentiation, leading to a more cytotoxic fate. Whether response size and T cell function are fully linked remains unknown. Likewise, it is unclear how population-level changes in T cell fate are regulated at the clonal level.
Here, we set out to investigate how different factors influence the relationship between response size and T cell function at the population and clonal level in acute infection in mice. We found that at the population level, whether and how response size and T cell functional state correlates depends on the priming conditions and response kinetics. To investigate how population-level changes in T cell fate are regulated at the clonal level, we made use of the cellular barcoding technology. Naïve OT-I cells carrying a unique heritable barcode were generated by retroviral transduction of thymocytes. We determined the fate of individual T cells by measuring the clone size and the functional states (using CD27 and CX3CR1 expression levels) generated by each clone upon acute viral infection.
Our results show that the infection dose has an impact on the diversity of the clonal responses: a higher virus inoculum induces a higher diversity at the clonal level, but lower clone size disparity. Additionally, the correlation between clonal size and differentiation is increased when a higher dose is used. Understanding how diversity of T cell responses is generated at the clonal level is crucial for improving T cell-based therapies, such as vaccines or chimeric antigen receptor (CAR) T cell therapies.

Purpose: Natural Killer (NK) cells may be deregulated in the lung of critical COVID-19 patients and contribute to the progression and pathology of the disease. NKG2C+ cells represent a subset of NK cells displaying memory-like properties and may specifically respond to antigens. However, alterations in this subset have not been fully elucidated in COVID-19.

Methods: N=19 peripheral blood (PB) and N=9 lung infiltrates from Bronchoalveolar Lavages and Aspirates (BAL-BAS, respectively) from hospitalized COVID-19 patients were recruited. PB from Healthy Donors (HD) were included as controls. Expression of CD56, CD16, NKG2C, CD57, TRAIL, TNFa and CD107a were analyzed in CD45+Lineage (CD3, CD19, CD14) negative NK cells at baseline or after 16h stimulation with SARS-CoV-2 Spike-1 (S1) or nucleoprotein (NP) peptides or with polyI:C. Histological analysis of NKG2C+ in lung tissue from deceased COVID-19 patients was also performed.

Results: Mature NKG2C+CD57+ cells were enriched in CD56lowCD16+ NK cells from blood but not in the lung of COVID-19 patients compared to HD (p=0.006). In contrast, frequencies of NKG2C+CD57- NK memory precursors were higher in pulmonary samples from these individuals (p=0.0052). Consistently, NKG2C+ cells were detected within highly infiltrated areas in lung parenchyma from deceased COVID-19 patients. We observed an increase in these NK precursors in HD exposed to SARS-CoV-2 S1 (p=0.07), while in COVID-19 patients this effect was observed in response to NP (p=0.04). Additionally, such differences in memory NK responses were associated with significantly higher levels of TNFa (p=0.03) and an increased expression of CD107a in NK cells lung samples compared to circulating NK cells (p=0.0303). Furthermore, the killing receptor TRAIL was expressed at higher levels in memory NKG2C+CD57- lung precursors compared to COVID-19 patients' blood (p=0.01). Finally, induction of these markers in memory NK cells from the lung was associated with higher levels of inflammatory parameters such as increased C-Reactive Protein (p=0.0027), Ferritin (p=0.016) and Procalcitonin (p=0.016).

Conclusion: Increased proportions of highly activated TRAIL+TNFa+ memory NKG2C+ in the lungs from critical COVID-19 patients may play a pathological role and represent an attractive target for future therapeutic strategies.

Dual blockade with α-PD-L1 and α-TIGIT antibodies restores immune activation on dendritic cells and T-cells during LCMV chronic infection

María Lázaro-Díez[1], Miguel A Marin[1;2], Valentina Casella[3], Laia Bernad Rosa[1], Eudald Vehí Piqué[1], Ruth Peña[1], Gabriel Felipe Rodríguez-Lozano[1], Enrique Martín-Gayo[4;5;6], Andreas Meyerhans[3;7], Julia G Prado[1;6;8]

Purpose: Chronic viral infections are characterized by sustained immune activation, which promotes the overexpression of inhibitory receptors in T-cells, including PD-1 and TIGIT. The interaction of PD-1 and TIGIT with PD-L1 and CD155 on APCs induces cellular-specific inhibitory signalling. Continuous inhibitory signalling of immune checkpoint pathways drives cellular immune exhaustion in chronic viral infection. Here, we aimed to overcome immune exhaustion by dual-blocking TIGIT and PD-L1 inhibitory pathways in the LCMV murine chronic infection model.
Methods: C57BL/6JOlaHsd mice were infected with $LCMV_{DOC}$ (n=20) or left uninfected (n=5). Once the chronic state is reached 20 days after infection, we administered 3 intraperitoneal doses of single (α-PD-L1; n=5 or α-TIGIT; n=5), combined treatment (α-PD-L1+α-TIGIT; n=5); or saline (n=5). The mice were euthanized 28 days post-infection. Splenocytes were harvested and immunophenotyped for activation markers (CD40, CD86 on DCs and CD11b on T-cells) by flow cytometry. Additionally, we tested a panel of pro- and anti-inflammatory cytokines in serum by ELISA Multiplex. Last, we evaluated viral infectious units by focus-forming assay (FFA) in the spleen.
Results: The dual blockade with α-PD-L1+α-TIGIT significantly increased activation by CD40 and CD86 on DCs (p=0.0077 and 0.0435, respectively). Meanwhile, by single α-PD-L1 blockade, we only observed a trend of CD40 increase on DCs (p=0.0597). Consistently, we found a specific signature of cytokines in animals treated with α-PD-L1+α-TIGIT with significantly higher levels of TNF, TNFRI, RANTES and IL-10. In CD4+ and CD8+ T-cells, α-PD-L1+α-TIGIT and α-PD-L1 blockade significantly increased activation by CD11b expression (p=0.0420, 0.0094 in CD4+; p= 0.0049, 0.0010 in CD8+, respectively). We observed a trend towards an FFU reduction by single α-PD-L1 blockade in the absence of changes for the rest of the conditions. Single blockade with α-TIGIT did not reveal any differences compared to untreated-infected animals.
Conclusion: Our work characterizes the immunoregulatory effect of α-PD-L1+α-TIGIT dual blockade in LCMV chronic viral infection. Our data support an enhanced immune activation of DCs, T-cells and specific cytokine profiles of dual α-PD-L1+α-TIGIT blockade and suggest the combinatorial targeting of both immune checkpoint pathways to reinvigorate immune function in chronic viral infection.

ULBP2-expressing HCMV mutants modulate NKG2D expression and function of CD8+ T cells

Greta Meyer[1;2], Anna R Simes[2;3], Irina Bevzenko[1;2], Jenny F Kuehne[1;2], Jana Keil[1], Kerstin Beushausen[1], Karen Wagner[3], Lars Steinbrück[3], Eva-Maria Borst[3], Martin Messerle[2;3], Christine Falk[1;2;4]
[1]Institute of Transplant Immunology, Hanover Medical School, Hanover, Germany; *[2]FOR 2830 Advanced Concepts in Cellular Immune Control of Cytomegalovirus, DFG, Würzburg, Germany*; *[3]Institute of Virology, Hanover Medical School, Hanover, Germany*; *[4]German Center for Infection Research (DZIF), TTU-IICH (Immunocompromised host), Hanover; Braunschweig, Germany*

Purpose: Solid organ transplant recipients with insufficient HCMV memory T-cell responses are at high-risk of viral reactivation and life-threatening complications due to immunosuppression. Especially for the high-risk group of the HCMV donor$^+$/recipient$^-$ constellation, a protective HCMV vaccine, which is currently not available, would not only reduce the risk for HCMV reactivation and disease in those patients. Therefore, we aim for an effective live-attenuated HCMV that should be able to induce HCMV-specific protective T cells. We attempted to compare the activating and costimulatory NKG2D ligand ULBP2 expressed by HCMV mutants in the presence/absence of immune-evasins for HLA class I molecules (US2-6, US10, US11) that are expected to differ in their ability to activate HCMV-specific CD8$^+$ T cells, respectively.
Methods: In the parental strains TB40 (ΔUS2-US6) or the TB40R containing the immune-evasins US2-US6, the UL16 region was replaced by ULBP2 which is expressed under a weak or strong promotor. Fibroblasts infected with these virus mutants were phenotypic characterized for ULBP2 and HLA class I expression. Co-culture experiments between partially matched virus-infected HFF and human PBMCs, were used to study CD8$^+$ T cell activation and NKG2D receptor modulation was investigated. Further, HCMV-specific CD8$^+$ T cells were analyzed by IFN-γ ELISpot assays
Results: Owing to the presence of US11, downregulation of HLA class I expression occurred in all infected cells. However, the downregulation of HLA class I expression was significantly stronger in TB40R-infected cells due to the expression of US2-6. Moreover, CD8$^+$ T cells were activated by the HCMV variants as evidenced by upregulation of CD69. Upon interaction with ULPB2, a significant down-modulation of NKG2D was observed on CD8$^+$ T cells and the intensity correlated with weak or strong ULBP2 expression. In addition, HCMV-specific CD8$^+$ T cells were found in response to our HCMV mutants, demonstrating high potential of ULBP2-expressing HCMV variants to elicit a cellular immune response. Co-stimulation via the ULBP2-NKG2D axis will be analyzed using the JE6.1 T cell line with fluorescent reporters for NF-κB, AP-1 and NFAT.
Conclusion: A promising approach for HCMV vaccine development is the deletion of HLA class I immune-evasins while expressing the costimulatory ligand ULBP2.

Latent cytomegalovirus infection and age do not affect de novo SARS-CoV-2 specific CD8+ T cell frequencies

Jet van den Dijssel[1;2], Veronique AL Konijn[1;2], Mariël Duurland[1;2], Rivka de Jongh[1;2], Lianne Koets[1;3], Barbera Veldhuisen[1;4], Hilde Raaphorst[5], Annelies Turksma[5], Julian J Freen-van Heeren[5], Maurice Steenhuis[1], Theo Rispens[1;2], C Ellen van der Schoot[1], Marieke van Ham[1;2;6], Rene AW van Lier[7], Klaas PJM van Gisbergen[1;2], Anja ten Brinke[1;2], Carolien E van de Sandt[1;2;8]
[1]Sanquin Research and Landsteiner Laboratory, Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands; *[2]Amsterdam Institute for Immunology and Infectious Diseases, Amsterdam, Netherlands*; *[3]National Screening Laboratory of Sanquin, Research and Laboratory Services, Amsterdam, Netherlands*; *[4]Department of Immunohematology Diagnostics, Sanquin Diagnostic Services, Amsterdam, Netherlands*; *[5]R&D, Sanquin Diagnostic Services, Amsterdam, Netherlands*; *[6]Swammerdam Institute for Life Sciences, University of Amsterdam, Amsterdam, Netherlands*; *[7]Division LAB, University Medical Center Utrecht, Utrecht, Netherlands*; *[8]Department of Microbiology and Immunology, University of Melbourne at the Peter Doherty Institute for Infection and Immunity, Melbourne, Australia*

Immunosenescence, the age-related dysregulated immune response, substantially contributes to reduced vaccine responsiveness, increased susceptibility to viral infections and is associated with higher morbidity and mortality in the elderly. Latent cytomegalovirus (CMV) infections contribute to immunosenescence, characterized by lower CD4:CD8 ratios, increasing terminally differentiated T-cell populations (T_{emra}) and accumulation of CMV-specific memory $CD8^+$ T-cells. To what extent the inflating CMV-specific memory and decreasing naïve T-cell populations may impact the immune response against novel pathogens is not fully understood. The SARS-CoV-2 pandemic presented a unique opportunity to investigate whether CMV-status affects the formation of a *de novo* $CD8^+$ T-cell response against a novel pathogen following primary infection in young and aged individuals.
Here we analysed the impact of CMV status (CMV^+/CMV^-) on the ability to generate *de novo* SARS-CoV-2-specific $CD8^+$ T-cell responses in 41 younger and 39 older convalescent SARS-CoV-2 donors. $CD8^+$ T-cells were analysed for their ability to recognize 35 SARS-CoV-2, 7 CMV, 2 Epstein-Barr virus and 2 influenza virus derived epitopes, restricted by 10 common HLA class-I allotypes, using heterotetramer combinatorial coding combined with phenotypic markers allowing in-depth *ex vivo* profiling of antigen-specific $CD8^+$ T-cell populations.
The frequency of SARS-CoV-2-specific $CD8^+$ T-cells was comparable between all groups regardless of CMV status and was consistent across different SARS-CoV-2 epitopes. Age was the predominant factor associated with a reduction in total $CD8^+$ $T_{naive\text{-}like}$ cells, while both age and CMV infections contributed to an increase in $CD8^+$ T_{emra} cells. Interestingly, SARS-CoV-2-specific $CD8^+$ $T_{naive\text{-}like}$ cells were decreased in older convalescent individuals, with the lowest frequencies observed in older CMV^- individuals. Interestingly, the highest SARS-CoV-2-specific $CD8^+$ T_{emra} and $PD1^+$ populations were observed in older CMV^- individuals, while the SARS-CoV-2-specific $CD8^+$ T_{emra} population of CMV^+ individuals were comparable to those observed in younger individuals regardless of CMV status.
Together, our results demonstrate that age and latent CMV infection do not impact the frequency of *de novo* generated SARS-CoV-2-specific $CD8^+$ T-cells. However, the observed differences in memory phenotypes may indicate that age and CMV status may impact long-term immunity against SARS-CoV-2

Eucalyptus essential oil inhibits cell infection by SARS-CoV-2 spikepseudotyped lentiviral particles

Sara Alonso Fernández[1], Hector F. Pelaez-Prestel[1], Fernando Gonzalez-Martin[1], Pedro A. Reche[1]
[1]*Department of Immunology, Ophthalmology and ORL, School of Medicine, Complutense University of Madrid, Madrid, Spain*

Despite mass vaccination, there is an ongoing emergence of new SARS-CoV-2 variants, resulting in new infections and potential reinfections, so, the virus is still a public health concern. Therefore, research into cost-effective preventive methods is of great value. Essential oils are known for their antimicrobial activity and compared with synthetic drugs, have fewer side effects and are easily accessible to the entire population. Among them, eucalyptus essential oil (EEO) and its main component, eucalyptol, have been shown to have anti-inflammatory properties and antiviral activity against common viruses. In this work, we investigated whether EEO and eucalyptol can prevent infection in an *in vitro* spike-dependent system. First, we determined the cytotoxic effects of these extracts on HEK293T cells by the MTT colorimetric assay. Then, we used SARS-CoV-2 Spike-pseudotyped lentiviral particles to infect hACE2-transfected HEK293T cells, incubating the lentiviral particles with non-toxic concentrations of EEO and eucalyptol. Viral infection was evaluated with a luciferase-based assay. We demonstrate that EEO and eucalyptol incubation decreased the infection rate by approximately 72% and 99%, respectively. In addition, incubation of EEO and eucalyptol with VSV-G pseudotyped lentiviral particles also showed a decreased infection rate on HEK293T cells. Hence, in this study, we report that EEO and eucalyptol are great candidates for preventing viral infection by SARS-CoV-2 through a spike-independent pathway.

Purpose: Hybrid immunity characterizing individuals infected with SARS-CoV-2 before their vaccination regimen was more robust than immunity deriving solely from vaccination. Yet, when the Omicron variant emerged, it infected all vaccinated patient groups due to mutations in the Spike protein. How immunity adapted after Omicron breakthrough infection depending on the hybrid status remains a poorly understood question.
Methods: Using a longitudinal prospective cohort of 714 healthcare workers, we selected individuals with hybrid immunity (n=15) or only vaccination immunity (n=15) before a BA.1 breakthrough infection. Control groups included individuals with hybrid (n=30) or vaccinal (n=15) immunity without breakthrough infection. We investigated antibody levels and functions and analyzed anti-RBD memory B cells phenotype.
Results: The levels of anti-RBD antibodies were increased upon BA.1 breakthrough infection, with a trend toward higher levels in the group with vaccination-induced immunity. Similarly, neutralizing antibodies against Omicron sub-variants were slightly higher in this group. This correlates with an increase in antibody avidity toward the spike protein. In this group, there was also a decrease in memory B cells against the ancestral strain coinciding with an increase in BA.1 specific and cross-reactive memory B cells. However, ADCC was lower in this group, probably as a consequence of class-switching towards IgG4 compared to individuals with hybrid immunity. As expected, the latter individuals also showed the strongest anti-N responses upon breakthrough infection.
Conclusion: Hybrid immunity prevents the dampening of ADCC responses by IgG4 class-switching but slightly limits the emergence of neutralizing antibodies against BA.1 following a breakthrough infection possibly through strong immune imprinting. The recall of the anti-N memory response post BA.1 breakthrough infection among individuals with hybrid immunity underlines the potential of utilizing cross-reactivity between diverse SARS-CoV-2 strains for vaccination purposes.

Funding: This study was supported by ANRS-MIE (Emergen study, grant ANRS-0154 to BL), by ANR (ANRJCJC to TB), institutional grants from INSERM, CNRS, UCBL1, and ENS de Lyon. These different funding sources had no role in study design, collection, analysis, and interpretation of data in the writing of the report and in the decision to submit the paper for publication.

Purpose: A significant portion of patients suffering from hypoxemic SARS-CoV-2 pneumonia, insufficiently controlled by early type I interferon (IFN) immunity in respiratory epithelium, experienced a delayed and prolonged IFN response during hospitalization. Employing a comprehensive approach, we aimed to identify host and viral factors associated with severe COVID-19 in subjects with type I IFN response.
Methods: Prospective collection of blood and nasal samples from mild and critical COVID-19 patients allowed us to compare N-antigenemia, humoral immunity, pulmonary and endothelial damage, virological parameters via metagenomics, and innate immune responses through circulating proteins and transcriptomic markers. Simultaneously, we used a human primary respiratory epithelium model to evaluate the impact of the IFN response on the integrity of the epithelium.
Results: Over 89% of critically-ill patients showed plasma N-protein positivity at ICU admission, with the strongest correlation found between viral particle blood dissemination and a sustained type I IFN response. Additionally, we demonstrated that sustained type I IFN pathway activation can disrupt the respiratory epithelium, facilitating the virus's transition from the respiratory compartment to circulation, thereby involving the host in a detrimental cycle.
Conclusion: These results suggest that viral particles may trigger systemic type I IFN responses, potentially explaining the observed delayed responses in critically-ill patients. Moreover, our results suggest that IFN response is essential for the preservation of respiratory epithelium's integrity. Taking together, these findings underscore the critical importance of the timing and duration of type I IFN immunity in COVID-19.

Financial support. This study received funding from the Agence Nationale de Recherches sur le Sida et les Hépatites Virales (ANRS-0154) and to ANR (ANR-RHU Program ANR-21- RHUS-08 (COVIFERON)) through France 2023 program.

The immune landscape of antiviral responses in multiple sclerosis

Silvia D'Orso[1], Gisella Guerrera[1], Elena Olivieri[1], Mario Picozza[1], Alice Verdiani[1], Marta Pirronello[1], Silvia Corbisiero[1], Manolo Sambucci[1], Daniela Angelini[1], Andrea Misiti[1], Beatrice Lista[1], Carla Tortorella[2], Marco Salvetti[3], Rosella Mechelli[4], Maria Chiara Buscarinu[3], Serena Ruggeri[2], Claudio Gasperini[2], Luca Battistini[1], Giovanna Borsellino[1]

Multiple sclerosis (MS) is an immune-mediated chronic inflammatory disease of the central nervous system. There is a long-lasting association between MS and viral infections, which have profound influences on the immune system. The strong correlation between Epstein-Barr virus (EBV) and MS has recently gained more support. The allostatic perturbation resulting from viral infection is capable of triggering specific antiviral responses that can cause autoimmune reactions and support neuroinflammation through direct and indirect mechanisms. To better understand how the immune system can be modulated and activated by viruses, freshly isolated Peripheral Blood Mononuclear Cells (PBMCs) were drawn for the parallel study of both innate and adaptive immunity in untreated, treated people with MS (pwMS) and healthy donors (HD).

For the study of innate immunity, whole blood was stimulated with R848, mimicking a viral infection. The responses of the innate immune cells were studied by multiparametric flow cytometry analysis, that allowed to investigate 10 myeloid subpopulations and the production of 8 different pro-inflammatory cytokines and chemokines. For the study of adaptive immunity, PBMCs were isolated from whole blood and challenged over night with overlapping peptides pool spanning the entire sequences of several specific viral proteins. To fully capture the antigen-specific T cell response and to maximize sensitivity, two separate assays for the detection of the expression of surface activation-induced markers (AIM) and for intracellular cytokine staining (ICS) were set up to evaluate the immune antiviral responses against Epstein-Barr, Cytomegalovirus (CMV), Influenza and Sars-Cov-2 viruses. This study revealed that untreated MS patients exhibit a robust monocyte response to r848, which is accompanied by an anergic response from DCs. The adaptive immune reactivity to viruses implicated in MS pathogenesis displays varying patterns of responsiveness. In contrast, patients who received a high efficacy immune depleting therapy, showed a significant decrease of EBV virus-specific T cells responses. Collectively, these insights contribute to our understanding of the interplay between viral infections, immune dysregulation, and MS pathogenesis.

Investigating non-structural proteins (NSPs) as novel targets for a SARS-CoV-2 and pan-coronaviridae vaccination

Ruby Fell[1], Tracey Haigh[1], Hannah Bollons[1], Graham Taylor[1], Heather Long[1]
[1]*University of Birmingham, Birmingham, United Kingdom*

Purpose: SARS-CoV-2 vaccine efforts have reduced infection rates and fatalities associated with COVID-19. However, SARS-CoV-2 still poses several challenges. Firstly, the high mutation rate of the major vaccination target, Spike, has led to the evolution of variants of concern able to evade vaccine induced immunity. Preparation for emerging human coronaviridae (HCoV) is also imperative. Therefore, this work aims to investigate targets for pan-coronaviridae vaccination, to provide protection against SARS-CoV-2 alongside current and emerging HCoVs. Specifically, we investigate non-structural proteins (NSPs), characterised by their indispensable roles early in the virus life cycle and high conservation across HCoVs.
Methods: Following in vitro expansion, we assessed the T-cell responses of recently infected individuals to 47 highly conserved peptides, derived from the NSP proteins. Cell lines were first screened for T-cell reactivity to pools of peptides and then screened against the individual peptides comprising the highlighted peptide mix. Intracellular cytokine staining for IFNg was used to determine whether T-cell responses were mediated by CD4+ or CD8+ T-cells. Subsequently, from successfully expanded NSP-specific T-cell lines, T-cell clones were generated by limited dilution cloning and characterised.
Results: Most donors displayed a response to at least one NSP peptide tested. This included responses to several NSP proteins from which peptides were derived, with both CD4+ and CD8+ T-cell responses identified. NSP-specific T-cell clones isolated were of high avidity and restricted through several common HLA alleles.
Conclusion: Responses to highly conserved NSP derived epitopes are common in recently infected individuals. The T-cell epitopes identified in this study are highly conserved across HCoVs and restricted through common HLA alleles, suggesting that T-cell cross-reactivity and therefore pan-coronaviridae reactivity could be likely. Further work is required to assess whether T-cells against these proteins can protect from infection.

Localized Immunological Memory in Cynomolgus Macaques Following SARS-CoV-2 Infection

Green Kim[1], Taehwan Oh[1], YoungMin Woo[1;2], Bon-Sang Koo[1], Seung Ho Baek[1], Eun-Ha Hwang[1], You Jung An[1], June-Young Koh[3], Jinyoung Won[1], Youngjeon Lee[1], Choong-Min Ryu[2;4], Kyung Seob Lim[5], Yujin Kim[1], Jung Joo Hong[1;2]
[1]Korea Research Institute of Bioscience and Biotechnology, Cheongju, Chungcheongbuk, South Korea; *[2]KRIBB School of Bioscience, Korea University of Science & Technology (UST), Daejeon, South Korea*; *[3]Korea Advanced Institute of Science and Technology, Daejeon, South Korea*; *[4]Korea Research Institute of Bioscience and Biotechnology, Daejeon, South Korea*; *[5]Futuristic Animal Resource and Research Center, Korea Research Institute of Bioscience and Biotechnology, Cheongju, Chungcheongbuk, South Korea*

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection induces localized immunological memory, notably within the lungs and lymph nodes of humans. Our study aims to assess if similar observations can be recapitulated in cynomolgus macaques, a model for SARS-CoV-2 infection, and determine whether this model can be used to further investigate the potential of localized immune memory in preventing re-infection. Samples from the upper respiratory tract, blood, spleens, lymph nodes, and lungs of healthy and SARS-CoV-2-infected macaques were analyzed using qPCR, TCID50, flow cytometry, intracellular cytokine staining, and enzyme-linked immunosorbent spot assay. Advanced techniques such as single-cell RNA-sequencing and spatial transcriptomics (ST) were utilized to explore lung-resident immunological memory. Following the resolution of SARS-CoV-2 infection, significant $CD4^+$ and $CD8^+$ T cell responses and germinal center activities were observed in lymphoid and lung tissues, with gene ontology analysis revealing an enhancement in immune and inflammatory response pathways. ST analysis highlighted distinct immune responses within lung structures, notably in inducible bronchus-associated lymphoid tissue and alveoli, emphasizing their crucial role in localized defense against SARS-CoV-2. Our findings confirm that, akin to humans, cynomolgus macaques develop localized immunological memory following SARS-CoV-2 infection, with marked immune activation in lung-specific regions essential for countering reinfection. These findings highlight the critical role of local immune memory in SARS-CoV-2 prophylaxis, providing valuable perspectives for the formulation of targeted immunological interventions and vaccine development.

Quicker and greater innate immune responses correlate with disease severity after controlled influenza infection of healthy adults

Loukas Papargyris[1], Jiayun Xu[1], Claire Broderick[1], Pete Dayananda[1], Ashley Collins[1], Min Kyu Park[1], Stephanie Ascough[1], Satwik Kar[1], Helen Wagstaffe[1], Jun Kwun[1], Richard McKendry[1], Emma Bergstrom[1], Lydia Slater[1], Tini Grauwet[2], Myrsini Kaforou[1], Christopher Chiu[1]
[1]Imperial College London, London, United Kingdom; *[2]SGS Clinical Pharmacology Unit, Edegem, Belgium*

Purpose: Influenza is a respiratory infection the severity of which varies considerably between individuals. Despite extensive research, morbidity and mortality remain high, while pathogenesis and immune determinants of influenza severity in humans are incompletely understood. Controlled human infection (CHI) studies involve the deliberate inoculation with pathogens and has the unique capacity to investigate host responses before, during and after infection while controlling for factors such as virus strain, dose and exposure. Here we report how early post-infection immune responses distinguish symptomatic and asymptomatic infection in volunteers challenged with influenza A(H3N2).
Methods: Healthy adults aged 18-55 years with serum neutralising antibody titres ≤1:20 were enrolled for inoculation with influenza A/Belgium/4217/2015 (H3N2) virus (SGS CPU, Belgium) intranasally, at a dose of $5x10^5$ TCID50 in 0.5ml PBS. Following inoculation, participants were quarantined until day 10 and returned for assessment and sampling at days 14, 28 and 180. Symptoms were monitored using self-reported symptom diaries. Viral load was quantified in nasal lavage fluid by qPCR. Soluble mediators were measured by multiplexed protein assays, cellular responses by flow cytometry and antibodies by ELISA, haemagglutination inhibition assay, and microneutralisation. Transcriptomic analysis was performed using RNA sequencing.
Results: Following inoculation of 27 individuals, 22 (81.5%) developed PCR-confirmed infection while 5 remained uninfected. Eighteen infected participants (81.8%) developed symptoms, with 4 remaining asymptomatic. A consistent pattern of greater and more rapid innate and adaptive antiviral responses was seen in symptomatic participants compared with asymptomatics. Early monocyte and dendritic cell activation correlated positively with symptom scores, soluble mediators, $CD8^+$ T and NK cell proliferation and later antibody responses.
Conclusion: The speed and magnitude of innate responses correlate with positive clinical and later immunological outcomes but also more severe symptoms after influenza infection. These findings suggest that early innate immune responses are a double-edged sword that could be fine-tuned by improved treatments and vaccines to mitigate disease, without preventing viral clearance.

Autoantibodies neutralizing type III interferons are uncommon in patients with severe COVID-19 pneumonia

Martti Vanker[1], Karita Sarekannu[1], Liis Haljasmägi[1], Anne Kallaste[2], Kalle Kisand[2], Margus Lember[2], Pärt Peterson[1], Kai Kisand[1]
[1]Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia; *[2]Department of Internal Medicine, Tartu University Hospital, Tartu, Estonia*

Purpose: Autoantibodies neutralizing type I interferons (IFN) underlie about 15% of cases of critical COVID-19 pneumonia. The impact of autoimmunity towards type III IFNs remains unexplored

Methods: We included samples from 1002 patients with COVID-19 (50% with severe disease) and 1,489 SARS-CoV-2-naïve individuals. We studied the prevalence and neutralizing capacity of autoantibodies towards IFNλ and IFNα. Luciferase based immunoprecipitation method was applied using pooled IFNα (subtypes 1, 2, 8 and 21) or pooled IFNλ1-3 as antigens, followed by reporter cell-based neutralization assay.

Results: In the SARS-CoV-2-naïve cohort IFNλ autoantibodies were more common (8.5%) than those targeting IFNα2 (2.9%) and were less associated with older age. In the COVID-19 cohort the presence of autoreactivity to IFNλ did not associate with severe disease (OR 0.84; 95% CI 0.40-1.73), unlike to IFNα (OR 4.88; 95% CI 2.40-11.06; $p<0.001$). Most IFNλ autoantibody positive COVID-19 samples (67%) did not neutralize any of the three IFNλ subtypes. Pan-IFNλ neutralization occurred in five patients (0.50%), who all suffered from severe COVID-19 pneumonia, and four of them neutralized IFNα2 in addition to IFNλ.

Conclusion: Autoantibodies to type III IFNs are rarely neutralizing, and do not seem to predispose to severe COVID-19 pneumonia on their own.

Screening and Application of SARS-CoV-2 Derived T cell Epitope Spectrum

Yu Zhao[1], Min Peng[1], Suyue Zhu[1], Yandan Wu[1], Fangping Yue[1], Ruixue Ji[1], Yi Wu[1], Guangyu Zhao[2], Chuanlai Shen[1]
[1]Department of Microbiology and Immunology, Medical School of Southeast University, Nanjing, China; *[2]State Key Laboratory of Pathogen and Biosecurity, Beijing Institute of Microbiology and Epidemiology, Beijing, China*

Purpose: Identifying a range of dominant SARS-CoV-2 derived T cell epitopes restricted by most prevalent HLA-A/DR allotypes for developing T cell-based vaccines and evaluating specific cellular immune responses to SARS-CoV-2 in most population.
Methods: We utilized multiple bioinformatics methods to predict candidate epitopes, and collected unexposed donor samples to perform dendritic cell-peptide-peripheral blood lymphocyte coculture experiment to assess the immunogenicity of candidate epitopes. Then, we collected several convalescents' PBMCs to culture with each validated epitope, and defined the HLA restriction and positive rate of epitope in population with prevalent HLA-A/DR allotypes. Several representational epitopes and inactivated virus were combined and generated a cocktail vaccine to immunize in HLA-A2/DR1 transgenic mice, and the humoral and cellular immunity elicited by this vaccine was systemically assessed. Based on ELISpot, we established SARS-CoV-2 specific $CD8^+$ T cell and $CD8^+$ T detection system.
Results: In this study, 93 $CD4^+$ T cell epitopes were screened by modified DC-peptide-PBL cell coculture system using healthy donor PBMCs. Subsequently, 117 $CD8^+$ T cell epitopes that were previously screened and 93 $CD4^+$ T cell epitopes were validated by convalescent individuals, covering most of the Chinese population in terms of HLA allotypes. For HLA-A restricted peptides, 117 of 117 (100%) could induce a specific $CD8^+$ T cell response in at least four samples. For HLA-DR restricted peptides, 91 of 93 (96.5%) could induce a specific $CD4^+$ T cell response in at least one sample. 27 epitopes restricted by HLA-A2 molecule, 19 epitopes restricted by HLA-DR1 molecule, and inactivated virus were combined and generated cocktail vaccine, and it elicited robust humoral and cellular immunity compared to single form vaccine in HLA-A2/DR1 transgenic mice. Moreover, SARS-CoV-2 specific T cell detection system based on ELISpot was established by validated T cell epitopes and exhibited great detection ability in unexposed and convalescent samples.
Conclusion: We screened and validated several SARS-CoV-2 derived T cell epitopes restricted by the most prevalent HLA-A/DR allotypes for facilitating the development of diagnostic, vaccine, and therapeutic measures for COVID-19.

Clinical evaluation of HBV-specific T cell reactivity in CHB patients using a broad-spectrum T-cell epitope peptide library and ELISpot assay

Yandan Wu[1], Ruixue Ji[1], Min Peng[1], Yu Zhao[1], Chuanlai Shen[1]
[1]*Department of Microbiology and Immunology, Medical School of Southeast University, Nanjing, China*

Purpose: The clinical routine test of HBV-specific T cell reactivity is still limited for random patients due to the lack of universal detection kit, thus the clinical implication remains disputed.
Methods: An universal ELISpot assay was set up using a peptide library which consists of 103 functionally validated CD8+ T-cell epitopes spanning overall HBsAg, HBeAg, HBx and HBpol proteins and fits to the human leukocyte antigen polymorphisms of China and Northeast Asia populations. 203 CHB patients were detected, and 33 CHB patients were longitudinally detected for 3 times with an interval of 3-5 months.
Results: Although the numbers of reactive HBV-specific T cells in PBMCs presented a significantly declined trend along with gradually increased serum viral DNA loads, HBsAg, HBeAg and ALT levels in CHB patients, but with a very low negative correlation coefficient (r = -0.21, -0.21, -0.27, -0.079, respectively). HBsAg-, HBpol-, HBx- or HBeAg-specific T cells maintained the tendencies similar to total HBV-specific T cells. NUCs/IFN-α combination led to much more reactive HBV-specific T cells than NUCs monotherapy. NUCs treatment more than 4 years presented higher reactivity of HBV-specific T cells than the NUCs treatment less than one year, especially TMF treatment, but different NUCs at the same treatment duration did not bring different reactivity of HBV-specific T cells. The dynamic numbers of reactive HBV-specific T cells were obviously increasing in CHB patients undergoing routine treatment, and came along with the gradual decline of serum viral DNA, HBsAg, HBeAg and ALT levels. The longitudinal trend of HBV-specific T cells possess an increased predictive power than the cross-sectional detection for liver function progression in CHB patients.
Conclusion: HBV-specific T cell reactivity mainly depends on host immune defense function rather than viral DNA load and antigens level in CHB patients undergoing routine treatment and their dynamic trend is a valued predictor for liver function progression.

Recovery plasma from patients with COVID-19 and intravenous immunoglobulin as rescue passive immunization in SARS-COV-2 infection

Vancho Donev[1], Georgi Nikolov[2]
[1]Bul Bio - NCIPD Ltd., sofia, Bulgaria; *[2]NCIPD, sofia, Bulgaria*

Purpose: To investigate the presence of specific anti-SARS-CoV-2 IgG and IgA antibodies in plasma from donors who recovered from COVID-19 and in IVIG batches produced from plasma collected during COVID-19 pandemic.
Methods and Materials: Donor convalescent plasma samples of 90 individuals collected in the period from 01.2021 to 06.2021 after SARS-CoV-2 infection and 13 batches IVIG derived from human plasma collected from 10.2021 to 03.2022. S1-binding SARS-CoV-2-specific IgG and IgA were determined by semiquantitative ELISA (Euroimmune, PerkinElmer Germany Diagnostics GmbH, Germany). According to the manufacturer's instructions for Etest/E calibrator > 1.1 is defined as a positive result). Neutralizing anti-SARS-CoV-2 antibodies were detected with ProcartaPlex Human SARS-CoV-2 Variants Neutralizing Antibody Panel 6plexl. The assay enables direct comparison of the neutralizing potential of antibodies towards the original wild type virus and five variants B.1.1.529 (o), B.1.617.2 (δ), P.1 (γ), B.1.351 (β), and B.1.1.7 (α). According to the manufacturer's instructions >20% of neutralization is positive result.
Results: Specific IgG was detected in 50/90 samples (55.5%), with levels ranging between 1.12 and 8.37, mean 5.19. Anti SARS-CoV-2 IgA was also detected in 50/90 samples (55.5%), mean (min-max) 5.84 (1.19 - 9.41). The levels of the two types of anti-SARS-CoV-2 specific immunoglobulins did not differ significantly (paired T-test p>0.05) The highest mean result of neutralization was detected against B.1.1.529 (o) (85%) and the lowest mean (54%) against B.1.617.2 (δ).
In IVIG specific IgG were detected in all 13 batches with levels ranging between 4.3 and 12.5, mean 9.3 compared to the control group of 3 batches with levels mean 0.4. The highest mean result (92%) of neutralization was detected against B.1.1.7 (α) and the lowest mean (75%) against P.1 (γ).
Conclusion: The effective use of CCP for passive immunization requires their preliminary examination for the presence and titter of SARS-CoV-2 specific IgG and IgA antibodies. The presence of specific Anti S1-IgG in Intravenous immunoglobulin enables their reliably effective use for passive immunization.

Characterization of a VSVΔG S (SARS-CoV-2) hybrid replicating virus as a possible model of mild COVID-19 disease

Brianna Kelly[1], Nicole Grass[1], Christa Davis[2], Jillian Matlock[1], Jessica Trevors[1], Christopher Ricardson[1;2;3], Saki Sultana[1], Kimberly Brewer[1;2]
[1]Dalhousie University, Halifax, Canada; *[2]IWK, Halifax, Canada*; *[3]Canadian Centre for Vaccinology, Halifax, Canada*

SARS-CoV-2 has a broad spectrum of severity, ranging from mild to fatal. Several unknowns remain about the pathology of SARS-CoV-2, particularly about the dynamics of long COVID-19 (PASC). A limitation in the study of SARS-CoV-2 is the availability of facilities that support risk group 3 research. By using a VSVΔG S hybrid replicating virus, the study of spike-mediated viral migration and pathology can be done in a level 2 lab. This study aimed to characterize the immune effects of VSVΔG S (original) using molecular imaging and immune phenotyping.
This study tested two titres of VSVΔG S (SARS-CoV-2 original): $5x10^4$ PFU/mL and $1x10^5$PFU/mL, administered intranasally at a volume of 30µL per mouse. Naïve and VSVΔG (empty) controls were also used. The K-18 hACE2 mouse model was chosen as its hACE2 expression pattern matches that of humans. Weekly anatomical and fluorodeoxyglucose positron emission tomography (FDG-PET) imaging was used to track increased glucose metabolism as a marker of viral-associated inflammation in a murine model. Flow cytometry (FC) was performed on weekly blood samples and terminal organ cells to investigate immune cell population changes.
Early imaging results show a moderate increase in FDG concentration in lungs of infected mice compared to naïve and VSVΔG controls. Temporal increases in FDG uptake were observed in the heart, lungs, brain, spleen, and kidneys for both infected groups, indicating sustained inflammation up to 4 weeks post-infection. FC data revealed heightened percentages of neutrophils, monocytes, eosinophils, basophils, and NK cells in infected mice. Conversely, CD4+ T cells notably decreased in infected groups versus controls.
Immune cell data suggests a milder disease phenotype compared to literature reports of that produced by full SARS-CoV-2 infection in the same mouse model. Elevated myeloid cells, NK cells, and reduced CD4+ T cells match reports of mild to moderate disease and are associated with PASC. The absence of an animal model for PASC underscores the significance of the findings, as our hybrid replicating virus offers a promising option for *in vivo* study of this phenomenon.

Coinfection of VSVΔG S (SARS-CoV-2 omicron) and E0771.lmb breast cancer results in novel immune phenotypes and increased tumour volumes

Brianna Kelly[1], Nicole Grass[1], Christa Davis[2], Jessica Trevors[1], Jillian Matlock[1], Christopher Ricardson[1;2;3], Saki Sultana[1], Kimberly Brewer[1;2]
[1]Dalhousie University, Halifax, Canada; *[2]IWK, Halifax, Canada*; *[3]Canadian Centre for Vaccinology, Halifax, Canada*

SARS-CoV-2 causes a systemic infection, with many patients experiencing a prolonged effect on the immune system, referred to as post-acute sequelae of SARS-CoV-2 infection (PASC). PASC is still not well understood, and due to the wide range of people affected, can lead to complications with a variety of diseases, including cancer. We have recently demonstrated that a hybrid replicating virus (HRV), VSVΔG, with the omicron spike protein, is a CL-2 pathogen demonstrating immunopathology like a mild SARS-CoV-2 infection/PASC. We wanted to characterize the co-occurrence of a chronic SARS-CoV-2 infection with cancer to understand systemic responses and evaluate disease and therapy responses impacted by infection.
This study used a K18-hACE2 mouse model. A subset of mice were implanted with E0771.lmb breast cancer cells, while others were infected with $1X10^6$PFU/mL of a VSVΔG S (SARS-CoV-2 omicron) HRV. Experimental groups included cancer only, virus only, and both, with infections occurring 3- or 14 days post-implant (representing different cancer stages). Fluorodeoxyglucose positron emission tomography (FDG-PET)/magnetic resonance imaging was performed weekly, and flow cytometry was performed on weekly blood draws and terminal organ harvests.
Co-infection of cancer and VSVΔG S showed increased FDG uptake in tested organs compared to cancer or VSVΔG S alone groups, particularly in the tumours, lymph nodes, and spleen. This corresponded to increased levels of NK cells and decreased CD4+ T cells and plasma cells in the same organs. Furthermore, D14-infected mice have increased macrophages in spleens and tumours. Tumour volumes were increased in combination groups compared to cancer alone, with the D14-infected group showing the largest tumours.
Intact VSV is known to be an oncolytic virus; therefore, the increase in tumour sizes in combination groups was unanticipated. This suggests that observed immune cell changes indicate a more immunosuppressive environment, with cells becoming pro-tumour or senescent. In D14-infected mice, it is possible that the addition of VSVΔG S when tumours were already established pushed the immune system into a state of exhaustion. This work represents valuable steps towards understanding these co-infections.

Mutations within the NS1 immunodominant T cell epitopes of the dengue virus serotype-2 cosmopolitan strain resulting in large outbreaks in Sri Lanka

Dinuka Ariyaratne[1], Shyrar Ramu[1], Ayesa Syenina[2], Diyanath Ranasinghe[1], Chandima Jeewandara[1], Graham Ogg[3], Eng Eong Ooi[2], Neelika Malavige[1;3]
[1]Department of Immunology & Molecular Medicine, Faculty of Medical Sciences/ AICBU, University of Sri Jayewardenepura, Nugegoda, Sri Lanka; *[2]Programme in Emerging Infectious Diseases, Duke-NUS Medical School, Singapore, Singapore*; *[3]MRC Translational Immune Discovery Unit, MRC Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom*

Purpose: Although the dengue virus (DENV) NS1 protein independently causes disease pathogenesis, there are limited data regarding NS1- specific T cell responses. Therefore, we sought to identify immunodominant epitopes within NS1, in individuals with past and acute DENV2 infection alongside mutational analysis of the DENV2 sequences in Sri Lanka to further characterize possible immune escape in these epitopes.
Methods: We utilized IFNγ ELISpot assays to map immune-dominant regions in those with past dengue (n=36) and characterized responding T cell subset by flow cytometry. To explore mutations within the immunodominant T cell epitopes within NS1, DENV2 strains from patients with acute dengue during 2017-2018 (n=59) were sequenced and analyzed. As key mutations were detected in the immunodominant T cell epitopes, we further evaluated the frequency of IFNγ ELISpot responses to the regions in the reference peptide (R22) in those with acute dengue fever (DF=35), dengue haemorrhagic fever (DHF=13) and healthy subjects (n=10). The probable HLA restriction was evaluated using SYFPEITHI (http://www.syfpeithi.de/) epitope prediction program.
Results: Individuals with past dengue (before 2016) showed the highest frequency of responses to a region within the wing domain of NS1(18/36). Out of the wing domain peptides, the highest responses were to the R22 peptide (9/20). This was found to be a CD4+ T cell epitope. However, 2017-2018 DENV2 isolates contained a T164M substitution in this epitope. Remarkably, T cell responses to the R22 bearing the T164M substitution (which we refer to as SL22) elicited a significantly higher frequency of T cell responses (p=0.04) in those with DHF (median10521, IQR 3030-20106 SFU/ million T cells) compared to those with DF (median 4900.6, IQR 615.69-8570.6 SFU/1 million T cells). The SYFPEITHI tool predicted that out the possible HLA restriction of this epitope to be through DRB1*1101(score=24) or HLA-DRB1*0701(score=22).
Conclusion: T cell responses to DENV2 NS1 epitopes were chiefly focused on the highly conserved wing domain region. As those with DHF had a higher frequency of responses to the peptide with the T164M mutation, it would be important to investigate if T cells specific to this region contribute to disease pathogenesis.

Background: There have been concerns about the effect of SARS-CoV-2 on the immune system, especially concerning "long COVID" or post-acute sequelae of COVID-19 (PASC). It has been reported that immunological dysfunction persists in PASC patients for at least 8 months post-COVID, including diminished naïve B cells. Previous studies have found that in acute COVID-19, plasmablasts and double negative B cells (DNs) are elevated and memory B cells are decreased. We studied the levels of different B cell subpopulations in the blood of COVID-19 patients in acute disease and convalescence and with and without PASC.
Methods: We collected a cohort of COVID-19 patients (n = 43) of varying disease severities in 2020-2021. Blood was collected at 1-3 different timepoints and PBMCs were isolated, stained for flow cytometry and analysed using the BD LSRFortessa cytometer. We also surveyed the patients for impaired olfaction as proxy for PASC (PASC+ n = 7, PASC- n = 16, no data n = 20). We divided the samples into acute (<30 d from symptom onset), convalescent (30-120 d) and recovered (>120 d) phases.
Results: We found that transitional, plasma, and plasmablast cells were proportionally higher and anergic, B1 and class switched memory cells lower in acute disease when compared with convalescent/recovered. Transitional cells were also significantly higher and anergic and class switched memory cells lower in the convalescent phase as compared with the recovered. We compared outpatients with inpatients: in acute disease non-switched and switched memory cells, B1 cells and CD21low CD38- cells were lower and plasmablasts higher in the inpatients. In recovered patients, higher proportions of anergic B cells could be found in the inpatients. In comparisons between PASC+ and PASC-, the only significant difference was found in the recovered phase, where naïve B cells were proportionally higher in PASC+ patients.
Conclusions: The B cell response to acute COVID is focused on rapidly acting APCs and maintaining homeostasis by producing new B cells. Memory cells are initially low, possibly due to the germinal center reaction not activating yet. Our finding of higher naive cells in PASC+ patients at 3-12 months post-COVID contrasts previous research.

Primary antibody response after influenza virus infection is first dominated by HA-stem antibodies followed by HA-head antibodies, which then remain stable over years

Jacco Bakx[1], Aafke Aartse[1], Daniella Mortier[1], Petra Mooij[1], Mathieu Claireaux[2;3], Willy M. Bogers[1], Ronald Bontrop[1], Marit J. van Gils[2;3], Gerrit Koopman[1]
[1]Biomedical Primate Research Centre, Rijswijk, Netherlands; *[2]Amsterdam UMC, Amsterdam, Netherlands*; *[3]Amsterdam Institute for Infection and Immunity, Amsterdam, Netherlands*

Current influenza vaccines mainly induce antibodies against immunodominant, but highly variable, parts of the head domain of the hemagglutinin (HA) protein of influenza and therefore need to be updated yearly. New vaccine concepts are being developed that aim to generate broadly cross reactive antibodies against more conserved stem region of the HA protein. In humans, low numbers of stem-binding antibodies are present. However, as influenza exposure in humans is often complex and difficult to trace, it can be challenging to determine the origin of these stem-binding antibodies. Therefore, we investigated the antibody response against HA over time in non-human primates as an influenza naive animal model, that is physiologically and immunologically closely related the human. During initial infection with influenza A/Mexico/InDRE4487/2009 (Mex4487; $H1N1_{pdm2009}$) virus, we observed that the initial antibody response to HA stem in serum is relatively high, but decreases over time. Conversely, the response to the immunodominant HA head region starts low and plateaus at day 56 after challenge. Four years after the initial infection, both the anti-HA head and HA-stem antibody response were maintained at comparable levels to the day 56 values. In conclusion, primary influenza virus infection can result in long lived anti-stem antibody responses.

SARS-CoV-2 infection with the Alpha variant B.1.1.7 induced higher levels of IgG antibodies against spike, receptor-binding domain and nucleocapsid than infection with Wuhan-like variants in a Norwegian prospective, longitudinal COVID-19 household study

Gro Tunheim[1], Marta Baranowska-Hustad[1], Fridtjof Lund-johansen[2], Sabin Bhandari[1], Liva Kukule[1], Thea Kristine Rogne Møller[1], Anna Hayman Robertson[1], Terese Bekkevold[1], Fredrik Oftung[1], Lisbeth Meyer Næss[1]
[1]Division of Infection Control, Norwegian Institute of Public Health, Oslo, Norway; *[2]Department of Immunology, Oslo University Hospital and University of Oslo, Oslo, Norway*

Purpose: SARS-CoV-2 infection leads to a variety of different clinical outcomes. Higher degree of severity and specific symptoms of disease have shown to be associated with higher levels of SARS-CoV-2 binding antibodies. Here, we have studied antibody trajectories in adult participants with mostly mild SARS-CoV-2 infection included in a Norwegian household study between May 2020 and April 2021. We investigated whether the antibody responses were associated with virus variant (Wuhan-like or Alpha (B.1.1.7)), symptoms, severity of disease, or viral load.
Methods: SARS-CoV-2 infection was confirmed by PCR. Questionnaire data and symptom diaries were collected. Serum samples were collected during home visits on days (D) 0, 7, 14, 28, 42 and 180. IgG levels against spike (S), the receptor binding domain (RBD) and nucleocapsid (N) were measured using an in-house multiplex assay based on original Wuhan antigens. Viral load was measured using digital-droplet PCR, and the virus isolates were whole genome sequenced. Antibodies inhibiting RBD-ACE2 interaction were measured as a proxy for neutralizing antibodies. Multivariate longitudinal analyses are ongoing.
Results: In infected individuals (n=107), antibody levels increased over time until D42, and subsequently decreased until D180. Individuals infected with the Alpha variant had higher anti-S, anti-RBD, and anti-N IgG levels, showed greater inhibition of ACE2-RBD-interaction, and had higher viral loads than individuals infected with Wuhan-like variants. Fever and chills were associated with higher levels of anti-N antibodies, whereas high viral load was not. No specific symptoms were associated with higher levels of anti-S or anti-RBD IgG. Self-reporting of more severe disease seemed to be associated with higher anti-N IgG levels and increased inhibition of ACE2-RBD interaction, but these findings were not significant. Further analyses will be conducted.
Conclusion: This study indicates a higher immune activation by the more transmissible Alpha variant compared to earlier virus variants in non-hospitalized COVID-19 cases with mild disease. Moreover, we show that increased severity of disease is associated with increased anti-N-IgG responses, as previously shown for more severe SARS-CoV-2 infection.

The project was funded by the Norwegian Institute of Public Health (NIPH)

Altered frequencies, phenotypes and functions of mucosa-associated invariant T cells and Vδ2+ γδ T cells in patients with severe COVID-19

Julie David[1], Nawal Taher[1], Nicole Wood[1], Eamon Breen[1], Jacklyn Sui[2], Angel George[2], Niall Conlon[2], Cliona Ni Cheallaigh[2], William Mc Cormack[1], Aideen Long[1], Derek Doherty[1]
[1]Trinity Translational Medicine Institute, Dublin, Ireland; *[2]St. James's Hospital, Dublin, Ireland*

Purpose: COVID-19 exhibits a wide spectrum of clinical manifestations ranging from asymptomatic infection to severe respiratory insufficiency and extrapulmonary manifestations. Severe disease is associated with pulmonary inflammation and lymphopenia. We investigated the potential involvement of innate T cells, including invariant natural killer T (iNKT) cells, γδ T cells and mucosa-associated invariant T (MAIT) cells in patients with acute COVID-19.
Methods: Peripheral blood mononuclear cells (PBMC) from 16 patients with severe COVID-19, 22 with moderate disease, 3 with mild disease and 5 healthy donors were recruited from the STTAR biobank at St. James's Hospital, Dublin. The frequencies of MAIT cells, iNKT cells and the Vδ1, Vδ2 and Vδ3 subsets of γδ T cells, their expression of activation, differentiation, exhaustion and homing markers, and their production of interferon-γ (IFN-γ), tumour necrosis factor-α (TNF-α), interleukin-2 (IL-2), perforin, granzyme B and CD154 in response to stimulation with phorbol myristate acetate with ionomycin, anti-CD3 and anti-CD28 antibodies, IL-12 with IL-18 and the Vδ2 T cell ligand (E)-4-Hydroxy-3-methyl-but-2-enyl pyrophosphate (HMB-PP) was analysed by multicolour flow cytometry.
Results: The frequencies and phenotypes of Vδ1, Vδ3 and iNKT cells were similar in healthy donors and in patients with mild, moderate and severe disease. MAIT cell frequencies were significantly reduced in patients with moderate and severe disease and these cells more frequently expressed CD69, PD-1 and CCR6. The production of IFN-γ, TNF-α, IL-2, perforin, granzyme B and CD154 by ex vivo stimulated MAIT cells was similar in the 4 subject groups. The frequencies of Vδ2 T cells were similar in the 4 subject groups but compared to healthy donors, Vδ2 T cells from patients with moderate and severe disease had increased expression of PD-1, but not CTLA-4 or TIM-3. Vδ2 T cells from these patients were impaired in their ability to produce IFN-γ upon activation. However, no differences in the production of TNF-α, IL-2, perforin, granzyme B or CD40L were observed.
Conclusion: MAIT cells and Vδ2 T cells may promote antiviral immunity in patients with COVID-19 but appear to be functionally impaired in patients with severe disease.

Selective autophagy impedes KSHV entry after recruiting the membrane damage sensor galectin-8 to virus-containing endosomes

Katarina Schmidt[1], Charlotte Montespan[1], Laure-Anne Ligeon[1], Harald Wodrich[2], Alexander Hahn[3], Urs Greber[4], Christian Münz[1]
[1]Institute of Experimental Immunology, University of Zurich, Zurich, Switzerland; *[2]Fundamental Microbiology and Pathogenicity, University of Bordeaux, Bordeaux, France*; *[3]German Primate Center, University of Göttingen, Göttingen, Germany*; *[4]Institute of Molecular Life Sciences, University of Zurich, Zurich, Switzerland*

When microorganisms invade host cells and access the cytoplasm, host defense mechanisms are deployed to direct pathogens to degradation by selective autophagy. Kaposi sarcoma-associated herpesvirus (KSHV) is an oncogenic ɣ-herpesvirus associated with several opportunistic malignancies, including the 4th most common cancer in Sub-Saharan Africa, Kaposi sarcoma. Numerous studies have investigated autophagy upon lytic reactivation of KSHV, however autophagy involvement in KSHV entry has remained unexplored. Using *in vitro* infection of human epithelial cell lines, we show that lipidation of the autophagy hallmark LC3 is induced shortly after KSHV entry. When components of the LC3 lipidation complex were depleted, infection increased. Accordingly, nuclear dot protein 52 kDa (NDP52), a receptor of selective autophagy, was recruited to endocytosed viral particles, and its reduction increased KSHV infection. Additionally, virus particles co-localized with both NDP52 and the endolysosome damage sensor galectin-8 upon KSHV entry and depletion of galectin-8 promoted KSHV infection. Using herpes simplex virus, listeriolysin, adenovirus and influenza virus as references, the KSHV data here reveal that, in contrast to what was previously thought about enveloped viruses, KSHV binding to EphA2 by its envelope protein gH could cause endolysosomal membrane damage, akin to non-enveloped viruses and bacteria. Taken together, our study identifies an important antiviral role for galectin-8 in the host cell-autonomous immune response to KSHV infection by recruitment of NDP52 and the autophagy machinery to virus-damaged endosomes. The resulting selective autophagy seems to restrict KSHV entry.

Purpose: Schizophrenia, affecting about 1% of the population, entails higher mortality rates and a lifespan reduction of 10 to 20 years. Around 30% of cases are resistant to conventional antipsychotic treatments, leading to the use of clozapine. While clozapine reduces overall mortality in severe schizophrenia cases, it's linked to various side effects, including a heightened risk of infections and pneumonia. Recent studies suggest that clozapine has immunomodulatory effects. Individuals on chronic clozapine treatment show patterns similar to primary immunodeficiencies, potentially reversible upon drug discontinuation, and inadequate vaccine responses. Given these findings and the COVID-19 pandemic, some studies have reported a higher risk of SARS-CoV-2 infection in individuals with psychotic spectrum disorders treated with clozapine.
This study aims to analyze the immune response to vaccination with the Spike (S) protein of SARS-CoV-2 in schizophrenia patients treated with clozapine, compared to those treated with other antipsychotics.
Methods: The study included 98 patients with schizophrenia and schizoaffective disorder, of whom 69 patients were taking clozapine. Demographic, clinical, and laboratory data were collected from all included patients. Antibodies against the S protein (Ab-S) were tested using the Elecsys® Anti-SARS-CoV-2 S test (Roche Diagnostics International Ltd., Rotkreuz, Switzerland).
Results: No significant differences were found in demographic, clinical, and laboratory data between patients with schizophrenia and schizoaffective disorders on clozapine, compared to those taking other antipsychotics. In the univariate analysis, Ab-S levels were increased in patients with smoking habit (Fold-Change, FC = 5.36, p=0.026) and with > 2 exposures to the virus (FC = 23.42, p < 0.001), and decreased with time since vaccination (Spearman Correlation, SC = -0.443, p<0.001) and with the clozapine dose (SC = -0.278, p=0.021). In the multivariate analysis, a significant decrease in Ab-S levels was observed in patients taking doses >350 mg/day of clozapine compared to those not taking clozapine (FC = 0.49, p=0.041), and to those on <200 mg/day of clozapine (FC = 0.39, p=0.024).
Conclusion: The use of high doses of clozapine in patients with schizophrenia and schizoaffective disorders is associated with a reduced response to vaccination against the S protein of SARS-CoV-2.

Immune recovery biomarkers in PLWH on long-term cART and CD4AC above 500

Damian Vangelov[1], Radoslava Emilova[1], Yana Todorova[1], Reneta Naydenova[1], Ivailo Alexiev[1], Lyubomira Grigorova[1], Nina Yancheva[2], Maria Nikolova[1]
[1]National Center of Infectious and Parasitic Diseases, Sofia, Bulgaria; *[2]Specialized Hospital for Active treatment of Infectious and Parasitic Diseases, Sofia, Bulgaria*

Purpose: Contemporary antiretroviral therapy (cART) has significantly increased the average life expectancy of people living with HIV (PLWH) while not resolving the issue of HIV reservoirs and low-level immune activation. We have previously described mitochondrial mass (MM) and membrane potential (MMP) as possible biomarkers of accelerated immune ageing in cART+ PLWH. The aim of this study was to investigate the applicability of superoxide dismutase activity in plasma (SOD3) and peripheral blood mononuclear cells (PBMC, SOD1) for monitoring of PWLH with complete response to cART.
Methods: Whole blood and freshly isolated PBMC from 20 PWLH (median age 46y, range 28-57y) on long-term cART (median 8.5, range 3-24y) with undetectable HIV VL, and CD4 absolute count (AC) >500 were analyzed. CD45RA, CD25, CD127, CD39, CCR7, CD27, CD28, CD57 and TIGIT expression, as MM and MMP in CD4 and CD8 T cells were analyzed by flow cytometry as previously described (FACSCanto II, BD Biosciences and Thermo Fisher). SOD3 and SOD1 activity were determined with Superoxide Dismutase assay kit (Sigma Aldrich). Statistical analyses were carried out with SPSS v. 23.
Results: In spite of restored CD4AC (median 748.0, range 576-1264), CD4/CD8 ratio largely varied among samples (median 1.12, range 0.5-2.12). Neither SOD1, nor SOD3 activity were associated with CD4/CD8 ratio, age or cART duration. SOD3 activity correlated directly with percentage of Treg (rho=.47, $p<0.05$), while high SOD1 activity was associated with a higher level of functional CD27+TIGIT-CD4 T (rho=0.48, $p<0.05$) and CD39 expression on Treg (rho=.511, $p<0.05$). Interestingly, in the settings of restored CD4/CD8 ratio (>0.9), a higher SOD1 activity correlated with higher CD4 T MM (rho=0.8, p=0.01) and higher MMP in both CD4 (rho=.75, $p<0.05$) and CD8 (rho=.77, $p<0.05$) T cells, while SOD3 was inversely correlated with CD57+ T cell subsets.
Conclusion: CD4/CD8 ratio is not sensitive enough for monitoring of PLWH on long term cART; SOD1, SOD3 and mitochondrial parameters may better describe accelerated immune ageing.

Vδ2 T cells effector response in PLWH and PLWoH up to three months from mpox infection

Eleonora Cimini[1], Eleonora Tartaglia[2], Andrea Coppola[1], Stefania Notari[1], Valentina Mazzotta[3], Giulia Matusali[2], Rita Casetti[1], Germana Grassi[1], Annalisa Mondi[3], Alessandra Oliva[3], Simona Gili[1], Flavia Cristofanelli[1], Massimo Tempestilli[1], Gianluca Prota[4], Enrico Girdardi[5], Fabrizio Maggi[2], Andrea Antinori[3]
[1]Laboratory of Cellular Immunology and Pharmacology, National Institute for Infectious Diseases Lazzaro Spallazani, Rome, Italy; *[2]Laboratory of Virology, National Institute for Infectious Diseases Lazzaro Spallazani, Rome, Italy*; *[3]Clinical and Research Infectious Diseases Department, National Institute for Infectious Diseases Lazzaro Spallanzani, Rome, Italy*; *[4]Biological Bank, National Institute for Infectious Diseases Lazzaro Spallanzani, Rome, Italy*; *[5]Scientific Direction, National Institute for Infectious Diseases Lazzaro Spallazani, Rome, Italy*

Purpose: The first evidence that *Orthopoxviruses* induced the *in vivo*-expansion and the recall of effector innate Vδ2 T-cells was described in a macaque model. Although, it was analysed an engagement of αβ T-cells specific response in patients infected with human monkeypox (mpox), little is known about the role of γδ T-cells during mpox infection. IFN-γ-producing γδ T-cells in the resistance to poxviruses may be a key role in inducing a protective type 1 memory immunity by influencing the effectiveness of vaccines. In this study, we analysed the kinetics of Vδ2 T-cells from symptoms onset (FSO) up to three months after mpox infection.
Methods: Nine MSM subjects (4 PLWH and 5 PLWoH) with confirmed mpox, were enrolled in a longitudinal study from May to July 2022. PLWH were all viro-immunologically suppressed. Blood samples were collected in the early phase of infection (T1) and at 3 months (T3) FSO. Vδ2 T-cells profile (CD45RA/CCR7), activation/exhaustion markers expression (CD38/HLA-DR/CD57/PD-1/TIM-3), cytokines production (IFN-γ/TNF-α) and CD107a expression after non-peptidic antigen stimulation, were assessed by multiparametric flow cytometry. Kinetics of Vδ2 T-cells response were compared with 13 healthy donors (HD) matched by sex and age. Mann-Whitney and Wilcoxon tests were used.
Results: At T1, Vδ2 T-cells frequency was lower than HD ($p<0.01$); in addition, an expansion of Effector Memory Vδ2 T-cells was observed ($p<0.002$), paralleled to a decrease of Central Memory Vδ2 T-cells ($p<0.0001$), reaching HD values after T3 FSO. Activation/exhaustion markers were significantly increased at T1 and resulted lower after T3. HLA-DR expression was higher in PLWH than PLWoH. No differences were observed for the other markers according to PLWH/PLWoH stratification. Vδ2 functionality decreased at T1 when compared to HD and it was associated to a CD38 higher expression ($p<0.02$). At T3, Vδ2 T-cells response was restored and seems linked to TIM-3 expression ($p<0.009$).

Conclusion: The presence of effector/activated Vδ2 T-cells in the early stages of infection and their capability to activate quickly, producing pro-inflammatory cytokines may be useful to enhance the early adaptive response to human mpox for the maintenance of the protective memory/effector T-cells response.

Inflammatory milieu and specific T cells response after three months and one year from SARS-CoV-2 infection

Eleonora Cimini[1], Claudia Cimaglia[2], Eleonora Tartaglia[3], Marta Camici[4], Stefania Notari[1], Francesca Colavita[3], Giulia Matusali[3], Ilaria Mastrorosa[4], Valentina Mazzotta[4], Pierangelo Chinello[4], Paola Mencarini[4], Maria Letizia Giancola[4], Amina Abdeddaim[4], Rita Casetti[1], Germana Grassi[1], Simona Gili[1], Flavia Cristofanelli[1], Fabrizio Maggi[3], Pierluca Piselli[2], Enrico Girdardi[5], Chiara Agrati[6], Andrea Antinori[4], Alessandra Vergori[4]
[1]Laboratory of Cellular Immunology and Pharmacology, National Institute for Infectious Diseases Lazzaro Spallazani, Rome, Italy; *[2]Clinical Epidemiology Unit, National Institute for Infectious Diseases Lazzaro Spallanzani, Rome, Italy*; *[3]Laboratory of Virology, National Institute for Infectious Diseases Lazzaro Spallazani, Rome, Italy*; *[4]Clinical Department, National Institute for Infectious Diseases Lazzaro Spallanzani, Rome, Italy*; *[5]Scientific Direction, National Institute for Infectious Diseases Lazzaro Spallazani, Rome, Italy*; *[6]Unit of Pathogen Specific Immunity, IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy*

Purpose: Post-COVID-19 condition (PCC) is characterized by a plethora of symptoms, whose aetiology is not fully understood. The aim of this study was to analyse inflammatory/coagulative factors and the specific T-cells response to SARS-CoV-2 and investigate if they are associated with the presence of PCC.
Methods: Adult participants, diagnosed with SARS-CoV-2 during 2020-2021 were enrolled. Blood and plasma samples were collected after three (T3M) and 12 months (T12M) post-acute COVID-19. Demographic and clinical data were collected during each visit and structured in an electronic system. Plasma inflammatory (IL-6, IL-8, TNF-a, IL-1b) and coagulative factors (D-Dimer, E-sel, ICAM, VCAM) were tested by Elisa at T3M and T12M. Peripheral blood mononuclear cells (PBMC) were stimulated with Spike (S) and Nucleocapside (N) peptides to analyse SARS-CoV-2 specific T-cells response. IFN-γ production was quantified by Elispot assay. Mann-Whitney/Wilcoxon tests were used.
Results: We included 196 subjects between 2020-2021: 39% female, with a median age of 56.5 years. 78% of them were previously hospitalized for COVID-19. The median time between SARS-CoV-2 infection and the post-COVID evaluation was 86 days (78-91), 34% reported post-COVID symptoms, of which 68% with only 1 symptom. Most symptoms were respiratory (54%), followed by asthenia (30%) and neuropsychological (14%). At T3M and T12M, according with symptoms onset (presence or not), the inflammatory profile generally didn't change (IL-8, TNF-a, IL1b) except for IL-6 which decreased significantly from T3M to T12M (p=0.02), with no differences according to symptoms. All coagulation factors showed a general increase at T12M (D-Dimer: p=0.0002; E-Sel and VCAM: p=0.0001; ICAM-1 p=0.006), independently from symptoms. Spike response was higher than N at T3M (p=0.0009), by reaching the same level at T12M, and was not associated with symptoms. A significant expression of inflammatory/coagulative factors was measured a T12M post-infection.
Conclusions: In this cohort, inflammatory/coagulative milieu analysis showed altered coagulation factors one year after the acute COVID-19, by meaning that SARS-CoV-2-damage lasts for a long time after infection. Moreover, T-cells specific response was detected one year after COVID-19, even though lower than that observed 3 months post-infection, suggesting protective memory T-cells response maintenance overtime.

Immune responses in HSV-2 genital herpes and HSV-2 meningitis: a comparative study

Moa Bjerhem Viklund[1], Alexandra Svensson[1], Marie Studahl[2], Petra Tunbäck[3], Christine Lingblom[4], Azadeh Reyahi[1], Karolina Thörn[1], Kristina Eriksson[1]
[1]Department of Rheumatology and Inflammation research, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden; *[2]Department of Infectious diseases, University of Gothenburg, Gothenburg, Sweden*; *[3]Department of Dermatovenereology, University of Gothenburg, Gothenburg, Sweden*; *[4]Department of Clinical Microbiology, Sahlgrenska University Hospital, Gothenburg, Sweden*

Genital herpes, caused by herpes simplex virus type 2 (HSV-2), is a sexually transmitted infection with a prevalence of 13% worldwide. The main symptoms of HSV-2 are genital ulcers, though some carriers are asymptomatic. In rare cases however, individuals infected with HSV-2 can develop meningitis. It is poorly understood why some individuals develop meningitis, and to what extent the innate and acquired immune system play a role.
To address this question, we use the multivariate method OPLS-DA to identify immune response patterns that differentiate patients with meningitis (n=49) to those with genital herpes (n=38). The multiplex analyses include a panel of HSV-2-induced T cell cytokine responses, innate antiviral cytokine responses and chemokine responses as well as levels of HSV-2 type-specific serum antibodies and antibodies indicating co-infection with herpes simplex virus type 1 (HSV-1). OPLS-DA analysis shows that the immune profile differed significantly between the two different HSV-2 disease outcomes. Both baseline levels of cytokines as well as virus-induced immune responses vary significantly between patients with HSV-2 genital herpes and patients with HSV-2 meningitis and could to 67% explain the differences between these two disease outcomes.

TfR-1 as a potential therapeutic target in severe SARS-CoV-2 infection by mitigating macrophage activation syndrome

Hussam Abd El Halim[1], Wilfried Posch[1], Stefanie Dichtl-Zweimüller[1], Guenter Weiss[2], Doris Wilflingseder[1]
[1]Medical University of Innsbruck - Institute of Hygiene and Medical Microbiology, Innsbruck, Austria; *[2]Medical University of Innsbruck - Department of Internal Medicine II, Innsbruck, Austria*

Purpose: The COVID-19 pandemic has raised questions about the role of iron metabolism due to elevated ferretin levels in severe cases, linking it to hyperferritinemic syndrome and serious conditions like macrophage activation syndrome and septic shock. Thus, in this study we aimed to investigate changes in macrophage iron metabolism in a human primary system, avoiding animal-derived components where possible to mimic the *in vivo* situation. We analyzed key regulators of iron metabolism – Transferrin Receptor (TfR), Ferroprotein 1 (FPN1), Hepcidin, Ferritin, IRP-2, HIF-1, IL-6, IL-1β and IL-10 and examined their gene and protein expression as well as localization upon virus infection.
Methods: M1 macrophages from healthy donors were exposed to SARS-CoV-2 variants of concern (VoC). After 4 to 24 hours (with and without TfR-1-blocking antibody treatment), we performed virus neutralization assays and analyzed pro- and anti-inflammatory cytokine patterns and iron-regulating proteins. Moreover, viral copy numbers were determined by absolute quantification, and virus localization, TfR, and FPN-1 levels were illustrated by confocal microscopy.
Results: SARS-CoV-2 VoCs exhibited different cytokine and iron-regulating protein profiles. While Omicron sub-variants BA.5 and XBB1.5 showed low levels of inflammatory signals and iron regulation, the VoC Delta induced these to significantly higher levels. Thus, Delta exhibited an altered iron regulation. We could illustrate a correlation between pro-inflammatory signals mediated by Delta and altered iron regulation. If blocking TfR-1, IL-6 production was signifincantly reduced in Delta-exposed M1 macrophages, suggesting its potential as a therapeutic target during SARS-CoV-2 infection, dysregulated iron homeostasis, and associated cytokine storm.
Conclusion: Within a primary, human macrophage model, we demonstrated that SARS-CoV-2 variants differently shape pro- and anti-inflammatory signals, crucial for cellular iron balance, in M1 macrophages. In particular, Delta, which was associated with more severe COVID-19 compared to the more recent Omicron variants, exerted an altered inflammatory pattern and iron regulation with signs of TfR retention and macrophage activation syndrome, thus highlightening TfR-1 as potential therapeutic target.

Interleukin-2 responses to whole spike antigen differentiate healthcare workers with frequent symptomatic SARS-CoV-2 infection and asymptomatic infection

Jean Dunne[1], Liam Townsend[2;3], Jacklyn Sui[1], Carla Sanchez Perez[4], William Mc Cormack[4], Gareth Brady[4], Niall Conlon[1;3]
[1]Department of Immunology, St James's Hospital, Dublin, Ireland; *[2]St James's Hospital, Dublin, Ireland*; *[3]School of Medicine, Trinity College Dublin, Dublin, Ireland*; *[4]Trinity Translational Medicine Institute, Trinity College Dublin, Dublin, Ireland*

Purpose: Healthcare workers (HCWs) are at increased risk of SARS-CoV-2 infection. A proportion of HCWs develop frequent symptomatic COVID-19 despite vaccination, while others have no evidence of historic infection or symptomatic disease. We propose that differences in polyfunctional T cell responses contribute to different disease phenotypes, with highly functional cellular immune responses in asymptomatic individuals allowing rapid virus clearance and preventing the development of clinical disease.
Methods: The PRECISE Study, established in 2020, is a multi-centre longitudinal HCW cohort study investigating serological and clinical parameters of COVID-19 infection. Nucleocapsid antibody levels were measured in October 2020, April 2021, November 2021, and December 2022. HCWs reporting no prior SARS-CoV-2 infection with negative anti-N antibodies at all timepoints were considered never-infected/asymptomatic, while those with positive anti-N antibodies and more than one COVID-19 infection between December 2022 and September 2023 were considered frequent infections. Whole blood stimulation assays were used to measure the cellular response to spike antigens of the Wuhan, Delta (B.1.617) and Omicron (BA.2, BA.2.75, BA4/5, XBB.1.5, BQ.1.1) variants of SARS-CoV-2, with supernatant IFNγ and IL-2 levels measured after 24 hours. Univariate analysis with Chi-squared and Mann-Whitney U tests were used to assess differences in demographics and immunological outcomes.
Results: N=15 frequent infections and n=19 asymptomatic/never infected were recruited between November 2023 – January 2024. Repeat anti-N antibody testing demonstrated that n=10 of the never infected had developed detectable levels, suggesting asymptomatic infection since prior testing in December 2022. There were no differences in age (U=120.5, p=0.45), sex (χ^2=0.60, p=0.44) or COVID-19 vaccine status (χ^2=0.12, p=0.73) between groups. There are no differences in IFNγ responses between the groups to any variant. Frequent infections have a significantly lower IL-2 response to Wuhan (U=51, p=0.001) and XBB.1.5 (U=77, p=0.02), with no significant differences across other variants.
Conclusions: HCWs with frequent infections significantly abrogated IL-2 responses to spike antigen from the original Wuhan strain, and do not demonstrate increased IL-2 responses to Omicron variants, despite likely being infected by these variants. This may support functional T cell defects underling recurrent symptomatic COVID-19 infection in individuals at ongoing risk of SARS-CoV-2 exposure.

Significance of IgE antibodies against SARS-CoV-2 in different clinical conditions

Juan Francisco Delgado de la Poza[1], Indira Bhambi Blanco[1], María Isabel Aparicio Calvente[1], Antoni Berenguer Llergo[2], Albert Rodrigo Parés[2]
[1]Immunology Laboratory. Clinical Laboratories Service. Consorci Corporació Sanitària Parc Taulí. Institut d'Investigació i Innovació I3PT., Sabadell, Spain; *[2]Inflammatory Joint Diseases, Bone Metabolism, and Systemic Autoimmune Diseases Research Group, Consorci Corporació Sanitària Parc Taulí, Institut d'Investigació i Innovació Parc Taulí (I3PT), Sabadell, Spain*

Purpose: COVID-19 appears to have a progression of three stages. The latter stages are characterized by a high level of cytokine release, which in turn triggers an uncontrolled reaction known as cytokine storm. Mast cells are involved in the cytokine storm. The presence of anti-IgE antibodies against SARS-CoV-2 in this phase has been previously reported, and appears to correlate with the severity of the disease. Our study aims to confirm the prognostic significance of IgE antibodies against SARS-CoV-2 across a spectrum of clinical presentations, including asymptomatic cases, individual with mild symptoms, hospitalized patients, and those requiring ICU admission.
Methods: The study included 87 patients distributed into the following groups: 22 critically ill hospitalized individuals (Critical); 21 non-critical hospitalized patients (Severe); 21 mild symptomatic non-hospitalized cases (Mild); and 23 healthy blood donors with samples collected in October 2019. Demographic, clinical, and laboratory data were collected from these patients. Anti-IgE antibodies against Spike (S) protein were detected using a homemade ELISA, where the plate was sensitized with the RBD of recombinant S protein. The cutoff point was established to achieve an assay specificity of 91.3% based on levels in healthy donors.
Results: Among 64 SARS-CoV-2 infected patients, 28.1% tested positive for IgE isotype antibodies against S protein RBD, whose prevalence was similar across severity groups: Mild 23.8%, Severe 28.6%, and Critical 31.8% (p=0.842). Patients with IgE response exhibited higher levels of LDH compared to non-IgE responders, with a 40% increase (p=0.031), and a non-statistically significant increase in other inflammatory markers. The frequency of obesity, dyslipidemia, and intensive care needs were twice as high in non-IgE respondents, with a statistically significant difference observed in dyslipidemia (p=0.027). Conversely, IgE responders were more frequently treated with Remdesivir (4% vs 25%) and twice as high for Tocilizumab, with only the former showing statistical significance (p=0.048).
Conclusion: In SARS-CoV-2 infection, roughly a fourth of patients develops an IgE isotype response. Although this response is homogeneous across different severity groups of patients in the studied cohort, there is an association trend with higher levels of inflammatory parameters, especially LDH and receiving treatment with Remdesivir.

Fluoxetine treatment improves the clinical outcome of age-dependent severe COVID-19

Davide Marotta[1], Chiara Perucchini[2], Marta Grillo[1], Chiara Malpighi[2], Valeria Fumagalli[1;2], Leonardo Giustini[2], Violette Mouro[1], Lorena Donnici[3], Raffaele De Francesco[3], Luca Guidotti[2], Matteo Iannacone[1;2], Marco De Giovanni[1;2]
[1]Università Vita-Salute San Raffaele, Milan, Italy; *[2]San Raffaele Scientific Institute, Division of Immunology, Transplantation, and Infectious Diseases, Dynamics of immune responses, Milan, Italy*; *[3]INGM - Istituto Nazionale di Genetica Molecolare Romeo ed Erica Invernizzi, Milan, Italy*

Severe coronavirus disease 2019 (COVID-19) continues to pose a significant threat, particularly among vulnerable populations such as the elderly and immunocompromised individuals. Coagulopathy and dysregulation of the coagulation cascade are recognized as key risk factors associated with the progression of SARS-CoV-2 infection to severe COVID-19. Additionally, recent studies have shed light on the potential role of platelets in modulating the antimicrobial immune response in various respiratory infection models through the uptake and conversion of serotonin. Notably, fluoxetine treatment, an inhibitor of serotonin uptake in platelets, has shown promise in improving clinical outcomes in COVID-19 patients.
In light of these findings, our study aims to investigate the impact of fluoxetine treatment in an age-dependent severe COVID-19 preclinical model. Specifically, we infected both old and young adult C57BL/6 mice with mouse-adapted SARS-CoV-2, resulting in distinct clinical outcomes based on the age of the mice. Old mice exhibited exacerbated clinical parameters and impaired pulmonary functions, which correlated with increased platelet activation and diminished infiltration of monocytes in the respiratory airways. However, upon preventive fluoxetine treatment, old mice demonstrated an ameliorated clinical outcome comparable to that observed in young adult mice. This phenotype was characterized by reduced weight loss, improved respiratory functions, and a concomitant reduction in platelet aggregation alongside enhanced monocyte infiltration. Results from this study suggest that fluoxetine treatment reverses the age-dependent severity of COVID-19 typically observed in elderly C57BL/6 mice following MA-CoV-2 infection. Our preliminary data indicate that this treatment leads to a reduction in platelet aggregation and activation, along with an increased infiltration of monocytes, which is typically associated with improved COVID-19 outcomes.
In future investigations, our focus will be on elucidating the cellular and molecular mechanisms underlying the observed improvement in clinical outcomes in fluoxetine-treated elderly C57BL/6 mice. Specifically, we aim to investigate whether a potential platelet-monocyte axis may underlie the observed phenotype.

In-depth analysis of Respiratory Syncytial Virus-specific Fc-mediated antibody effector functions in children and adults

Anke Lakerveld[1;2], Rutger Schepp[1], Anne Gelderloos[1], Nynke Rots[1], Puck van Kasteren[1]
[1]National Institute for Public Health and the Environment (RIVM), Bilthoven, Netherlands; *[2]Leiden University Medical Center (LUMC), Leiden, Netherlands*

Respiratory syncytial virus (RSV) infections are a major cause of bronchiolitis and pneumonia in infants and older adults, for which there is no known correlate of protection. Increasing evidence suggests that Fc-mediated antibody effector functions play an important role in protection, but much remains unknown about these functions in different age groups. In light of future vaccination strategies, a clear view of the immunological background and differences between various target populations is of crucial importance. We have previously shown that RSV-specific antibodies of adults are better inducers of antibody-dependent NK cell activation(ADNKA) than those of children, which is not explained by antibody levels. To further investigate this, the current study aims for a further in-depth analysis of RSV-specific serology in children and adults.
Here, we have assessed different aspects of RSV post-F-, pre-F-, and N-specific serum antibodies, including IgG/IgA levels, IgG subclasses, IgG avidity, neutralization titers, antibody-dependent complement deposition(ADCD), cellular phagocytosis(ADCP), and ADNKA. Samples were collected cross-sectionally in 2-year-old children and adults (n=46 per group) in the winter of 2015/2016.
We found that RSV-specific serum IgG levels were generally comparable between children and adults. In contrast, RSV-specific IgA levels and IgG avidity were significantly higher in adults. Additionally, several differences were found in antigen-specific IgG subclasses between children and adults. Furthermore, adults generally show increased antibody functionality (neutralization, ADNKA, and ADCP) compared to children, even after correction for antibody levels. Despite a strong correlation between Fc- effector functions and IgG1 levels, antibody levels alone do not fully explain the observed differences in functionality. IgG avidity does not correlate with Fc-effector functions *within* age groups, but does seem to influence the increased antibody functionality in adults compared to children. Surprisingly, IgG3, known for its high potency in inducing Fc-effector functions, also did not correlate with functionality and was generally lower in adults than children.
Together, these data provide an overview of the functional landscape of RSV-specific serum antibodies in these age groups, highlighting significant differences between children and adults. This knowledge may support the rational design of future vaccination strategies.

The pathogenesis of MIS-C involves a distinct T cell profile compared to pediatric COVID-19 cases

Muhammed Ali Kızmaz[1], Abdurrahman Simsek[1], Tugce Bozkurt[1], Eren Cagan[2], Ali Eren Iskin[1], Ferah Budak[1]
[1]Department of Immunology, Faculty of Medicine, Bursa Uludağ University, bursa, Turkey; *[2]Department of Pediatric Infectious Diseases, Bursa Yuksek Ihtisas Training and Research Hospital, bursa, Turkey*

Purpose: Multisystem inflammatory syndrome in children (MIS-C) presents with fever, inflammation, and multi-organ damage subsequent to infection with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). Despite the typically mild course of SARS-CoV-2 infection in children, the factors contributing to the development of MIS-C remain ambiguous. Recent investigations into COVID-19 have highlighted the pivotal involvement of T cells in orchestrating the immune response. Our study aims to elucidate the potential contributions of cytotoxic T cell subsets (CTL) and regulatory T cells (Tregs) in the pathogenesis of MIS-C.
Methods: 17 MIS-C, 17 pediatric COVID-19 cases and 17 healthy control were included in the study. Flow Cytometry evaluation was performed with a 10-color MoAb panel from peripheral blood samples.
Results: It was observed that effector memory T cells (EM; $CD3^{+}CD8^{+}CD45RA^{-}CCR7^{-}$) were decreased in MIS-C compared with pediatric COVID-19 cases and healthy control group. Effector memory 1 (EM1; $CD45RA^{-}CCR7^{-}CD27^{+}CD28^{+}$) CD8+ T cells increased in MIS-C compared to pediatric COVID-19 cases. Effector memory 2 (EM2; $CD45RA^{-}CCR7^{-}CD27^{+}CD28^{-}$) $CD8^{+}$ T cells decreased in MIS-C compared with pediatric COVID-19 cases and healthy controls. Exhausted CD8+ T cells ($PD\text{-}1^{+}$), naive ($CD45RA^{+}FoxP3^{low}$), activated affector ($CD45RA^{-}$ $FoxP3^{high}$), and nonsuppressive ($CD45RA^{-}$ $FoxP3^{low}$)Treg cells, decreased in MIS-C cases compared with pediatric COVID-19 cases and healthy controls.
Conclusions: The observed decline in the frequency of CD45RA-CCR7- effector memory (EM) CD8+ T cells within peripheral blood, known for their tropism towards non-lymphoid tissues, alongside an augmentation in the rapidly activated CD8+ T cell subsets (EM1, EM2) expressing the co-stimulatory molecule CD28, as well as elevated levels of effector (E) CD8+ T cells, signify notable immunological alterations in patients with MIS-C. Furthermore, the re-expression of CD45RA in antigen-induced senescent T cells, coupled with the downregulation of CD28 and CD27 expression, alongside a reduced abundance of exhausted CD8+ T cells and Tregs, collectively suggest a potential association with sustained inflammatory responses and subsequent multi-organ injury in MIS-C patients.

TLR7 deficiency accelerates severe COVID-19 through reduced IRF7 activation and interferon production

Xuebin Qin[1;2], Chenxiao Wang[1], Shumei Liu[1]
[1]*Tulane National Primate Research Center, Covington, United States*; [2]*Tulane Univeristy School of Medicine, New Orleans, LA, United States*

TLR7 deficiency-accelerated severe COVID-19 is associated with reduced production of interferons (IFNs), a key innate immunity. However, the underlying mechanisms remain elusive. Here, we utilized *Tlr7* and IFN regulatory factor 7 (*Irf7)* deficient mice, single-cell RNA seq, and bone marrow chimerism studies to define the Tlr7 pathway in vivo. The deficiency of *Tlr7* globally or in immune cells accelerated severe COVID-19 via impaired IFN activation in both immune and non-immune cells, leading to an increased lung viral load from 2 to 14-day-post-infection (DPI). IRF7 is specifically activated by TLR7 activation for regulating IFN production at 2 DPI. Despite higher amounts of lung viral antigen, *Tlr7* or *Irf7* deficiency resulted in substantially reduced production of antibodies against SARS-CoV-2, thereby delaying the viral clearance. These results highlight the importance of the activation of *Tlr7* and *Irf7* leading to the IFN production on both the development of innate and adaptive immunity against COVID-19.

Immunological Profile of Long COVID Patients Reveals Persistent Virus-Specific T Cell Response

Ben Goodwin[1], Thiago Cerqueira-Silva[2], Cintia Araujo@Fiocruz.Br[2], Adolfo Hidalgo[3], Marcioa Barreto[2], Blenda Pereira[2], Jessica Jesus-Silva[2], Sara Sara[2], Ana Barreto[4], Ananda Marinho[2], Ricardo Khouri[2;5], Vinicius Maracaja-Coutinho[3], Manoel Barral-Netto[2], Aldina Barral[2], Cristina Cardoso[6], Natalia Tavares[2], Jennifer Dan[1;7], Viviane Boaventura[2;5]
[1]la Jolla Institute for Immunology, San Diego, United States; *[2]FIOCRUZ, Salvador, Brazil*; *[3]University of Chile, Santiago, Chile*; *[4]Hospital Otavio Mangabeira, Salvador, Brazil*; *[5]Federal University of Bahia, Salvador, Brazil*; *[6]Universidade de São Paulo, Ribeirão Preto, Brazil*; *[7]University of California San Diego, San Diego, United States*

Purpose: We aimed to explore the pathogenetic mechanisms underlying Long COVID (LC).
Methods: We conducted a cross-sectional study at a post-COVID-19 center in Brazil from September 2020 to February 2021, involving non-vaccinated individuals with confirmed SARS-CoV-2 infection that were fully recovered or developed LC symptoms. Standardized medical evaluations were performed to collect comprehensive sociodemographic, clinical, and quality of life data, ensuring a well-characterized population. IgG for SARS-CoV-2 RBD, EBV and CMV were measured and Peripheral Blood Mononuclear Cells were obtained and cryopreserved within four hours post-collection. After 24-hour of stimulation with SARS-CoV-2 antigens, CD4+ T cell populations were sorted for single-cell sequencing (scRNAseq) of whole-genome and T-cell receptor (TCR). Pseudobulk analysis was performed to account for dependency across cells of the same individual.
Results: scRNAseq was performed for 18 LC cases and 5 recovered individuals. In naïve CD4+ T cells, we identified a gene expression profile distinctive to LC, that may be potentially useful as a biomarker of LC. In AIM+ CD4+ T cell, 9 genes were significantly upregulated in LC, including IFITM1, a gene that codes interferon-induced transmembrane proteins, implicated in facilitating SARS-CoV-2 invasion. Transcriptional analysis of TCRs revealed that SARS-CoV-2-specific AIM+ CD4+ T cells were more frequently observed in LC patients compared to recovered (median: 8.3% vs 5.1%, p=0.03). However, TCRs specific to other pathogens like CMV and EBV did not show significant differences between the groups, suggesting a selective, ongoing immune response in LC specifically targeted towards SARS-CoV-2. No difference was observed in the serologic analysis of IgG anti- SARS-CoV-2 RBD, EBV and CMV of 76 LC patients and 25 recovered.
Conclusion: These findings suggest a persistent and specific immune activation in individuals with LC, marked by distinct gene upregulation and a prevalence of virus-specific T cells. The absence of a generalized hyperactivation of the immune system suggests a targeted immunological dysregulation in LC. The improved comprehension of T-cell-mediated responses in LC provides new opportunities for therapeutic intervention, potentially guiding precision medicine approaches to manage and treat the long-term sequelae of COVID-19. Further research is essential to explore the utility of these molecules as potential biomarkers for LC.

A new perspective on cellular complement and how opsonized HIV 1 enhances dendritic cell maturation and survival via Mcl-1 stabilization regulated by anaphylatoxin receptors

Gabriel Diem[1], Wilfried Posch[1], Doris Wilflingseder[1]
[1]*Institute of Hygiene and Medical Microbiology, Innsbruck, Austria*

The complement system is an ancient component of innate immunity. Its functions were previously believed to be limited to recruiting other immune cells and recognizing/destroying invading pathogens. However, recent studies have revealed the system's multiple roles in immune regulation and its interaction with other cellular effector systems. Recent evidence indicates that complement has additional functions within the immune system beyond pathogen recognition and immune recruitment.
Monocyte-derived dendritic cells (moDCs) were infected with HIV or complement-opsonised HIV (HIV-C) in the presence or absence of specific inhibitors for 24 hours. The expression levels of complement factors and cathepsins were measured, along with intra- and extracellular anaphylatoxin generation, regulation of anti-apoptotic Bcl-2 family members, as well as cell stress, maturation, and survival.
It was demonstrated that HIV-C promotes elevated anaphylatoxin production, maturation, and increased survival by stabilizing the anti-apoptotic Bcl-2 family member Mcl-1 through phosphorylation at threonine 163. This stabilization is regulated by the interaction of anaphylatoxin C5a and its receptor (C5aR) since inhibition of C5aR impeded this stabilization. The upstream pathways that control this specific phosphorylation event are dependent on MAP kinase and, to a lesser extent, protein kinase C. Inhibition of either pathway resulted in reduced Mcl-1 stabilization. This work demonstrates a complement-dependent mechanism that improves DC survival and maturation. This could represent a novel approach for enhancing antigen presentation and protective immunity against viral infections.

This project was funded by the Austrian Science Fund (FWF number P33510-B13 to Prof. Doris Wilflingseder).

Latent human cytomegalovirus infection is not associated with decreased vaccine effectiveness against SARS-CoV-2 in patients with stage 5 chronic kidney disease

Alexander Jerman[1;2;3], Vanja Persic[2;3]
[1]Sferogen LLC, Ajdovscina, Slovenia; *[2]Dept. of Nephrology, UMC Ljubljana, Ljubljana, Slovenia*; *[3]Medical Faculty, University of Ljubljana, Ljubljana, Slovenia*

Purpose: Human cytomegalovirus (CMV) is associated with immunosenescence and contributes to greater morbidity and mortality. The association with reduced vaccine effectiveness is inconclusive. Recent reports suggest that latent CMV infection decreases vaccine-induced serologic response. Additionally, patients with stage 5 chronic kidney disease experience accelerated senescence and vaccine hyporesponsiveness. We aimed to analyze the association between latent CMV infection in the population with CKD stage 5 and the SARS-CoV-2 infection-free survival after completion of the primary vaccination series.
Methods: We conducted a retrospective, single-center analysis of the time to first confirmed SARS-CoV-2 infection in patients with stage 5 CKD. The study included a healthier subset of patients who were candidates for renal transplantation and whose CMV serostatus was available. Patients with prior SARS-CoV-2 infection and unavailable vaccination data were excluded. Time to first SARS-CoV-2 positive test and vaccine type were recorded, irrespective of the symptoms. Patients were censored at death or transplantation.
Results: We included 263 patients. CMV-negative patients were younger (median 47 vs. 56 years), but otherwise did not differ in terms of sex, diabetes, dialysis vintage, atherosclerosis, and smoking history. While time to first infection was expectedly lower for unvaccinated individuals (log-rank, $p<0.0001$), we observed a better protection with ChAdOx1 vaccine (log-rank, $p = 0.02$). The CMV serostatus was not associated with better vaccine effectiveness (log-rank, $p = 0.61$). In a Cox regression analysis, adjusted for age, latent CMV was not associated with a different risk of infection. Interestingly, when comparing survival curves before VOCs circulated, there was an apparent lower risk of infection in CMV-negative patients. However, the numbers were small and the association was not significant ($p = 0.088$). The effect of booster vaccination was not analyzed.
Conclusion: In our cohort, we found no evidence that latent CMV infection reduced the effectiveness of the anti-SARS-CoV-2 vaccines. Interestingly, there seems to be a non-significant difference in the period before the emergence of VOCs, but the number of cases was small. Given the retrospective design and limited sample size, and not-per-protocol testing, our results remain inconclusive and highlight the need for further research.

Introduction: Post-COVID syndrome (PCS) is a heterogeneous, multisystemic clinical picture that occurs in 5 - 10 % of patients after mild to moderate Coronavirus disease 2019 (COVID-19). Symptoms persist for over three months after severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) infection and include fatigue, postexertional malaise (PEM), respiratory distress, pain, and cognitive dysfunction. A subset of PCS patients meets the Canadian Consensus Criteria (CCC) or the Institute of Medicine (IOM) criteria for the diagnosis of myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS). Evidence suggests immunological dysregulation with studies having identified inflammation, antibody-mediated autoimmunity, vascular inflammation and SARS-CoV-2 persistence as potentially involved pathomechanisms. The lack of diagnostic tests and the prevalence of the disease made this project urgent and important.
Objective: To assess the state of research and own results of single-cell RNA-sequencing (scRNA-seq) analyses, cellular signatures were analyzed by flow cytometry comparatively in PCS/ME/CFS patients and convalescent healthy controls (CHC).
Methods: The suitability of flow cytometric immunophenotyping was investigated by comparison of staining of "untouched" lysed whole blood (WB) and isolated and cryopreserved peripheral blood mononuclear cells (PBMCs) from 9 PCS/ME/CFS patients and 10 CHC 6 - 12 months after SARS-CoV-2 infection. Several panels to characterize immune cell subsets, inflammation and activation markers were applied.
Results: Immunophenotypical alterations were found in PCS/ME/CFS patients, including higher frequencies of CD4+ effector memory T cells and decreased frequencies of CD69+ and CD16+ subsets. Furthermore, frequencies of $CD56_{dim}$ NK cells and CX3CR1+ NK cell subsets were decreased. Frequencies of CXCR4+ monocytes were increased. While the different staining procedures had no impact on immune cell subset alterations of T cells, NK cells, and monocytes, they impacted detection/analysis of activation markers such as CD69 and chemokine receptors CX3CR1 and CXCR4.
Conclusion: Various alterations in immune cell subset frequencies and activation markers were found in PCS/ME/CFS. Further we found that processing procedures impact the expression of activation markers and chemokine receptors, which should be considered in future analyses. The here identified immunological dysregulations in a small cohort of PCS/ME/CFS patients provide a basis for future biomarker research.

Viral infection makes us feel sick. The extent of these changes to our metabolism are relative to the severity of disease. Whether blood glucose levels are subject to infection-induced modulation is largely unknown. Here we show that strong, non-lethal infection restricts systemic glucose availability which promotes the antiviral IFN-I response. Following systemic viral infection of mice, we find that IFNγ produced by γδ T cells directly stimulates pancreatic β-cells to increase glucose-induced insulin release. Subsequently, hyperinsulinemia lessens endogenous glucose output by the liver. Glucose restriction enhances type-I interferon production by curtailing lactate-mediated inhibition of IRF3 and NF-κB signaling. Induced hyperglycemia constrained IFN-I production and increased mortality upon infection. Our findings identify glucose restriction as a physiological mechanism to bring the body into a heightened state of responsiveness to viral pathogens. This immune-endocrine circuit is disrupted in hyperglycemia, which explains why patients with metabolic disease are more susceptible to viral infection.

Myeloperoxidase and Xanthine oxidase in association with T cell subsets of people living with HIV on cART with sustained viral suppression

Radoslava Emilova[1], Yana Todorova[1], Reneta Naydenova[2], Damian Vangelov[1], Lyubomira Grigorova[2], Ivailo Alexiev[2], Nina Yancheva[3], Maria Nikolova[1]
[1]National Reference Laboratory of Immunology, National Centre of Infectious and Parasitic Diseases, Sofia, Bulgaria; *[2]National Reference Confirmatory Laboratory of HIV, National Centre of Infectious and Parasitic Diseases, Sofia, Bulgaria*; *[3]Specialized Hospital for Active Treatment of Infectious and Parasitic Diseases, Sofia, Bulgaria*

Objectives: Xanthine oxidase (XO) and Myeloperoxidase (MPO) play a crucial role in inflammation and oxidative stress in many pathological conditions.
The aim of this study was to evaluate the levels of plasma MPO and XO of people living with HIV (PLHIV) on combined antiretroviral therapy (cART), with sustained viral suppression and to analyze their association with T cell subsets.
Material and Methods: Peripheral blood samples (Li-heparin) were collected from PLHIV (n=27) on cART and age and sex-matched HIV-negative donors (HC, n=11). Plasma HIV viral load was determined by Abbott Real time HIV-1 PCR (LLOD 40 copies/mL). CD4 absolute count (AC), the share of naïve (CD45RA+CCR7+), central-memory (CD45RA-CCR7+), effector-memory (CD45RA-CCR7-), terminal effector (CD45RA+CCR7-) and exhausted (CD57+) CD8+ and CD4+ T were determined by multiparameter flow cytometry. Plasma concentrations of MPO and XO [mU/ml] were measured by fluorometric method.
Results: Despite undetectable viral load (< 40 copies/mL) and similar CD4 AC between groups (903±283 vs. 1057±237, $p>0.05$), CD4/CD8 ratio were significantly lower in HIV+ individuals (1.31±0.46 vs. 2.28±0.71, $p<0.05$).
The difference in MPO concentrations did not reach statistical significance (70±25 vs. 20±15, $p>0.05$) as opposed to XO levels (387±448 vs. 42±33, $p<0.01$).
In PLHIV group a positive correlation between MPO and the shares of terminal effector (CD45RA+CCR7-) CD4, and exhausted CD57+CD8+T cells ($R= 0.5$, $p<0.01$, for both) were observed. Furthermore, negative correlations between MPO and central-memory (CD45RA-CCR7+) CD8+ and CD4+T cells were established ($R=-0.6$, $p<0.03$, for both).
Conclusion: These data suggest that XO and MPO plasma levels may have an important role in the pathways of the regulation on T-cells and immune homeostasis maintenance.

Interference with Co-stimulatory molecule ICOSL by human herpesviruses: impact on antigen presentation and immune evasion

Guillem Angulo[1], Martin Messerle[2], Pablo Engel[1], Ana Angulo[1]
[1]University of Barcelona, Barcelona, Spain; *[2]Hannover Medical School, Hannover, Germany*

Co-signaling molecules play a pivotal role in shaping cellular adaptive immune responses by regulating T-cell activation. Pathogens, in turn, have developed mechanisms to disrupt their signals, dampening host immune responses to facilitate their replication. The inducible co-stimulator (ICOS, CD278), primarily expressed on activated T cells and on T follicular helper cells, enhances T-cell activation and promotes optimal germinal center (GC) formation through binding to its natural ligand ICOSL (CD275). ICOSL is constitutively expressed on antigen-presenting cells such as dendritic cells, macrophages, and B cells, and is upregulated by inflammatory stimuli. Our previous work has shown that the murine cytomegalovirus (MCMV) protein m138/fcr-1 interacts with ICOSL, preventing its cell-surface expression, thereby limiting MCMV-specific T-cell responses and viral control during acute infection.
Here, we demonstrate that human cytomegalovirus (HCMV) infection of primary monocyte-derived macrophages or PMA-differentiated THP-1 cells results in significant and specific downregulation of ICOSL, a process that requires viral gene expression. Kinetic assays performed in THP-1 cells indicated that by 24 hours post-infection ICOSL levels were already drastically reduced. While HCMV lacks an ortholog of m138, performing experiments with GFP-expressing HCMV deletion mutants, we identified one mutant, HCMVΔUS14-US22, which was unable to significantly downmodulate ICOSL in THP-1 cells. The region deleted in this viral mutant encompasses most members of the US12 family of HCMV, encoding distantly related proteins predicted to have seven transmembrane segments and to be related to G-protein coupled receptors. Flow cytometric analysis revealed that cells transfected with US16-GFP exhibited a significant reduction of cell surface ICOSL as compared to untransfected cells, thereby evidencing that the viral protein was capable to mediate these effects by itself, outside the infectious context. US16 is an early protein that localizes intracellularly in the viral assembly compartment and is important for shaping virion composition, affecting HCMV tropism. This viral molecule perturbs cellular ICOSL levels through a lysosomal degradation-independent process. Furthermore, we observed a similar depletion of ICOSL on differentiated THP-1 cells during infection with two α-herpesviruses, HSV-1 and HSV-2. These findings underscore the critical role of the ICOS:ICOSL axis in host defense against various herpesviruses.

Dynamism of anti-SARS-CoV-2 vaccine efficacy studied in mouse model

Peter Nemeth[1], Monika Soos[1], Fanni Földes[2], Tímea Berki[1]
[1]University of Pécs, Department of Immunology and Biotechnology, Pécs, Hungary; *[2]Szentagothai Research Center, Pécs, Hungary*

Purpose: Our development had several objectives: to produce a stable monoclonal antibody with high affinity and high virus neutralizing capacity for research, as well as for diagnostic and potential therapeutic applications. Another objective was to study the time kinetics of the immune response induced by the mRNA-based vaccine in immunized mice.
Methods: We used commercially available recombinant antigens including the spike protein, and an mRNA-based vaccine (Pfizer-BioNTech Comirnaty Covid 19), to immunize 6-8 week old female BALB/c mice. Hybridomas were produced and selected on usual way. Characterization of the clones were made immunserologically by ELISA technique and by Western-blot. The affinity measurement performed by Octet K2 System. Virus neutralization capacity was tested on VeroE6 *in vitro* cultured SARS-CoV-2 virus holding cells.
Results: A significantly higher number of positive (mostly IgM-producing) clones were found among hybridomas from mice immunized with S protein antigens than after mRNA vaccine-based immunization. Among the hybridomas after mRNA immunization, the clones with good affinity head IgG (mostly IgG2a) isotype subclass. Based on the affinity measurements and specific viral neutralizing capacity, subclone 3/H8-H1-D4 (IgG2b) was selected for further studies. The time dynamics of mRNA-based vaccine induced immune reaction was tested immunoserologically and by characterization of hybridomas produced 6 weeks and 30 monts after the immunization. Specific anti-SARS-CoV-2 antibody production was detected in high titer during the whole investigation period, however, hybridomas specific immunoglobulin producing were not able to select from the 30 monts old mice.
Conclusion: Both the S protein antigen and the mRNA vaccine were able to induce intense immune response with high specificity, but the isotype profiles were significantly different after immunization by these two antigens. For testing the long-term efficacy of SARS-CoV-2 vaccines we used BALB/c mice that had been vaccinated with an mRNA-based vaccine two years earlier. Although a high specific anti-SARS-CoV-2 antibody titer was detected in the serum, we were unable to isolate clones with specific antibody production by repeated cloning from the hybridomas obtained by somatic cell hybridization of splenic lymphocytes. Presumably, the long-term memory B cells in old mice are no longer in the spleen but in the bone marrow.

∗ ntessandier@uliege.be

Purpose: Human papillomavirus (HPV) infections drive one in twenty new cancer cases. Despite the potential for improving treatment, screening, and vaccination strategies, little is known as to why most HPV infections clear spontaneously within two years.

Methods: To untangle the dynamics of these non-persisting infections, we performed a combined quantitative analysis of virological, immunological, and clinical data from an original longitudinal cohort of 189 women with high temporal resolution.

Results: We find that HPV viral load reaches a plateau within two months, and clears within a median time of 14 months. Furthermore, we identify immune correlates associated with infection clearance, especially TCR-gamma-delta cells.

Conclusions: Our results open new perspectives for understanding the frontier between acute and chronic infections and for controlling HPV-associated diseases.

Inflammatory signature as an early predictor of severe respiratory viral infection

Eleonora Olivetta[1], Ilaria Schiavoni[2], Annapina Palmieri[3], Pasqualina Leone[2], Angelo Carfì[4], Graziano Onder[4;5], Paola Stefanelli[2], Giorgio Fedele[2]
[1]National Center for Global Health, Istituto Superiore di Sanità, Rome, Italy; *[2]Department of Infectious Diseases, Istituto Superiore di Sanità, Rome, Italy*; *[3]Department of Cardiovascular, Endocrine-Metabolic Diseases and Aging, Istituto Superiore di Sanità, Rome, Italy*; *[4]Fondazione Policlinico Universitario "Agostino Gemelli" IRCCS, Rome, Italy*; *[5]Office of the President, Istituto Superiore di Sanità, Rome, Italy*

Purpose: The aim of this study is to analyse the inflammatory signatures associated to infection caused by emergent and re-emergent respiratory viruses. Host response to viral pathogens may drive an exacerbated inflammatory response, leading to detrimental tissue damage in a dysregulated effort to fight the invading pathogen. Our purpose is to set up *ex vivo* and *in vitro* models to identify predictive biomarkers of pathogenic inflammation induced by Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2), Respiratory Syncytial virus (RSV) and Influenza virus (IV).
Methods: *Ex vivo* experiments were performed on whole blood samples from uninfected adults aged 65 and older visiting the Geriatric Clinic at Agostino Gemelli University hospital, Rome. Exclusion criteria other than an ongoing infection included immunodeficiency/immunodepression, autoimmune disease, cancer, diabetes, chronic obstructive pulmonary disease, obesity, hypertension/coronary artery disease, metabolic syndrome, and inflammatory conditions. Whole blood was stimulated with UV-inactivated RSV (subtype A), IV (H1N1), and SARS-CoV-2 (Wuhan). The expression of 22 genes involved in inflammation and immune response was assayed by RT-PCR array plates.
In vitro models to study respiratory viral infections were established by using the respiratory epithelial cells A549 infected by RSV-A and IV (H1N1) and the A549-ACE-2 cells infected by SARS-CoV-2 (Wuhan). RNA was extracted at different time points to evaluate gene expression.
Results: Whole blood experiments showed the induction of a common type1-IFN response by the three inactivated respiratory viruses in elderly subjects. RSV stimulation was characterized by a unique IL-15 upregulation and by higher chemokines expression. *In vitro* infections of A549 cells showed that IV and RSV share the ability to activate a set of pro-inflammatory genes comprising TNF-α, IL-6, CCL5 and ICAM-1. Experiments on the induction of inflammatory mediators driven by SARS-CoV-2 infection of A549-ACE-2 cells are in progress.
Conclusion: Our results highlighted the induction of a core of common inflammatory genes by three emerging and re-emerging respiratory viruses, albeit virus-dependent disparities in the host response occur. These results are instrumental to wider investigations pointing out to the association between the onset of severe disease and the activation of a divergent immune response.

Human immunodeficiency virus based pseudotype assays overestimate severe acute respiratory syndrome coronavirus 2 neutralising activity in sera from areas of high human immunodeficiency virus prevalence

Mhairi McCormack[1], Louis Banda[2], Stephen Kasenda[2], Abena Amoah[2], Ellen Hughes[1], Chris Davis[1], Agnieszka Szemiel[1], Amelia Crampin[2], Antonia Ho[1], Brian Willett[1]
[1]MRC-University of Glasgow Centre for Virus Research, Glasgow, United Kingdom; *[2]Malawi Epidemiology and Intervention Research Unit, Lilongwe/Karonga, Malawi*

Purpose: Estimating functional humoral immunity requires the measurement of neutralising antibodies. As live virus assays require high-containment level laboratories, pseudotyped virus neutralisation assays (PVNAs) offer a practical, low-containment alternative. While human immunodeficiency virus (HIV)-based PVNAs are used widely due to their ease of manipulation and high dynamic range, their application in high HIV prevalence populations is limited. We assessed the use of HIV-based PVNAs to quantify SARS-CoV-2 neutralisation in HIV-infected sera.
Methods: HIV(SARS-CoV-2) pseudotypes bearing B.1 (ancestral), B.1.351 (Beta), B.1.617.2 (Delta) and BA.1 (Omicron) spikes were used to assess SARS-CoV-2 neutralising activity in sera from a longitudinal cohort in Malawi. Self-reported HIV prevalence in cohort was 4.9% (n=99), 82 of which reported receiving antiretroviral therapy (ART). Sera from HIV-infected participants were re-tested using vesicular stomatitis virus (VSV)-based SARS-CoV-2 pseudotypes (VSV(SARS-CoV-2)). HIV(VSV-G) pseudotypes, bearing the VSV-G protein, were used to confirm the target of any inhibitory activity. Neutralising activity in sera from HIV-infected participants, as measured with HIV- and VSV-based SARS-CoV-2 PVNAs, was then compared with activity estimated using live virus assays. Ethical approval was provided by the Malawi College of Medicine Research Ethics Committee 9P11/20/3177) and the University of Glasgow College of Medicine, Veterinary and Life Sciences Research Ethics Committee (200200056).
Results: Seroprevalence measured using HIV(SARS-CoV-2) PVNAs was significantly higher in HIV-infected participants (85.5-93.9%) compared with HIV-uninfected participants (8.1-54.5%) ($p=0.006$). VSV(SARS-CoV-2) PVNAs suggested a lower seroprevalence (5.6-65.2%) in HIV-infected individuals, indicating potential overestimation by HIV(SARS-CoV-2) PVNAs. HIV-infected participant sera inhibited HIV(VSV-G) pseudotypes (observed in 75.0-87.9% of HIV-infected samples), confirming interference with the HIV vector system. VSV(SARS-CoV-2) PVNA results correlated well with live virus assays in HIV-infected individuals ($r>0.5$), while HIV(SARS-CoV-2) PVNAs showed poor correlation ($r<0$). Among HIV-infected participants, there was no significant difference in HIV- or VSV-based seroprevalence by ART status ($p>0.05$).
Conclusions: HIV(SARS-CoV-2) PVNAs overestimated neutralisation seroprevalence from HIV-infected individuals, independent of ART usage. HIV-based pseudotyped virus assays should therefore not be used in high HIV prevalence cohorts. Protective immunity to many viruses estimated by HIV-based assays is likely over-reported in high HIV prevalence populations.

High titer against OC43 seasonal coronavirus enhances susceptibility to SARS-CoV-2 infections

Hanna Oppenheimer[1], Shosh Zismanov[2], Lilach M. Friedman[2], Lior Nesher[3], Tomer Hertz[2;4]
[1]1.Department of Microbiology, Immunology and Genetics, and the National Institute for Biotechnology in the Negev, Beer Sheva, Israel; *[2]Department of Microbiology, Immunology and Genetics, and the National Institute for Biotechnology in the Negev, Beer Sheva, Israel*; *[3]Infectious Disease Institute, Soroka University Medical Center, and Faculty of Health Sciences, Ben-Gurion University, Beer Sheva, Israel*; *[4]Vaccine and Infectious Disease Division, Fred Hutch Caner Research Center, Seattle, WA, United States*

Several recent studies reported significant associations between the antibody levels against seasonal human coronavirus (hCoV) OC43 and susceptibility to SARS-CoV-2 infection. While in some studies these cross-reactive antibodies were protective, in others they were detrimental, i.e. increased suceptiblity to SARS-CoV-2. Here we studied their potential role using samples from two independent clinical cohorts.
In the first study, we longitudinally tracked 50 participants comprising university staff and students along 9 months. Both symptomatic and asymptomatic viral infections were identified through weekly symptom questionnaires and oronasal swabs. Cornonavirus viral infections, including SARS-CoV-2 and the four seasonal hCoVs (HKU1, OC43, NL63, 229E), were diagnosed using qRT-PCR. Monthly blood samples were collected to facilitate analyses of peripheral blood mononuclear cells (PBMCs), cytokines, and antibodies. Baseline serum samples were sorted according to their IgG or IgA titers to each of the seasonal hCoVs, and SARS-CoV-2 infection rates were compared in the highest and lowest quartiles. We observed a stark contrast between participants in the highest and lowest quartiles for OC43 IgG: All (100%) individuals in the highest quartile were infected with SARS-CoV-2, whereas the infection rate in individuals in the lowest quartile peaked at 50% (Fisher's exact test: OR = 0.000, p = 0.01373). In support of these findings, we found that the baseline and pre-infection anti-OC43 IgG antibody levels of individuals who were subsequently infected with SARS-CoV-2 were significnatly higher than those of individauls who were not infected with SARS-CoV-2 (p=0.019 and p=0.002, respectively).
We then used samples from a multi-center study of 606 healthcare workers folowed over a seven-month period, who were monitored for symptomatic SARS-CoV-2 infections via qRT-PCR. Remarkbly, we observed a similar pattern: Only 52% of individuals with higher anti OC43 IgA titers (highest quartile) were subsequently symptomatically infected with SARS-CoV-2, and 37.5% of individuals in the lowest quartile were infected with SARS-CoV-2 (Fisher's exact test: OR = 0.554, p = 0.0152).
Our findings suggest a potential correlation between elevated OC43 antibody titers in the serum and increased susceptibility to SARS-CoV-2 infections. These observations underscore the intricate interplay between different coronaviruses and shed light on factors influencing susceptibility to viral infections.

Differing systemic and mucosal antibody profiles to SARS-CoV-2 in a vaccinated University cohort- revealing increased male salivary anti-Spike IgA and anti–Spike IgG.

John Mac Sharry[1], Eolann Dinneen[1], Aideen Long[2], Mary Horgan[3], Joshua Flynn[2]
[1]University College Cork, Cork, Ireland; *[2]Trinity College Dublin, Dublin, Ireland*; *[3]University College Dublin, Dublin, Ireland*

Background: Immunity to SARS-CoV-2 induced by RNA vaccines has increased study into the antibody response to both the virus and vaccine targets. We compared the antigen specificity of antibody types in a vaccinated University cohort using rapid and conventional tests to determine systemic and mucosal immunity.
Methods: 472 participants were enlisted and consented over a 3 month period and asked to declare exposure to SARS-CoV-2 in the past 6 months. Serum & Saliva samples were subsequently obtained, and serum screened on site using rapid point of care (POC) tests detecting antibodies to viral nucleocapsid and spike antigens. Subsequent ELISA analysis was used to confirm results and to characterise serum and salivary IgG and IgA.
Results: The survey revealed 54 % (245) of participants believed they had been exposed to SARS-CoV-2 in the past 6 months. However, nucleocapsid antibody POC results revealed that 95% (431) had exposure to SARS-CoV-2 in the past 6 months. Neutralising anti- Spike levels were also assessed using POC tests and ELISA revealing varying levels of protection. Anti-Spike antibody POC images were digitally scored and compared to titrated antibody levels in competitive binding neutralisation assay ELISA revealing a detection level of 62.5 ng/ml equating to 55% competitive binding. Comparison of the serum and saliva by ELISA revealed increased anti-Spike IgA and anti–Spike IgG in male salivary samples compared to female volunteers (186 males vs 286 females) with no difference in serum (systemic) anti-Spike antibody levels.
Conclusions: Detection of antigen specific antibody profiles to SARS-CoV-2 can identify recent exposure and possible waning neutralising immunity. Further study of the differential gender specific antibody immune response at the mucosa is warranted in SARS-CoV-2 biology.

Mathematical modeling of IL-6 driven T lymphocyte cross-talk for the selection of treatment modality in rheumatoid arthritis patients

Nona Janikashvili[1], Nino Nanava[1], Zviad Kalichava[2], Vladimer Odisharia[3], Tinatin Chikovani[1]
[1]Tbilisi State Medical University, Tbilisi, Georgia; *[2]N. Muskhelishvili Institute of Computational Mathematics, Tbilisi, Georgia*; *[3]Iv. Javakhishvili Tbilisi State University, Tbilisi, Georgia*

Mathematical models of immune mediated disorders provide an analytic platform in which we can address specific treatment choice in the vast personalized manner. Our interdisciplinary team has previously reported on the development of a mathematical model of rheumatoid arthritis pathogenesis by determining the progression of the disease over time using a system of non-linear differential equations. The mentioned model considers the inter-relating variables between B and T lymphocytes and, accordingly the level of cartilage damage in the course of the disease.
Objective of the present study was to create the model for rheumatoid arthritis management, in which the different modalities of treatment can be addressed. Still using the approach of non-linear differential equations, we issued the system explaining IL-6 driven cross-talk of pro- and anti-inflammatory CD4+ T cell subsets in the disease course and, based on it, we created the disease treatment model, in which the modalities of treatment with methotrexate and tocilizumab in a separate or combined scheme are considered. In this treatment model, the corresponding Cauchy problem was posed and its solution has been found.
In conclusion, we propose a novel mathematical model that best describes the readouts of the outcomes of different treatment modalities in patients with rheumatoid arthritis and, therefore, may take a rapid pace towards its individualized testing schemes.

Using bioorthogonal chemistry to measure single immune cells metabolic fluxes

Xinyuan Wang[1], Connor Corrigan[1], Sander van Kasteren[2], Linda Sinclair[3], David Finlay[1]
[1]School of Biochemistry and Immunology, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland; *[2]Leiden Institute of Chemistry and the Institute of Chemical Immunology, Leiden University, Leiden, Netherlands*; *[3]School of Life Sciences, University of Dundee, Dundee, United Kingdom*

Purpose: Immunometabolism research is advancing our understanding of how cellular and whole-body metabolism shapes immune responses. Immune cells exhibit highly dynamic physiology, whereby their metabolic and biosynthetic capacities are dramatically regulated in response to immune stimulation and cell activation. The nutrient uptake capability reflects the functional performance of immune cells in diseased environments. However, it is becoming clear that many nutrient uptake discoveries performed using immune cells cultured *in vitro* do not accurately translate to *in vivo* cellular metabolism features. Consequently, there is an urgent need to devise a methodology capable of accurately measuring the nutrient uptake capacities of immune cells at disease sites and visualizing their metabolic characteristics.
Method: Our research introduces a novel metabolic assay utilizing bioorthogonal, or 'click' chemistry that attach fluorophores to the different nutrients after it has been transported into cells. Subsequently coupled with flow cytometry sorting, this approach can be used to investigate how individual cells take up nutrients including amino acids, and long-chain fatty acids, at these sites of disease. This is highly informative because the uptake of nutrients is the first limiting step for cellular metabolism.
Results: The data show that this technology enables us to simultaneously measure the uptake of amino acid into individual immune cells *ex vivo* (Single-Click), as well as effectively assess the new protein synthesis capacity of cells after combining with OP-Puromycin（Double-Click）. Our findings also suggest promising *in vivo* applications of select bioorthogonal nutrient probes, enabling the visualization of nutrient uptake at the disease site with single-cell resolution. Furthermore, our investigations validate the utility of this technique in measuring fatty acid uptake into individual immune cells *ex vivo*. We aim to advance this methodology by developing the 'Triple-Click,' which will offer comprehensive metabolic flux information in up to four dimensions for each analyzed cell.
Conclusion: We are currently employing this approach to enhance our understand of immune cell metabolism across various disease models. By generating the detailed footprint of metabolic alterations in immune cells at the disease site, this research aims to produce novel insights driving innovation towards novel immunotherapies.

Exploring Small Vulnerable Newborn Immune Development in Urban Burkina Faso: Novel Biospecimen Collection Procedures for Flow Cytometery in Low-Income Settings

Lionel Olivier Ouedraogo[1], Simon.J. Tavernier[2], Laeticia Celine Toé[1], Carl Lachat[1], Filomeen Haerynck[2], Trenton Dailey-Chwalibóg[1]
[1]Ghent University, Ghent, Belgium; *[2]Ghent University Hospital, Ghent, Belgium*

Purpose: Newborn mortality remains a key issue worldwide, particularly in low-income contexts. While high-income countries benefit from robust infrastructure and advanced technology to explore infants' immune system development, limited resources hinder similar research in low- and middle-income countries. Our study aims to address this gap by combining local expertise with modern diagnostic tools from high-income countries, allowing effective collection and analysis of fragile biospecimens from urban Burkina Faso.
Methods: In the DenBalo study, 140 pregnant women are be followed up from the third trimester postpartum and divided into control (mothers with full-term neonates) and cases (mothers with small vulnerable newborns) groups after delivery. During the first two months of neonates' lives, non-invasive methods such as finger-prick sampling for mothers and heel-prick sampling for neonates are used to collect ≤ 500 µl blood samples at specific time points. These samples are be stained, preserved in Burkina Faso and shipped to Belgium for advanced analysis including cytokine multiplexing and flow cytometry. The study aims to provide valuable insights into the relatively unexplored area of immune system development in small vulnerable newborns. Immune cell types including dendritic, natural killer, T, B, and Mucosal-Associated Invariant T (MAIT) cells will be examined for their activation, immature, or memory states, along with the exploration of pro-inflammatory cytokines, chemotaxis cytokines, and other immune regulatory cytokines.
This research is a part of a broader study that investigate the interplay between immune system, gut microbiome and breastmilk (ClinicalTrials.gov ID NCT05730569).
Results: Based on the input of expert partners and results from a pilot immunostaining analysis which showed strong signals, standard protocols for blood collection, preservation and immunostaining were created.
Conclusion: The purpose of this presentation is to introduce the scientific community to a novel approach for studying neonates' immune system in low- and middle-income countries through standardizing biospecimen collection and processing, thereby allowing repeatability and reproducibility of experimental results.

This study has been reviewed and approved by the ethical committee of the Ghent University Hospital (B670201734334) and the Burkinabe ethics committee (050-2022/CEIRES). This work is supported by the Bill & Melinda Gates Foundation [INV-004773].

Effector $CD4^+$ T cells are confronted with complex environments when recruited to an infection site. In *Leishmania* skin infections, the situation is even more complex. Monocyte-derived phagocytes, the usual T cell activators, provide the niche for the parasite. This results in heterogenic phagocyte subpopulations with different activation states and pathogen proliferation rates. Whether effector $CD4^+$ T cells can detect the different pathogen proliferation rates and differentially address these cell populations is currently unknown. To spatial and temporally unravel this interplay by we use intravital 2-photon microscopy (IV-2PM) of the infection site and single cell RNAseq.
IV-2PM revealed decreased $CD4^+$ T cell speeds in close proximity (<10µm) to cells harbouring low-proliferating parasites compared to cells carrying high-proliferating pathogens. This suggests are preferred and more stable interaction of effector $CD4^+$ T cells with this subpopulation. Paradoxically, slow replicating *Leishmania* are mainly observed in host cells with an anti-inflammatory transcriptomic profile, while high-proliferating pathogens are prevalent in phagocytic cells exhibiting a pro-inflammatory gene expression.
By exploring on the molecular mechanism of this phenomenon, we focused on genes specifically expressed in such anti-inflammatory pathogen-harbouring phagocytes. Among the highest hits of individually expressed genes was Cathepsin B (CTSB), a protein involved in intracellular processes as well as in remodelling of the extracellular matrix. We demonstrated that knocking out CTSB in monocytes leads to efficient T cell engagement of infected phagocytes and increase their Th1 response. Implying that upregulation of CTSB in host cells result in an immunomodulation in favour of the parasite.
Together the data indicate that in an acute *Leishmania* skin infection it is possible to link pathogen proliferation to the dynamics and activation of effector $CD4^+$ T cells. Insights like this provide a start for informed host-directed therapies to counteract pathogen persistence and ultimately to control infection diseases.

This project was funded by research grants from the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation program (StG ImmProDynamics, grant agreement 714233 to A.J.M and grant 677200 to N.J.) and the German Research Foundation (DFG) (SFB854-B31, MU3744/6-1, and SPP2225 EXIT (MU3744/5-1 to A.J.M.)).

Role of regulatory T cells in the cellular immune response to influenza vaccine in older adults

Monica Espinar Garcia[1], Isabel María Vallejo Bermúdez[1], Maria Ángeles Onieva[2], Ester Irene Reina Alfonso[1], Pablo Álvarez Heredia[1], Carmen María Gutiérrez González[1], Fakhri Hassouneh[1], Inmaculada Salcedo[2], Alejandra Pera Rojas[3], Alexander Batista Duharte[1]
[1]Instituto Maimónides de Investigación Biomédica de Córdoba, Córdoba, Spain; *[2]Hospital Universitario Reina Sofía, Córdoba, Spain*; *[3]Universidad de Córdoba, Córdoba, Spain*

Purpose: Influenza significantly affects the health of older adults, associated with a decrease in the effectiveness of the vaccine. Previous studies have noted increased regulatory T cells (Tregs) potentially limiting vaccine efficacy. However, conclusive evidence remains lacking. Herein, we evaluate the effect of the Treg response in young and old before and after vaccination and its effects on the Th1 and CD8 T response.
Methods: Tregs' influence on influenza vaccination responses in both young and older participants, administered with influenza vaccine, was examined. Flow cytometry was employed to assess their impact on T-helper and CD8+ T cell responses. This analysis involved individuals vaccinated during the 2023/2024 campaign.
Results: After vaccination, older individuals displayed a heightened response of central memory Tregs, indicated by increased frequency in peripheral blood. Both age groups exhibited augmented suppressive activity of Tregs (CD39+) post-vaccination, while older individuals showed reduced response of Helios+ Tregs, suggesting a peripheral induction origin. Conversely, young individuals demonstrated increased proliferation of CD8 T cells (Ki67+). Notably, older individuals maintained a baseline activation profile (Ki67+) in CD8 T cells post-vaccination, implying a response to antigens other than the vaccine. Furthermore, an inverse correlation was observed between effector memory Tregs and the post-vaccination Th1 and CD8 TemRA cell response, mainly in older adults.
Conclusion: These results highlight the adverse influence of Tregs on the vaccine-triggered response of TCD8 and Th1 lymphocytes. Considering the importance of these cell populations in the anti-influenza response, this suggests a detrimental effect of Tregs on the effectiveness of influenza vaccines. Further research is underway to explore additional effects of Tregs on these groups, including specific antibody and cytokine responses.

Establishment of a highly sensitive live-cell imaging-based cytotoxicity assay for functional validation of rare epitope-specific CTLs

Kathrin Wellach[1;2;3], Angelika Riemer[1;2]
[1]Immunotherapy & Immunoprevention, German Cancer Research Center (DKFZ), Heidelberg, Germany; *[2]Molecular Vaccine Design, German Center for Infection Research (DZIF), Heidelberg, Germany*; *[3]Faculty of Biosciences, Heidelberg University, Heidelberg, Germany*

Recognition of pathologically altered cells by cytotoxic T lymphocytes (CTLs) is a prerequisite for successful disease clearance. Thus, many immunotherapeutic approaches, e.g. therapeutic vaccination or adoptive T cell transfer, rely on the identification of specific epitopes. Possible epitopes can be identified *in silico* or by *in vitro* T cell immunogenicity assays. However, their functional validation in cytotoxicity assays can be challenging and often requires the generation of epitope-specific T cell clones. Here, we describe a highly sensitive image-based cytotoxicity assay that allows functional analysis of low-frequency T cells, e.g. from peripheral blood.
To obtain sufficient numbers of effector cells, peptide-specific T cell 14 day-expansion lines are generated from PBMCs, through addition of the peptide of interest and cytokines to support APC activation and T cell proliferation. For the assay setup, $CD8^+$ T cells are enriched by MACS.
In the live-cell imaging-based setup, transient red labeling of the target cells combined with a green caspase 3/7 probe allows reliable measurement of the frequency of apoptotic target cells. Moreover, the time course analysis enables monitoring of subtle differences. To detect the peptide-specific cytotoxicity executed by a small CTL fraction within the population of $CD8^+$ T cells, the frequency of apoptotic target cells in co-culture with specific T cell lines is compared to this frequency observed in co-culture with unspecific T cell lines. Thereby, recognition of naturally presented epitopes can be validated. Alternatively, if the peptide of interest is not presented on the target cells, the same T cell line can be tested in coculture with peptide-loaded and unloaded target cells.
The assay is very flexible and can – due to utilizing a transient dye - easily be adapted to the use of different target cells. In validation experiments with EBV- and CMV-specific CTLs, titration of the fraction of peptide-specific CTLs in the T cell line demonstrated that killing mediated by 0.5% peptide-specific T cells can still be detected. The assay was successfully applied to functionally validate HPV16 epitopes in the context of several HLA-types.
Overall, this cytotoxicity assay setup provides a straightforward approach to assess the cytotoxic ability of rare CTL populations.

Human iPSC-derived Cerebral Organoids as Neuroinflammation Models

Juan Hidalgo de Quintana[1], Zhen Qi[2], Idil Arioz[3], Rosanna Zhang[2]
[1]ACROBIOSYSTEMS, London, United Kingdom; *[2]ACROBIOSYSTEMS, Boston, United States*; *[3]ACROBIOSYSTEMS, Basel, Switzerland*

Neuroinflammation is a multifaceted process involving various cell types and signalling pathways. This complexity makes it challenging to model, overall, including in organoids, which are three-dimensional miniature organs that mimic the structure, organization, and functionality of human organs. One of the challenges has been finding standardized protocols that inherently give rise to microglia, the immune component of the brain that plays a crucial role in neuroinflammation. At ACROBiosystems, we have developed novel, hydrogel-free human iPSC-derived cerebral organoid systems. These organoids inherently contain neurons, astrocytes, oligodendrocytes, microglia, and vascular cells, as verified by RNA-seq and marker immunolabeling. We have functionally validated these organoids in terms of physiological electrical activity, both intracellularly via patch clamp and extracellularly via MEA and silicon probes. Upon LPS stimulation of the cerebral organoids, increased IL-6 cytokine levels were observed. To study neuroinflammation associated with neurodegenerative diseases, we created non-genetic 3D models of Alzheimer's and Parkinson's disease by treating the cerebral organoids with Tau and Alpha-synuclein pre-formed fibrils (PFFs), respectively. Additionally, a small molecule drug, TRx0237, was able to alleviate the high phosphorylation of the Tau upon addition of Tau PFFs. Furthermore, these organoids can be used for AAV-mediated transgene delivery to modify gene expression or investigate therapeutic applications in diseases associated with neuroinflammation. We utilized the three following AAV serotypes to evaluate transgene efficiency using the cerebral organoid model: AAV5-wt, as negative control, IVB-1, and IVB-2. IVB-2 was the most efficient serotype for delivering the eGFP transgene. In conclusion, we outline the use of commercially available ACROBiosystems human iPSC-derived cerebral organoids as improved models to study neuroinflammation. This may help provide better guidance for neuroinflammation research, gene therapy development, disease modeling and drug development.

Predict the response to CD3xBCMA bispecific immunotherapy in multiple myeloma

Nicolas Deredec[1], Lisa Aziez[1], Ismael Boussaid[1;2], Patricia Franchi[2], Michaela Fontenay[1;2], Lise Willems[1;2], Olivier Kosmider[1;2], Justine Decroocq[1;2], Rudy Birsen[1;2], Didier Bouscary[1;2], Nicolas Chapuis[1;2], Marguerite Vignon[2], Yannick Simoni[1]
[1]Université Paris Cité, Paris, France; *[2]APHP – Hopital Cochin, Paris, France*

Background: Recently, the development of engineered bi-specific antibodies opened a new era in immunotherapy. In the context of Multiple Myeloma (MM), bi-specific antibody treatment brings together T cells (CD3 antigen) and tumor cells (BCMA antigen), leading to tumor cells lysis by T cells. Recently, T cells receptor (TCR) analysis in MM patients treated with BCMAxCD3 bi-specific antibodies reveals a clonal expansion of T cells, suggesting an anti- tumoral T cells response induce by this treatment. Overall, these data clearly demonstrate that MM can be targeted by immunotherapy, but treatment efficiency needs to be improved. Therefore, identification and characterization of tumor antigens specific T cells, represent an important axis of research in MM to improve patients' response (e.g. Immune check point inhibitor antibodies, vaccination with tumor antigens...) in combination with the current treatment (i.e. CD3xBCMA bi-specific treatment).
Objectives: Identification and characterization of anti-tumor T lymphocytes in patients at diagnosis and remission, to determine whether the identification of these populations could constitute a predictive marker for the response to this treatment.
Methods: We used mass-cytometry approach to characterize T cells populations.
Results: Our data shows much greater complexity in the CD4 and CD8 T cell population than previously appreciated at early time point. Moreover, we observed a non-uniform pattern of variations across patients tested, which highlights a broad diversity of these cells as previously described. These observations, particularly with respect to markers associated with T cells exhaustion, may help to explain heterogeneity in clinical outcomes following various forms of immunotherapy.
Conclusion: Great diversity of CD4 and CD8 T cells between patients and across time-point following CD3xBCMA bi-specific treatment.

Spatially resolved single-cell metabolic profiling of the melanoma tumor microenvironment using Multiplexed Ion Beam Imaging (MIBI)

Sven Truxa[1], Wiecken Melanie[2], Hassel Jessica[2], Hartmann Felix[1;3]
[1]German Cancer Research Center (DKFZ), Heidelberg, Germany; *[2]National Center for Tumor Diseases (NCT), Heidelberg, Germany*; *[3]German Consortium for Translational Cancer Research (DKTK), Heidelberg, Germany*

Purpose: Melanoma tumors are heterogeneous ecosystems composed of different cell types, including cancer, immune, epithelial and stromal cells. Constant metabolic interactions between these cells within the tumor microenvironment have been linked to the formation of an immunosuppressive niche, poor prognosis, and the development of therapeutic resistance. Despite its relevance, metabolic profiling of human tumors in general is hampered by technological limitations of existing approaches, such as lack of true single-cell resolution, spatial information, and scalability to larger patient cohorts.
Methods: To address this issue, our group employs multiplexed ion beam imaging (MIBI), a novel antibody-based highly multiplexed imaging platform. In MIBI, heavy metal conjugated antibodies are used to measure the expression of up to 40 targets directly in formalin-fixed, paraffin-embedded (FFPE) samples, while providing subcellular resolution over a linear dynamic range of four orders of magnitude. By measuring the expression of carefully curated rate-limiting metabolic regulators as a surrogate for metabolic activity, our approach enables spatially resolved metabolic characterization of individual cells alongside their functional phenotypes in situ.
Results & Conclusions: In the present work, we perform spatially resolved single cell metabolic profiling on a cohort of metastatic melanoma patients (n = 27 patients) stratified for immune checkpoint inhibition. To this end, lineage annotations were thoroughly curated for a dataset of 500,000 cells spanning 12 cell types, and bioinformatic analyses revealed pronounced metabolic heterogeneity among cell types and patients. In ongoing work, we are in the process of compiling a large feature set containing various aspects of metabolic and spatial information. Using this feature set as input for machine learning models, we aim to identify features that predict therapeutic response. Such insights may in the future help to stratify patients into appropriate treatment regimens.

Characterizing the immunometabolism of both the tumor microenvironment and tumor cells at the single-cell level in leukemia

Ekaterina Popova[1], Bailey Leadford[1], Antoine Monteiro[1], Lisa Aziez[1], Ismael Boussaid[1;2], Rudy Birsen[1;2], Michaela Fontenay[1;2], Didier Bouscary[1;2], Nicolas Chapuis[1;2], Yannick Simoni[1]
[1]*Université Paris Cité, Paris, France*; [2]*APHP – Hopital Cochin, Paris, France*

Purpose: Metabolism holds pivotal significance in immunity, serving as the cornerstone of cellular functionality. Distinct metabolic traits delineate various immune cell types and their activation statuses. Nonetheless, the intricacies of immunometabolism remain enigmatic. Targeting metabolic pathways emerges as a promising avenue in immunotherapy, particularly in T lymphocytes, owing to their pivotal role in anti-cancer immunity.
Methods: We devised an antibody panel comprising 23 surface markers for discerning cell subpopulations (including CD4, CD8, exhausted, and senescent cells) alongside 16 metabolic markers and 5 histone marks, delineating the activity of diverse pathways. Mass cytometry facilitated comprehensive data acquisition.
Results: Our findings underscore the efficacy of our methodology in scrutinizing metabolism and histone mark expression at the single-cell level across immune cell subpopulations. Moreover, our assay underwent validation using bone marrow samples from acute myeloid leukemia patients, revealing discrete immune cell and leukemic blast cohorts harboring distinct metabolic profiles.
Conclusion: The potential for metabolic therapeutic interventions to modulate T cell functionality and enhance adaptive metabolism is apparent. However, the translational utility of metabolic therapeutics hinges upon a comprehensive understanding of T cell metabolism under physiological conditions and during immune responses. The outcomes of this study stand to significantly advance our comprehension of T cell metabolic dynamics, thereby fostering advancements in therapeutic research endeavors.

Multiplex immunoassays to visualize immune responses in large population-based cohort studies to increase pandemic preparedness, support disease modelling/eradication and define prevalence of climate sensitive infections

Manuela Harries[1], Daniel Junker[2], Matthias Becker[2], Patrick Marsall[2], Tanja Michel[2], Carolina Klett-Tammen[1], Barbora Kessel[1], Nathalie Fernández Villalobos[1], Max Hassentein[1], Julia Häring[2], Rodiah Isti[1], Gerard Krause[1], Stefanie Castell[1], Lange Berit[1], Alex Dulovic[2], Nicole Schneiderhan-Marra[2], Monika Strengert[1]
[1]Helmholtz Centre for Infection Research, Brunswick, Germany; *[2]NMI Natural and Medical Sciences Institute at the University of Tübingen, Reutlingen, Germany*

Capturing protective immunity or providing differential immunity estimates on population level as part of large epidemiological cohort studies is challenging as currently available methods are not able to capture complex aspects of B-cell driven immune responses such as different isotype or antigenic responses profiles after infection or vaccination
By combining our expertise in infectious disease epidemiology, virology, immunology and assay development, we have developed a comprehensive multiplex immunoassays portfolio to provide such differential immunity estimates in particular for HZI-managed epidemic panels like MuSPAD/RESPINOW or prospectively any other (long-term) cohort study to aid translational (public) health research.
Prime efforts of our work are MULTICOV-AB™ a SARS-CoV-2 immunoassay with over 40 coronavirus antigens including multiple VoCs RBDs and a complementary surrogate neutralization assay RBDCoV-ACE2. Both assays were used to screen more than 100.000 samples and have supplied valuable real-time data to support decision-making in the COVID-19 pandemic by providing seroprevalence estimates and characterizing SARS-CoV-2 (VoC) humoral immunity after infection and vaccination in multiple populations such as children, adults, in indigenous or “difficult to vaccinate”-individuals such as dialysis patients or between mild and severely ill individuals.
A RSV assay shows potential to define population estimators of re-infections to provide input for informed dynamic scenario modelling predicting disease burden, hospitalizations and impact of non-pharmaceutical interventions. A mPOX assay, which includes vaccinia virus antigens, can be used to determine population immunity from previous small pox immunizations towards emerging zoonotic mPOX strains as wells as to assess mPOX prevalence in population-based cohorts. In case of measles, differentiation of vaccination versus infection-induced antibodies could support global elimination efforts, while an assay developed to measure antibody levels towards all currently known hepatitis viruses can support public health efforts to eliminate hepatitis virus-induced diseases and deaths which particularly effect low and middle income countries in a resource-efficient manner. Last, with the on-going climate change and the associated alterations in transmission dynamics, geographic spread, we plan to develop further assay to assess the (re)emergence of vector-borne diseases such as dengue or west nile virus, while an existing borrelia assay already allows to monitor increases in subtype-specific seroprevalence estimates.

Biomechanics of macrophages during interaction with etxracellular stimuli

Massimiliano Galluzzi[1], Zixin Huo[1], Diana Boraschi[1]
[1]*Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, Shenzhen, China*

Purpose: Macrophages are involved in every stage of the immune responses in the body tissues, including the resolution of the inflammatory reaction. The modulation of macrophages' behavior is closely linked with extracellular environment and physicochemical stimulation. Within these stimuli, macrophages are especially sensitive to surface properties, such as mechanical and geometrical characteristics, directly influencing adhesion, migration, and consequently their immune response.
Methods: In this investigation, we combine atomic force microscopy (AFM), finite element modeling (FEM) and quantitative biochemical approaches in order to understand the mechanotransduction from the extracellular matrix (ECM) and phagocytic particles into cellular response. The mechanical cues from the substrate are transduced into the cells through the formation of integrin-regulated focal adhesions and cytoskeletal reorganization, which in turn modulate cell biomechanics by decreasing cell stiffness.
Results: Surface topography and consequent biomechanical response impact the overall behavior of macrophages by increasing movement and phagocytic ability, without significantly influencing their inflammatory behavior. Along with ECM modification, the shape and stiffness of phagocytic particles also influenced the actin cytoskeletal organization, a fundamental process during phagocytosis. In particular, macrophages can exert internal forces able to bend and curl elongated particles with a stiffness of 150 Kpa or less. Finally, we explored the biomechanical mapping of macrophages as a novel classifier to distinguish their activation status. Applying AI algorithms to different data maps we realize that mechanical data layer is very efficient to automatically distinguish macrophages' phenotypes.
Conclusion: Our investigations suggest a strong potential of biomechanics as stimuli for the regulation of macrophage functions, as well as a novel classifier to determine their physiological status.

Antiviral immunity revealed by B cell ImmunoSpot informs immunity to future viral exposures

Stephen Todryk[1;2], Georgia Stylianou[1], Zhigang Liu[2], Yong Gao[2], Noemi Becza[2], Jack Chepke[2], Xing-Xuang Gao[2], Paul Lehmann[2], Greg Kirchenbaum[2]
[1]Northumbria University, Newcastle upon Tyne, United Kingdom; [2]Cellular Technology Ltd, Cleveland, United States

Viruses circulating in the human population such as SARS-CoV-2 are subject to immune-mediated selection pressure (naturally-acquired or vaccine-mediated) that drives the emergence of antigenic variants, some of which are variants of concern (VOC) due to increased virulence. Such variants can cause reinfections in immune individuals due to their ability to evade neutralizing antibody activity. In the face of declining effective antibodies, viral-specific pre-existing memory B cells (B_{mem}) serve as a durable secondary wall of humoral defence. While the B_{mem} may initially possess a reduced affinity for the new viral variant, they are maintained at a stable precursor frequency. Moreover, such B_{mem} can be re-recruited at a future time into germinal centre reactions where they undergo further rounds of proliferation and acquire somatic mutations to refine both the specificity and affinity of their antigen receptors and ultimately their secreted antibodies. Identification of such cross-reactive B_{mem}, together with a measure of their affinity, indicates a person's ability to mount an effective recall response upon viral re-encounter and thus could inform vaccination regimens. Owing to the scarcity in blood of antigen-specific B_{mem}, and technical difficulties associated with their identification, assessment of B_{mem} reactivity and affinity against emerging SARS-CoV-2 variants in large donor cohorts has been largely neglected. Using recent innovations in the B cell ImmunoSpot platform, including the ability to assess affinity and cross-reactivity of cultured B_{mem} at the single cell level, our study evaluated B_{mem} reactivity in subjects infected early in the pandemic with the prototype Wuhan virus (Hu-1) for recognition of Receptor-Binding Domain (RBD) antigens representing the Delta (B.1.617.2) and Omicron (BA.1) VOC. Fluorescent spots in the assay revealed B_{mem} secreting specific antibodies of varying affinity for the VOC antigens based on spot size and intensity. This study was further able to demonstrate B cell cross-reactivity against key antigens from VOCs. Collectively, this study demonstrates the feasibility of performing B cell ImmunoSpot assays to efficiently, and with limiting cell input numbers, identify cross-reactive B_{mem} and their affinity, at single-cell resolution. This assay is therefore a useful addition to the current immune monitoring toolbox in the battle against VOC.

Designing in vitro platforms to study transendothelial T cell migration in colorectal cancer

David Bartolomé Català[1], Jordi Comelles[1], Aina Abad[1], María García-Díaz[1;2], Elena Martínez[1;2;3]
[1]Biomimetic Systems for Cell Engineering Laboratory, Institute for Bioengineering of Catalonia (IBEC), The Barcelona Institute of Science and Technology (BIST), Barcelona, Spain; *[2]Department of Electronics and Biomedical Engineering, University of Barcelona (UB), Barcelona, Spain*; *[3]Centro de Investigación Biomédica en Red (CIBER), Barcelona, Spain*

Over the years, a better understanding of the tumor microenvironment (TME) in colorectal cancer (CRC) has highlighted its critical role in tumor development and progression. The infiltration of cytotoxic T lymphocytes into the tumor is one of the most predictive factors of prognosis in CRC. Therefore, great interest has been focused on understanding the ability of T lymphocytes to cross the endothelial barrier, navigate the stroma and access the tumor, and how the TME affects this migration. However, studying this process in vivo is extremely difficult and costly, and standard in vitro models are too simplistic to fully recapitulate the journey of T cells from the blood stream to the tumor. Recent advances in biofabrication such as 3D bioprinting have opened new avenues to obtain three-dimensional in vitro models mimicking the in vivo TME. To this end, we use a tiered approach developing increasingly complex in vitro models to dissect the mechanisms underlying transendothelial migration (TEM) and T cell motility within the stromal microenvironment. Specifically, we investigate distinct barriers using Transwell models (i) coated with adhesion molecules (ICAM1 or Fibronectin) or (ii) cultured with endothelial cells mimicking the leukocyte endothelial transmigration; (iii) primary T cells embedded in hydrogels together with primary fibroblasts, mimicking the migration through the stromal compartment, and (iv) the extravasation model that combines the stromal compartment and endothelial barrier to effectively recapitulate the transendothelial and stromal T cell migration dynamics. In order to recapitulate the signalling cascades present during the early stages of CRC, we use APC-/- intestinal organoids cultured on monolayers. Each of these models will help understand the effect of the different barriers and TME in the T cell migration, providing a toolbox to study the mechanical and biochemical signals during immune cell recruitment within a complex tissue-like CRC model.
