During our experiments, we isolated vesicles from *Candida albicans* and *Candida parapsilosis*. In the case of *C. albicans*, it was isolated from both yeast and hyphal forms. The uptake and mechanism of *Candida*-derived EVs were investigated by flow cytometry and confocal microscopy. We also investigated the effect of *Candida*-derived EV treatment on various processes involved in the epithelial-mesenchymal transformation of the tumor, such as the migration, MMP activity and gene expression profile of the HSC-2 human OSCC cells used.

As a result of the experiments, we found that EV treatment affects the migration and morphology of tumor cells. In addition, *C. albicans*-derived EV treatment significantly increase the MMP activity of the cells. Gene expression changes were also detected after *Candida* EV treatment.

These results suggest that *Candida* EVs play a role in promoting OSCC epithelial-mesenchymal transition and thus in tumor progression.

Can trained immunity decrease Candida albicans induced cancer progression in human oral epithelial cells?

Máté Lajos Csikós[1], Zsolt Tasi[1], Máté Vadovics[1], Csaba Papp[1], Petra Molnár[1], Attila Gacser[2;3;4]

[1]Department of Microbiology, University of Szeged, Szeged, Hungary; *[2]HCEMM-SZTE Pathogen Fungi Research Group, University of Szeged, Szeged, Hungary*; *[3]HUN-REN-SZTE Pathomechanisms of Fungal Infections Research Group, Szeged, Hungary*; *[4]University of Szeged, IKIKK, Competence Centre for Molecular Biology, Bionics and Biotechnology, Szeged, Hungary*

Trained immunity is part of the innate immune system that is regulated by epigenetic modifications and is only temporary. Antibodies are not produced during short-term memory formation therefore the secondary immune response can be activated by similar pathogens whose antigens are recognised by the same pattern recognition receptors. This phenomenon is present in professional immune cells as well as in epithelial cells.

Oral squamous cell carcinoma (OSCC) is a global health problem often associated with various fungal infections caused particularly by *Candida*. Moreover, large amount of evidence suggests that *Candida* can contribute to carcinogenic events in the oral cavity by upregulating oncogenes in non-malignant cells. Recently, our group reported that the immune response induced by *Candida parapsilosis* and *Candida albicans* in OSCC cells is different. *C. parapsilosis* induces a mild host response while *C. albicans* enhances OSCC progression by stimulating pro-tumor signalling pathways and the production of matrix metalloproteinases.

Based on these differences, our goal was to investigate whether immune training with *C. parapsilosis* effect the ability of *C. albicans* to form and enhance cancer progression events. For our experiments, we used the oral epithelial cell line OKF6/TERT-2 which is an immortalized cell line and HSC-2 which is an OSCC cell line as the host, and two distinctive strains of *C. parapsilosis* (GA1 and CLIB214) and *C. albicans* (SC5314 and WO-1) as pathogens. *C. albicans* SC5314 has a much greater impact on epithelial cells than *C. albicans* WO-1. The host cells were pre-treated for 24 hours with live *C. parapsilosis* cells. After that we eliminated the fungal cells with the antifungal agent nourseothricin. After 5 days of rest, we stimulated host cells with *C. albicans* cells for 24 hours and examined the extent of host cell damage, cytokine production, adhesion capacities and gene expression changes.

The pre-treatment with *C. parapsilosis* species decreased cytotoxicity caused by *C. albicans* species in both cell line and increased IL-6 and IL-8 production in OKF6/TERT-2 cell line and decreased in HSC-2 cell line. Adhesion capacity studies and defining gene expression changes are in progress. The pre-treatment holds potential to decrease *C. albicans* induced cancer progression.

Transcriptomic signature of pediatric sepsis

Koichi Yuki[1], Sophia Koutsogiannaki[1]

[1]*Boston Children's Hospital, Boston, United States*

Purpose: Immune dysregulation is a hallmark of sepsis pathophysiology. First, pediatric immune system is subjected to developmental changes. Second, adult and pediatric sepsis differ in predisposing diseases and sites of infection. However, current sepsis management is the same for both; primarily supportive, including fluid resuscitation, early antibiotic therapy, and cardiorespiratory support. Leukocytes are major players to fight against invading microorganisms. The contribution of immune dysregulation to morbidity and mortality has been described in adult sepsis. However, there is a limited literature describing leukocyte phenotypic characteristics in pediatric sepsis. While adult and pediatric sepsis are clinically distinct as described above, their immunological delineation remained limited.

Methods: We tackled to delineate immunological profiles of pediatric sepsis at a single-cell level by analyzing blood samples from six septic children, at both acute and recovery phases, and four healthy children. Using Adult sepsis data available from the public domain, we also compared the transcriptomic profiles of pediatric and adult sepsis.

Results: 16 single-cell transcriptomic datasets (96,156 cells) were analyzed and compared to adult sepsis dataset. As expected, neutrophilia, T cell lymphopenia and HLR-DR cells depletion were observed in our pediatric cohort. We showed a unique shift in neutrophil subpopulations and functions between acute and recovery phases, along with examining the regulatory role of resistin. Neutrophil signatures were comparable between adult and pediatric sepsis. In contrast, T cell profiles differed between pediatric and adult sepsis. Innate-like CD4 T cells were predominantly and uniquely observed in the acute phase of pediatric sepsis. T2 CD4 cells were dominant in CD4 T cells in pediatric sepsis.

Conclusion: Our study serves as a rich source of information about the phenotypic diversity and trajectory of circulating immune cells during pediatric sepsis.

Memory γδT cells demonstrate a unique metabolic profile resulting in enhanced protection against Staphylococcus aureus.

Brenda Morris[1], Eoin O'Brien[1], Simon Carlile[1], Rachel McLoughlin[1]

[1]*Trinity College Dublin, Dublin, Ireland*

Gamma delta (γδ) Tcells are a lymphocyte subset with characteristics of innate and adaptive immune cells. γδT cells are subdivided based on the T cell receptor γ chain. Subsets have been shown to play differential roles in autoimmunity, cancer and are emerging as key players in the pathogenesis of infectious disease. One important aspect of the adaptive characteristics of γδT cells is the acquisition of a memory phenotype to previously encountered antigens. The memory γδT cell phenotype and its importance to effector function in infection is not yet understood. Our group has previously shown that exposure and convalescence from *Staphylococcus aureus* systemic infection results in an expansion of γδT cell subset Vγ6, with concomitant production of IL-17, which is protective during *S. aureus* infection. Critically, these cells could offer a significant advantage when developing novel therapeutics against intracellular pathogens such as *S. aureus*.

Following intra-peritoneal challenge with *S. aureus*, Vγ6 γδT cells are expanded by day four, dominate γδT cell population and remain resident in the abdominal adipose tissue for up to 35 days. Upon reinfection, these resident Vγ6 cells rapidly produce IL-17 and granzyme B, reducing bacterial load. We have further uncovered that the heightened response of these Vγ6 cells is controlled by metabolic changes. Seahorse analysis demonstrates increased baseline oxidative phosphorylation in convalescent γδT cells which is further increased upon re-challenge, in addition to an increase in glycolysis. Inhibition of glycolysis reduced Vγ6 cell production of IL-17 and increased bacterial burden. SCENITH metabolic profiling has further demonstrated that Vγ6 cells exhibit increased glucose dependence but additionally a novel finding that memory Vγ6 cells have an increased dependence on fatty acid oxidation.

Taken together, these data suggest that targeting γδT cell immmunometabolic pathways can potentiate host response to *S. aureus* infection. Host directed therapies against this significant global threat, that focus on γδT cell metabolism is an unexploited avenue for development.

Pneumococcal surface protein A (PspA) prevents killing of Streptococcus pneumoniae by the antimicrobial peptide indolicidin

Natalha T. Waz[1], Barbara Milani[1], Maria Eduarda P. Mendes[1], Emilly Rodrigues[1], Anders Hakansson[2], Thiago Rojas Converso[1], Michelle Darrieux[1]

[1]*Molecular Microbiology Department, São Francisco University, Bragança Paulista, Brazil*; [2]*Experimental Infection Medicine, Lund University, Lund, Sweden*

Streptococcus pneumoniae is a major human pathogen, responsible for high mortality rates worldwide. An important virulence factor in the pneumococcus is the pneumococcal surface protein A (PspA), a surface-exposed protein that prevents complement deposition on the bacterium. PspA is a widely studied candidate for serotype-independent pneumococcal vaccines. PspA can also bind to lactoferrin, an antimicrobial protein with bactericidal and bacteriostatic effects against a wide range of pathogens. The expression of PspA protects the bacterium from the bactericidal action of lactoferricins – cationic peptides released upon lactoferrin proteolysis. Since the negative charge of the exposed portion of PspA contributes to its ability to prevent lactoferrin-mediated killing, the present study sought to determine if PspA can prevent killing by another cationic peptide, indolicidin. PspA-negative pneumococci were more sensitive to indolicidin-induced killing than bacteria expressing PspA, suggesting that PspA prevents the bactericidal action of indolicidin. Similarly, removal of choline-binding proteins through choline chloride washes increased sensitivity to indolicidin. The absence of capsule and PspA had an additive effect on pneumococcal killing by the AMP. Furthermore, anti-PspA antibodies enhanced the bactericidal effect of indolicidin on pneumococci, while addition of soluble PspA fragments competitively inhibited indolicidin action. Previous *in silico* analysis suggests a possible interaction between PspA and indolicidin. Thus, we hypothesize that PspA may act by sequestering indolicidin, thus preventing it from reaching the bacterial membrane. Taken together, the results reinforce the vaccine potential of PspA and suggest a possible mechanism of innate immune evasion employed by pneumococci, which involves binding to cationic peptides and hindering their ability to damage the bacterial membranes.

Effect of in vitro indolicidin teatment in polymyxin-susceptible and polymyxin-resistant Acinetobacter baumanni

Natalha T. Waz[1], Jhosany R. Madeira[1], Clarissa O.A. Ramos[1], Raquel Girardello[1], Michelle Darrieux[1]

[1]*Molecular Microbiology Department, São Francisco University, Bragança Paulista, Brazil*

Microbial resistance to antibiotics is one of the greatest public health challenges. Among the bacteria with broad antimicrobial resistance is *Acinetobacter baumannii*, an aerobic Gram-negative coccobacillus responsible for a high number of nosocomial infections, mainly affecting ICU patients. *A. baumannii* colonizes different host tissues, including the genitourinary and respiratory tracts and post-surgical scars, from where it can spread to the blood, causing systemic infections with high mortality. The high resistance to antibiotics and the ability to form biofilms favor the dissemination of the bacteria and limit the control strategies. Thus, the development of new therapeutic strategies is considered a global priority. Antimicrobial peptides (AMPs) are a group of small molecules produced by different organisms, which have broad antimicrobial activity against viruses, bacteria, protozoa and fungi. Many AMPs have a cationic and amphipathic structure, which favors their insertion into microbial membranes, causing destabilization and death of the microorganism. Unlike antibiotics, bacterial resistance to AMPs is not easily acquired, strengthening the therapeutic potential of these molecules. The present project aims to evaluate the resistance of *A. baumannii* to the cationic antimicrobial peptide indolicidin and to determine its correlation with resistance to antibiotics. The resistance of different clinical isolates to the action of AMP was determined through an *in vitro* bactericidal assay. To determine the effects of antimicrobial resistance on AMP action, resistance to polymyxin was induced by cultivating susceptible strains in increasing concentrations of the antibiotic. Different isolates of *A. baumannii* exhibited variable susceptibility to indolicidin-mediated killing. Preliminary data comparing strains before and after induction of polymyxin resistance showed a similar sensitivity to the AMP, suggesting that different mechanisms are involved in resistance against polymyxin and indolicidin. Further analysis will confirm if resistance to polymyxin affects the ability of *A. baumannii* to survive treatment with indolicidin. The results of this study should contribute to the development of new therapeutic strategies against bacteria that are multi resistant to antibiotics, in addition to elucidating the mechanisms involved in resistance to antimicrobial peptides.

Antibody levels and predictors for low response to childhood vaccines among 7–14-year-old children in Norway

Johanna Bodin[1], Nina Iszatt[2], Marta Baranowska-Hustad[1], Berit Berit Brunstad Granum[2], Thea Kristine Rogne Møller[1], Tove Karin Herstad[1], Audun Aase[1], Merete Åse Eggesbø[2], Gro Tunheim[1]

[1]*Division of Infectious Control, Norwegian Institute of Public Health, Oslo, Norway*; [2]*Division of Environment and Climate, Norwegian Institute of Public Health, Oslo, Norway*

Purpose: Children in Norway are offered vaccination with 5 doses against diphtheria, tetanus and pertussis (DTP) at 2, 3 and 5 months of age, and 6 and 15 years. A vaccine against measles, mumps, and rubella (MMR) are given at 15 months of age and at 11 years. In this study we analysed antibody levels and factors predicting low antibody responses to vaccinations.

Methods: The study participants came from The Norwegian Environmental Biobank (NEB) and Human Early Life Exposome (HELIX), both sub-cohorts of the Norwegian Mother, Father and Child Cohort Study (MoBa). Plasma samples were collected between May 2014 and September 2017. IgG antibody levels against DTP and MMR were measured in in-house multiplex immunoassays (MIA). Data on immunization and predictors for vaccine response (maternal and child factors) were collected from the Norwegian Immunisation Registry (SYSVAK) and through questionnaires completed by the children's parents, respectively.

Results: Antibodies against DTP and MMR were measured in 901 children aged 7 to 14 years of which 49.7% were female. Among children who had received 4 doses of DTP vaccine (median age 10 years), 5.1% and 20.6% had antibody levels below 0.1 IU/ml against tetanus and diphtheria, respectively. 14.2% and 1.7% had an anti-rubella concentration of <10 IU/ml after 1 dose (median age 9 years) or 2 doses (median age 12 years) of MMR vaccine, respectively. Preliminary analyses suggest that high BMI at sampling age was associated with having antibody levels below 0.1 IU/ml for tetanus and diphtheria. Delivery by C-section was associated with lower levels of tetanus antibodies. There was a trend among children who had received 1 or 2 doses of MMR vaccine that antibody levels against rubella were lower among those who had been breastfeed for >6 months compared to those breastfeed for a shorter time. Data analysis on additional predictors are ongoing.

Conclusion: Despite a high vaccination coverage in Norway, vaccine antibody levels were low in some of the children. Child BMI at sampling time, C-section and duration of breastfeeding could be potential predictors of lower vaccine responses to childhood vaccinations.

Mice deficient for either interleukin-27 receptor-alpha or Eppstein-Barr virus-induced gene 3 are differentially susceptible to Mycobacterium tuberculosis infection

Kristina Ritter[1], Alexandra Hölscher[1], Johanna Volz[1], Jochen Behrends[1;2], Hanna Erdmann[1], Christoph Hölscher[1]

[1]*Infection Immunology, Research Center Borstel, Borstel, Germany*; [2]*Core Facility Fluorescence Cytometry, Research Center Borstel, Borstel, Germany*

Within the IL-12 cytokine family, the beta (β)-subunit Epstein Barr virus induced gene 3 (EBI3) forms, together with the alpha (α)-subunits IL-27p28, IL-12p35 and IL-23p19, the three different heterodimeric cytokines IL-27, IL-35 and IL-39, respectively. Whereas IL-27 is mainly produced by dendritic cells and macrophages and signals through the receptor complex IL-27 receptor (R) composed of IL-27Rα and gp130, the immunosuppressive cytokine IL-35 which signals through IL-12Rβ2/gp130 is preferentially secreted in regulatory T (T_{reg}) and B (B_{reg}) cells. The most recently described cytokine IL-39 induces pro-inflammatory immune responses through IL-23R/gp130.

After infection with *Mycobacterium tuberculosis* (Mtb), mice lacking the IL-27Rα exhibit lower bacterial burden in comparison to wildtype mice that correlate with an enhanced IL-17A production. By comparing the outcome of Mtb infection in C57BL/6, IL-27Rα deficient ($^{-/-}$) and IL-27Rα/IL-17A double deficient mice, we observed that the increased protection upon IL-27Rα deficiency is supported by IL-17A. Whereas IL-17A does neither impact the development of Tr1 cells nor the expression of PD1 and KLRG1 on T cells in IL-27Rα$^{-/-}$ mice during infection, it significantly regulates the presence of multifunctional T cells along with the formation of highly stratified granulomas in the lungs.

In contrast to the enhanced protection upon IL-27Rα deficiency, we observed unchanged bacterial loads in mice lacking EBI3 in comparison to wildtype mice. Moreover, despite EBI3$^{-/-}$ mice exhibit increased levels of IL-17A, the frequency of multifunctional T cells was not altered in those animals. Notably, the relative amount of natural killer (NK) T cells was highly reduced in the absence of EBI3.

Together, distinct mechanisms mediated through IL-27R or EBI3 may account for this opposing effect during experimental tuberculosis. To analyze the contribution of T_{reg}-derived IL-35 to the protective immune response, we are presently comparing the outcome of Mtb infection in T_{reg}-specific EBI3-deficient mice (Foxp3^{cre}-positive EBI3loxP$^{/loxP}$), Foxp3^{cre}-negative EBI3$^{loxP/loxP}$ control animals and global EBI3$^{-/-}$ mice. Conclusively, gaining a deeper understanding of the differential role of these two subunits may help to elucidate the complex interplay between protective and pathologic immune mechanisms during Mtb infection.

Exploring the effect of Leishmania infantum and Trypanosoma cruzi extracellular vesicles on dendritic cell-lymphocyte interactions

Mafalda Meunier[1], João Durães-Oliveira[1], Armanda Rodrigues[1], Ana Valério-Bolas[1], Joana Palma-Marques[1], Flávia Fróis-Martins[1], Rui Ferreira[2], Inês Cardoso[2], Graça Alexandre-Pires[3;4], Telmo Nunes[5], Isabel Pereira da Fonseca[3;4], Gabriela Santos-Gomes[1]

[1]Global Health and Tropical Medicine, GHTM, Associate Laboratory in Translation and Innovation Towards Global Health, LA-REAL, Instituto de Higiene e Medicina Tropical, IHMT, Universidade NOVA de Lisboa, UNL, Lisbon, Portugal; *[2]Banco de Sangue Animal, Porto, Portugal*; *[3]Centre for Interdisciplinary Research in Animal Health, CIISA, Faculty of Veterinary Medicine, FMV, University of Lisbon, ULisboa, Lisbon, Portugal*; *[4]Associate Laboratory for Animal and Veterinary Sciences (AL4AnimalS), Lisbon, Portugal*; *[5]Faculty of Sciences, University of Lisbon, Lisbon, Portugal*

Purpose *Leishmania* spp. and *Trypanosoma cruzi* parasites are the aetiological agent of Leishmaniasis and Chagas disease, respectively, and belong to the Trypanosomatidae family. In both cases, the dog represents the main domestic reservoir and these diseases can be fatal if left untreated. Antigen-presenting cells such as dendritic cells (DCs) are seen as important therapy vehicles since they can establish a link between innate and adaptive immunity, therefore reshaping the outcome of infection due to their immunostimulatory role. Moreover, extracellular vesicles (EVs) shed by parasites appear to play an immune modulatory role in disease pathogenesis. Therefore, the present study aimed to examine the interaction of DCs with EVs shed by *L. infantum* (*Li*EVs) and *T. cruzi* (*Tc*EVs) parasites and the subsequent immune response of lymphocytes induced by EVs-primed DCs.

Methods Monocyte-derived DCs (moDCs) were obtained *in vitro* from healthy canine peripheral blood mononuclear cells and exposed separately to *Li*EVs and *Tc*EVs. Afterwards, co-cultures of EVs-primed moDCs and autologous lymphocytes were established, and the gene expression of surface innate receptors (TLRs) and immune mediators evaluated by RT-PCR.

Results The results indicate that *Li*EVs and *Tc*EVs stimulate moDCs to express TLRs, triggering the upregulation of pro-inflammatory cytokines (tumor necrosis factor (TNF)-α and interleukin (IL)-12p40), followed by the generation of the regulatory cytokine IL-10. Furthermore, *Li*EVs-primed moDCs induced lymphocytes to upregulate TNF-α and IL-4 and *Tc*EVs-primed moDCs led lymphocytes to trigger IFN-g and IL-10 gene expression.

Conclusion EVs from both parasites trigger analogous activation of moDCs, which can be justified by the similarity between these trypanosomatids. Although EVs-primed moDCs direct lymphocytes to exhibit a mix pro and anti-inflammatory response, specific immune mediators are generated depending on the parasite. Taken together, these findings indicate that EVs shed by *T. cruzi* and *L. infantum* parasites can establish communication with DCs and specifically shape the adaptive immune response, highlighting the great immunomodulator potential of parasitic EVs.

Exploring the immunomodulatory properties of zymosan on human peripheral blood mononuclear cells: an in vitro study

Elżbieta Kozłowska[1], Justyna Agier[1], Sylwia Różalska[2], Aleksandra Góralczyk-Bińkowska[1], Paulina Żelechowska[1]

[1]Department of Microbiology, Genetics and Experimental Immunology; MOLecoLAB: Lodz Centre of Molecular Studies on Civilisation Diseases; Medical University of Lodz, Lodz, Poland; *[2]Department of Industrial Microbiology and Biotechnology; Faculty of Biology and Environmental Protection; University of Lodz, Lodz, Poland*

Purpose: Recent evidence suggests that symbiotic fungi play a critical role in shaping host immunity, with fungal cell wall components influencing immune cell activity. Pattern recognition receptors (PRRs) are crucial in recognizing fungal antigens, yet further research is needed to elucidate their precise impact on immune cell biology. This study aimed to evaluate the effects of the significant fungal cell wall component, zymosan, on the expression of C-type lectin receptors (CLRs) representatives (Dectin-1 and Dectin-2) on human peripheral blood mononuclear cells (PBMCs) and its potential to activate these cells for antifungal immune mechanisms, such as reactive oxygen species (ROS) generation and cytokine (IL-17, IL-23, TNF) synthesis.

Methods: PBMCs at a concentration of $1x10^6$ cells per mL, cultured *in vitro* at 37°C in a 5% CO2 humidified atmosphere, with or without zymosan (1 μg/mL and 10 μg/mL), derived from *Saccharomyces cerevisiae* cell wall, and harvested after 72 hours of incubation. Quantitative RT-PCR (qRT-PCR) was used to assess the mRNA gene expression of CLRs and cytokine in human PBMCs. Spectrofluorimetry was used to examine zymosan-induced ROS generation in PBMCs.

Results: Zymosan induced an increase in the mRNA expression level of Dectin-1 (1.7- and 4.5-fold) and Dectin-2 (2.3- and 2.5-fold) in PBMCs stimulated with 1 and 10 μg/mL, respectively when compared to unstimulated control cells. Exposure of PBMCs to zymosan at concentrations of 1 and 10 μg/mL resulted in a slight up-regulation of IL-17 mRNA levels by 1.6- and 2-fold, respectively, while significant up-regulation of IL-23 mRNA expression by 31- and 51-fold, and TNF mRNA expression by 45- and 55-fold, respectively, compared to non-stimulated cells. PBMCs exhibited substantial ROS production upon stimulation with zymosan at concentrations of 1 μg/mL ($p<0.001$) and 10 μg/mL ($p<0.0001$) compared to unstimulated cells.

Conclusion: This study's findings underscore the pivotal role of zymosan in modulating the immune response through the upregulation of CLRs and cytokine expression and the induction of ROS production in human PBMCs. These insights shed light on potential targets for enhancing antifungal immune mechanisms and offer avenues for further exploration in therapeutic interventions against fungal infections.

Development of an ex vivo bronchoalveolar lavage model towards in vivo neonatal non-human primate models of respiratory infections

Alistair Ridyard[1], Claire-Maelle Fovet[1], Laetitia Lacroix[1], Camille Pimienta[1], Julie Morin[1], Nathalie Bosquet[1], Quentin Pascal[1], Francis Relouzat[1], Elisabeth Menu[1], Roger Le Grand[1], Nabila Seddiki[1]

[1]*Université Paris-Saclay, INSERM, CEA, Center for Immunology of Viral, Auto-immune, Hematological and Bacterial Diseases (IMVA-HB/IDMIT), Fontenay-aux-Roses, France*

Purpose: Respiratory infections, particularly in neonates, result in a large amount of hospitalisation and death. Respiratory syncytial virus (RSV) and *Streptococcus pneumoniae* (SP) are the leading cause of bronchiolitis and pneumonia in those under 5, respectively. It is imperative to understand the pathophysiology underpinning them, but difficult to determine in neonatal cohort for many reasons, thus requiring use of an animal model. Our team is developing neonatal non-human primate (NHP) models to help understand immunopathogenesis of RSV and SP infections, while providing a model for testing novel therapeutics. To help reduce the use of neonatal NHPs, we developed an *ex vivo* bronchoalveolar lavage (BAL) model of infection, primarily alveolar macrophages, to assess and compare cellular immune profiles following exposure to RSV and SP.

Methods: BALs from healthy adult macaques were collected, cultured and exposed to RSV M37 (strain used in human challenge and obtained from C. Chiu, Imperial College London) and/or SP at different MOIs for 6hrs, 24hrs and 48hrs. Cells were collected and stained with optimized antibody-panels for myeloid cell characterization by flow cytometry, and culture supernatants were analysed for cytokines/growth factors expression by multiplex bead-based immunoassay. Immunohistochemistry staining was also performed on infected and non-infected cells.

Results: We successfully cultured and exposed cells from NHP BAL, primarily alveolar macrophages, with M37-RSV. Our data show positive staining with anti-RSV antibody compared to mock uninfected cells. The majority of vacuolated and/or multi-nucleated BAL cells were alveolar macrophages. Supernatants at 24 hours from infected cells showed increased IL-10, TGF-a, IL1Ra, IL-18 and VEGF, with decreased MIP-1a, IL-6 and TNF-a. Flow cytometry showed a significant decrease in HLA-DR expression in exposed alveolar CD163+ macrophages compared to non-infected cells. Altogether, these results suggest that RSV infection induce a more immunosuppressive profile of the cells. Results from SP infections (ongoing experiments) will be compared to RSV.

Conclusion: We were able to establish an *ex vivo* model of NHP alveolar macrophages to study immunopathogenesis of RSV and SP. Results from this model will complement future *in vivo* studies of neonatal NHP models to better understand the pathophysiology of RSV and SP severe infections.

Interleukin-32 producing CD8+ memory T cells define IDO1 / PD-L1 niche in human cutaneous leishmaniasis

Nidhi Sharma Dey[1], Shoumit Dey[1], Naj Brown[1], Sujai Senaratne[2], Luiza Campos Reis[3], Ritika Sengupta[4], Shalindra Ranasinghe[2], Mitali Chatterjee[4], Paul Kaye[1], Hiro Goto[3]

[1]YBRI, University of York, York, United Kingdom; *[2]University of Sri Jayewardenepura, Nugegoda, Sri Lanka*; *[3]Universidade de São Paulo, Brazil, Sao Paulo, Brazil*; *[4]Institute of Postgraduate Medical Education and Research, Kolkata, India*

Immune checkpoint (IC) expression has been extensively studied in vitro, revealing potential regulatory pathways, particularly in myeloid cells. However, these in vitro data fail to explain how IC expression is regulated at disease sites, such as leishmaniasis lesions or the tumor microenvironment. To understand IC regulation in the context of the complex cellular and molecular niches present in vivo, it is necessary to study IC expression in situ. To address this, we used spatial transcriptomics to study IC expression in skin lesions from patients with cutaneous leishmaniasis (CL), a disease characterized by chronic skin pathology. Previously, we found that indoleamine 2,3-dioxygenase 1 (IDO1) and programmed death-ligand 1 (PD-L1) are enriched in CL lesions, and reduced PD-L1 early after treatment predicts cure in Sri Lankan patients. Here, we used spatial cell interaction mapping to identify IL-32-expressing CD8+ memory T cells and regulatory T cells as key components of the IDO1/PD-L1 niche in CL lesions across patient cohorts from Sri Lanka, Brazil, and India. Importantly, the abundance of IL-32+ cells and IL-32+CD8+ T cells at treatment onset was prognostic for cure rate in Sri Lankan patients. This study provides a unique spatial perspective on the mechanisms underlying IC expression during CL and identifies novel biomarkers of treatment response, with implications for understanding IC regulation in the complex in vivo environments of other chronic inflammatory and infectious diseases.

Impaired NK cell response contributes to ageing-associated susceptibility to pneumococcal pneumonia

Rong Xu[1], Daan Beentjes[1], Laura C. Jacques[1], Daniel R. Neill[1;2], Neil French[1], Aras Kadioglu[1]

[1]1Department of Clinical Infection, Microbiology and Immunology, University of Liverpool, Liverpool, United Kingdom; *[2]Molecular Microbiology, School of Life Sciences, University of Dundee, Dundee, Scotland, United Kingdom*

Streptococcus pneumoniae (the pneumococcus) is the leading cause of bacterial pneumonia, with high morbidity and mortality worldwide, and the elderly are the most significantly affected population. This is thought to be related to ageing-associated immunological changes, which impair the host defence against infection. In the context of pneumococcal infection, defects in immune components and responses that are specifically related to disease progression and severity in aged lungs is poorly understood.

Pneumococcal carriage in the nasopharynx is a prerequisite for the development of pulmonary infection. Considering the potential influence of prior carriage events on host immunity, we established a secondary pneumonia model by challenging mice that had a prior carriage exposure to the same strain of pneumococcus. Using this re-infection model, we explored how ageing affects leukocyte trafficking during pulmonary pneumococcal infection, with a specific focus on the role of NK cells.

We found that most adult mice were protected from the secondary pneumonia challenge whilst aged mice remained susceptible, which closely replicates increased susceptibility to pneumococcal pneumonia with age in human. In adult mice, a more efficient NK cell recruitment was observed in those mice that did not develop bacteraemia, suggesting a protective role of NK cells at preventing systemic dissemination of bacteria. Compared to adults, elderly mice showed a delayed recruitment of neutrophils which accumulated in the vasculature, and more surprisingly, a completely abolished systemic recruitment of NK cells. Furthermore, NK cells from aged adults (both in mice and humans) had markedly lower production of IFNγ and granzyme-B in response to pneumococcal stimulation. The elderly had an expanded effector $CD8^+$ T-cell population, which compensated for the diminished IFNγ production by NK cells but not the cytotoxic response against pneumococcus. Treating aged mice with IL-15/IL-15Ra complex significantly increased NK cell trafficking to the lungs during infection, and this increase was correlated to reduced bacterial loads in blood.

Our results suggest that competent NK cell responses are critical for protective anti-pneumococcal immunity in the lung and that ageing leads to deficient NK responses to pneumococcal infection, which is a major contributing factor to increased susceptibility to disease.

Towards novel COVID-19 therapy based on natural products with anti-SARS-CoV-2 activity

Dorentina Osmani[1;2], Stine Hellestø[1], Fan Zhou[1], Manpreet Hans[1], Vilde Sigfrid Skar Bulling[2], Malgorzata Dominika Szymczak[2], Knut Teigen[3], Rebecca Jane Cox Brokstad[1], Marta Kaminska[1], Torgils Fossen[2], Silke Appel[1]

[1]The Department of Clinical Science, University of Bergen, Bergen, Norway; *[2]The Department of Chemistry, University of Bergen, Bergen, Norway*; *[3]The Department of Biomedicine, University of Bergen, Bergen, Norway*

In this multidisciplinary project, we aim to discover new natural products that can treat or prevent COVID-19 infections caused by SARS-CoV-2. Thus far, 171 natural products from endemic plants originating from northern Europe and Tanzania have been isolated and elucidated by employing nuclear magnetic resonance (NMR); many of which are novel or rare.

In order to evaluate the potential selective inhibitory effects of natural products against the virus without harming the cells, cell cytotoxicity assays were performed. For this, in vitro MTT and XTT assays were utilized on A549 human pulmonary epithelial cells . The antiviral efficacy was evaluated using a neutralization assay using pseudo typed viruses encapsulating spike proteins of prevalent SARS-CoV-2 variants, namely Omicron (XBB 1) and Delta (B.1.617.2). An ACE2 and TMPRSS2-expressing A549 cell model was utilized in the assessment of viral entry inhibition.

Most of the compounds had little cytotoxic effects on the cells. From 171 compounds tested, seven exhibited significant inhibitory activity regarding viral cell entry, achieving up to 100% inhibition at 10μM concentrations with minimal cytotoxic effects. The next step will be to assess potential effects on viral replication using infectious SARS-CoV-2 isolates and quantitative RT-PCR with TaqMan probes. With that we will elucidate whether the natural compounds hinder viral propagation solely at the entry phase or extend their inhibitory action to subsequent stages of the viral life cycle. In addition, we will continue with computational docking studies with the most promising compounds to predict the interaction between these compounds and viral proteins.

This research signifies a strategic expansion in the search for antiviral agents derived from natural sources. The compounds identified offer promising options for the development of anti-SARS-CoV-2 therapeutics. The outcomes of this study will potentially facilitate the progression of these phytochemicals, underscoring the importance of natural products in addressing contemporary health challenges.

Serum calprotectin in severe and mild COVID-19 patients

Germà Julià Agulló[1], Marc Pedrosa Aragon[1], Juan Francisco Delgado de la Poza[1], Silvia Vidal Alcorisa[2]

[1]Consorci corporació sanitària Parc Tauli, Sabadell, Spain; [2]Institut de recerca Sant Pau, Barcelona, Spain

Purpose: The aim of the study is to evaluate the levels of serum calprotectin between healthy controls and COVID-19 patients.

Methods: Serum samples were collected from 16 healthy controls and 50 COVID-19 hospitalized patients, 17 with severe evolution and 33 mild evolution, at two times: hospitalization (T0) and 11 days post hospitalization (T1). Serum samples were stored at -80 Cº and serum calprotectin was subsequently determined with the Chemoluminiscent immunoassay QUANTA Flash® Circulating Calprotectin, according to the manufacturer's specifications. Statistical analyses were performed with Graphpad prism v5.0 software.

Results: COVID-19 patients showed statistically higher levels of serum calprotectin at T0 and T1 compared with healthy controls. Statistically significant differences have been detected in serum calprotectin of patients with COVID-19 between the time of hospitalization and 11 days later.

Conclusion: Elevated levels of serum calprotectin observed in COVID-19 patients could reflect that neutrophils participate in the COVID-19 pathophysiology.

Regulation of NLRP3 inflammasome-related gene expressions in the progression to chronicity in brucellosis with bone joint involvement

Tugba Senbuz[1], muhammed ali kızmaz[1], Ali Eren Iskin[1], Abdurrahman Simsek[1], Tugce Bozkurt[1], GÜLÇİN TEZCAN[2], Ferah Budak[1]

[1]*Department of Immunology, Faculty of Medicine, Bursa Uludağ University, Bursa, Turkey*; [2]*Department of Fundamental Science, Faculty of Dentistry, Bursa Uludağ University, Bursa, Turkiye, Bursa, Turkey*

Purpose: Bone joint involvement (BJI) is commonly observed in the zoonotic infection, brucellosis, caused by the intracellular pathogen Brucella. Caspase-1 and caspase-11 initiate joint inflammation and proinflammatory cytokine production and participate in infection control thereafter. Caspase-1 and Caspase-11 involve inflammation by activating the NLR family pyrin domain containing 3 (NLRP3). The role of NLRP3 dysfunctions in bone and joint diseases was shown, however, the function of NLRP3 in the chronicity of BJI+ Brucellosis remains unknown. Our study determined the mRNA levels of genes involved in NLRP3 inflammasome activation during the chronicity process in BJI+ brucellosis.

Method: The study included ten acute and six chronic BJI+ brucellosis cases and eight healthy controls. Cases were classified as acute (0-2 months) and chronic (>12 months) according to the onset time of symptoms. A human mRNA microarray analyzed the expression of over 30,000 genes in mononuclear cells separated from peripheral blood by Ficoll density-gradient centrifugation. An independent sample T-test analyzed the changes of genes in BJI+ brucellosis. A KEGG pathway analysis determined the association of those genes with NLRP3 expression and activation.

Results: NLRP3 mRNA was decreased in BJI+ chronic brucellosis compared to control (p=0.015). Supporting this, TRIM31, which is involved in the degradation of the NLRP3 inflammasome, increased in these cases compared to the control (p=0.009). In contrast; P2RX7, which plays a role in forming the NLRP3 complex by uptake of extracellular ATP into the cell, was increased in BJI+ acute brucellosis compared to the control (p=0.015). Similarly, NEK7, which acts as a component of the NLRP3 inflammasome complex, increased in these cases (p=0.019 and p=0.013).

Conclusion: Our findings suggest that the expression NLRP3-related genes increase in BJI+ acute brucellosis, whereas these pathways are suppressed at the mRNA level in BJI+ chronic brucellosis.

Schistosoma mansoni proteases and their effect on host extracellular vesicle production: A strategy to modulate the immune system

Michael Thaler[1], Lukas Neuninger[1], Magda Wysmolek[1], Agnieszka Razim[1], Anna Schmid[1], Jan Dvořák[2], Martin Horn[3], Adrian Leontovyč[3], Michael Mareš[3], Muhammed Faruk Saglam[1], Viktor Cerny[1], Aleksandra Inic-Kanada[1], Ursula Wiedermann Schmidt[1], Irma Schabussova[1]

[1]Institute of Specific Prophylaxis and Tropical Medicine, Center for Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria; *[2]Czech University of Life Sciences Prague, Prague, Czech Republic*; *[3]Institute of Organic Chemistry and Biochemistry of the Czech Academy of Sciences, Prague, Czech Republic*

Background: In schistosomiasis, caused by *Schistosoma mansoni*, the parasite invades the host through the skin. The parasite is using proteases like Cathepsin B1 (SmCB1) and SmCL3 to degrade tissue and blood. Extracellular vesicles (EVs) play a key role in intercellular communication and in the response to parasitic infections. EVs can be characterized by the presence of tetraspanins. These transmembrane proteins play a crucial role in all phases of EV biogenesis**.**

Methods: The recombinant proteins SmCB1 and SmCL3 were produced in yeast *P. pastoris*. Their activity was assessed at different pH values using an enzymatic activity assay. Human adenocarcinoma basal epithelial cells (A549), human monocytes THP-1 and mouse macrophage cells (RAW) were treated with active and E-64-inactivated SmCB1 or SmCL3. EVs were collected by ultracentrifugation and size exclusion chromatography. Size and concentration of EVs were measured using Zetasizer. Western blot analysis was performed to detect the tetraspanins CD63, CD81 and CD9 in the cells. Mice were treated intranasally for three consecutive days with active and E-64-inactivated SmCB1 or with EVs from SmCB1-treated A549 cells. Lung cells were analysed by flow cytometry.

Results: The activity of SmCB1 was optimal at or below pH 7.0, while SmCL3 was active at all pH values tested. Treatment with SmCB1 (active and E-64-inactivated) and SmCL3 resulted in the release of EVs from A549 cells. These EVs were mainly ~100 nm in diameter. Each of the cells expressed CD63, CD81 and CD9. Intranasal treatment with active SmCB1 reduced the number of alveolar macrophages and CD11c+ cells, and inactivation with E-64 abolished this effect. SmCB1-induced EVs reduced the number of alveolar macrophages, CD11c+ cells and NK cells in the lung compared to sham-treated controls.

Conclusion: Our results show that SmCB1 triggers the release of EVs from A549 cells and that these vesicles have immunomodulatory potential. This study sheds light on the complex interplay between *S. mansoni* proteases and host EV dynamics and contributes to our understanding of the immune response to S*chistosoma* parasites**.**

Toll-like receptor 4 improves replication of *Chlamydia trachomatis* serovar D in the uroepithelial T24/83 cell line

Svetlana Kuhn[1;2], Simone Albrecht[1;2], Lina Kellner[1;2], Xaver Rait[1;2], Hannah Griffiths[1;2], Carolina De La Torre[3], Norbert Gretz[3], Thomas Miethke[1;2]

[1]Institute of Medical Microbiology and Hygiene, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany; *[2]Mannheim Institute for Innate Immunoscience (MI3), Mannheim, Germany*; *[3]Center of Experimental Medicine, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany*

Chlamydia trachomatis infection remains mostly symptomless but can cause tissue modulating processes like hydrosalpinx, pelvic inflammatory disorder or lead to infertility. Uroepithelium is the point of entry for the chlamydial infection. In order to identify the immune signaling cascades activated by *Chlamydia*, compared to polyI:C or LPS, we infected T24/83 human uroepithelial cell line with *C. trachomatis* serovar D. Here we used microarray analysis and quantitative Real Time PCR, and observed an induction in the mRNA transcription of inflammatory genes such as il-1β, il-6 and tnf-α. However, the ELISA showed, that the corresponding cytokines were not secreted upon infection. T24/83 cells secrete the mentioned cytokines after a stimulation with polyI:C or LPS which are ligands for Toll-like receptor (TLR) 3 and 4, respectively. Thus, the pattern of the gene induction is different compared to infection with *C. trachomatis*. Additionally, we identified a set of genes like matrix metallopeptidase 1 and 3 and histatin 1, which were most induced upon *C. trachomatis* infection. It was reported, that TLR3 and TLR4 play an important role in the host pathogen interaction. Therefore we wanted to identify the role of TLR3 and TLR4 in T24/83 cells using CRISPR/Cas9 knock-outs. Unexpectedly we could show that in TLR4KO cells *C. trachomatis* serovar D replicates less well than in the wildtype. Whereas TLR3KO cells showed no difference in chlamydial replication compared to the wild type host cells. Hence, we assume that chlamydia can use TLR4 as a supporter for its own growth.

Antibody-based approaches for studying potential adhesion proteins of *Gardnerella spp.*

Indre Dalgediene[1], Aistė Bulavaitė[1], Raminta Reskeviciute[1], Danas Ivanauskas[1], Aurelija Zvirbliene[1], Milda Plečkaitytė[1]

[1]*Vilnius University, Vilnius, Lithuania*

Bacterial vaginosis (BV) is characterized by a disruption of lactobacillus-dominated vaginal microbiota and the overgrowth of *Gardnerella* spp. and other anaerobic bacterial species. This shift in vaginal microbiota is associated with women's reproductive health issues. The defining characteristic of BV is a polymicrobial bacterial biofilm primarily dominated by *Gardnerella*. The displacement of lactobacilli, colonization, and biofilm formation depends on the adherence capacity of *Gardnerella*. *Gardnerella* surface-associated proteins, such as the collagen-binding protein (CNA) and the M protein repeat protein (MPR), are suggested to be to play a role as bacterial adhesins. This study aimed to explore the interactions between CNA and MPR with extracellular matrix (EM) proteins and assess their presence on the surface of *Gardnerella* spp. using newly developed monoclonal antibodies (MAbs).

Hybridoma technology was utilized to generate mouse MAbs targeting CNA and MPR proteins. MAb-based ELISA revealed an interaction between CNA and human fibrinogen, while MPR demonstrated interaction with fibrinogen and fibronectin. Flow cytometry using both MAbs and polyclonal antibodies against CNA and MPR was then employed to assess potential adhesins expressed on various *Gardnerella* strains. Before analysis, optimization steps for CFDA-SE dye and antibody quantities were conducted. Results indicated a stronger interaction between surface MPR and corresponding antibodies compared to surface CNA.

The utilization of recently developed MAbs revealed the interaction between CNA and MPR with EM proteins, signifying the role of these surface proteins as adhesins. Flow cytometry findings provided valuable information regarding adhesins on *Gardnerella* spp. surfaces, which could inspire future investigations on their interactions with EM proteins on epithelial cells. This study contributes to advancing our understanding of BV molecular mechanisms and lays the groundwork for developing targeted strategies for its diagnosis and treatment.

Promising vaccine antigens against Klebsiella pneumoniae reduce bacterial burden in a sepsis model

Yueran Hou[1], Paulina Zarodkiewicz[2], Julen Tomás Cortázar[1], Dominic Stoner[1], Miguel Valvano[2], Rebecca Ingram[2], Siobhán McClean[1]

[1]University College Dublin, Dublin, Ireland; *[2]Queen's University Belfast, Belfast, United Kingdom*

Klebsiella pneumoniae is a Gram–negative bacterium, which causes septicaemia, respiratory tract infections, urinary tract infections and soft tissue infections. It is a major opportunistic pathogen, accounting for 11.9 % of reported bacterial species in 2021 in the EU/EEA, according to EARS-Net surveillance data, and antimicrobial resistant strains are associated with high mortality rates.

The aim of this project was to identify proteins used by *K. pneumoniae* to attach to host epithelial cells and their potential as novel protective vaccine antigens. In total, 31 bacterial adhesins from *K. pneumoniae* were identified by the Cell Blot approach developed by the McClean Lab, 24 of which were novel. Three antigens were selected as potential vaccine candidates. These were confirmed to play a role in *K. pneumoniae* attachment to lung cells *in vitro*, as BL21 cells expressing recombinant proteins showed 14.3–, 7.22–, 6.48–, and 13.3–fold (p=0.012, p=0.0199, p=0.0011, p=0.045) increased levels of attachment to 16HBE14o$^-$ cells respectively. Immunisation of mice with Antigens O, D or A individually showed reduced *K. pneumoniae* burden in peritoneal cavities (2.50 log, 2.69 log, 1.54 log (p=0.0007, p=0.0007, p=0.0080), respectively) in a sepsis challenge model and also reduced dissemination to the spleen (1.01 log, 1.44 log, 0.86 log (p=0.0003, p=0.043, p=0.0263), respectively). Strong anti–specific IgG titers were raised in mice immunised with Antigen L and Antigen O compared with mice treated with adjuvant alone. Serological analysis showed the expression of high antigen–specific antibody responses compared to the control group (titres ~ 3.9×10^6), the ratio of IgG1 / IgG2a (ratio = >5) suggests that Th2 responses were induced by both Antigen L or Antigen O immunisations. T–cell recall response analysis following immunisation of Antigen L or O demonstrated stimulation of IL–17 and IL–22 expression. Overall, these antigens were protective against *K. pneumoniae* sepsis and have potential as vaccine candidates.

Purpose: Osteomyelitis (OM) is a severe bone infection originating from hematogenous spreading of microbes or contamination of surgery/fracture. OM is primarily caused by the opportunistic bacterium *Staphylococcus aureus* (SA). This evades the host immune response, acquires antibiotic resistance, and chronically colonizes the musculoskeletal tissue[1], yet the underlying molecular and cellular processes are largely unclear. Here we aimed to characterize the pathogenetic mechanisms of SA-OM by focusing on the long pentraxin 3 (PTX3), a soluble pattern recognition molecule and bone component that is emerging as a new player in osteoimmunology[2] and a diagnostic marker of periprosthetic joint infections (PJI), a common form of OM[3].

Methods: A murine model of OM, based on intra-bone injection of SA, was developed that closely mimicked surgery/trauma-related OM in humans and allowed addressing the role of PTX3 in gene-modified (*Ptx3*$^{-/-}$) animals. Local and systemic infection and inflammation were assessed via microbiology, flow cytometry, histochemistry and microCT techniques.

Results: SA-injected mice developed chronic infection with pronounced inflammation and extensive tissue remodeling. Concentration of inflammatory markers (including IL-6, IL-1b, and TNF-a) and PTX3 in the serum and bone homogenate was higher in SA- than vehicle-injected WT animals. Noticeably, we found more bacteria in WT than *Ptx3*$^{-/-}$ mice at 6 and 14 days from challenge, with viable SA confined to the treated limbs only. Furthermore, administration of a PTX3-targeting antibody dampened infection in the bones of SA-infected WT mice. These also had enhanced systemic inflammation compared to *Ptx3*$^{-/-}$ littermates, with expanded innate immune compartment in the spleen and increased serum levels of inflammatory mediators. However, the local (in the bone) inflammatory reaction was more pronounced in the absence of PTX3 with increased levels of Th1 cytokines (IL-1b) and antimicrobial chemokines (CXCL9).

Conclusion: In a mouse model of SA-OM, genetic deficiency of PTX3 protected from infection and inflammation, pointing to this pentraxin as a crucial player in OM pathogenesis and a novel therapeutic target in bone infections.

Chemical and infectious colitis models show different immune profiles

Elena Blázquez-López[1], Marta Fernández-Castillo[1], Ainara Barco-Tejada[1;2], Marjorie Pion[1], Rafael Correa-Rocha[1], Patricia Múñoz[3], Manuel Desco[1;2;4], Lorena Cussó[1;4]

Centro Nacional de Investigaciones Cardiovasculares Carlos III (CNIC), Madrid, Spain*

Background: Ulcerative colitis is a type of inflammatory bowel diseases (IBD) characterized by a chronic immune response imbalance within the gastrointestinal tract. While the precise origins remain elusive, researchers have turned to animal models to explore the pathogenesis, causes and diagnosis of human IBD. Among these models, one of the most prevalent involves the use of dextran sodium sulfate (DSS) to induce damage to the intestinal epithelium. Its advantages include the rapid onset, reproducibility, and precise control. Another widely used model is a *Clostridioides difficile* infection (CDI) model, which, after treatment with antibiotics, has been shown to develop a colitis similar to that suffered by patients. However, although both models generate similar clinical symptoms to ulcerative colitis, being two different insults (chemical and infectious), they may generate a different immune response.

Objectives: To define the differences in the immunological profile between the DSS and CDI models.

Methods: DSS model was induced by 2,5% (w/v) DSS in drinking water continuously for 5 days in 10 C57BL/6 female mice. CDI model was induced in 9 C57BL/6 female mice following the protocol by Cussó et al. (DOI: 10.1007/s11307-019-01408-4), employing 10^6 CFUs of ribotype 027. 100 µl of peripheral blood samples were collected at basal and 2 days post-treatment; and incubated with 2 multiparametric antibodies panels to analyse lymphoid and myeloid populations. Then erythrocytes were lysed, and the samples were acquired by flow cytometry using a 16-channel flow cytometer.

Results: The results of flow cytometry analysis showed that DSS group presented a marked increase in granulocytes, proinflammatory monocytes and NK cells, and a significant decrease in dendritic cells compare to CDI mice. While, DSS model did not present variations in lymphoid populations, CDI model was characterized by an increase in B cells, especially plasmablasts, T lymphocytes and NKT cells. Within T cells, effector memory and activated phenotypes of both CD4+ and CD8+ T cells were increased in the CDI group compared to DSS model.

Conclusion: Although clinically and histopathologically both models are similar, their immune response is clearly different and must be taken into consideration when selecting one model over another.

Triacetylfusarinine C (TAFC) as a potential diagnostic biomarker of invasive pulmonary aspergillosis

Kristyna Sloupenska[1;2], Vladimir Havlicek[3], Hynek Macha[3], Radim Dobias[4], Milan Raska[1;2]

[1]Department of Immunology, Palacky University in Olomouc, Olomouc, Czech Republic; *[2]Department of Allergology and Clinical Immunology, University Hospital Olomouc, Olomouc, Czech Republic*; *[3]Institute of Microbiology of the CAS, v. v. i, Praha, Czech Republic*; *[4]Institute of Molecular and Clinical Pathology and Medical Genetics, Faculty of Medicine University of Ostrava, Ostrava, Czech Republic*

Purpose: Invasive pulmonary aspergillosis (IPA) is a severe fungal infection caused by *Aspergillus* spp. and usually occurs in immunocompromised patients. The most common causative pathogen is *Aspergillus fumigatus*. This pathogen causes a range of manifestations, from allergic forms to invasive and chronic infections or underlying pulmonary dysfunctions. The mortality rate of IPA ranges between 30-95 %. Diagnostic tools for detection biomarkers (galactomannan, 1,3-β-D-glucan, IgA, and IgG specific to *A. fumigatus*, *Aspergillus* DNA) and medical imaging constitute the basis of the screening approach, although both have some limitations in specificity. *A. fumigatus* synthesizes several siderophores, the major extracellular hydroxymate siderophore being triacetylfusarinine C (TAFC). Siderophores are low molecular weight iron-specific chelators that are essential virulence factors. Detection of TAFC may be a promising biomarker of IPA in urine and BALF samples.

Methods: We developed recombinant lipocalin (Lcn) coupled to agarose resin for affinity purification of selected siderophores, including TAFC. His-tagged Lcn1/Lcn2 were prepared in a prokaryote expression system where the designed sequence was inserted into the pET28B+ plasmid. The transformation was performed into *E. coli* BL21 expressing bacteria and coupled with Ni-NTA agarose resin in a centrifugation minicolumn. Lcn 1 was analyzed by mass spectrometry. Biological samples were loaded onto an affinity column, and TAFC was eluted by molecular excess of rhodotorulic acid. Detection of TAFC was performed by mass spectrometry.

Results: Recombinant Lcn1 was successfully expressed and amino acid sequence analysis by mass spectrometry revealed 13 peptides with 44,9% sequence coverage. The interaction of Lcn1 with TAFC was probed by native mass spectrometry. The non-covalent complex was not detected, contrary to enterobactin-Lcn1 complex, run in parallel in a control experiment. This observation rationalized the negative binding observed with the affinity column we prepared for patients´ sample analysis. In the next step, two other protein-TAFC binding systems will be designed and tested.

Conclusion: An engineered microarray for pre-concentration of siderophore TAFC from urine and BAL samples for subsequent detection using MALDI TOF technology is needed for routine siderophore detection useful in diagnosing IPA**.**

B-cell responses induced by *Neoehrlichia mikurensis* infection in patients with malignant B-cell lymphomas

Rima Alsalihi[1], Linda Wass[1;2], Anna Grankvist[2], Beatrice Bergström[3], Catharina Lewerin[4;5], Christine Lingblom[1;2], Christine Wennerås[1;2]

[1]*Department of Infectious Diseases, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*; [2]*Department of Clinical Microbiology, Sahlgrenska University Hospital, Gothenburg, Sweden*; [3]*Department of Clinical Immunology and Transfusion Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden*; [4]*Department of Hematology and Coagulation, Sahlgrenska University Hospital, Gothenburg, Sweden*; [5]*Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*

Purpose: *Neoehrlichia mikurensis (N. mikurensis)* is an intracellular tick-borne bacterium that belongs to the family of *Anaplasmataceae*. It is associated with persistent infection of vascular endothelial cells, leading to severe infections in individuals with compromised B-cell immunity, including patients with malignant B-cell lymphomas. As B cells seem to play a crucial role in the defense against *N. mikurensis*, the purpose of this study was to characterize the B-cell subsets induced by *N. mikurensis* infection in immunocompetent individuals and individuals with malignant B-cell lymphomas.

Methods: Peripheral blood mononuclear cells were isolated from the blood of immunocompetent individuals, infected with *N. mikurensis* (n = 6), non-infected immunocompetent individuals (n = 4), individuals with malignant B-cell lymphomas, infected with *N. mikurensis* (n = 3), and non-infected individuals with malignant B-cell lymphomas (n = 3). The cells were incubated with monoclonal antibodies directed against 28 B-cell markers and analyzed by Cytometry by Time-of-Flight (CyTOF). The multiparameter data was processed through cluster analysis to create minimum spanning tree plots, illustrating the sizes and phenotypes of various B-cell subsets, alongside univariate analyses.

Results: The characteristics of B-cell subsets in immunocompetent individuals and immunocompromised individuals with malignant B-cell lymphomas were compared with non-infected, immunocompetent individuals and non-infected individuals with malignant B-cell lymphomas. Regardless of immune status, infected individuals expressed a higher proportion of plasmablasts, memory B cells and resting memory B cells. In contrast, non-infected individuals expressed a higher proportion of naïve B cells and CD5+ B cells.

Conclusion: There were significant differences observed in B-cell subset distributions among immunocompetent and immunocompromised individuals infected with *N. mikurensis* compared with the non-infected individuals, fortifying the notion that B cells play a crucial role in the host defense against *N. mikurensis*.

Immune programs in human dendritic cells upon immunization with *Chlamydia trachomatis*

Katja Knapp[1;2], Marlene Kranawetter[3], Ruth Dingelmaier-Hovorka[1], Ram Pandey[1], Christoph Grimm[3], Georg Stary[1;2]

[1]Department of Dermatology, Medical University of Vienna, Vienna, Austria; *[2]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria*; *[3]Department of Obstetrics and Gynecology, Medical University of Vienna, Vienna, Austria*

Purpose: *Chlamydia trachomatis* (Ct) is responsible for more sexually transmitted infections worldwide than any other bacterium. However, to date the immune response in humans against Ct remains incompletely understood. From studies in mice we know that immunization with live Ct leads to priming of protective immune responses by activation of effector T cells, whereas immunization with UV-inactivated Ct produces responses of tolerance by activation of regulatory T cells. We aim to assess the role of human dendritic cell (DC) subsets in Ct infection to understand the natural immune response against Ct and its manipulation by vaccination strategies.

Methods: We are using monocyte derived DCs (moDCs) to test the direct effect of Ct on DCs. In addition, we successfully established an *ex vivo* Ct infection model of cervix samples from donors undergoing hysterectomy. To investigate immune mechanisms in Ct-immunized DC, we performed flow cytometric analysis, RNA-Seq and functional *in vitro* experiments.

Results: MoDCs stimulated with Ct or UV-Ct show differential transcriptional immune programs regulating cytokine response and apoptosis. One striking difference between moDC infected with live and UV-Ct was inclusion formation in a proportion of moDC infected with live Ct, indicating active proliferation of Ct in immune cells, which might influence their T cell priming properties. Furthermore, we observed decreased levels of CCR7 expression upon infection with UV-Ct. In comparison to LPS-stimulated moDC, migration is in general lower in Ct-primed cells, which could explain the absence of long-lasting immunity upon Ct infection. When assessing the *ex vivo* Ct infection model in cervix-derived immune cells, we observed the main immune cell subset taking up Ct being CD14+CD11c+ and CD14-CD11c+ antigen presenting cells.

Conclusions: Our studies provide a first step towards understanding antigen uptake and presentation during human Ct infection, which, ultimately, can lead to new vaccine strategies against this important bacterial sexually transmitted disease.

Microbial SIMs: role in inflammatory balace

Dr. Vani Janakiram[1;2]

[1]*Indian Instute of Technology Madras, Chennai, India*; [2]*Indian Institute of Technology Madras, India*

The two important aspects of an infection include the incoming pathogen and the defending host immune system. *Mycobacterium tuberculosis* (Mtb) is an intra-cellular pathogen that has developed specific mechanisms to invade and survive within its host cells. Immunomodulation in tuberculosis by Mtb has been discussed only as a virtue of the pathogen; however the mechanistic intricacies of the pathogen mediators of immune response alterations have received less attention. Several bacterial proteins have been scrutinized for their immunogenicity since proteins are known to be antigenic in comparison to other macromolecules. However, virulence of Mtb has also been ascribed to a plethora of cell surface lipid moieties for their abundance in the Mtb cell wall. Whilst such large macromolecules and surface associated signatures have often received the deserving attention, the role of small secondary molecules (SIMs) synthesized by the pathogen and their consequence on the host-mycobacteria balance has remained elusive. This talk will discuss preliminary results towards identification of such alternative bacterial mechanisms that may contribute to subversion of host immune responses allowing better survival with least fitness cost to the host.

Immunometabolic profiling of myeloid cells in pediatric patients represents a tool how to depict the dynamics of sepsis progression

Marcela Hortova-Kohoutkova[1;2], Lukas Homola[3], Gabriela Blazkova[1], Rafael Argüello[4], Jan Frič[1;5]

[1]International Clinical Research Center (ICRC), St.Anne's Hospital, Brno, Czech Republic; *[2]International Clinical Research Center (ICRC), Masaryk University, Brno, Czech Republic*; *[3]Department of Pediatric Infection Diseases, University Hospital Brno, Brno, Czech Republic*; *[4]Aix Marseille Univ, CNRS, INSERM, CIML, Centre d'Immunologie de Marseille-Luminy, Marseille, France*; *[5]Institute of Hematology and Blood Transfusion, Prague, Czech Republic*

Background: Sepsis is heterogeneous syndrome with dynamic progression, in late phases associated with immunosuppression, which can persist many months after sepsis onset. The exposure of myeloid cells to environmental stimuli such as invading pathogens or pathogen-originated ligands is followed by their activation leading to a metabolic switch, represented by increased glycolysis linked with anabolic processes. Hence, immunometabolism represents the main governing force for immunity and its defensive functions. Changes in immunometabolic profile occur within minutes and represent the major source of intermediate molecules for defensive processes and also for epigenetic changes associated with long-lasting immunosuppression. This immunometabolic switch ensures the gain of required amount of energy and intermediate metabolites for defensive processes, vital for host protection and his subsequent recovery.

Objectives: The metabolic changes in immune cells represent possible approach how to depict the sepsis dynamics and can reflect the functional ability of cells during sepsis progression. This project aimed to characterize immunometabolic pattern of myeloid cells within sepsis progression.

Methods: Blood samples from pediatric septic shock patients were collected in two time points to cover sepsis progression (TP1 – within first day after ICU admission, TP2 – 5-7 days after ICU admission). We performed the flow cytometry profiling of single-cell energetic metabolism by SCENITH completed with detailed immunophenotypic analysis of myeloid cell subpopulations and their associated functional status.

Results: Using SCENITH we investigated specific metabolic pattern of myeloid cells and their glucose dependence or fatty acid oxidation capacity. We also focused on detailed analysis of myeloid cells, their subsets and activation status by CD86, CD163, CD354 or HLA-DR, together with altered cytokine production. All markers were correlated to the severity of sepsis (SOFA score) to obtain comprehensive information associated also with clinical picture of patients.

Conclusion: In summary, we showed a detailed immunometabolic analysis of myeloid cells of pediatric septic patients together with a characterization of sepsis-altered cells' subset frequency and their ability to perform defensive processes.

A comprehensive immune single-cell atlas of (auto)immune-related diseases: exploring disease and treatment risks in cancer immune-checkpoint therapy

António Sousa[1], Sini Junttila[1], Laura Elo[1;2]

[1]*Turku Bioscience Centre, University of Turku and Åbo Akademi University, Turku, Finland*; [2]*Institute of Biomedicine, University of Turku, Turku, Finland*

Immune-checkpoint therapy (ICT) is one of the most successful treatments against cancer; however, some patients develop immune-related adverse events (irAEs) during the treatment, such as colitis or arthritis. Our study aims to identify immunotherapy-related disease and treatment signatures through the integration of a *Human immune single-cell atlas of (auto)immune-related diseases* comprising ICT, irAEs, and matching autoimmune-related single-cell transcriptomics data.

We built the atlas by integrating six publicly available scRNA-seq datasets, comprising cancer patients under ICT (82 patients; mostly melanoma), with and without irAEs (22 colitis and 8 arthritis patients), and autoimmune datasets matching the irAEs (51 patients). Disease and treatment signatures were assessed through pseudobulk differential gene expression analysis by cluster cell type.

Our human immune single-cell atlas of (auto)immune-related diseases comprises 484,446 cells, 54 clusters, and 27 harmonized cell types. The comparison between ICT-induced and spontaneous colitis signatures identified two cell clusters that shared significant genes (FDR<0.05): naive helper T cells and regulatory T cells. In the former, we identified a 4-gene signature that was upregulated in induced but downregulated in spontaneous colitis, whereas in the latter, a 3-gene signature upregulated in both was identified.

Our atlas can aid identification of disease and treatment signatures in ICT at the immune cell level.

This project has received funding from the European Union's Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement No.: 955321.

Towards deciphering the T cell receptor-antigen-HLA code with single cell genomics

Lisa Dratva[1;2], Lorenz Kretschmer[2], Yizhou Yu[2], Krzysztof Polanski[2], Lisa Marie Milchsack[2], Sarah Teichmann[1]

[1]Wellcome-MRC Cambridge Stem Cell Institute, Cambridge, United Kingdom; *[2]Wellcome Sanger Institute, Hinxton, United Kingdom*

T cells can recognise a plethora of different antigens, presented on HLA molecules, through specific T cell receptors (TCRs) that are unique to individual cells. However, predicting the specificity of a given TCR from its genomic sequence currently presents a major bottleneck for improving our understanding of immune repertoires and developing data-driven approaches for immunotherapies. Recent technological advances in single-cell sequencing have enabled joint profiling of cellular transcriptomes with paired-chain TCR sequences, offering unprecedented insights into disease states and human TCR repertoires. However, interpretation of the data is not straightforward and existing computational tools only focus on individual analysis tasks, such as resolving TCR clones (e.g. Dandelion, MiXCR), sequence similarity-based clustering (e.g. GLIPH, tcrdist3), structural modelling (e.g. AlphaFold), or predicting antigen-HLA binding (e.g. netMHCpan). In order to build a more integrative analysis tool that can facilitate advances in TCR specificity prediction, we have developed Cell2TCR, an open-source package that segments paired-chain TCR sequencing data into functional groups called TCR motifs. Cell2TCR identifies convergent TCR motifs triggered by SARS-CoV-2 infection that are shared across different donors, multiple tissues, and strongly confined to distinct activated T cell states. We experimentally validate the specificity of these TCR motifs and provide compelling statistical evidence for their HLA-restriction. Cell2TCR offers integrated database querying capacities to infer putative antigen specificities for TCR motifs and can inform structural TCR modelling. We showcase the broad applicability of Cell2TCR in various disease contexts, such as cancer and autoimmunity. Overall, Cell2TCR represents a powerful and integrative analysis tool for single cell genomics that opens up new avenues for deciphering the TCR-antigen-HLA code.

Identification of transcriptional regulatory networks that control variable human immune responses.

Anthony Bertrand[1;2], Florian Dubois[1], Lluis Quintana-Murci[3;4], Violaine Saint-André[1;5], Darragh Duffy[1]

[1]Translational Immunology Unit, Institut Pasteur, UPC, Paris, France; *[2]Frontiers of Innovation in Research and Education PhD program, LPI, UPC, Paris, France*; *[3]Human Evolutionary Genetics Unit, Institut Pasteur, UPC, CNRS UMR2000, Paris, France*; *[4]Chair of Human Genomics and Evolution, Collège de France, Paris, France*; *[5]Institut Pasteur, UPC, Bioinformatics and Biostatistics Hub, Paris, France*

There is a strong variability among individuals regarding responses to immune challenges. The “Milieu Intérieur” (MI) project was developed to assess the factors controlling immunity in a healthy population. To do this we established a cohort of 1,000 healthy individuals, balanced for age and sex, and from a homogenous genetic background. From this cohort we previously identified features such as age, sex, genetics, smoking behavior, cytomegalovirus serostatus (CMV) and socioeconomic status (SES) as important factors driving inter-individual differences in human immune response. To have a better understanding of the underlying molecular processes in this variation, transcriptomic data were generated for 200 individuals, aged 20 to 29 years and 60 to 69 years. This data set consists of bulk RNA-Seq data derived from whole blood samples, which were stimulated for 22h with diverse immune agonists including bacterial (LPS), viral (poly(I:C), gardiquimod, ODN and R848) and T-cell activator stimuli (SEB).

Differential analysis of the RNA-Seq data followed by dimension reduction with Regularized Generalized Canonical Correlation Analysis (RGCCA) identified groups of individuals with differential immune responses. Testing associations between these groups of individuals and the characteristics of donors revealed associations of gene expression profiles with the donors’ sex, age, smoking behavior, and cytomegalovirus (CMV) serostatus. Our work thus highlighted subgroups of individuals with different immunological outcomes based on their transcriptional profiles. These findings suggest a strong stimulus specificity in immune responses and also highlight the influences of socio-demographic and immunological factors on gene expression profiles.

Based on these subgroups of individuals we will next study differential transcriptional regulation induced by immune stimulations, by inferring transcriptional networks using tools such as CRCmapper, GRNboost2, or Genie3. Analysis of the differences in these regulatory networks between subgroups of individuals should provide a better understanding of the underlying immune processes and causal role of immune variability in determining disease risk and differential responses to treatments, for improved prevention and patient management strategies.

This programme is managed by the Agence Nationale de la Recherche. This work benefited from support of the French government’s Invest in the Future programme; reference ANR-10-LABX-69-01.

Exploring systemic immune response and faecal microbiome associations in the Milieu Intérieur healthy donor cohort

Auxence Desrentes[1], Etienne Villain[2], Vincent Bondet[2], Jamie Sugrue[2], Allyson Byrd[3], Lluís Quintana-Murci[4], Darragh Duffy[1;2]

[1]Cytometry and Biomarkers UTechS, Institut Pasteur, Université Paris Cité, Paris, France; *[2]Translational Immunology Unit, Institut Pasteur, Université Paris Cité, Paris, France*; *[3]Department of Cancer Immunology, Genentech Inc., San Francisco, United States*; *[4]Human Evolutionary Genetics Unit, Institut Pasteur, Université Paris Cité, Paris, France*

The gut microbiome has been shown to have a significant impact on immune responses in multiple models. However, many of these studies have been performed in disease states, when both the immune response and the microbiome are perturbed. Few studies have examined the impact of the microbiome on healthy immune states. We asked the question of how faecal microbiome and systemic immune responses are associated in a healthy adult human context: the Milieu Intérieur cohort, a genetically homogeneous cohort of 1,000 healthy donors of French ancestry, equally distributed between males and females and between the ages of 20 and 69.

To do this we first defined systemic immune response phenotypes by calculating gene expression scores after whole-blood stimulation with diverse microbes in the donors of the Milieu Intérieur cohort. To characterise the microbiome, we used shotgun sequencing datasets obtained from paired faecal samples. To test for significant associations, we applied either linear regression models or PERMANOVA, on microbiome and blood immune phenotypes, while correcting for potential confounders: age, sex, day of sampling, genetics, BMI, smoking, diet, and frequency of major immune cell components.

While we found no consistent significant correlations between immune scores and alpha diversity measurements, for beta diversity, we saw significant correlations with specific immune responses after Influenza, BCG, and *C. albicans* stimulation. Analysis at the taxa level identified significant associations between the relative abundance of Lactobacillales and Influenza-induced IFNγ, IL-1B, and TNF gene scores. An association was also found for TNF secretion at the protein level. In parallel, we observed significant associations between the relative abundance of Christensenellaceae and Poly:IC-induced IFN-I gene score, which was also found at the protein level for IFNα.

In summary, we identified significant associations between the relative abundance of specific faecal microbiome taxa with systemic immune responses. This included the identification of novel associations as well as confirmation of previously described associations in other contexts. Ongoing and future work will further dissect the immune pathways affected, and test specific hypotheses related to microbiome metabolite immune interactions.

This work benefited from support of the French government's Invest in the Future programme; reference ANR-10-LABX-69-01.

A unique human cord blood CD8+CD45RA+CD27+CD161+ T cell subset identified by flow cytometric data analysis using Seurat

Duan Ni[1], Julen Reyes[1], Brigitte Nanan[1], Gabriela Pinget[1], Lucie Kraftova[1], Thomas Ashhurst[1], Felix Marsh-wakefield[1], Claire Wishart[1], Jian Tan[1], Peter Hsu[1], Nicholas King[1], Laurence Macia[1], Ralph Nanan[1]

[1]*The University of Sydney, Sydney, Australia*

Advances in single-cell level analytical techniques, especially cytometric approaches, have led to profound innovation in biomedical research, particularly in the field of clinical immunology. This has resulted in an expansion of high-dimensional data, posing great challenges for comprehensive and unbiased analysis. Conventional manual analysis is thus becoming untenable to handle these challenges. Furthermore, most newly developed computational methods lack flexibility and interoperability, hampering their accessibility and usability. Here, we adapted Seurat, an R package originally developed for single-cell RNA sequencing (scRNA-seq) analysis, for high-dimensional flow cytometric data analysis. Based on a 20-marker antibody panel and analyses of T cell profiles in both adult blood and cord blood, we showcased the robust capacity of Seurat in flow cytometric data analysis, which was further validated by Spectre, another high-dimensional cytometric data analysis package, and conventional manual analysis. Importantly, we identified a unique $CD8^+$ T cell population defined as $CD8^+CD45RA^+CD27^+CD161^+$ T cell, that was predominantly present in cord blood. We characterized its IFN-γ-producing and potential cytotoxic properties using flow cytometry experiments and scRNA-seq analysis from a published dataset. Collectively, we identified a unique human cord blood $CD8^+CD45RA^+CD27^+CD161^+$ T cell subset and demonstrated that Seurat, a widely used package for scRNA-seq analysis, possesses great potential to be repurposed for cytometric data analysis. This facilitates an unbiased and thorough interpretation of complicated high-dimensional data using a single analytical pipeline and opens a novel avenue for data-driven investigation in clinical immunology.

Purpose: Studies have unveiled a crucial role for the centrosome in T cell activation and that the transition from quiescent to effector T cells is specifically regulated at the translational level. Post-translational modifications (PTMs) are now seen as an increasingly relevant target of investigation due to their great effect on the functional diversity of proteomes and their association to several pathological processes. Newly developed bioinformatics and statistical tools, such as "open search" engines and weighted spectrum, peptide, and protein (WSPP) models, allow the assessment of the proteome-wide variety of PTMs as well as their quantification. Our project aims to handle the unknown wide diversity of PTMs in the T cell centrosomal proteome from both a qualitative and a quantitative point of view using novel algorithms and software specifically developed for this type of -Omic data.

Methods: iTRAQ 4-plex LC-MS/MS data of resting and activated T lymphoblasts centrosome-enriched fractions obtained from thirty healthy donors were analysed. Results were validated in separate label-free T lymphoblast centrosome samples as well as in a TMT 10-plex T lymphoblast activation kinetics.

Results: This work describes the comprehensive T cell centrosome PTM map and assesses the differential PTM levels analysis, showing coordinated changes of specific modifications during T cell activation.

Conclusion: Altogether our results underscore PTMs as a potential regulatory element of the centrosome role in T cell activation.

Purpose: Autoimmune diseases are characterised by an immune response against self-antigens. This dysregulated response evolves as the disease progresses, and is dependent on a plethora of complex yet scarcely explored cellular interactions. Primary Sjögren's Syndrome (pSS) is an autoimmune disease that chiefly affects salivary and lacrimal glands, causing a deterioration of the tissue and its function. Over time, infiltrating immune cells organise into Tertiary Lymphoid Structures (TLS), which will contain active Germinal Centres responsible for the continued maturation and activation of self-reactive B cells. In a subset of patients, this potentiates the appearance of intraglandular B cell lymphoma. However, it is still unknown which alterations in infiltrating immune cells and the tissue milieu correlate with disease progression, and how they promote the appearance of this malignancy.

Methods: In order to reveal the varying cellular heterogeneity in the immune and non-immune populations of salivary glands, we recruited pSS patients at early (<2 years since diagnosis) and late (>10 years since diagnosis) disease stages, and performed high-throughput single-cell RNA-seq (scRNA-seq) on minor salivary gland biopsies, with paired blood samples.

Results: Using data integration, we identified increased infiltrating B and T cell proportions with a heightened immune activation correlating with disease progression. Furthermore, cell-cell communication analysis revealed crucial ligands produced by various stromal cell populations important for maintaining the TLS immune functions.

Conclusion: By identifying these early-to-late patterns in the immune cells infiltrating the salivary gland, we will be able to survey the patient's associated blood sample and assess which genes can be used as biomarkers to track disease progression in the clinic.

Purpose: Months after acute COVID-19 disease, a substantial proportion of patients suffer from long-term symptoms known as post-COVID-19 syndrome, which comprises a heterogeneous multitude of symptoms involving different organs. As a newly arising disease, the underlying pathomechanisms of post-COVID-19 syndrome are not resolved yet, but ongoing inflammation is discussed as one of the drivers of these long-term sequelae. Focusing on patients suffering from post-COVID-19 syndrome with persistent fatigue and exertion intolerance after mild to moderate acute disease, this study was designed to examine if there are transcriptional changes in circulating blood immune cells of these patients - at steady state or after ex vivo stimulation - that could help clinical diagnosis as well as guide the development of therapeutic strategies.

Methods: Single-cell RNA sequencing of blood immune cells from post-COVID patients and control donors, fully recovered from SARS-CoV-2 infection, was performed at steady state and after *ex vivo* whole blood stimulation.

Results: Peripheral blood mononuclear cells presented with distinct disease-associated transcriptional changes pointing towards an inflammatory state in the circulation of post-COVID-19 patients. Specifically, NK cell subpopulations characterized by cytokine production and a *FCGR3A* (CD16)-expressing cytotoxic T cell population, previously described in acute COVID-19 disease and shown to induce endothelial cell damage, were more abundant in post-COVID-19 patients. Further, monocytes displayed an inflammatory transcriptional profile in patients with post-COVID syndrome. Ex vivo stimulation revealed a comparable transcriptional response of monocytes from post-COVID-19 patients and recovered individuals to TLR4/TCR- and TLR3-stimulation, while the response to SARS-CoV-2 spike protein was heterogeneous among the post-COVID-19 patients especially in the expression of several chemokines.

Conclusion: This study provides insights into the systemic immunological alterations of post-COVID-19 patients during the disease's steady-state as well as under immune challenge, contributing to a better characterization of this disease paving the way for biomarker development and exploration of therapeutic strategies.

The dog as the immunologist's best friend for identifying potential genomic biomarkers for atopic dermatitis: an integrated bioinformatic analysis with translational potential.

Carolina R. Sanz[1;2], Inés Rodríguez[3], Soledad Sanz-Alférez[3]

[1]Animal Health Department, School of Veterinary Medicine, Complutense University of Madrid, Madrid, Spain; *[2]Department of Veterinary Medicines, Spanish Agency of Medicines and Medical Products, Madrid, Spain*; *[3]Biology Department, Faculty of Science, Autonomous University of Madrid, Madrid, Spain*

Purpose: Canine atopic dermatitis (AD) is a complex skin disease commonly seen in veterinary practice that resembles human AD, particularly in clinical and immunological aspects. AD may be influenced by multiple environmental and genetic factors in both species, with a strong breed predisposition described in dogs. Considering that the dog is the most suitable spontaneous model for several human genetic diseases, exploring the molecular mechanisms underlying canine AD also may contribute to better understand the pathogenesis of human AD. Thus, we aimed to identify shared genomic variants among dog breeds highly susceptible for AD, that also differ from breeds with the lowest incidence of the disease, as they might influence the pathogenesis of AD.

Methods: We integrated multiple bioinformatic approaches to analyse the whole-genome sequences of 171 purebred dogs from 14 AD-susceptible and 14 AD-protected breeds. Firstly, we applied the XP-EHH method, followed by a GWAS, functional enrichment analyses for GO terms related to biological processes and KEGG pathways and, finally, a SIFT-value estimation for predicting the effects of candidate variants on protein functions. Analyses were performed using PLINKv1.90 and Rv3.2.2. The threshold for statistical significance was set at p-value ≤0.05.

Results: We identified 11 genomic regions that significantly differed between susceptible and protected dog breeds and contained 32 candidate genes (e.g. *SOCS6, IL9, CD4, CD27, MAPK8, C1R, C1S,* among others) that were enriched in GO terms related to immune response. Furthermore, we detected a total of 549 variants predicted to have detrimental effects on protein function (SIFT-value ≤0.05) that were also located in these regions. Functional analyses revealed that candidate genes specifically participate in the following biological processes: complement activation via classical pathway, Th2 cell differentiation, humoral immune response mediated by circulating immunoglobulin, and PI3K-Akt signaling pathway, which is essential during inflammation, as it regulates the activation of neutrophils and mast cells, and promotes phagocytosis and cytokine production.

Conclusion: Genomic variants located within the candidate genes here identified are likely to play a key role in the immunopathogenesis of AD. Further studies are warranted to validate their potential use as biomarkers in human and veterinary clinical practice.

Computational stabilization and functional characterization of single-chain T cell receptors targeting a cancer epitope

Johanna Moeller[1;2], Max Alexander Lingner[2], Victoria Most[2], Clara Tabea Schoeder[1;2;3]

[1]Center for Scalable Data Analytics and Artificial Intelligence (ScaDS.AI) Dresden/Leipzig, Leipzig University, Leipzig, Germany; *[2]Institute for Drug Discovery, Faculty of Medicine, Leipzig University, Leipzig, Germany*; *[3]Fraunhofer Institute for Cell Therapy and Immunology, Leipzig, Germany*

Advances in the development of targeted immunotherapy with T cell-based therapeutics have led to an increased interest in the T cell receptor (TCR) and its natural ligand, the peptide loaded major histocompatibility complex (pMHC). TCRs are heterodimeric proteins, which complicates handling in research and their application as therapeutics. For the structurally similar antibody Fab region, this problem has been solved by generating single-chain variable fragment (scFv). In return, a single-chain TCR (scTv) construct would be highly beneficial, combining the assets and flexible applications of scFv's and the specific TCR binding properties. Here, we apply rational protein design to increase stability of the highly unstable scTvs. Mutants were expressed *in vitro* and evaluated for stability as well as functionality.

To produce scTvs with increased stability compared to wild type, the known 1G4 (targeting NY-ESO1$_{157\text{-}165}$ peptide bound to HLA-A*0201) was chosen as a template. The scTv was rationally designed using ProteinMPNN, a deep learning-based method for the design of protein sequences (Dauparas J *et al.*, 2022), and Rosetta, a software-suite that allows for protein design with a physics- and statistics-based energy function (Kuhlman B, 2019). The resultant mutants were expressed in Expi293 cells. Functionality of the scTvs was evaluated *in vitro* using biolayer interferometry (BLI), determining scTv pMHC binding kinetics compared to wild type and TCR-like antibodies as a positive control.

Computational protein design of the chosen scTv led to improved expression rates for the tested constructs compared to wild type. A BLI assay was established and used to evaluate the kinetics of the pMHC-scTv interaction. The measured affinities of scTvs and control antibodies agreed well with K_D values known from literature, confirming the functionality of the stabilized scTvs. In conclusion, we introduced a pipeline for the computational stabilization and expression of pMHC-binders, which can then be tested for functionality in a robust BLI assay, thus facilitating the streamlined design and optimization of specific T-cell epitope binders for different pMHCs of interest.

A simple and robust bulk TCR sequencing-based method for identification of antigen-specific TCRαβ pairs

Evgeny Egorov[1], Ekaterina Serebrovskaia[1], Lilian Andrea Martinez Carrera[1], Nojan Jelveh[1], Kevin Bisdorf[1], Simona Karolin Matzke[1], Svetlana Khorkova[1], Andreas Bosio[1], Dmitriy Chudakov[2], Olaf Hardt[1]

[1]*Miltenyi Biotec, Bergisch Gladbach, Germany*; [2]*Central European Institute of Technology, Masaryk University, Brno, Czech Republic*

Purpose: Despite progress in the recent years, there is still high need for simple, robust and easily multiplexible methods for identification of TCRs specific to antigens of interest, including identification of native TCRαβ pairs. In this study we aimed to develop a bulk TCR sequencing-based approach for antigen-specific TCR identification that exploits the ability of T cells to respond to antigenic stimuli by proliferation in vitro.

Methods: Peripheral blood mononuclear cells (PBMCs) isolated from healthy donor blood were stimulated with peptide mixes for 7 days in the conditions allowing for antigen-specific proliferation. Proliferation was monitored by the dye-dilution assay and flow cytometry. Following the cultivation stage, cells were lyzed and used for TCR repertoire library generation. Pre-cultivation CD4 and CD8 T cell repertoires were obtained from PBMCs magnetically enriched for the respective subsets. Subsequent bioinformatic analysis consisted of 1. identification of antigen-expanded clonotypes, 2. attribution of the identified clonotypes to the CD4 or CD8 subset, and 3. frequency correlation-based TCRαβ pairing.

Results: The described approach allows to identify expanded CD4 T cell clonotypes with initial frequency as low as 1 in 100000 cells, and CD8 T cell clonotypes with initial frequency of 1 in 10000 cells. For approximately 25% of TCRβ clonotypes, a corresponding TCRα paired clonotype could be identified. Comparison with single cell TCR sequencing data revealed 45% sensitivity and 71% specificity of our pairing approach. CD4/CD8 attribution of paired clonotypes further supported accuracy of this pairing approach, with no attribution conflicts observed for paired clonotypes.

Conclusion: We believe that the approach described hereby will further enable and simplify TCR discovery in various fields, including cancer immunology, autoimmune and infectious disease research.

Development of an User-Friendly Application for Automated Analysis of Skin Immune Landscape based on the Multiplex Annotated Tissue Imaging System technology.

Manon Scholaert[1], Raissa Houmadi[2], Jeremy Martin[2], Nadine Serhan[2], Marie Tauber[2], Emilie Braun[1], Mathias Peries[1], Lilian Basso[1;2], Eric Merles[3], Pascal Descargues[3], Carle Paul[2], Cristina Bulai Livideanu[2], Laurence Lamant[2], Emeline Pages[1], Nicolas Gaudenzio[1;2]

[1]Genoskin, Toulouse, France; *[2]Toulouse Institute for Infectious and Inflammatory Diseases (Infinity) INSERM UMR1291 - CNRS UMR5051 - University Toulouse III, Toulouse, France*; *[3]Genoskin, Salem, United States*

Purpose: The aim of the project is to develop an user-friendly interface to automate the analysis of 3D multiplexed images generated with Multiplex Annotated Tissue Imaging System (MANTIS) and explore complex immune environments in human tissue. MANTIS allows to quickly generate and explore 10 fluorescent signals acquired simultaneously in 3D using conventional confocal microscopes. This application aims to facilitate a comprehensive analysis of the skin immune landscape with integrated cell attribution, spatial analysis, and statistical comparisons.

Methods: The application was previously designed for automated phenotypic attribution based on selected combinations of biomarkers to identify immune subsets, while considering structural compartments (e.g. vessels, dermis or epidermis). Leveraging multiplexed 3-D imaging data and unsupervised bioinformatics, we developed an interactive data exploration pipeline. This includes graphical representations of cell counts, digital maps for spatial localization, and clustering analysis via t-distributed stochastic neighbor embedding (t-SNE). Additionally, it facilitates spatial visualization of biomarker expression, heatmap generation for biomarker intensity, automatic identification of regions of interest (ROI) using an alpha shape algorithm, calculation of cell-to-distances and statistical comparisons between conditions. Analysis can be performed per sample, per donor, or per cohort. We analyzed and compared acral lesions from patients with systemic lupus erythematosus, Kawasaki syndrome, or COVID-19–associated skin manifestations.

Results: By integrating advanced analytical tools into our user-friendly interface, we observed that severe pathological lesions from systemic lupus erythematosus, Kawasaki syndrome, or COVID-19–associated skin manifestations shared common quantitative immune features while displaying a nonrandom distribution of cells with the formation of disease-specific dermal immune structures. Notably, COVID-19-associated acral lesions were preferentially enriched in CD8 $CD57^{high}$ T cells, a subset previously described to damage tissues during viral infections, that heavily infiltrated epidermal layers.

Conclusion: The MANTIS user-friendly application enabled to combine the power of automated processing and interactive visualization tools, to offer a comprehensive solution for exploring, understanding, and interpreting complex immune environments in the skin.

Glycosyltransferase and glycosidase changes in Natural Killer (NK) cells after cytokine stimulation; a bioinformatic analysis

Catherine Bannon[1], Roisín O'Flaherty[1], Mark Robinson[1]

[1]*Maynooth University, Maynooth, Ireland*

Purpose: Protein glycosylation is a ubiquitous post-translational modification occurring in the endoplasmic reticulum (ER) and Golgi apparatus. The types and frequency of protein N-glycosylation is modified in different cellular states and directly influences the functional properties of cellular proteins. Natural killer (NK) cells are innate cytotoxic lymphocytes with important anti-tumour functions, however, the role that glycosylation plays in the function of NK cells is poorly understood. Glycan profiles are studied through the expression and activity of biosynthetic enzymes, namely glycosyltransferases and glycosidases. This study aims to define the changes in expression of glycosylation enzymes before and after cytokine stimulation of *ex vivo* populations of NK cells.

Methods: Next generation RNA sequencing datasets of cytokine stimulated human NK cells were identified and selected for suitability from the genome expression omnibus (GEO) data repository. Utilising the Galaxy EU web platform fastq files were aligned to the Human Reference Genome hg38 by HISAT2. Read counts were determined by *htseq-count* in reference to hg38 annotated features. Differential gene expression was examined using the DESEQ2 tool. From the data, read counts of glycan biosynthetic enzyme transcripts were collated and statistically analysed.

Results: A total of nine datasets compared unstimulated NK cells to NK cells following 12-72 hours of cytokine stimulation. The results showed significant upregulation of enzymes involved in early biosynthesis of glycan core structures and transfer to proteins prior to folding in the ER, suggesting increased demand for glycan synthesis after NK activation. Mannosidases trim mannose moieties from initial high mannose templates, as glycoproteins move from the ER to Golgi apparatus. These enzymes regulate the transition to multi-antennary complex and hybrid glycans. Differential expression hints at increased production of hybrid glycans. The remaining enzyme changes indicate increased poly-N-acetyllactosamine (LAcNAc) chain formation, fostering the formation of ABO and Lewis antigens, and serving as ligands for galectin carbohydrate-binding proteins (CBP). The CBP family has been shown to increase activation of innate immune responses and induce proinflammatory cytokine production from monocytes.

Conclusion: Our results show that upon cytokine stimulation, glycan biosynthesis increases, with a trend towards LacNac chain formation, possibly enhancing galectin binding activity.

Genetic signature for early prediction of anti-TNF response in Rheumatoid Arthritis Patients

Lucía Santiago Lamelas[1;2], Josefina Durán[3], Enrique J de Andrés Galiana[4], Juan Luis Fernández Martínez[4;5], Patricia Castro Santos[1;2;6], Roberto Díaz Peña[1;2;6]

[1]Health Research Institute of Santiago de Compostela, Santiago de Compostela, Spain; *[2]Fundación Pública Galega de Medicina Xenómica, Santiago de Compostela, Spain*; *[3]Pontificia Universidad Católica de Chile, Santiago, Chile*; *[4]Universidad de Oviedo, Oviedo, Spain*; *[5]DeepBioInsights, Spain, Spain*; *[6]Universidad Autónoma de Chile, Talca, Chile*

Rheumatoid arthritis (RA) is a chronic inflammatory disease affecting approximately 0.5-1% of the global population, being higher in females. It is characterized by synovial joint inflammation and destruction, progressive disability, and reduced quality of life. In fact, 80% of insufficient treated patients develops misaligned joints, and half of them are unable to work within ten years after the diagnosis.

Anti-TNF agents have revolutionized the treatment of RA, significantly improving clinical outcomes. However, almost 30% of treated patients show an inadequate response and reliable response predictors are not described until now. Therefore, the aim of our study was the determination of biomarkers useful in the prediction of the response to anti-TNF therapy in RA patients. Here, we hypothesized that transcriptomic data could serve as a prognostic and predictive biomarker in RA patients under anti-TNF. Indeed, we reported a transcriptomic signature with high capacity to predict the response to anti-TNF treatment in patients with RA, before its initiation.

We perform a retrospective analysis of whole peripheral blood mononuclear cells (PBMC) transcriptomic profiling of patients with RA, to define the small-scale signature genes involved in the response to anti-TNF treatment. We carry out differential gene expression analysis and ranked the most discriminatory genes to establish a small-scale genetic signature.

Based on the initial analysis of RNA-Seq results, 53 differentially expressed genes were identified between responders (R) and non-responders (NR) and the selection of the 18 most discriminatory genes reached a predictive accuracy of 88.75%When we evaluated the minimal number of genes with relevant discriminatory power using ROC analyses, we stated a predictive model composed of 6 genes that effectively discriminate R and NR, with an area under the curve (AUC) of 0.81.

Our 6-gene genetic signature could be used as a method to distinguish between R and NR to anti-TNF treatments and therefore, to predict the response of RA patients to these therapies.

Employing single-cell RNA sequencing dataset analysis to probe the functional and metabolic state of NK cells infiltrating Glioblastoma tumour sites, and comparing them to the transcriptomic profiles of circulating NK cells derived from healthy donor datasets

Andrew Roche[1], David Finlay[1], Clair Gardiner[1]

[1]*Trinity College Dublin, Dublin 2, Ireland*

Purpose: Glioblastoma Multiforme (GBM) is the most common and aggressive type of brain cancer in adults, with a poor 5-year survival rate. A prominent contributing factor to this poor prognosis is the hostile tumour microenvironment (TME) of GBM, that induces immune failure and impedes efficacy of immunotherapies. Therefore, it is vital to characterise the epigenetic changes that tumour infiltrating NK Cells (TINKs) undergo to become dysfunctional. As innate responders to cancer, illustrating the differences in gene expression of healthy circulating NK cells and TINKs may be insightful for underlining the fundamental factors of NK cell dysfunction immune failure in GBM. Utilising single cell RNA-seq compiled from multiple datasets can be highly informative for exploring these questions. We hypothesised that GBM TINKs convey have dysregulated gene expressions that are reflected both in function and metabolism.

Methods: Data used in this bioinformatic research was sourced from the pre-published work of Netskar et al., 2023. This preliminary paper integrated data from over 40 single-cell and bulk datasets, sourced from cancer patients and healthy donors, into a ready-to-use, open access data resource. From this, we specifically focused on examining NK cell transcriptome profiles from healthy and GBM patient datasets.

Results: The resultant work highlighted the altered transcriptomic profiles of TINKs compared to Healthy peripheral NKs. This included upregulated gene signature for reactive oxygen species (ROS) and associated mitochondrial complexes - sources of ROS in TINKs. Further alterations of gene signatures implicated in NK Cell dysfunction included TGF-Beta signalling pathway and ER stress etc. Finally, we modelled specific metabolic and cellular signalling pathways that could help explain TINK dysfunction in GBM.

Conclusion: Our data provides an insightful perspective to understanding the TME's impact on NK cell dysfunction. The findings produced from this work can inform practical approaches to examining the immune challenges of GBM and help in the design NK cell immunotherapies.

Natural killer (NK) cells are innate-like lymphocytes that belong to the family of type-1 innate lymphoid cells and rapidly respond to virus-infected and tumor cells. In this study, we have combined scRNA-seq data and bulk RNA-seq data to define phenotypic and molecular characteristics of peripheral blood NK cells. While the role of NK cells in immune surveillance against virus infections and tumors has been well established, their contribution to protective responses to other intracellular microorganisms, such as *Mycobacterium tuberculosis* (Mtb) is still poorly understood. In this study we have combined scRNA-seq data and bulk RNA-seq data to illuminate molecular characteristics of circulating NK cells in patients with active tuberculosis (TB) disease and subjects with latent *Mycobacterium tuberculosis* infections (LTBI) and compared these characteristics with those of healthy donors and patients with non-TB other pulmonary infectious diseases and have validated relevant results by flow cytometry on a small cohort of subjects. We show here that LTBI subjects have a significant expansion of NK cells characterized by the prevalence of a memory-like $CD52^{+}NKG2C^{+}$ NK cells. Altogether, our results provide some new information on the role of NK cells in protective immune responses to Mtb.

Identification of relevant tissue-specific factors regarding the formation and maintenance of human tertiary lymphoid structures

Tomás Guerreiro[1], Rui do Amaral Vieira[1], Beatriz Filipe[1], Pedro Gaspar[1;2], Luís Graça[1], Tomás Gomes[1]

[1]*Instituto de Medicina Molecular, Lisbon, Portugal*; [2]*Hospital Santa Maria, Lisbon, Portugal*

Purpose: Immune cell infiltration can lead to the formation of Tertiary Lymphoid Structures (TLS), composed of cells highly engaged in antigen presentation, T cell activation, and B cell maturation in Germinal Centre-like structures. The presence of such structures in disease-afflicted tissues significantly shapes the prognosis of multiple autoimmune diseases and cancers.

We aim to identify human tissue-specific factors, cell-cell interactions, cell types, and cell states taking part in the formation and maintenance of TLS. Besides gaining a better insight into the poorly explored biology of TLS in a tissue-specific context, we seek to possibly establish a starting point for diagnostic (patient stratification) and therapeutic approaches.

Methods: Single-cell RNA sequencing data of autoimmune diseases from various tissues were collected and analysed to obtain a cell type and state census for each tissue. Cell-cell interaction inference methods were used to predict general and tissue-specific signalling events related to TLS. The relevance of these genes is then assessed by comparison with disease-specific databases.

Results: A collection of annotated cell types and interactions, associated with different tissues and autoimmune diseases.

Human DNA adaptome: the unbiased multiplex PCR-based profiling of the whole set of TCR and BCR chains at the DNA level

Anna Miroshnichenkova[1], Bella Minasyan[1], Valeria Tkachenko[2], Anna Fedosova[1], Oleg Suchalko[1], Pavel Shelyakin[1], Dmitriy Chudakov[1;3], Alexander Komkov[1]

[1]Abu Dhabi Stem Cells Center, Abu Dhabi, United Arab Emirates; *[2]Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Moscow, Russian Federation*; *[3]CEITEC, Masaryk University, Brno, Czech Republic*

Sequencing of T and B-cell receptor (TCR and BCR) genes is an insightful practice in basic and applied immunological research that indicates normal and pathological conditions. Here, we present the first-ever ultra-multiplex DNA-based PCR system designed to simultaneously analyze all TCR chains (TRA, TRB, TRG, TRD) and all BCR chains (IGH, IGK, IGL) in a single assay.

The study analyzed DNA from the venous blood of 40 healthy donors and bone marrow of 10 patients with B-cell leukemia before and after therapy. The sequencing data was processed using MiXCR software.

The actual DNA adaptome assay includes multiplex primers annealing to V- and J-gene regions, and upstream of D-gene regions. To reduce PCR bias, primer concentration is optimized using a new computational approach based on the ratio of weighted and unweighted frequencies of V, D, and J genes among nonproductive TCR and BCR rearrangements. The results obtained for normal samples show the ability to identify all functional V and J genes in productive (in-frame) and nonproductive (out-of-frame), partial (D-J, V-D) and complete (V-D-J and V-J) rearrangements in TCR and BCR loci. In fact, we detected 47 TRAV, 59 TRAJ, 56 TRBV, 13 TRBJ, 12 TRGV, 5 TRGJ, 8 TRD, 4 TRDJ, 63 IGHV, 6 IGHJ, 46 IGKV, 5 IGKJ, 44 IGLV, 5 IGLJ genes across the analyzed samples. Productive rearrangements have been presented in samples in ratios proximal to physiological. Tested DNA load from 100 pg (15 cells) to 400 ng (60 000 cells) per 25 uL assay shows flexibility and sensitivity suitable for most applications. Applying adaptome assay for leukemic samples, we identified abnormally expanded clonotypes (rearrangements) in onset time points. Using these clonotypes as biomarkers for Measurable Residual Disease we were able to detect the presence of remaining leukemic cells in patient samples after therapy.

The presented adaptome assay is characterized by low time consumption and a high level of simplicity in use, which prevents human errors and allows automatization. It allows the extraction of maximum information from the analyzed sample with high sensitivity and precision, required for research and diagnostics.

VISH-Pred: An ensemble of fine-tuned ESM models for protein toxicity prediction

Ankita Singh[1], raghvendra Mall[1], Chirag Patel[1], Gregory Guirimand[1], Filippo Castiglione[1]

[1]*Technology Innovation Institute, Abu Dhabhi, United Arab Emirates*

Purpose: Peptide and protein based therapeutics are becoming a promising treatment regimen for myriad diseases. Toxicity of proteins is the primary hurdle for protein-based therapies. Thus, there is a need for accurate *in silico* methods for determining toxic proteins to filter the pool of potential candidates.

Methods: To address this challenge, we proposed an ensemble framework, called VISH-Pred, comprising models built by fine-tuning ESM2 transformer models on a experimentally validated and curated large dataset of protein and peptide toxicities. The primary steps in VISH-Pred framework is to efficiently estimate protein toxicities taking just the protein sequence as input, employing an under sampling technique to handle the humongous class-imbalance in the data, and learning representations from fine-tuned ESM2 protein language models which are then fed to machine learning techniques such as Lightgbm and XGBoost.

Results: The VISH-Pred framework is able to correctly identify both peptides/proteins with potential toxicity and non-toxic proteins, achieving an MCC of 0.737, 0.716 and 0.322 and F1-score of 0.759, 0.696, and 0.713 on three non-redundant blind tests respectively, outperforming other methods by over 10% on these quality metrics. Moreover, VISH-Pred achieved the best accuracy and AUC scores on these independent test sets, highlighting the robustness and generalization capability of the framework.

Conclusion: By making VISH-Pred available as an easy-to-use web-server, we expect it will serve as a valuable asset for upcoming endeavors aimed at discerning the toxicity of peptides, enabling efficient protein-based therapeutics.

Purpose: Sepsis is a life-threatening condition that is characterised by an abherrent immune response to trauma or infection. Throughout the course of sepsis, the function and diversity of peripheral blood mononuclear cells (PBMCs) become perturbed. These alterations persist post recovery from sepsis, however many of those who survive experience long term sequelae. Understanding these alterations may identify prognostic and potential therapeutic markers to help reduce the burden of this condition.

Methods: This study used a multi-omic approach involving the BD Rhapsody™ single cell sequencing pipeline, utilising PBMCs from people with sepsis, bacteraemia without sepsis and 'healthy' controls. We leveraged the concurrent measurement of transcriptome and surface protein expression to identify and characterise PBMC populations.

Results: Using this multi-omic approach, we identified 18 distinct cell types, including 14 T cell populations, 1 NK cell and 3 B cell populations using the surface protein expression of conventional and phenotypic markers. Among the T cell populations, we detected a population of *CD69*+ naïve T CD4+ T cells via their expression of naïve markers CD45RA and CD197 surface protein and *CD69* gene expression. Interestingly, this population of T cells was present at higher proportions (1.99 log2 FC) in people with sepsis compared to the control group. Other increased PBMC populations in the sepsis group included Th17 (0.99 log2 FC), Treg (0.99 log2 FC), Th2 (0.75 log2 FC) and Th1 (0.7 log2 FC) cells compared to controls. Conversely, when compared to both the control and bacteraemia groups, sepsis samples presented with significantly decreased proportions of cytotoxic cell subsets, including NK cells (-2.19 & -0.61 log2FC *vs* control and bacteraemia respectively), CD56+ T cells (-2.13 & -2.17 log2 FC), terminally differentiated CD8+ T cells (-1.27 & -3.23 log2 FC), and γδ T cells (-0.74 & -0.83 log2 FC).

Conclusion: Overall, these results highlight the value of using a multi-omic approach to studying immune cell populations and highlight the proportional perturbations to functional immune cell subsets in sepsis.

Programmed Salmonella blocks cancer metastasis by activating NK cells in an IFN-γ-dependent manner

Li Rong[1], Qiubin Lin[1], Shuhai Lin[2], Guo Fu[2], Jiandong Huang[1]

[1]The University of Hong Kong, Pokfulam; *[2]Xiamen University, Xiamen, China*

Purpose: To investigate the potential of bacterial cancer therapies, specifically attenuated Salmonella typhimurium strain YB1, as a novel approach for evoking anti-tumor immune responses and suppressing metastasis in various cancer types.

Methods: We utilized an attenuated Salmonella typhimurium strain YB1 engineered by our lab to study its effect on cancer metastasis. We analyzed the induced cytokines, identified the indispensable factors, and used CyTOF analysis and antibody-mediated cell depletion to determine the major immune cells involved in Salmonella-provoked metastasis suppression.

Results: Our study revealed that attenuated Salmonella effectively suppressed cancer metastasis, regardless of cancer types and genetic background, by evoking strong anti-metastatic immune responses. We identified IFN-γ as an indispensable factor for inhibiting cancer metastasis, and NK cells as the major immune cell type responsible for Salmonella-induced metastasis suppression. We found that IFN-γ was primarily produced by NK cells during early Salmonella infection, which in turn promoted the accumulation, activation, and cytotoxicity of NK cells.

Conclusion: Attenuated Salmonella typhimurium strain YB1 has a potent suppressive effect on cancer metastasis by evoking strong anti-metastatic immune responses, primarily through IFN-γ-dependent NK cells. This bacterial cancer therapy represents a promising alternative approach for targeting solid tumors and warrants further investigation for potential clinical applications in cancer treatment.

Ex vivo modeling of precision immuno-oncology responses in lung cancer

Bassel Alsaed[1;2], Johannes Smolander[1;2], Linh Lin[1;2], Lilja Lahtinen[1;2], Hanna Laitinen[1;2], Mikko Rasanen[2;3], Ville Heistman[2;3], Shadi Jansouz[2;4], Mari Ainola[2;5], Eva Sutinen[2;6], Pipsa Saharinen[2;4], Ilkka Ilonen[2;3], Heidi Haikala[1;2]

[1]Translational Immunology Research Program (TRIMM), Research Programs Unit, Faculty of Medicine, University of Helsinki, and Helsinki University Hospital Comprehensive Cancer Center, Helsinki, Finland; *[2]iCAN Digital Precision Cancer Medicine Flagship, Helsinki, Finland*; *[3]Department of General Thoracic and Esophageal Surgery, Helsinki University Hospital, Helsinki, Finland*; *[4]Translational Cancer Medicine Program (CAN-PRO), Research Programs Unit, Faculty of Medicine, University of Helsinki, Helsinki, Finland*; *[5]Individualized Drug Therapy Research Program, Faculty of Medicine, University of Helsinki, Helsinki, Finland*; *[6]Department of Pulmonary Medicine, Heart and Lung Center, Helsinki University Hospital, Helsinki, Finland*

Immunotherapy has changed the treatment landscape in some cancers and even led to favorable outcomes in previously incurable cancer types. Despite the potential benefits, only a fraction of patients respond to current immuno-oncology (IO) treatments. Lack of predictive biomarkers, unknown mechanisms of immune resistance, complex tumor-immune interactions, and the understudied role of the tumor microenvironment pose significant challenges to the use of IO drugs. Moreover, predicting which patients would benefit from the expensive new treatments remains a significant challenge.

To address these challenges, we have developed a personalized ex vivo tumor model, which can be used to screen for immunotherapy responses and discover immunotherapy biomarkers in lung cancer. We are doing so by first stimulating the patient's immune cells with autologous tumor organoids. This is followed by a tumor-killing assay utilizing the stimulated immune cells with or without different immunotherapy combinations. Lastly, we single-cell sequence different treatment conditions to reveal changes occurring to the immune cells after their interactions with the tumor organoids.

By using this set-up, we were able to model lung cancer anti-PD-1 (Nivolumab) primary resistance ex vivo, and identify individual responders to anti-PD-1 combined with chemotherapy agents. In addition, we have discovered a novel IO-drug combination of anti-PD-1 and another immune checkpoint inhibitor that was able to overcome Nivolumab resistance in some patients. Furthermore, we have identified potential biomarkers for both combination resistance and response, which will be further validated in the future.

CD40 agonist affects maintenance of B-cell acute lymphoblastic leukemia in patient-derived xenograft mouse models

Pierre-Simon Bellaye[1;2], Paola Ballerini[3], Corentin Richard[2], Romain Boidot[2], Guillaume Chevreux[4], Véronique Legros[4], Aleksandra Georgievski[1], Julien Guy[1;5], Jessica Racine[5], Bertrand Collin[2], Carmen Garrido[1;2], Ronan Quéré[1]

[1]*Inserm UMR1231, Dijon, France*; [2]*Centre Georges-François Leclerc-Unicancer, Dijon, France*; [3]*Laboratoire d'Hématologie, Assistance Publique Hôpitaux de Paris, Hôpital Armand Trousseau, Paris, France*; [4]*Université Paris Cité, CNRS, Institut Jacques Monod, Paris, France*; [5]*Service d'Hématologie biologique, Centre Hospitalier Universitaire de Dijon, Dijon, France*

Purpose: We investigated the effect of a CD40 agonist antibody on B-cell acute lymphoblastic leukemia (B-ALL) using patient-derived xenograft (PDX) mouse models. Specifically, the study aimed to assess the impact of CD40 stimulation on B-ALL cell proliferation, signaling pathways, apoptosis induction, and leukemia-initiating cell frequency.

Methods: Patient-derived xenograft (PDX) mouse models were utilized to study the effect of a CD40 agonist antibody on B-ALL. Intravenous injection of the CD40 agonist antibody was administered to the PDX mice. Various assays were employed to evaluate the effects of CD40 stimulation, including RNAseq analysis, western blotting, flow cytometry, and proteomic analysis. Specific parameters assessed included alterations in cell proliferation, activation of signaling pathways, apoptosis induction, cell cycle progression, and changes in protein expression profiles.

Results: The i.v. injection of the CD40 agonist significantly altered the proliferation and growth of B-ALL cells in vivo. CD40 stimulation rapidly activated the ERK1/2 pathway in B-ALL cells. Flow cytometry analysis demonstrated that the CD40 agonist induced apoptosis and affected the cell cycle and proliferation of B-ALL cells in PDX mice. Proteomic analysis revealed alterations in proteins associated with B-cell receptor signaling, the mitotic cell cycle, and homeostatic processes, suggesting significant impacts on crucial signaling pathways involved in B-ALL cell expansion and maintenance. Administration of the CD40 agonist profoundly altered the frequency of leukemia-initiating cells and the development of leukemia in PDX mice.

Conclusion: The study findings indicate that CD40 agonists represent a promising immunotherapeutic strategy for the treatment of pediatric B-ALL. These preclinical results provide a basis for future clinical trials aimed at evaluating the efficacy of CD40 agonists in the treatment of B-ALL, offering potential avenues for improving patient outcomes in this disease.

Purpose: Oesophageal adenocarcinoma (OAC) is a poor prognosis cancer with a 5-year survival rate of less than 25%. Current response rates to chemo-radiotherapy are only ~30% and new therapeutics are urgently needed. The pro-inflammatory chemokine fractalkine plays a role in the disruption of anti-tumour immunity in OAC via its recruitment of Natural Killer (NK) cells to the visceral adipose tissue (VAT). Furthermore, our group have shown that CX3CR1 modulator E6130 can redirect NK cells away from chemotactic cues of OAC omentum and towards tumour. Here, we propose that fractalkine may also directly promote OAC tumour growth and that E6130 can attenuate this effect.

Methods: OAC cell line OE33, metastatic OAC cell line FLO-1 and FLO-1^{LM}, OAC radiosensitive OE33P and radioresistant OE33R were pre-treated with CX3CR1 modulator E6130 (0.1-1000nM) and/or treated with recombinant fractalkine (0.1-200ng/mL) for 24 hours. Cell viability and proliferation was assessed using CCK8 and BrdU assays. Expression of epithelial-to-mesenchymal transition markers SLUG, Vimentin and E-cadherin was assessed by flow cytometry. Tumour samples from OAC patients were treated with E6130 and LDH release was measured to assess for tumouricidal activity and expression levels of IFN-y and IL-2 were assessed by ELISA.

Results: Fractalkine significantly increased OE33, FLO-1, FLO-1^{LM}, OE33P and OE33R cell viability and proliferation. Pre-treatment with E6130 attenuated these effects in all cell lines. Fractalkine elicited no significant changes in SLUG, Vimentin and E-cadherin expression in OE33, FLO-1 and FLO-1^{LM} cells, suggesting limited effect in tumour cell metastasis. Furthermore, E6130 elicited tumouricidal effects on OAC patient tumour, while decreasing IFN-y and increasing IL-2 release.

Conclusion: Our data show that fractalkine significantly increases OAC tumour cell survival and proliferation and that E6130 can significantly attenuate such increases. E6130 reduces IFN-y in line with fractalkine's induction of this cytokine in previous studies, but also increases IL-2 suggesting that this drug may elicit activation of NK cells in the TME. Future *in vitro* and *in vivo* studies will further elucidate the role of fractalkine in OAC tumour growth, resistance to cell death, inflammation, metastasis and metabolism, and confirm the therapeutic utility of CX3CR1 modulation in this hard-to-treat cancer.

ANTI-TUMORAL POTENTIAL OF THE NEW GRANULYSIN-BASED AND Tn/MUC-1-TARGETED 5E5GRNLY INMUNOTOXIN

Ana Pilar Tobajas[1;2], Raquel Ibáñez-Pérez[1;2], Patricia Guerrero-Ochoa[1;2], Ruth Soler-Agesta[1;2], Evelyn Galano-Frutos[1;2], Laura Cambronero[1;2], Blanca Conde[1;2], Eva Barrio[1;2], Ramón Hurtado-Guerrero[1;3], Alberto Anel[1;2]

[1]*University of Zaragoza, Zaragoza, Spain*; [2]*IIS-Aragón, Zaragoza, Spain*; [3]*BIFI, Zaragoza, Spain*

Purpouse: 5E5GRNLY is an immunotoxin composed by granulysin (GRNLY), a human protein with cytolytic activity against microbes and tumors present in the granules of human CTLs and NK cells, and a single-chain fragment variable (scFv) derived from the mAb 5E5 directed against the Tn antigen, generated by the aberrant glycosylation of the MUC-1 membrane protein in several types of cancer.

Methods: 1) Recombinant GRNLY and 5E5GRNLY were produced in *Pichia pastoris* and purified by affinity chromatography. 2) Immunotoxin binding on the surface of cells expressing Tn antigen were demonstrated and quantified by flow cytometry. 3) Cell death induced on human tumor cell lines by GRNLY or 5E5GRNLY was assessed by quantifying Annexin-V-FITC binding to phosphatidylserine and/or 7-AAD to DNA by flow cytometry. 4) The *in vivo* anti-tumor capacity of 5E5GRNLY or GRNLY was tested in athymic mice xenotransplanted with the Tn-positive multiple myeloma H929.

Results: The new granulysin-based anti-Tn immunotoxin 5E5GRNLY was produced in *Pichia pastoris* and purified with good yield. 5E5GRNLY specifically bound to cancer cells expressing the Tn-MUC1 antigen, such as the acute lymphoblastic leukemia Jurkat, the multiple myeloma H929 or the pancreatic adenocarcinoma Capan-2. 5E5GRNLY exerted cytotoxicity against these cell lines, reducing the IC50 of GRNLY at least 2.5-fold. Finally, *in vivo* experiments based on the systemic injection of GRNLY or 5E5GRNLY in athymic mice xenotransplanted with H929 cells showed that both GRNLY and the immunotoxin efficiently inhibited the development of this tumor.

Conclusion. 5E5GRNLY augments the cytotoxicity of GRNLY on cells that express the Tn-MUC1 antigen and is also effective *in vivo*. We intend now to test 5E5GRNLY in another *in vivo* model using Capan-2 cells, which are less sensitive to GRNLY than H929 cells, and which shows a higher *in vitro* improvement of the IC50 by the immunotoxin.

Combination of the granulysin-based and CEA-targeted MFE23GRNLY immunotoxin with a BCLXL-selective BH3-mimetic in a lung cancer model

Raquel Ibáñez-Pérez[1;2], Ana Pilar Tobajas[1;2], Patricia Guerrero-Ochoa[1;2], Laura Cambronero[1;2], Ruth Soler-Agesta[1;2], Isabel Marzo[1;2], Javier Naval[1;2], Laura Sanz[3], Alberto Anel[1;2]

[1]University of Zaragoza, Zaragoza, Spain; *[2]IIS-Aragón, Zaragoza, Spain*; *[3]Puerta de Hierro Hospital, Majadahonda, Madrid, Spain*

MFE23GRNLY is an immunotoxin composed by the scFv anti-carcinoembryonic antigen (CEA) MFE23 fused to granulysin (GRNLY), a human protein with cytolytic activity against microbes and tumors present in the granules of human CTLs and NK cells. It has shown specific tumor targeting activity and potent anti-tumor effect after systemic administration in preclinical tumor models. Here, we explore MFE23GRNLY combination with a BH3-mimetic selective for the anti-apoptotic protein Bcl-x_L in order to increase its therapeutic potential *in vitro* and *in vivo*. MFE23GRNLY was produced in *Pichia pastoris* and purified by affinity chromatography as previously described. Cell death induced on human tumor cell lines by MFE23GRNLY alone or in combination with the Bcl-x_L-selective BH3 mimetic drug A-1155463 was assessed by flow cytometry, quantifying Annexin-V-FITC binding to phosphatidylserine and/or 7-AAD to DNA. We had previously demonstrated in other tumor cells that MFE23GRNLY induced cell death through activation of the mitochondrial apoptotic pathway, resulting finally in caspase activation and cell dismantling. However, when testing CEA-positive A549 lung adenocarcinoma cells, the general caspase inhibitor Z-VAD-fmk did not inhibit cell death induced by the MFE23GRNLY immunotoxin *in vitro*, in contrast to results obtained in other cell lines. This result correlated with a high level of expression of the anti-apoptotic protein Bcl-x_L in this cell line and we hypothesized that combination of MFE23GRNLY with the Bcl-x_L-selective BH3 mimetic A-1155463 could have a synergic effect, something that was clearly demonstrated in *in vitro* experiments using the methodology outlined above. Since we had previously demonstrated that MFE23GRNLY alone was able to inhibit by 70% the development of this tumor in athymic mice after systemic injection, we have now initiated an *in vivo* experiment in this mice model to test the anti-tumoral potential of its combination with the BH3 mimetic A-1155463.

Effect of the HLA-G/ILT2 pathway as an immune system checkpoint in gastric cancer

Christian Vaquero-Yuste[1], Oscar Aguilar Sopena[1], Inmaculada Lasa-Unzue[2], Adela Lopez-Garcia[2], Remedios Gomez-Sanz[2], Alberto Gutierrez-Calvo[2], Pedro Roda Navarro[1;3], Jose Manuel Martin-Villa[1;4], Ignacio Juarez[1]

[1]Dept. of Immunology, Ophthalmology and ENT. Faculty of Medicine. UCM, Madrid, Spain; *[2]Department of General Surgery and Digestive System, Hospital Universitario Príncipe de Asturias, Alcala de Henares, Spain*; *[3]12 de Octubre Health Research Institute, Madrid, Spain*; *[4]Department of Immunology, Hospital Universitario Gregorio Marañon, Madrid, Spain*

Introduction: Approximately 80-85% of patients do not benefit from conventional Immune Checkpoint Inhibitor (ICI) therapies (anti-PD1/PDL1/CTLA4) in the context of gastric cancer. Therefore, identifying new potentially treatable immunosuppressive pathways is crucial for the development of innovative immunotherapy strategies in gastric cancer.

The HLA-G/ILT2 pathway plays a role in immunosuppression in both physiological contexts (maternal-fetal tolerance) and pathological conditions such as cancer. The interaction between HLA-G and the ILT2 receptor promotes the activation of inhibitory phosphatases (SHP1/2) that block the immune response mediated by the T-cell receptor (TCR).

Objectives: The aim of this study is to investigate the presence of HLA-G and its receptors in patients with gastric cancer and its effect on the activation of T lymphocytes, in order to open new therapeutic possibilities for these patients.

Results: Using multiparametric flow cytometry, we observed an increase in the ILT2+ cell population in the peripheral blood of patients with gastric cancer compared to a control cohort, both in total T lymphocytes (27.5% vs. 5.6%, $p<0.0001$) and more significantly in the CD8 T lymphocyte population (49.0% vs. 11.1%, $p<0.0001$). Furthermore, we identified elevated expression of HLA-G and ILT2 in the tumor tissues of patients (immunohistochemistry). Using HLA-G (+) and HLA-G (-) tumor cells, we formed conjugates with CD8 T lymphocytes from patients with gastric cancer. No defects were found in the formation of conjugates with HLA-G (+) cells (40.7±10.1%) compared to HLA-G (-) cells (44.4±6.7%, $p>0.05$). Immune synapse formation assessed by confocal microscopy showed that CD8 T lymphocytes were capable of generating activating synapses with HLA-G (+) cells (60.8±3.8%) and degranulating perforin and granzyme (45.3±12.1% and 57.5±22.5%) similarly to HLA-G (-) cells (66.1±6.2%, 49.4±20.9%, 57.9±18.7%, $p>0.05$). However, co-cultures of ILT2+ T lymphocytes with HLA-G (+) cells reduced its activation capacity upon TCR stimulation, measured by IFNy production (paired T-test $p=0.0006$) and proliferation (10.0±13.4% vs. 24.6±17.0%, $p<0.0001$) compared to co-cultures with HLA-G (-) cells.

Conclusion: Molecules in the HLA-G/ILT2 pathway are overexpressed in patients with gastric cancer. HLA-G does not prevent the formation of tumor-T lymphocyte conjugates but inhibits the activation of ILT2+ CD8 T lymphocytes, becoming a potential new immune checkpoint.

UniCAR T-cell potency – A matter of affinity?

Hugo Boutier[1], Liliana Rodrigues Loureiro[1], Lydia Hoffmann[1], Claudia Arndt[1;2], Anja Feldmann[1;3;4], Michael Bachmann[1;3;4]

[1]Institute of Radiopharmaceutical Cancer Research, Helmholtz-Zentrum Dresden-Rossendorf (HZDR), Dresden, Germany; *[2]Mildred Scheel Early Career Center, Faculty of Medicine Carl Gustav Carus, TU Dresden, Dresden, Germany*; *[3]National Center for Tumor Diseases (NCT), Partner Site Dresden, Dresden, Germany*; *[4]German Cancer Consortium (DKTK), Partner Site Dresden, Dresden, Germany*

Over the past decades, there has been a significant focus on reprogramming immune cells for targeting tumor cells, with Chimeric Antigen Receptor (CAR) T-cells emerging as a highly promising technology. Despite remarkable efficacy in hematologic malignancies, CAR T-cell therapy can cause severe to life-threatening adverse events. To address these safety issues, we and others have developed adaptor CAR platforms, such as the Universal CAR (UniCAR) system. In the UniCAR system, T-cells are engineered to express a UniCAR directed to the non-tumoral peptide epitope E5B9 derived from the nuclear La protein. UniCAR T-cell activation relies on the presence of a Target Module (TM), a bridging molecule that contains the E5B9 epitope and a binding moiety that specifically recognizes antigens on the tumor cells. The redirection of the UniCAR T-cells to target cells thus involves two interactions with different affinities, between (i) the TM and the CAR T-cell or (ii) the TM and the target cell.

So far, little is known about how the affinity between adaptor molecules and adaptor CAR T-cells impacts their functionality. In the case of the UniCAR platform, the interaction between the UniCAR and the TM can easily be tuned by engineering the amino acid sequence of the E5B9 peptide, without the need to re-modify the CAR.

Here, we investigate whether and how the amino acid sequence of the UniCAR epitope, including the amino acids flanking the E5B9 epitope in the native La protein, may affect the interaction between a UniCAR TM and UniCAR T-cells. By engineering the E5B9 peptide in previously published UniCAR TMs directed to the Fibroblast Activation Protein (FAP), we assess whether the modified E5B9 epitope (named E5B9L) affect the potency of UniCAR T-cells.

Overall, our work indicates that the binding affinity between the TM and the UniCAR T-cells does not play a crucial role. This affinity can fluctuate across a broad spectrum, ranging from low picomolar to nanomolar values, without significantly impacting the functionality and/or potency of the UniCAR T-cells.

Development Of Patient-Derived 3D Tumor Organoids Combined With Immune Cells, As Preclinical Testing Platform For Personalized Cancer Immunotherapy

Gabriella Antignani[1]

[1]*University of Helsinki, Helsinki, Finland*

Currently available models to validate preclinical efficiency of Immunotherapies lack in mirroring or poorly recapitulate the original patient's tumor. Active immunotherapy, which is dependent on HLA-TCR interaction, can only be tested in fully human based *in vitro* systems or humanized mice (complex, expensive, and time-consuming). Therefore, we need to develop more sophisticated systems to address immunotherapies correct mode of actions in humans.

Successful in recalling the tumor heterogeneity and complexity *in vitro*, Patient-Derived Tumor Organoids (PDTOs) can provide a robust *ex vivo* system for modelling human cancer, holding great potential as pre-clinical human platform for testing personalized therapies.

My work is focused on combining patient-derived immune cells and PDTOs to develop complex immuno-organoids that retain both patient's tumor unique features and immune system-mediated response. This allows to test tumor cell killing by the patient's own immune system after a personalized immunotherapy treatment.

Moreover, after in-depth patient´s tumor characterization, we design a personalized immunotherapy approach to specifically target the patient´s tumor.

Oncolytic vaccines have a dual mechanism: direct oncolysis of cancer cells and release of tumor antigens, causing cytotoxic T cell activation against cancer cells. To develop patient-specific oncolytic vaccine-based immunotherapies, our strategy is coating oncolytic vaccines with patient-specific tumor peptides (PeptiCRAd technology).

We established PDTOs from Renal Cell Carcinoma and Bladder Cancer, which we characterized by DNA sequencing, immunofluorescence, drug screens. HLA ligandome analysis of the PDTOs allowed the identification of 52 patient-specific tumor peptides. We validated the immunogenicity of these peptides by stimulating healthy donor Peripheral Blood Mononuclear Cells (PBMCs) and analyzing IFN-gamma secretion or CD107a degranulation. We will also use patient-derived PBMCs to unravel the best candidate peptides able to recall a T cell antitumor response. Finally, we will investigate how an oncolytic vaccine decorated with patient-specific tumor peptides (personalized PeptiCRAd) is able to trigger tumor-specific adaptive immune response, measuring specific T cell killing of PDTOs with impedance-based Xcelligence system, LDH release and live cell microscopy.

Establishing such a pre-clinical human model will pave the way for testing patient-specific responses, developing individualized treatments and accelerate their track to the clinic.

Unveiling the potential of oncolytic virotherapy in inducing tertiary lymphoid structures for enhanced anti-tumor responses

Ana Houel[1;2;3], Johann Foloppe[1], Marie-Caroline Dieu-Nosjean[2;3]

[1]Transgene, Illkirch-Graffenstaden, France; *[2]Inserm U1135, Paris, France*; *[3]Center of Immunology and Microbial Infections (Cimi), Paris, France*

Tertiary lymphoid structures (TLS) are organized clusters of immune cells that develop in non-lymphoid tissues in response to chronic inflammation. Mature TLS, resembling lymph nodes, correlate with favorable prognoses in solid tumor cancers and predict immunotherapy responses in patients. This study investigates oncolytic virotherapy's potential to induce TLS in the tumor microenvironment (TME) for enhanced anti-tumor responses.

To assess the oncolytic vaccinia virus (OVV)'s ability to induce TLS in the TME, we administered it via intranasal instillation in TC-1 lung tumor-bearing mice. Compared to modified vaccinia Ankara virus (MVA), known to induce TLS in the lungs of naïve mice following intranasal instillation, OVV elicited a higher density of TLS, likely due to its oncolytic properties.

To enhance this property, we generated a recombinant OVV expressing three murine chemokines (OVV-3mCK). We validated its oncolytic properties, as well as its capacity to secrete chemokines both in vitro and in vivo across syngeneic murine models. Chemotaxis assays revealed a synergistic effect of the three chemokines secreted in the supernatant of infected cancer cells. Both the unarmed OVV and the OVV-3mCK enhanced immune cell infiltration in subcutaneous tumors, overcame tumor resistance to anti-PD-1 treatment, and restricted tumor growth compared to the control group. Although no difference in therapeutic efficacy was observed between the viruses, a significant increase in T and B cell aggregates was noted in MC38 hot tumors treated with OVV-3mCK. We are currently conducting research in a humanized mouse model using a virus armed with human chemokines (OVV-3hCK). Initial results have shown enhanced infection of human tumors by chemokine-armed OVV in this model and up to a 50-fold increase in chemokine secretion.

Our results confirm our hypothesis regarding the role of these three chemokines in TLS formation, as well as the relevance of using OVV for this purpose. However, no positive correlation between TLS presence and therapeutic outcomes has been observed yet. By focusing now on specific T cell responses, we aim to discern whether this lack of correlation is due to model invasiveness or the inefficiency of ectopic TLS induced by a different inflammatory signal than that provoked by the tumor.

First-in-class inhibitors of ERAP1 generate novel cancer antigens as targets for MHC-I-directed therapies

Wayne Paes[1], Sam Humphrey[1], Juanita Carrey[1], Kris Clark[1], Emma Sparrow[2], Ana Ribeiro[2], Michael Cundell[2], Milos Aleksic[2], Henry Leonard[3], Ali Remtulla[3], Michael Pinggera[1], Kate Anderton[1], Jason Shiers[4], Juliet Morgan[4], Maik Mueller[5], Nicola Ternette[6], Martin Quibell[1], Peter Joyce[1]

[1]Grey Wolf Therapeutics, Oxford, United Kingdom; *[2]Immunocore, Oxford, United Kingdom*; *[3]Charles River Laboratories, Oxford, United Kingdom*; *[4]Sygnature Discovery, Nottingham, United Kingdom*; *[5]Biognosys, Zurich, Switzerland*; *[6]University of Oxford, Oxford, United Kingdom*

Purpose: The antigen processing machinery of a cell shapes the repertoire of peptides presented for immunosurveillance on the cell surface. Human leukocyte antigen class I (HLA-I) molecules present peptides that are recognised by both $CD8^+$ T cells and NK cells, and these complexes play a vital role in the recognition and eradication of transformed cancer cells. However, selective pressure by $CD8^+$ T cells in many tumour types often results in immunoediting that can drive tumour evolution and progression, and many tumour-infiltrating lymphocytes also display exhausted phenotypes following chronic antigen stimulation. Endoplasmic reticulum aminopeptidases (ERAPs) process peptides translocated into the ER following intracellular proteasomal degradation, thereby editing the final pool of ligands able to compete for binding to HLA-I molecules. Hence, modulation of ERAP processing presents an opportunity to profoundly alter the immune landscape of cancer, and elicit priming of de novo $CD8^+$ T cell responses against a novel suite of tumour-specific epitopes which additionally comprise novel targets for HLA-I-directed therapeutics (TCR-bispecifics and vaccines) to enhance anti-tumoural efficacy.

Methods: Here, we developed a highly potent and selective allosteric inhibitor of ERAP1. Using diverse immunopeptidomics approaches, we show that pharmacological inhibition of multiple ERAP1 haplotypes across several cancers is able to unmask an alternative suite of tumour-associated peptides that are presented by an array of HLA-I molecules.

Results: Crucially, we demonstrate that (i) ERAP1 inhibitors are able to significantly enhance the potency of TCR-based therapeutics targeting A*02:01-restricted tumour-specific epitopes (ii) several epitopes either significantly upregulated or uniquely presented following ERAP1 inhibition are recognised by pre-existing $CD8^+$ T cell populations in multiple healthy human donors and (iii) $CD8^+$ T cell populations recognising these ERAP1 inhibitor-dependent epitopes demonstrate anti-tumoural efficacy in vitro.

Conclusion: These advancements demonstrate that combination of MHC-I-directed therapies in concert with pharmacological inhibition of ERAP1 are able to both augment anti-tumour immunity with the potential to subvert tumour immune evasion mechanisms, and have culminated in our lead candidate molecule entering clinical trials in 2023. Current work is focused on validating optimal ERAP1 inhibitor-dependent cancer-specific epitopes across multiple cancer types which can be taken forward for TCR-based immunotherapeutic development.

CCL20 is upregulated in KRAS-driven non-small cell lung cancer via a FOXL2 - NF-κB axis and displays prognostic ambivalence

Oliver Kindler[1], Philipp Moser[1], Kathrin Maitz[1], Anna Lueger[1], Marah Runtsch[1], Eva Achhammer[1], Ana Santiso[1], Vito Telebar-Zbulj[1], Xiaodong Zhu[2], A. McGarry Houghton[2], Vanessa Jäger[3], Michael Dengler[3], Philipp Jost[3], Julia Kargl[1]

[1]Otto Loewi Research Center - Division of Pharmacology, Graz, Austria; *[2]Fred Hutchinson Cancer Center, Seattle, United States*; *[3]Department of Oncology, Graz, Austria*

Purpose: Immune Checkpoint Blockade (ICB) led to better outcomes in non-small cell lung cancer (NSCLC) but only a subset of patients benefits from current treatment regimens. Different molecular subtypes show diverse treatment responses. It was reported that patients with KRAS-mutant tumors respond better to ICB therapy, in contrast, EGFR-mutant tumors show higher resistance to this type of therapy. In order to evaluate distinctions between these subtypes, a thorough characterization of the immune environment (IE) was performed in patients with untreated NSCLC.

Methods: A cohort of 54 NSCLC cases underwent targeted RNA sequencing, with results validated using public datasets and further explored through in vitro and in vivo experiments. Potential therapeutic targets were evaluated in flank tumor mouse models.

Results: Elevated CCL20 expression was observed in KRAS-mutated NSCLC, driven by tumor cells through an NF-κB-FOXL2 axis. In an orthotopic mouse model combined with a tumor-specific CCL20 knockout, reduced tumor formation was observed. Additionally, antibody-mediated CCL20 blockade in a mouse tumor flank model led to slower tumor progression and decreased regulatory T cell infiltration compared to isotype controls. Survival analysis revealed conflicting prognostic impacts of high CCL20 expression in KRAS-mutated NSCLC under chemotherapy and ICB, validated across multiple datasets. Specifically, KRAS G12C mutated cell lines with TP53 co-mutation displayed an elevated activity in the NF-κB-FOXL2 axis and other inflammatory pathways. Further analysis of the TCGA-LUAD dataset revealed an elevated CD8+ T cell frequency with these specific mutations indicating a more responsive IE to ICB.

Conclusion: A novel KRAS-CCL20 link was identified and validated, suggesting CCL20 targeting as a potential therapeutic avenue, with further investigation warranted, particularly in the context of ICB. Additionally, CCL20 merits exploration as a biomarker for identifying ICB-responsive patients.

Breaking Boundaries: Next-Level γδ-T Cell Isolation with REAlease

Vanessa Brühl[1], Maike Lang[1], Christin Donner[1], Ermanila Dhana[1], Lotta Räty[1], José Alberto Villacorta Hidalgo[1], Susanne Höher-Peters[1], Gregor Winkels[1]

[1]*Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Germany*

Purpose: γδ-T cells represent a unique subset of immune cells that exhibit characteristics of both the innate and adaptive immune systems. Their non-MHC-bound nature makes them promising candidates for allogeneic CAR T cell therapies. Due to their low frequency, the enrichment of γδ T cells is often a necessary step in many experimental workflows. Therefore, there is a great need for protocols that enable the enrichment of highly purified γδ T cells with intact functionality to simplify research, improve the understanding of their biology and facilitate therapeutic development. The new StraightFrom REAlease technology provides a direct method for the enrichment of highly purified, unlabeled cells from various blood materials, while also offering the possibility of full automation for standardized separations.

Methods: : γδ T cells were isolated from Leukopak, Buffy Coat, and Whole Blood using REAlease γδ T-cell MicroBead Kits. Flow cytometric analysis assessed cell separation performance, γδ T cell subtype frequency, and activation status of enriched or TransAct expanded cells. MACSplex technology was used to analyze cytokine secretion profiles in stimulated cells, while the cytotoxic potential of enriched and expanded γδ T cells against target cells was investigated in co-culture experiments

Results: The newly developed REAlease γδ T-cell MicroBead Kits allowed the isolation of high purity γδ T cells from Leukopak, Buffy Coat and Whole Blood. Isolated cells exhibited no expression of the activation markers CD25 and CD69. Stimulation effectively activated the cells, showcasing their full functionality. Expansion rates of up to 300x for Vd1 cells and 90x for Vd2 cells after 8 days were achieved. Expanded cells exhibited efficient killing of target cells, validating their cytotoxic potential

Conclusion: StraightFrom REAlease technology demonstrates efficacy in isolating functional γδ T cells with high purity from various blood sources. The results highlight the potential of this technology to streamline research efforts and advance therapeutic strategies related to γδ T cell biology and allogeneic CAR T cell therapies.

Purpose: We investigated the hypothesis that Transforming Growth Factor Beta Inducer (TGFBI), an extracellular matrix protein secreted within the tumor microenvironment (TME) of various tumors, functions as a secreted immune checkpoint (sIC), and contributes to the restriction of anti-tumor T cell responses.

Methods and Results: Serum TGFBI concentrations were elevated in colorectal cancer (CRC) and hepatocellular carcinoma (HCC) patients compared to healthy individuals, and correlating with high protein TGFBI expression on cancer tissues and poorer survival outcomes. Notably, TGFBI exhibited abundant expression on tumor cells but also on monocytes, $CD4^+$ T cells, $CD8^+$ T cells, B cells, and NK cells from tumor tissues and periphery of cancer patients. Its neutralization significantly enhanced both CD4+ and CD8+ T cell activation *in vitro*. This effect was highlighted by utilizing freshly purified TGFBI-secreting CD4+ and CD8+ T cells, which, upon TGFBI neutralization, exhibited a significant enhancement in their effector functions (IFNg and TNFa production) and capacity to differentiate into cells expressing the requisite phenotype for migration into tissues and tumors. These insights were further supported by *in vivo* evidence, showing increased T cell activation and reduced tumor volume following TGFBI blockade in a colon cancer mouse model.

Conclusion: These findings unveil a counter-regulatory loop via T-cell-intrinsic TGFBI secretion as a novel immunosuppressive mechanism within the TME, which can be restored through TGFBI neutralization.

Split identity of IFNγ in remodeling of undifferentiated pleomorphic sarcoma cell line JBT19 towards chemotherapeutic resistance and anti-tumor immunity and its implication for adoptive cellular immunotherapy

Pavla Táborská[1], Dmitry Stakheev[1], Daniel Smrž[1]

[1]*Department of Immunology, Second Faculty of Medicine, Charles University, Prague, Czech Republic*

Purpose: IFNγ is a key proinflammatory cytokine produced by macrophages, natural killer T cells, NK cells, cytotoxic $CD8^+$ T cells, and Th1 $CD4^+$ T cells. The cytokine modulates the function of both immune cells and their targets, including tumor cells. However, IFNγ can have either pro- or anti-tumorigenic activities depending on the mechanisms involved. Thus, the impact of IFNγ on the therapeutic efficacy of oncologic treatment is difficult to determine.

Methods: The patient-derived UPS cell line, JBT19, was treated with IFNγ (200 µg/ml) for seven days (γJBT19). The γJBT19 phenotype, proliferation, and sensitivity to docetaxel treatment were determined, respectively, by flow cytometry and MTT assay. The γJBT19 immunomodulatory potential was evaluated by co-culture with monocytes upon their GM-CSF (concentration)- and M-CSF (concentration)-mediated differentiation into M1 or M2 macrophages. The γJBT19 immunogenicity was evaluated through *ex vivo* enrichment and expansion of JBT19-reactive lymphocytes.

Results: The γJBT19 cells had abrogated proliferation and were resistant to docetaxel. The IFNγ treatment increased their surface expression of CD44, CD47, CD95, MHC-I, and PD-L1, and, *de novo*, induced the surface expression of MHC-II. On the other hand, γJBT19 cells could abrogate the differentiation of monocytes into M2 macrophages in the presence of M-CSF and licensed the JBT19 cells to a robust *ex vivo* enrichment and expansion of JBT19-reactive lymphocytes, which were able to *in vitro* efficiently eliminate both JBT19 and γJBT19 cells.

Conclusions: IFNγ engages different mechanisms in JBT19 cells, which, on the one hand, transform the cells into minimally proliferating and highly chemoresistant cells and, on the other hand, into efficient immunomodulatory and immunogenic cells that can induce efficient antitumor cellular immune responses. These findings can have substantial ramifications for therapeutic strategies combining chemotherapy and immunotherapy.

Improving CAR-T cell immunotherapy with CRISPR/Cas9 gene editing

Andrea Šarac[1;2], Karen Butina Ogorelec[2;3], Jelka Pohar[2], Simon Horvat[1], Anže Smole[2]

[1]University of Ljubljana, Biotechnical Faculty, Department of Animal Science, Chair of Genetics, Animal Biotechnology and Immunology, Ljubljana, Slovenia; *[2]Immunology and Cellular Immunotherapy Group, Department of Genetic Toxicology and Cancer Biology, National Institute of Biology, Ljubljana, Slovenia*; *[3]InnoRenew CoE, Wood Modification Group, Izola, Slovenia*

Chimeric antigen receptors (CARs) are synthetic receptors comprised of the extracellular antigen recognition antibody-derived single chain variable fragment (scFv) and the intracellular T cell signaling domains. CARs endow T cells with the designed specificity and function. Since 2017, CAR-T cell immunotherapy is an approved cancer treatment approach for patients with certain types of leukemia and lymphoma. Here, we present the general principles of CAR-T cell therapy, the CAR structure, the production of the cellular product, and some of the major challenges in existing therapies, including the limited persistence of CAR-T cells and the lack of tumor-specific targets. We aim to produce safer and more effective mouse CAR-T cells by improving the individual design steps. One such improvement is developing CAR-T cells with the knock-out (KO) of the endogenous T-cell receptor (TCR). TCR KO prior to the introduction of the CAR molecule to the T cells reduces alloreactivity and contributes to the production of a more homogenous, and therefore safer, cellular product. We tested the knock-out of the TCR with the CRISPR/Cas9 system and designed sgRNAs targeting TCR α constant (TRAC) locus in the Jurkat cell line and primary mouse $CD4^+$ and $CD8^+$ T cells. Flow cytometry analysis showed that the KO efficiency was high in both Jurkat cell line (up to 90 %) and mouse primary T cells (up to 60 %). Therefore, in addition to upgrading CAR-T cell functions, manufacturing of the cellular product represents an opportunity to make CAR-T cells safer, more effective, and broadly available. The advantage and rationale for focusing on mouse CAR-T cells is the ability to comprehensively access mechanisms of action in the presence of an interacting immune system in future preclinical *in vivo* studies.

Targeting cellular metabolism for modulation of T lymphocytes function

Mojca Pavlin[1], Jernej Repas[1], Tadeja Snedec[1], Tjaša Frlic[1], Andreja Natasa Kopitar[2], Andrej Janež[3], Harald Sourij[4]

[1]Faculty of Medicine, University of Ljubljana, Institute of Biophysics, Ljubljana, Slovenia; *[2]Faculty of Medicine, University of Ljubljana, Institute of Microbiology and Immunology, Ljubljana, Slovenia*; *[3]Clinical Department of Endocrinology, Diabetes and Metabolic Diseases, University Medical Centre Ljubljana, Ljubljna, Slovenia*; *[4]Trials Unit for Interdisciplinary Metabolic Medicine, Division of Endocrinology and Diabetology, Medical University Graz, Graz, Austria*

Purpose: Recent discoveries in field of Immunometabolism presents a unique opportunity for improvement of existing immunotherapies. T cells differentiation and effector functions are intrinsically interconnected with cellular metabolism, therefore compounds that target metabolism could be used as adjuvant therapy. A glycolysis inhibitor 2-deoxy-D-glucose (2DG) is a promising compound that has also immunomodulatory effects, therefore we set to investigated how it modulates T cells from healthy donors.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated and activated with anti- CD3/anti-CD28 antibodies. Following activation, PBMCs were treated with 2DG and analyzed. ELISA and flow cytometry were used for immunophenotyping, cellular respiration and rate of glycolysis were measured with Seahorse analyzer. In parallel, samples were prepared for RNAseq.

Results: We show that treatment with 2DG decreased PD1 in a dose dependent manner, at low dose 2DG also increased CD69 expression. The effect of low 2DG was partially caused by inhibition of protein N-glycosylation rather than glycolysis. Interestingly, 2DG treatment of T cells followed by re-stimulation led to an increase in IFN-γ at low 2DG concentration while at higher concentration the levels returned to control levels. Transcriptomics showed differences in transcription of genes involved in metabolism, activation and differentiation, exhaustion as wells as genes related to ER stress and unfolded protein response. Bioenergetics measurements showed shift from glycolytic to oxidative metabolism.

Conclusion: We demonstrate that 2DG at physiologically achievable concentrations decreases PD-1 and increases IFN-γ secretion mostly due to inhibition of N-glycosylation. Together with the effect of 2DG on PD-1/PD-L1 axis, this provides important evidence that 2DG could potentially improve the T cell anti-tumor responses. The transcriptomics analysis showed multiple alterations relevant for T cells anticancer functionality in line with 2DG multimodal action. Our findings revealed that 2DG have important effects on T cells metabolism, function and differentiation. Altogether our results are promising and demonstrate that 2DG could be used to improve the T cell anti-tumor responses, but further research is needed.

Funding: Research was funded by the Slovenian Research Agency grants P1-0055, J3-3077 and Young researchers program.

Semaglutide as a potent activator of anti-tumor immune response in breast cancer

Isidora Stanisavljevic[1], Ivan Jovanovic[1], Bojana Simovic Markovic[1], Irfan Corovic[1], Tamara Krajnovic[2], Sanja Mijatovic[2], Sladjana Pavlovic[1]

[1]Center for Molecular Medicine and Stem Cell Research, Faculty of Medical Sciences, Kragujevac, Serbia; *[2]Institute for Biological Research "Siniša Stanković", Belgrade, Serbia*

Breast cancer is the most common malignant tumor in women and is usually associated with early metastasis, representing a significant health problem. The immune response against cancer is based on the effector actions of cells of the immune system, among which NK cells and $CD8^+$ T lymphocytes are the most significant. Semaglutide is an antidiabetic, belonging to the group of incretin mimetics. It exerts its effects through agonistic action on receptors for glucagon-like peptide-1 (GLP-1). The anti-tumor effect of GLP-1 receptor agonists manifests as inhibition of growth, proliferation, migration, and invasiveness of tumor cells. The aim of this study is to investigate the anti-tumor effect of semaglutide in the 4T1 experimental model of murine breast cancer. After induction of breast cancer, BALB/c mice were treated with semaglutide intraperitoneally. Semaglutide application significantly delayed the onset of palpable tumors and slowed tumor growth. At the same time, the antidiabetic did not show a direct anti-tumor effect in *in vitro* experiments. The results of the study indicate that semaglutide affects the functional phenotype of $CD3^-CD49b^+$ NK cells by enhancing the expression of activation receptors CD69 and NKG2D, while reducing the expression of the PD-1 inhibitory receptor and IL-10. Additionally, semaglutide increased the infiltration of $CD3^+CD49b^-$ T lymphocytes into the tumor as well as the expression of activation markers CD69 and NKG2D, and enhanced granzyme production. It also significantly reduced the expression of PD-1 and IL-10 on $CD3^+CD49b^-$ T lymphocytes. Semaglutide did not affect the overall number of tumor-infiltrating dendritic cells but significantly increased the expression of the costimulator CD86. These results indicate that semaglutide has the potential as a therapeutic agent for stimulating the immune system against tumors.

2-deoxy-D-glucose and metformin alter effector functions of T cells from peripheral blood mononuclear cells

Tjaša Frlic[1], Tadeja Snedec[1], Jernej Repas[1], Mojca Pavlin[1]

[1]*Institute of Biophysics, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia*

Purpose: The most prominent development in cancer treatment in recent years has been T cell targeted immunotherapy. However, poor response to therapy has led to a continuing search for ways to improve anti-tumor T cell responses. Immunometabolism has revealed that T cells functions are intimately tied to changes in cellular metabolic processes. With modulating immune cell metabolism, we could therefore improve cancer immunotherapy. Metformin, a standard first line antidiabetic drug, and glycolysis inhibitor 2-deoxy-D-glucose (2DG) are metabolic drugs with several promising anti-cancer and immunomodulatory effects. We conducted a transcriptomics study to explore their effect on various pathways in PBMCs, especially in relation to exhaustion, effector functions and T cell metabolism.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from buffy coats of healthy donors, activated with anti-CD3/anti-CD28 antibodies for 48h, treated with 2DG or metformin for 24h and prepared for transcriptome sequencing. In parallel, bioenergetics in terms of respiration and rate of glycolysis was measured with Seahorse analyser, the expression of differentiation and activation cell surface markers on T cells was determined by flow cytometry.

Results: Transcriptomics showed differences in expression of genes involved in crucial metabolic pathways of PBMCs. We have also observed differences in expression of activation, differentiation, and exhaustion markers, as well as in effector properties (cytokine expression). Both treatments similarly downregulated ROS generating pathway. Specifically, 2DG treatment increased mRNA level of genes related to ER stress and unfolded protein response (UPR), while high dose of metformin decreased effector functions of T cells.

Conclusion: The transcriptomics analysis showed multiple alterations relevant for T cells anticancer functionality in line with their multimodal action, with the specific differences between the two compounds. Our findings revealed that metformin and 2DG have important effects on T cells metabolism, function, differentiation, and persistence. This can be explored in further development of adjuvant therapies that could improve cancer immunotherapies.

Targeting the sialic acid-Siglec glyco-immune checkpoint in melanoma

Magali Coccimiglio[1;2;3], Laura Kruijssen[1;2;3], Ernesto Rodriguez Camejo[1;2;3], Babet Springer[1;2;3], Fabrizio Chiodo[1;2;3], Yvette van Kooyk[1;2;3]

[1]Amsterdam University Medical Centers, Amsterdam, Netherlands; *[2]Cancer Center Amsterdam, Amsterdam, Netherlands*; *[3]Amsterdam institute for Immunology and Infectious Diseases, Amsterdam, Netherlands*

Immune checkpoint blockade (ICB) therapies have revolutionized the treatment of melanoma in the past decade. These therapies interfere with immune checkpoint molecules present on T cells, which lead to immune suppression upon engagement with their ligands. However, many patients still do not show a beneficial response from ICB, so the search for novel targets and combinatorial therapies is ongoing. Particularly, a recent interest in identifying immune checkpoint molecules on myeloid cells paves the way for achieving higher response rates to ICB. The increased expression of sialic acid glycans found in melanoma plays a key role in anti-tumor immune responses through engagement of Siglec receptors expressed on both lymphoid and myeloid cells. Hence, the sialic acid-Siglec axis has emerged as a novel myeloid and lymphoid glyco-immune checkpoint to target in cancer therapies.

In order to manipulate the sialic acid-Siglec axis in the tumor microenvironment (TME) of melanoma, we used the B16OVA melanoma cell line and knocked out the gene CMAS that encodes an essential enzyme for sialic acid expression, which was found to be altered in melanoma patients. After subcutaneous injection *in vivo*, the sialic acid negative CMAS KO tumors grew significantly slower than the sialic acid positive MOCK tumors. Mice that controlled the growth of the CMAS KO tumors were rechallenged after 21 days by subcutaneous injection of the B16OVA cell line in the opposite flank, which showed also delayed growth, indicating that the initial lack of sialic acid on tumor cells stimulated the development of a memory immune response. To alter sialic acid expression *in situ* we injected sialylation inhibitors close to the subcutaneous tumors. We could reduce tumor growth at early time points, however this effect was lost over time. Local tumor treatments with sialylation inhibitors showed a clear increase in CD8+ T effector memory cells in the TME, which expressed higher levels of PD1.

Our work shows that the sialic acid-Siglec facilitates CD8 T cell accumulation in the TME, and can be combined with anti-PD1 therapy. We are currently focusing in the study of this axis on myeloid cells.

Introduction: Pancreatic cancer is one of the most difficult malignancies to treat, with dismal survival rates and limited therapeutic options. Despite advances in conventional therapies such as surgery, chemotherapy and radiotherapy, the prognosis for pancreatic cancer patients remains poor. In recent years, immunotherapy has emerged as a promising approach to combat this aggressive disease and monoclonal antibodies (mAbs) are essential for the success of targeted therapies.

Methods: In this study, the effectiveness of a human HLA-specific mAb in targeting tumor cells was evaluated in pancreatic ductal carcinoma cells (PANC-1) by the complement-dependent cytotoxicity assay (CDC). The human HLA-specific mAb was generated through recombinant techniques and tested for cytotoxicity against PANC-1 cells and PANC-1 cells transfected to express the target HLA molecule by CDC. Each cell line was incubated separately with the human HLA-specific mAb, a human mAb of different specificity (negative control) or a hyper-immunized serum (positive control), afterwards 5 µl of rabbit complement was added and left to incubate for 2 hours at room temperature. Finally, a fluorescent dye was added to each well and cell death was observed under a fluorescence microscope.

Results: Our findings reveal a significant reduction in tumor cell viability following treatment with the hyper-immunized serum. Furthermore, we observed higher cell death in the transfected lines incubated with the hyper-immunized serum and the mAb compared to negative control Ab.

Conclusion: Our results demonstrate a significant reduction in cell viability following treatment with the mAb in the case of transfected lines, indicating its potential as a therapeutic agent for targeted therapy. These findings highlight the importance of targeted immunotherapeutic approaches in the management of pancreatic malignancies.

DSP502 – A novel approach for targeting TIGIT and PD-1 for cancer immunotherapy

Lucy Ghantous[1;2;3], Esther Stern[1], Ori Wald[1;4], Shirley Greenwald[3], Jasmine Avichzer[3], Lior Tsveyer[3], Jacob Rachmilewitz[1], Michal Dranitzki Elhalel[2], Ayelet Chajut[3]

[1]Goldyne Savad Institute of Gene Therapy, Hadassah Medical Center, Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, Israel; *[2]Department of Nephrology and Hypertension, Hadassah Medical Center, Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, Israel*; *[3]Kahr Medical Ltd, Modi'in-Maccabim-Re'ut, Israel*; *[4]Department of Cardiothoracic Surgery, Hadassah Medical Center, Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, Israel*

Purpose: Dual Signaling Protein 502 (DSP502), a novel, multi-functional IgG1-Fc-fusion protein targets the PD1 and TIGIT molecular pathways in a unique way. DSP502, comprises the extracellular domains of TIGIT and PD-1, is designed to simultaneously bind its two respective ligands, PVR and PD-L1, expressed on cancer and myeloid cells in the tumor microenvironment. Here we describe the effect of DSP502 on anti-tumor immunity in vitro and in vivo.

Methods: Using human PBMCs, purified T-cells, purified NK cells and Macrophages of healthy donors and NSCLC patients, we evaluated DSP502-mediated activation of immune cells against human K562 CML cells wild type or the same cells overexpressing PVR, PD-L1 or both. PBMC, T-cell & NK cytotoxicity, T-cell, NK & macrophage activation, and phagocytosis induction methods were used. DSP502 anticancer activity was further evaluated in an AB12 mesothelioma syngeneic mouse model.

Results: DSP502 significantly augmented PBMC and T-cell mediated killing of tumor cells, which was dependent on the ligand's expression. DSP502 significantly enhanced NSCLC patients derived PBMC's killing of tumor cells. In a co-culture system, DSP502 significantly increased complex formation of NK cells with the target tumor cells, when both ligands were expressed on the cancer cells. In addition, NK-mediated cytotoxicity over tumor cells was increased following treatment with DSP502. Macrophages activity was also affected by DSP502 evident by reduction of M2 macrophages expressing $CD11b^{+}CD163^{+}$, increase in M1 macrophages expressing $CD11b^{+}CD86^{+}$ and the increasesd phagocytic activity over tumor cells. Importantly, DSP502 significantly prolonged the survival of AB12 mesothelioma tumor bearing mice.

Conclusions: DSP502 presents numerous functionalities that can work together in synchrony and synergy to enhance anti-tumor immunity. Beyond targeting PVR and PD-L1, DSP502 has the potential to further affect TIGIT pathway via its effects on CD96 and DNAM-1.

A new pathway towards immunotherapy-supported radiology

Klaus Spohr[1], Marius Jurca[1], Neagu Teodora Monica[2], Paunescu Virgil[3;3]

[1]Extreme LIght Infrastructure - Nuclear Physics (ELI-NP), Buchgarest-Magurele, Romania; *[2]National Institute of Pathology, Victor Babes, Bucharest, Romania*; *[3]Victor Babes University of Medicine and Pharmacy Timisoara, Timisoara, Romania*

Purpose: Immunology has revolutionized the treatment of blood-borne cancer over the past few decades. Nonetheless, the core challenge remains to apply its proficiency to solid tumors due to their peculiarity, which, among others, is characterized by the absence of unique biomarkers.

Methods: Herein, we present the new approach of immunotherapy-supported radiology to augment conventional Boron Neutron Capture Therapy (BNCT). This fledgling radiologic treatment modality is in need of efficient delivery methods, as depicted herein. Knowing about the ability of solid cancers to 'chemically hide' in a gamut of surrounding fibroblast, thus preventing the immunocompetent cells from releasing their cytotoxins, we use selected immunocompetent cells instead as a new class of highly selective delivery agents (nanorobots) for nanoparticles to place high concentrations of radiotherapeutic 10-boron payloads. After delivery into the cancerous cells or in their close vicinity, the non-radioactive, stable 10-boron nanoparticles can be activated with the highest controllability by exposure to a beam of low energetic (epithermal) neutrons provided by an accelerator, thus paving the way to overcome the cancer-induced cytotoxin revocation by simple radiology. In detail, as high payloads of several ug/g in the malignant cells that form a tumor can be achieved, the FDA-approved BNCT uses the neutron-induced decay of 10-boron in an alpha-particle and a lithium-ion to destroy the cancerous cell. The incident thermal neutron dose is patient-save but leads to several Gy of treatment dose triggered by the steered nuclear disintegration of 10-boron in a few hour-long exposures with a neutron flux of 10^8 neutrons/(cm^2s). As the cancer-killing linear electron transfer (LET) induced by BNCT is physically curtailed to under ten micro-meters, roughly the radial dimension of one cell, our method of high-yield ultra-precise boron delivery destroys mainly the impaired cells, sparing surrounding healthy tissue, an advantage compared to existing ion- and gamma-radiation based treatments.

Results/Conclusions: Our in-situ loading mechanism allows a high upload of nanoparticles in the selected immunocompetent cells so that the treatment of solid cancers at a depth of up to several cm inside a patient's body can be envisaged. The presentation will summarize the status quo of our current research.

Metformin promotes antitumor activity of NKT cells via overexpression of NFAT and STAT4

Anđela Petrović[1], Ivan Jovanovic[1], Bojan Stojanovic[2], Milena Jurisevic[3], Bojana Simovic Markovic[1], Marina Jovanovic[4], Milan Jovanovic[5], Mihailo Jovanovic[6], Nevena Gajovic[1]

[1]Center for Molecular Medicine and Stem Cell Research, Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia; *[2]Department of Surgery, Faculty of Medical Sciences, University of Kragujevac, Serbia, Kragujevac, Serbia*; *[3]Department of Pharmacy, Faculty of Medical Sciences, University of Kragujevac, Serbia, Kragujevac, Serbia*; *[4]Department of Internal medicine, Faculty of Medical Sciences, University of Kragujevac, Serbia, Kragujevac, Serbia*; *[5]Department of Abdominal Surgery, Military Medical Academy, Belgrade, Serbia*; *[6]Clinic for Orthopaedics and Traumatology, University Clinical Center, Kragujevac, Serbia*

Purpose: Over the past few decades, metformin, an anti-glycemic drug, has emerged as a potent activator of the immune system, offering promising prospects in the fight against tumors. While prior research has provided some insights into the impact of metformin on various immune cells, there remains much to uncover. Our study aimed to investigate the potential effects of metformin on the functional phenotype of NKT cells, recognizing their potential as an antitumor weapon through modulation of the tumor microenvironment.

Methods: 4T1 breast cancer was induced in BALB/C wild-type (WT) mice, subsequently treated with metformin. The functional phenotype of splenocytes and tumor-infiltrating leukocytes were investigated.

Results: Metformin exhibited significant inhibition of 4T1 breast carcinoma appearance and growth in WT mice. Furthermore, metformin increased the percentage of interferon (IFN)-γ^+, and CD107a MFI$^+$ CD3$^+$CD49b$^+$ NKT cells while decreased the percentage of PD-1$^+$, FoxP3$^+$, and interleukin (IL)-10$^+$ in spleens of metformin-treated mice. In primary tumors, metformin significantly increased percentages of NKp46$^+$ and FasL MFI$^+$ NKT cells and reduced the percentages of FoxP3$^+$, PD-1$^+$, KLRG1 MFI$^+$, and IL-10-producing NKT cells. Additionally, a significantly elevated percentage of FasL$^+$ and a decreased percentage of PD-1$^+$ and KLRG1$^+$ T cells were measured in spleens of metformin-treated mice. Metformin increased the percentage of FasL$^+$, NKp46$^+$, IL-17$^+$, and STAT3$^+$ T cells while decreased the percentage of PD-1$^+$, FoxP3$^+$, and KLRG1$^+$ T cells in tumor tissue. Furthermore, metformin decreased the accumulation of IL-10$^+$ and FoxP3$^+$ Tregs, as well as Gr-1$^+$ myeloid-derived suppressor cells (MDSCs) in the spleens of metformin-treated mice, and IL-10$^+$ and FoxP3$^+$ Tregs, Gr-1$^+$, NFκB$^+$, and iNOS$^+$ MDSCs, and iNOS$^+$ dendritic cells (DCs) in tumor tissue, while increasing the quantity of DCs. Notably, metformin administration significantly upregulated the expression levels of MIP1a, STAT4, and NFAT in splenocytes isolated from metformin-treated mice, suggesting increased NKT cell activity.

Conclusion: Metformin administration directly altered the phenotype of NKT cells, further stimulating T cells either directly or through dendritic cells, while also inhibiting the immunosuppressive effects of MDSCs and Tregs. Future studies should aim to clarify the precise mechanism of NKT cells in the antitumor immune response.

Phenotypic and Functional Analysis of Cytokine-Induced Memory-Like Natural Killer Cells

Isabel María Vallejo Bermúdez[1], Monica Espinar Garcia[1], Carmen María Gutiérrez González[1], Ester Irene Reina Alfonso[1], Pablo Álvarez Heredia[1], Alexander Batista Duharte[1], Alejandra Pera Rojas[1;2], Raquel Tarazona[3], Rafael Solana Lara[1;2], Fakhri Hassouneh[1]

[1]*Immunology and Allergy, Maimonides Biomedical Research Institute of Cordoba (IMIBIC), Cordoba, Spain*; [2]*Department of Cell Biology, Physiology, and Immunology. University of Córdoba, Cordoba, Spain*; [3]*Immunology Unit, Department of Physiology, University of Extremadura, Cáceres, Spain*

Introduction: Natural Killer (NK) cells play a crucial role in innate immunity against virus-infected and tumor cells. Interleukin-12/15/18 exposure in vitro induces a memory-like phenotype in NK cells, termed cytokine-induced memory-like (CIML) NK cells, characterized by heightened cytotoxicity and prolonged survival. This study focuses on exploring the expression patterns of activating and inhibitory receptors in CIML NK cells and evaluate its cytotoxic capacity against target cell lines, that is crucial for understanding their therapeutic potential.

Methods: To obtain human CIML cells, peripheral blood NK cells were isolated and preactivated with IL-12/15/18 overnight and expanded during 7 days with IL-15. Multiparametric flow cytometry analysis to assess phenotypic profiles was performed on day 0 (before stimulation), at 16 hours and at 7 days of incubation. Functional assays, including CD107a degranulation and IFN-γ and TNF-α production, were conducted to evaluate CIML NK cell cytotoxicity against target cells K562 and 721.221.

Results: CIML NK cells exhibited increased expression of NKG2A, NKG2D, NKp30, NKp46, CD25, and CD69 compared to control NK cells stimulated with IL-15, highlighting the potency of IL-12/15/18 in stimulating a functionally enhanced phenotype. Additionally, preactivation with IL-12/15/18 significantly increased CD107a expression in CIML NK cells after stimulation with target cells compared to control NK cells, indicating higher cytotoxicity against tumor cells. Moreover, CIML NK cells demonstrated elevated intracellular IFN-γ and TNF-α production when stimulated with IL-12/15/18, underscoring their enhanced antitumor functionality.

Conclusion: This study underscores the potential use of CIML NK cells in cancer immunotherapy. Enhanced expression of activating receptors and increased functional capacities, including degranulation and cytokine production, suggest CIML NK cells as promising candidates as antitumor agents. Further investigations into refining CIML NK cell expansion protocols and understanding their mechanisms of action are needed to advance their clinical translation and improve cancer treatment outcomes.

Sex differences in immune checkpoint receptor expression in patients with upper gastrointestinal malignancies: potential implications for patient response to immune checkpoint inhibitor therapy

Aoife Kilgallon[1], Meghana Menon[2], Kirstan Murphy[2], Brendan Moran[1], John V Reynolds[3], Joanne Lysaght[1]

[1]*Cancer Immunology and Immunotherapy Group, Department of Surgery, School of Medicine, Trinity St. James's Cancer Institute, Trinity College Dublin, Dublin, Ireland*; [2]*Department of Surgery, School of Medicine, Trinity St. James's Cancer Institute, Trinity College Dublin, Dublin, Ireland*; [3]*Department of Clinical Surgery, St. James's Hospital, Dublin, Ireland*

Incidence of upper gastrointestinal malignancies continues to increase and 5-year survival rates remain dismal at ~20%. This is due to an advanced stage at diagnosis and a lack of response to conventional therapies. The intention to treat standard-of-care is surgery with peri-operative chemotherapy or neoadjuvant chemoradiotherapy. Recently immune checkpoint (IC) inhibitor therapy has been added to this arsenal of treatment in certain clinical settings. However, less than 30% of patients treated achieve a meaningful response. Our group has previously shown in a cohort of oesophageal adenocarcinoma (OAC) patients that expression of certain immune checkpoint receptors on circulating T cells and tumour infiltrating lymphocytes positively correlated with a higher grade of tumour and a poor response to neoadjuvant treatment. Response rates in upper GI patient cohorts treated with IC inhibitors remain low.

As part of this study, peripheral blood T cells from treatment naïve patients with upper gastrointestinal malignancies (n=16) were profiled by flow cytometry. Patients with gastric adenocarcinoma, adenocarcinoma of the oesophagus/gastro-oesophageal junction or oesophageal squamous cell carcinoma were included in this study. Cell surface expression of key IC receptors (PD-1, TIGIT, TIM-3, CTLA-4 and LAG-3) were measured on CD4 and CD8 T cells. The expression of these receptors was measured again after 48 hours during which T cells were activated or rested.

We correlated this data with clinical parameters and discovered significant differences in expression of key IC receptors based on sex both basally and following T cell activation. The expression of these ICRs on peripheral T cells is also influenced by the anatomical location of the tumour (oesophagus/gastro-oesophageal junction vs. gastric tumours).

These preliminary results suggest that patient sex may have implications for response to certain IC inhibitors. They also suggest differential T cell phenotype based on tumour location within the upper GI tract. Our results may improve tailored selection of patients to receive IC inhibitor therapy with the ultimate goal of expanding the relatively limited cohort of patients who currently benefit from IC blockade.

Role of ion channels in CAR T cells

Ghofrane Medyouni[1], VIVIEN Jusztus[1], Orsolya Vörös[1], György Panyi[1], Péter Béla Hajdu[1;2]

[1]University of Debrecen, Department of Biophysics and Cell Biology, Debrecen, Hungary; *[2]University of Debrecen, Division of Dental Biochemistry, Debrecen, Hungary*

Cancer immunotherapy partly depends on the reprogramming of host immune cells to recognize and eliminate cancerous cells. Genetic modification of T cells to express chimeric antigen receptors (CARs) has shown great results in treating hematological malignancies. However, despite its success, many challenges remain to be overcome improving the efficacy and safety of this therapy. Ion channels in T-cells participate in the regulation of activation via modulation of the Ca^{2+}-dependent pathway. Moreover, ion channels play a role in multiple effector functions that are inevitable for target cell abolition. Consequently, modification of ion channels' function can contribute to successful immune therapy. However, no study has been reported about the expression and functional role of CAR T-cell ion channels so far.

In the present study, we established a 3rd-generation CAR-expressing cell line (targeting CD19, CD19-CAR cells) from Jurkat E6-1 cells. We used the whole-cell patch-clamp technique and FURA-2-based Ca^{2+}-imaging to determine the biophysical properties of Kv1.3 and Ca^{2+}-response of CD19-CAR cells, respectively. We used a Calcein Red-based killing assay to test CD19-CAR cells' target killing cytotoxicity. By immunocytochemistry, we evaluated the localization of Kv1.3 in standalone and in the CAR-synapse-engaged CD19-CAR cells.

We demonstrated that Kv1.3 activation and inactivation kinetics are the same in Jurkat non-transfected (control) and CD19-CAR Jurkat cells, while voltage-dependent equilibrium activation was different. Thapsigargin-induced Ca^{2+}-response of CD19-CAR cells was lower as compared to the non-transduced cells. We could show that Kv1.3 channels are colocalized with CARs in standalone CD19-CAR cells, and they redistribute the contact region between a CD19-CAR cell and a target cell (Raji B cell line). To test the effect of Kv1.3 blocking, we used Vm24 (specific Kv1.3 inhibitor, 1 nM), and surprisingly the target killing potential of CD19-CAR cells was impaired. Based on these results, we suppose that ion channels can affect the outcome of immunotherapy, and further experiments are needed to clarify their functional role.

Miniaturization of T cell cultivation and utilization for process development

Hanne Haslene-Hox[1], Hanne Hein Trøen[1], Margrét Sigfúsdóttir[1], Ane Marit Wågbø[1], Lea Rosselle[2], Fatemeh Kaveh[2], Maxi-Lu Boeschen[3], Evan Zynda[3], Tuva Holt Hereng[3], Sebastien Walchli[2], Håvard Sletta[1], Else Marit Inderberg[2], Geir Klinkenberg[1]

The use of T-lymphocytes in adoptive cell therapy shows great promise for treatment of cancers, and there is an increasing number of cell therapies being developed. The rapid increase in novel immunotherapies necessitates alternative approaches in process development, to increase capacity and provide opportunities for flexible and personalized production of a large variety of products. Good therapeutic cell manufacturing needs to encompass rapid production of the right type of cells, with optimal activity. Both T-cell quality and cellular subsets can have large impacts on therapeutic efficacy.

With in vitro cell expansion, the resulting T-cell populations are heterogeneous with many subsets. It has been demonstrated that the less differentiated populations of T-cells lead to a more persistent anti-tumour response. In particular, the memory stem-like T-cells (T_{SCM}) have higher renewal properties and the ability to reconstitute the entire heterogeneity of memory T-cell subsets. However, we currently lack a complete understanding of how cultivation parameters impact the resulting T-cell populations, and current cultivation approaches provide for limited throughput and side-by-side comparisons of such conditions.

Here, we asked whether miniaturized high-throughput systems could be adapted to achieve screening of T-cell cultivation processes. Furthermore, we asked how process parameters, traditionally measured manually (e.g. cell culture density), could be replaced by high-throughput-compatible analyses and automatic read-outs.

T-cell cultivation was optimized in microtiter plates, and the set-up was used to compare the impact of culture media, signalling molecules and metabolite additions on T-cell proliferation and early memory markers. Robotic methods for cell processing and image-based high-throughput methods were developed for quantification of cell culture density, viability and specific T-cell markers. The established platform is generic and readily translatable for screening of a large number of process parameters and media components.

The project is funded by the Research Council of Norway, grant number 326811.

Polymorphonuclear myeloid-derived suppressor cells impair the anti-tumor efficacy of GD2. CAR T-cells in patients with neuroblastoma

Nicola Tumino[1], Gerrit Weber[2], Francesca Besi[1], Francesca Del Bufalo[1], Valentina Bertaina[1], Paola Paci[3], Linda Quatrini[1], Matilde Sinibaldi[1], Concetta Quintarelli[1], Biagio De Angelis[1], Franco Locatelli[1], Lorenzo Moretta[1], Ignazio Caruana[2], Paola Vacca[1]

[1]*Bambino Gesù Children's Hospital, IRCCS, Rome, Italy*; [2]*University Hospital of Würzburg, Würzburg, Germany*; [3]*University La Sapienza, Rome, Italy*

The outcome of patients affected by high-risk or metastatic neuroblastoma (NB) remains grim, with >50% of the children experiencing relapse or progression of the disease despite multimodal, intensive treatment. To identify new strategies to improve the overall survival and the quality of life of these children, we recently developed and optimized a third-generation GD2-specific chimeric antigen receptor (CAR) T-cells (NCT03373097) for the treatment of patients with relapsed/refractory NB. We found that our CAR T-cells can induce marked tumor reduction and even achieve complete remission more efficiently than previous studies. However, often responses are not sustained and relapses occur. Here, we demonstrate a mechanism of resistance to GD2 for the first time.CAR T-cell treatment, showing how polymorphonuclear myeloid-derived suppressor cells (PMN-MDSC) increase in the peripheral blood (PB) of NB patients after GD2.CAR T-cell treatment in case of relapse or loss of response. *In vitro*, isolated PMN-MDSC inhibited the anti-tumor cytotoxicity of different generations of GD2.CAR T-cells. Gene-expression profiling of GD2.CAR T-cells "conditioned" with PMN-MDSC show downregulation of genes involved in cell activation, signal transduction, inflammation, and cytokine/chemokine secretion. Analysis of NB gene-expression dataset confirms a correlation between the expression of these genes and patient outcome. Moreover, in patients treated with GD2.CAR T-cells, the frequency of circulating PMN-MDSC inversely correlated with the levels of GD2.CAR T-cells, resulting more elevated in patients who did not respond or lost response to the treatment.

The evaluation of PMN-MDSC in PB of high-risk or metastatic NB represent novel useful prognostic markers to predict the response to GD2.CAR T-cells or other adoptive immunotherapies. This study underlines the importance of further optimizing both CAR T-cells and the design of clinical trials by targeting inhibitory cells that compromise the clinical outcome.

Development of Novel Anti BCMA (B Cell Maturation Antigen) Antibody as a live cell therapy candidate in Multiple Myeloma

Ashna Gupta[1], Gunjan Dagar[1], Ravi Chauhan[1], Kalpana Luthra[1], Mayank Singh[1]

[1]*All India Institute of Medical sciences, Delhi, India*

Purpose: Multiple myeloma (MM) is characterized by the expansion of malignant plasma cells (PCs) in the bone marrow (BM) which is associated with excessive production of monoclonal immunoglobulins in blood and urine in patients. The addition of monoclonal antibodies (MoAbs) as immunotherapies in MM has further improved patient outcome. However, MM remains incurable for most patients, since drug-resistant clones constantly emerge and evolve. BCMA (B Cell Maturation Antigen) has been found to be overexpressed in MM and is being explored as a target for both antibody based and live cell therapy.

Method: BCMA expression in MM patients was quantified using RQ PCR as well as soluble BCMA was quantified using ELISA. The consensus BCMA ECD sequence was cloned in the vector which was sequenced and Protein expression was carried out using Expi293 system which were characterized using SDS page. Mice immunization was carried out and hybridoma cells were generated for production of Anti BCMA ECD antibodies which were further purified and characterized using western blotting and other assays. Best binders were identified and ScFv sequence was incorporated to novel second generation CAR (Chimeric antigen receptor) T cells which screened using flow cytometry.

Results: We characterized the expression of BCMA in cohort of MM patients and found it be elevated at mRNA level furthermore we found serum BCMA or soluble BCMA levels were also elevated which is the predictor of inferior therapeutic outcome in patients with MM. We further Validated BCMA as a candidate for development of Anti BCMA therapy and achieved expression of BCMA ECD protein in eukaryotic system which was further used to generate hybridomas, Overall we generated twenty different clones which were further screened for best binders which were characterized for bind with BCMA ECD protein using ELISA. The best binder (9C4) was further used for deciphering ScFv which was used for development of novel second generation CAR T cells. which were further characterized for expression of this Novel Anti BCMA CAR.

Conclusion: The current study has led to characterization of BCMA expression and variation in Indian MM patients as well as development of Anti BCMA second generation CAR.

Continuous B cell destruction and regeneration is crucial for effective response to anti CD19 CAR-T cell therapy

Neta Nevo[1], Neta Milman[1], Tim J. Cooper[1], Tsila Zuckerman[2], Shai S. Shen - Orr[1]

[1]Technion, Haifa, Israel; *[2]Rambam hospital, Haifa, Israel*

Purpose: Chimeric Antigen Receptor (CAR)-T cell therapy targeting CD19, whereby genetically engineered T cells target CD19+ malignant cells, is a promising immunotherapy. The resulting interactions induce an inflammatory response that destroys the cancer cells and further activates CAR-T cells. However, patients with low tumor burden are more likely to respond, raising the question: who activates the CAR-T cells? We hypothesized that the outcome relies on early interactions between CD19+ normal B cells and CAR-T cells that stimulate B lymphopoiesis in the bone-marrow (BM). Accordingly, we explored the elimination of B cells and the resulting BM B lymphopoiesis post CAR-T infusion. **Methods:** 39 patients treated with anti CD19 CAR-T cells at Rambam hospital were enrolled. Plasma proteins' levels were measured by high throughput multiplex assay. scRNASeq data of healthy humans' BM samples was analyzed to in-depth study the B lymphopoiesis process.

Results: To study the destruction of normal B cells following infusion, we analyzed the reduction in IgG, the main product of B cells. Unsurprisingly, 30 days post CAR-T infusion IgG levels decrease. Importantly, in multivariable analysis the percentages of IgG drop significantly correlate with response. It has been demonstrated that depletion of B cells stimulates BM B lymphopoiesis. We therefore tracked the levels of CXCL12, a regulator of nascent B cells in the BM, that has been shown to fluctuate post B cell depletion. Importantly, we found that within day 10 and day 20 post-infusion, following the average peak concentration of CAR-T cells and nearing its elimination from peripheral blood, the increase in CXCL12 is significantly higher in responders. Beyond that we revealed a significant increase in VEGFA, MIP1, MCP1 and Eotaxin within responders. By exploring the cell-cell interactions in the BM and analyzing scRNAseq data of BM samples, we identified that they are B lymphopoiesis associated proteins since they interact with progenitor B cells subpopulations along their developmental trajectory in the BM.

Conclusion: Early interactions between normal B cells and CAR-T cells that further stimulate BM B cell regeneration correlate with response to therapy. This may be leveraged to infer early predictors and improve outcomes.

Local repeated delivery of checkpoint blockade therapy through an actuatable reservoir to treat Ovarian Cancer.

Hannah Prendeville[1], Aoibhín Sheedy[1], Michael O'Dwyer[2], Garry Duffy[3;4], Eimear Dolan[1]

[1]Department of Biomedical Engineering, University of Galway, Galway, Ireland; *[2]Department of Haematology, University Hospital Galway, Galway, Ireland*; *[3]Anatomy and Regenerative Medicine Institute (REMEDI), University of Galway, Galway, Ireland*; *[4]Advanced Materials and BioEngineering Research Centre (AMBER), Trinity College Dublin, Dublin, Ireland*

Background: Ovarian cancer is the most lethal gynaecological cancer with a global 5-year survival rate of 30-50%. Treatment with chemotherapy is effective initially, however most women ultimately relapse and develop chemotherapy-resistant tumours. Delivering chemotherapy directly to the abdomen through an implanted catheter significantly increases patient survival as compared to standard intravenous infusion. However, complications involving fibrosis and impaired therapy distribution prevents the use of this strategy. Therefore, there is a pressing need to develop novel therapies and strategies to prevent cancer recurrence and increase patient survival. We have developed an implantable mechanotherapeutic platform to deliver immunotherapy to the abdomen to treat Ovarian Cancer. Our strategy enables the repeated delivery of therapy directly to the tumour site, without causing fibrosis around the implanted catheter.

Methods / Results: We previously demonstrated that cyclic inflation and deflation (intermittent actuation (IA)) of an implanted device modulates the foreign body response (FBR). Briefly, devices were implanted subcutaneously in rats or mice and cyclically actuated for 5min every 12hrs. IA interfered with the development of a fibrotic capsule surrounding the device and consequently improved drug delivery for up to 8-weeks post implantation. This was compared to non-actuated devices which developed a thick surrounding fibrous capsule and demonstrated a near complete loss of drug delivery due to the FBR. Furthermore, we showed that rapid, on-demand actuation can be used to accelerate the transport and distribution of therapy from the device into the surrounding tissues, enabling temporally controlled drug delivery[4]. Using mouse models of Ovarian Cancer, we have shown that intraperitoneal implantation of our device does not interfere with tumour growth, as measured by bioluminescent imaging. We will deliver anti-TIGIT monoclonal antibodies directly to the peritoneal cavity of Ovarian Cancer bearing mice through our custom-made actuatable reservoir. TIGIT blockade promotes potent Natural Killer and CD8 T cell cytotoxic responses by increasing IFNγ and GranzymeB production in multiple cancer models.

Conclusion: Our strategy aims to overcome the current challenges in treating Ovarian Cancer, by enabling the rapid delivery of repeated doses of immunotherapy directly to the tumour site, without causing patient discomfort resulting from fibrosis around an implanted catheter.

Adeno-associated virus-mediated IL-10 delivery reduces the infiltration of tumor-associated macrophages and suppresses tumor growth in hepatocellular carcinoma

Yu-Hsin Hsu[1], Yu-Wen Wang[1], Ya-Hui Chuang[1]

[1]*Department of Clinical Laboratory Sciences and Medical Biotechnology, College of Medicine, National Taiwan University, Taipei, Taiwan*

Purpose: Hepatocellular carcinoma (HCC) is the most common primary liver cancer in adults. Previous research has identified interleukin-10 (IL-10) as a factor inducing the transformation of macrophages into M2 macrophages, thereby promoting tumor growth. IL-10 has also been associated with reducing macrophage activation and pro-inflammatory functions. However, our previous study demonstrated that the administration of exogenous IL-10 delivered by adeno-associated virus (AAV-IL-10) suppressed tumor growth and improved survival in a syngeneic orthotopic HCC mouse model. In this study, we aim to investigate the effect of AAV-IL-10 treatment on macrophages, including Kupffer cells in the liver and tumor-associated macrophages (TAMs) in HCC.

Methods: The orthotopic HCC mouse model was established by intrahepatic injection of Hep55.1c into male C57BL/6 mice. Mice received AAV-IL-10 or control virus via tail vein injection after 5 days of tumor implantation. Tumors were harvested fourteen days after tumor implantation. Serum was collected on Day 14 to confirm the IL-10 concentration. We used immunohistochemistry, immunofluorescence, and flow cytometry to assess the distribution and infiltration number of TAMs in HCC tumors and non-tumor liver tissue.

Results: Our findings revealed a pronounced infiltration of TAMs within the Hep55.1c-inoculated HCC model, predominantly comprising M2-like TAMs. Notably, treatment with AAV-IL-10 led to suppressed tumor growth in HCC mice, concomitant with a decreased number of TAMs. Specifically, there was a marked decline in M2 macrophages, whereas M1 macrophages exhibited no significant alteration, resulting in a reduced M2/M1 macrophage ratio. Regarding non-tumor liver tissue in HCC mice receiving IL-10 treatment versus controls, the percentage of Kupffer cells remained unchanged, while the percentage of M1 macrophages increased and that of M2 macrophages decreased. These observations suggest that AAV-IL-10 therapy diminishes TAM numbers in HCC, particularly M2 macrophages, consequently altering the M2/M1 macrophage ratio.

Conclusion: AAV-IL-10 can suppress tumor growth and reduce the infiltration of TAMs in HCC. Additionally, it can decrease the M2/M1 macrophage ratio in both tumor and non-tumor liver tissue.

The impact of antigen-binding domains on antigen-directed and tonic chimeric antigen receptor (CAR) signaling

Vivian Haas[1], Markus Barden[2], Patrick Elsenbroich[2], Moritz Ertelt[1;3], Hinrich Abken[2], Clara Tabea Schoeder[1;3;4]

[1]Institute for Drug Discovery, Faculty of Medicine, Leipzig University, Leipzig, Germany; *[2]Leibniz Institute for Immunotherapy, Regensburg, Germany*; *[3]Center for Scalable Data Analytics and Artificial Intelligence ScaDS.AI, Dresden/Leipzig, Germany*; *[4]Fraunhofer Institute for Cell Therapy and Immunology, Leipzig, Germany*

CAR T cell therapies have transformed the treatment of hematological malignancies. However, the targeting of solid tumors remains hindered by their complex tumor environment. Additionally, potential targets often comprise proteins which are overexpressed by cancer cells but are also present on healthy cells, such as the human epidermal growth factor receptor 2 (HER2) in a number of carcinoma or the carcinoembryonic antigen (CEA) in adenocarcinoma. Thus, optimizing affinity for the cancer specific target is crucial and strongly dependent on the antigen-recognition domain of the CAR, the single-chain variable fragment (scFv). Binding of the scFv initiates activation of the CAR T cell; however, excessive high affinity or non-specific binding may reduce response rates due to accelerated exhaustion and antigen-independent activation, so-called tonic signaling.

In this study, our objective was to elucidate how structural properties of the scFvs are linked to antigen-dependent and independent CAR T cell properties through examination of their biophysical and binding characteristics at the molecular level. Therefore, panels of low to high affinity scFvs against CEA and HER2 were designed using structure-based and machine learning methods and compared to a previously published panel. Subsequently, all scFvs were analyzed with regard to their stability, specific and non-specific binding, as well as their binding kinetics and self-binding. Initial experiments showed major differences in protein stability and antigen-specific binding, as well as non-specific binding of the scFv caused by single amino acid substitutions.

To investigate the correlation between biophysical properties at the molecular level and the anti-tumor behavior of CAR T cells, these affinity panels were also analyzed at the cellular level. Overall, activation of the cells seems to follow the affinity hierarchy measured by NFAT activity. Additionally, prolonged survival without the target antigen was observed in some high affinity variants.

In summary, we highlight that the efficacy of CAR T cells for solid tumors is strongly affected by the biophysical properties of the antigen-binding domain and that affinity tuning modulates the antigen-dependent but also independent CAR signaling. Fully understanding these properties will be the key to the design of next generation CARs, overcoming the current challenges in solid tumor targeting.

Identification of novel ICOSL isoforms recurrently expressed in Sezary syndrome

Loubna Oumeslakht[1;2;3], Armand Bensussan[1;4], Jerome Giustiniani[2], Sanae Benmkaddem[1], Nicolas Ortonne[2;5]

[1]Mohammed VI Polytechnic University, Benguerir, Morocco; *[2]Mondor Institute of Biomedical Research (IMRB), Inserm U955, créteil, France*; *[3]Paris-Est Créteil University (UPEC), créteil, Morocco*; *[4]INSERM UMRS976, Saint Louis Hospital, Paris, France*; *[5]Pathology Department, AP-HP Inserm U955, Henri Mondor Hospital, créteil, France*

Sezary syndrome (SS), is an aggressive T-cell lymphoma with poor prognosis and no efficient therapy, characterized by a clonal proliferation of neoplastic $CD4^+$ T cells, named Sezary cells (CS), in the blood, the skin, and lymph nodes. These cells co-express different markers and their ligands such as PD1/PDL1/2 and OX40/OX40L. In this study, we have shown that besides ICOS, a TCR-costimulatory receptor of the CD28 family, SC do also express its ligand (ICOSL), known to be mainly expressed by antigen presenting cells. This expression was validated on different clinical samples and cell lines of SS, as well as other subtypes of T-cell lymphoma. Interestingly, we have identified in CS two long isoforms of ICOSL, ICOSL4.1 and ICOSL4.2, containing one or two intra-cytoplasmic proline-rich domain(s), which may have a distinct signalling function in CS. Furthermore, we have demonstrated that blocking the ICOS/ICOSL axis significantly increases tumor cell death and caspase-3 cleavage, indicating its role in the maintenance of tumor cell survival. To scrutinize the molecular mechanisms underlying this axis, we have performed a phospho-proteome profiling in a SS cell line after blocking the ICOS-ICOSL interaction. Results revealed that ICOS-ICOSL axis is implicated in the activation of AKT/AMPK signalling. We further demonstrated that targeting ICOSL in SS using an ICOS-Fc construct increases significantly tumor death through the recruitment of NK cells and the induction of antibody dependent cell cytotoxicity. Hence, targeting ICOSL in SS could open potentially a new avenue for the treatment of this disease.

Leveraging single B cell technologies in the development of anti-PD-L1 antibodies

Ali Mert Sencer[1;2], Bilgi Güngör[1], Asli Kurden-Pekmezci[1], Dogu Sayili[1], Ayca Zeybek Kuyucu[1], Serhat Ozgenc[1], Ceren Ulker[1], Sibel Kalyoncu[1], Mehmet Inan[1;3]

[1]Izmir Biomedicine and Genome Center, İzmir; *[2]Izmir International Biomedicine and Genome Institute, Dokuz Eylul University, İzmir*; *[3]Akdeniz University, Antalya, Turkey*

Purpose: The novel single B cell technologies offer a convenient discovery platform for antibody research. Especially, direct staining of IgG-switched memory B cell receptors with fluorophore-conjugated antigens allows functional evaluation of each antibody clone at the earliest stages of antibody discovery. Herein, we report our ongoing studies on developing novel anti-PD-L1 antibodies by employing this technology.

Methods: First, a full-length extracellular domain of human PD-L1 protein was produced in CHODG44 cells in-house. New Zealand White rabbits were injected s.c. with the recombinant PD-L1 in a mixture with Freund's complete and incomplete adjuvants for primary and booster immunizations, respectively. Blood was sampled on days 0, 14, 28, 42, 56, 70 and serum anti-PDL1 IgG titers were evaluated by ELISA. 14 days after the second injection, PBMCs were isolated by Ficoll density separation and stained for flow cytometry based single cell sorting. PD-L1 recognizing IgG^+ viable cells were sorted one cell per well using BD FACSAria III Cell Sorter. Expression cassettes were developed by cloning the IgG gene from naive rabbit splenocytes between the CMV promoter and poly(A) tail by overlap extension PCR. We transiently expressed recombinant rabbit IgG molecules in HEK293 cells and the resulting antibody titers were determined by ELISA.

Results: Anti-PD-L1 titers were found to be steady after a peak increase following the second immunization. In the PBMCs from the same day, approximately 10% of the IgG^+ cells displayed binding activity to PD-L1. We observed distinct binding patterns for each single cell when we normalized the PD-L1 fluorescence signal to surface IgG expression in index sorting analysis. This can be attributed to the diversity in antigen binding affinities of different IgG clones. The expression cassettes were successfully developed by overlap extension PCR for each rabbit IgG heavy and light chains and accomplished to produce recombinant rabbit IgG. Right now, we are working towards obtaining amino acid sequences of these anti-PD-L1 antibodies.

Conclusion: The high-throughput screening property of flow cytometry, together with the simultaneous analyzing capabilities at the single cell sorting step, presents an attractive approach for antibody discovery technologies.

Computational free flow cytometry for Sézary cells identification and quantification

Thi Van Anh TA[1], Elisabeth Cohen[1], Vial Jean Philippe[2], Veyrrat-Masson Richard[3], Marie Beylot Barry[4], Martine Bagot[5], Adèle de Masson[5], Caroline Ram Wolff[5], Helene Moins[1]

[1]INSERM1160 Hôpital Saint-Louis, Paris, France; *[2]CHU Bordeaux, Pessac, France*; *[3]CHU ESTAING, Clermont Ferrand, France*; *[4]CHU Bordeaux, Bordeaux, France*; *[5]Dermatology department, Paris, France*

Purpose: The specificity and reliability of KIR3DL2 as a positive marker for Sézary cell (SC) is now established to help initial diagnosis of Mycosis fungoides (MF) and Sézary syndrome (SS). During treatment, blood tumor burden is expected to decrease and flow cytometry (FCM) monitoring of blood SCs is essential. Here, we combined the use of the internationally recognized markers CD7, CD26, together with KIR3DL2 and the surrogate of T-cell clonality, TCR-Cb1 as routine tools for SC detection.

Methods: 566 samples from 265 patients with either confirmed or suspected SS/MF diagnosis were prospectively evaluated at the hematology routine laboratory between February 2023 and September 2023. The panel included 13 markers. We used our previously published gating strategy which was refined for the purpose of this study. In addition, data files were blindly analyzed by the two other leading groups from the Sézary group of the French CytHem association (www.cythem) which is aimed at promoting hematological cytometry. SC counts were compared to the results from blood clonal expansions detected by high throughput sequencing.

Results: During the 8 months study, 70 and 76 already diagnosed SS and MF patients, respectively, were analyzed. 9 newly SS diagnosed patients were identified with B2 stage according to CD7 and CD26 expression. All SCs expressed KIR3DL2 with a monophasic distribution of TCR-Cb1.

The use of TCR-Cb1 during the monitoring of treated SS, pre-SS or MF patients was particularly helpful in distinguishing non-malignant from malignant cells and in detecting low frequencies of SCs

Conclusion: This prospective study investigated the added value of both KIRDL2 and TCR-Cb1 to the recommended FCM markers for SS/MF initial diagnosis and blood tumor burden follow-up. Using a 13 colors panel, SC detection and quantification was improved using an indirect marker of T cell clonality, leading to a better assessment of blood stage at initial diagnosis and during therapy. This strategy is a simple, no time-consuming methodology which does not need high skills in FCM and computational analysis.

The MHC MACSimer technology combines flexibility, quality and releasabilty for the detection of antigen specific T cells

Urmi Roy[1], Lea Henschel[1], Lilly Geiger[1], Lennart Wessels[1], Gritt Günther[1], Marc Schuster[1], Jennifer Jaufmann[1], Marek Wieczorek[1]

[1]*Miltenyi Biotec B.V. & Co. KG, Be*

Antigen (Ag)-specific T cell responses play an essential role in monitoring and combating cancer, infectious diseases and autoimmunity and the precise analysis, isolation and characterization of rare Ag-specific T cells is crucial for the development of cellular therapies and cancer- or virus-specific vaccinations. Given the strong personal component of Ag-specific T cell responses ("MHC/HLA" restriction), innovative tools must provide researchers with full flexibility and high quality enabling integration into translational workflows.

We have therefore designed a new reagent, the MHC MACSimer. MHC MACSimers feature superior specificity and fluorescence brightness through an optimally balanced amount and ratio of MHC molecules and fluorophores, enabling the detection of even very rare T cell subsets with highest reliability, stability and robustness.

To further satisfy the demand for flexibility and compatibility of our MHC MACSimer with translation workflows, we have additionally integrated

(i) A peptide-loading technology into our peptide-loadable **MHC MACSimer FleX Kits** allowing for extensive T cell epitope screening.
(ii) The REAlease® technology into our MHC MACSimer FLeX Kits and **peptide-loaded MHC MACSimers** for label-free T cells after sorting, e.g. for multiple sequential sorting steps or functional downstream assays.
(iii) A broad collection of **MACSpep** single peptides covering a broad variety of T cell epitopes related to human diseases, such as cancer, infection, and autoimmunity and the ideal comparability with our MHC MACSimer FleX kits.

We show that our MHC MACSimers feature superior performance when staining and analysing shared cancer antigens, Neo-Ags or virus-specific T cells of different origins (PBMCs, whole bloods samples or dissociated organs) and comparing them to other state-of-the art MHC multimer reagents.

They perfectly integrate into secondary antibody staining panels with multimer staining approved Abs, e.g. T cell exhaustion or differentiation panels, allowing to get the most information out of the rarest T cells. Combining them with fluorochrome-specific magnetic beads using MACS technology leads to highly pure (>>90%) and high-yield-enriched T cell populations, displaying the "expected" T cell phenotype.

In conclusion, our three reagent classes improve Ag-specific T cell analysis, enumeration and isolation and cover the need for flexibility, stability and standardization.

Preparación de nanopartículas para evaluación del efecto antitumoral en un modelo de melanoma

Ariel Ramírez Cortes[1], Andres Elieu Castell Rodríguez[2], Miguel Herrera Enríque[3], Katya Jarquín Yáñez[3], Gabriela Piñón Zarate[3]

[1]Univerisdad Nacional Autónoma de México, Ciudad de México; *[2]Universidad Nacional Autónoma de México, Ciuda de México, Mexico*; *[3]Universidad Nacional Autónoma de México, Ciuda de México*

Purpose: Prepare nanoparticles with the simple emulsion and ianotropic gelation technique, to be applied in an in vivo melanoma model.

Methods: The preparation of the nanospheres was carried out using the method of simple emulsion and cross-linking, with 2% chitosan and 0.1% albumin in distilled water for 24 hours. Subsequently, 100 ml of oil were mixed mineral with 1% SPAN 80, stirred at 700 rpm for three minutes and washed with 25% glutaraldehyde, subsequently through Scanning electron microscopy evaluated its morphology.

The weight of a dry and clean Eppendorf tube was calculated, then the solution with the nanoparticles was placed in the dry tube and left in the incubator to dry the water. They were then weighed again and the initial weight was subtracted to infer the mass of the nanoparticles.

For in vivo experiments, six mice were used for each experimental group.

male C57BL/6 with H2K b from 6 to 8 weeks of age, which were maintained in light-dark conditions, controlled temperatures, and fed ad libitum in the Bioterio of the Department of Cellular and Tissue Biology of the Faculty of Medicine of the UNAM.

Results: In relation to survival and tumor size. Mice without treatment showed a notable increase in tumor volume, reaching a maximum on day 26 (22.38 cm 2). While tumor development was very similar in mice treated with the nanoparticles alone or coupled to CpG, MAGE-AX, MAGE-AX-CpG and MAGE-AX-CpGs- ClecA9. On day 28, a considerable change was noted in the mice treated with the

chitosan nanoparticles coupled to MAGE-AX-CpGs-ClecA9, since the volume was increased widely, reaching a maximum on day 30 after inoculation of melanoma.

Conclusion: The best method to make nano-sized microparticles is to ionic gelation. It was possible to effectively load tumor lysates from melanoma in nanoparticles.

The CLEC-9 group had a lower tumor growth rate compared to the others.

Enabling Fast and Convenient Immune Profiling of Fresh and Long-Term Stabilized Human Whole Blood Samples With CyTOF

Michael Cohen[1], Shakir Hasan[1], Stephen Li[1], Christina Loh[1], Dawar Pasha[1], Gloria Martrus Zapater[2]

[1]Standard BioTools, Markham, Canada, [2]Standard BioTools, Spain

Purpose: Accurate immune cell phenotyping in cancer patients' whole blood (WB) is crucial for disease prognosis and monitoring immunotherapy efficacy. Fresh WB analysis within 24 hours is vital to preserve cellular composition. However, logistical challenges arise when WB collection and cytometric analysis occur at different sites, leading to processing delays. To mitigate this, various WB preservation reagents like PROT1 and Cytodelics have been introduced. Nonetheless, not all antibody panels are compatible with these reagents. To address this issue, a CyTOF® panel compatible with commercial WB stabilizers has been developed for pharmaceutical and clinical research purposes.

Method and Material: CyTOF flow cytometry utilizes metal-tagged antibodies for cellular and functional phenotype identification, enabling rapid design and application of 50-plus-marker panels. Its low signal spillover and absence of autofluorescence eliminate the need for compensation. Additionally, antibody cocktails and stained samples can be frozen for future use, offering a streamlined and flexible workflow in clinical research, overcoming limitations of fluorescence-based cytometry. The CyTOF panel contains 20 antibodies to identify over 30 immune cell populations. For easy customization, there are more than 30 additional open channels to analyze markers of interest. The panel works with fresh and stabilized WB samples and is amenable to different staining and acquisition workflows. To show the flexibility of sample staining and stabilization, WB from three healthy donors was assessed using two stabilization workflows. First, fresh WB samples were stained with the antibody panel, followed by PROT1 or Cytodelics stabilization and storage at –80 °C. The second workflow involved immediate stabilization/fixation of WB with PROT1 or Cytodelics and storage at –80 °C. Subsequently, the samples for the second workflow were thawed, surface stained, and acquired. To reduce technical variability from staining, the antibodies were pooled together and frozen at –80 °C as single-use aliquots. Furthermore, all samples were barcoded and acquired as a single tube to reduce variability from sample acquisition.

Conclusion: The CyTOF panel, compatible with WB stabilizers, tackles traditional challenges in WB processing and acquisition. Freezing antibody cocktails ensures batch-to-batch consistency in clinical research, facilitating swift and convenient WB sample analysis through CyTOF workflows.

Exposure to cancer spheroids leads to human NK cell degranulation and anti-tumor activity, which is enhanced with cytokine preactivation and/or cetuximab

Ainara Lopez-Pardo[1], Mario Stan Fontoba[1], Ainhoa Amarilla-Irusta[1], Victor Sandá[1], Gabirel Astarloa[1], Laura Amo[1;2], Francisco Borrego[1;2]

[1]*IIS Biobizkaia, Barakaldo, Spain*; [2]*Ikerbasque. Basque Foundation for Science, Bilbao, Spain*

Adoptive natural killer (NK) cell-based immunotherapy is a promising treatment approach in cancer that is showing notable efficacy against hematological malignancies. However, the success of NK cell immunotherapy in patients with solid tumors is limited due to several barriers, which include the immunosuppressive tumor microenvironment, poor NK cell infiltration into the tumor and heterogeneity of tumor cells. Advances in 3D *in vitro* culture technologies have enabled the development of more physiological human cancer models that mimic important tumor features absent in 2D cultures, which may be essential for designing improved immunotherapies against solid tumors.

This study aims to analyze the interaction of NK cells with 3D tumor models and the enhancement of NK cell anti-tumor activity. In order to do so, we have developed tumor spheroids from a colorectal cancer cell line (HCT-116) and from a lung adenocarcinoma cell line (A549). We have established co-cultures of the tumor spheroids with NK cells isolated from healthy donors and we have observed that the integrity of the spheroids is notably affected when exposed to NK cells. Our flow cytometry-based functional analyses evidence an increased degranulation, as measured by the CD107a marker, and a higher production of IFN-γ and TNF-α cytokines in NK cells exposed to tumor spheroids. Our study has shown that NK cell degranulation and production of IFN-γ and TNF-α can be enhanced by different mechanisms. These include the *in vitro* priming of NK cells by exposure to pro-inflammatory cytokines (IL-12, IL-15 and IL-18) and/or the induction of NK cell antibody-dependent cell-mediated cytotoxicity (ADCC) in the presence of the monoclonal antibody cetuximab. Additionally, confocal microscopy allows us to both analyze NK cell-induced apoptosis of spheroids and infiltration of the NK cells into the spheroids. Currently, we are working with cancer organoids, as another 3D tumor model, to evaluate their interaction with human NK cells. The results from this project could potentially provide very valuable information to define effective combination therapies able to generate NK cells with high cytotoxic potential that could lead to more successful adoptive NK cell-based therapy for the treatment of solid tumors.

The impact of Fc receptors and host characteristics on myeloid phagocytic response to rituximab-treated 3D-cultured B-cell lymphoma

Sandra Kleinau[1]

[1]*Uppsala University, Uppsala, Sweden*

Antibody-based immunotherapy is successful in treating cancer, however its effectiveness varies among patients. To improve treatment outcome in each patient we need to understand what factors affect biological activities of therapeutic antibodies. Antibodies depend very much on the functional properties of immune cells that express Fc receptors (FcR). In this study, we explored FcR expression as well as host characteristics of monocytes in the capacity to phagocyte 3D-cultured human $CD20^+$ B-cell lymphoma (spheroids) treated with isotype variants of anti-CD20 rituximab (RTX) monoclonal antibody. The monocytes were obtained from healthy donors of different ages and sexes and their FcR for IgG (FcγRI, FcγRIIa, FcγRIIIa) and IgA (FcαRI) were determined, as well as FcR gene polymorphisms. Antibody-dependent phagocytosis was assessed using flow cytometry, confocal imaging, and Fc receptor blocking. Different RTX isotypes showed varying efficacy in stimulating phagocytosis of lymphoma spheroids. RTX-IgG3 proved to be most efficient, followed by RTX-IgG1, while moderate efficacy was observed by RTX-IgA1, RTX-IgA2, RTX-IgG4, and RTX-IgG2 had minor effect. RTX-stimulated monocytes infiltrated lymphoma spheroids predominantly at the periphery, but monocytes could also be identified in the spheroid core. Blocking FcγRI or FcγRIIa, but not FcγRIIIa, with antibodies inhibited RTX-IgG1 and RTX-IgG3-mediated phagocytosis. Monocytes derived from younger women exhibited elevated levels of FcγRI and FcγRIIa in comparison to their older counterparts. Conversely, in older men, there was a notable rise in FcγRI and FcγRIIIa levels when contrasted with younger men. This pattern was further supported by the observation that monocytes isolated from younger women displayed heightened phagocytic activity compared to those from older women. Similarly, older men demonstrated superior IgG-mediated phagocytosis relative to younger men. Single Fc receptor levels, or FcγRIIa and FcγRIIIa genetic variants, had low correlation with phagocytic intensity, possibly due to the involvement of multiple Fc receptors in IgG-mediated phagocytosis. In conclusion, the interplay of antibody isotype, Fc receptors, age, and sex significantly affects tumor phagocytosis. This study unveils a critical connection between host characteristics and the effectiveness of therapeutic antibodies, offering invaluable insights for advancing cancer immunotherapy treatments.

Deciphering the role of immune microenvironment during CD19 CAR-T treatment in leukemia

Mathilde Chambre[1], Lisa Aziez[1], Ismael Boussaid[1;2], Rudy Birsen[1;2], Marguerite Vignon[2], Didier Bouscary[1;2], Justine Decroocq[1;2], Nicolas Chapuis[1;2], Yannick Simoni[1]

[1]*Université Paris Cité, Paris, France*; [2]*APHP – Hopital Cochin, Paris, France*

Background: CD19 CAR-T therapy has shown remarkable clinical responses in patients with B-cell acute lymphoblastic leukemia or B-cell non-Hodgkin's lymphoma. However, many parameters such as cytokine release syndrome (CRS), neurological resistance, modest anti-tumor activity of CAR-T cells after infusion, loss of the CD19 antigen by the tumor cells can limit the therapeutic efficacy.

Objectives: Here, we explore the interactions between the tumor microenvironment (i.e. patient's immune system) and CAR-T cells, to determine if the immune composition constitute a predictive biomarkers for CAR-T efficacy and side effect.

Methods: We used mass-cytometry approach to characterize the immune cells compartment pre- and post-treatment (1 week, 2 weeks, 1 month, 2 months, 6 months).

Results: Our data shows much greater complexity in the CAR-T, conventional CD4 and CD8 T cell population than previously appreciated. Moreover, we observed a non-uniform pattern of variations across patients tested, which highlights a broad diversity of these cells as previously described. These observations, particularly with respect to markers associated with T cells exhaustion, may help to explain heterogeneity in clinical outcomes.

Conclusion: Great diversity of CAR-T, CD4 and CD8 T cells between patients and across time-point. Next step: investigate the antigen specificity of these T cells using an MHC class I tetramer screening approach.

Complexes of IL-2 and anti-IL-2 mAb selectively stimulating CD25+ T cells in combination with immune checkpoint inhibitors possess potent antitumor activity but the timing is crucial

Irfan Baki Kilic[1], Petra Weberova[1], Katerina Behalova[1], Bohumil Ptacek[1], Milada Sirova[1], Vladyslav Mazhara[1], Katerina Kubesova[1], Blanka Rihova[1], Marek Kovar[1]

[1]*Institute of Microbiology of the Czech Academy of Sciences, Prague, Czech Republic*

Purpose: Complexes of IL-2 and anti-IL-2 mAb (IL-2co) were shown previously to possess high biological activity *in vivo*. IL-2co exert selective stimulatory activity for either intermediate-affinity dimeric or high-affinity trimeric IL-2R expressing cells depending on the clone of anti-IL-2 mAb used. IL-2/anti-IL-2 mAb S4B6 complexes (IL-2/S4B6) are highly stimulatory for $CD122^{high}$ populations (memory $CD8^+$ T and NK cells), while only moderate stimulatory activity for T_{reg} cells was found. Conversely, IL-2/anti-IL-2 mAb JES6-1A12 complexes (IL-2/JES6) highly selectively and potently stimulate the expansion of $CD25^+$ cell population (Treg cells). Thus, it has been considered that IL-2/S4B6 are suitable for tumor immunotherapy while IL-2/JES6 are convenient for the treatment of autoimmune diseases or to facilitate long-term allograft acceptance. However, we recently found that IL-2/JES6 surprisingly possess antitumor activity, particularly in combination with immune-checkpoint inhibitors (anti-CTLA-4 plus anti-PD-1 mAb; ICIs henceforth). Thus, the purpose of this study was to investigate the potential of immunotherapy through combination of ICIs and IL-2co and to determine whether CD122-biased IL-2/S4B6 or CD25-biased IL-2/JES6 are more efficient.

Methods: We investigated the stimulatory activity of IL-2co for primed $CD8^+$ and $CD4^+$ T cells *in vitro* via (^{3}H)-thymidine incorporation and *in vivo* via adoptive transfer experiments. Phenotype of T cells and other immune cell population was evaluated via flow cytometry and *in vivo* antitumor activity of ICIs plus IL-2co was studied in CT26 tumor model.

Results: IL-2/JES6 possess antitumor activity comparable to IL-2/S4B6 at equimolar dosage when combined with ICIs. However, the timing of ICIs and IL-2/JES6 administration is crucial since IL-2/JES6 administered before ICIs do not improve the antitumor activity of ICIs, but IL-2/JES6 given after ICIs significantly potentiate it. Moreover, IL-2/JES6 possess much lower toxicity than IL-2/S4B6 thus enabling high-dosage treatment leading to superior antitumor effect.

Conclusion: IL-2/JES6 or similar $CD25^+$ T cell-biased IL-2 therapeutics may be efficient tool for cancer immunotherapy particularly in combination with ICIs due to their low toxicity and high stimulatory activity for activated $CD8^+$ T cells.

CD25-biased IL-2-based immunocytokines in combination with immune-checkpoint inhibitors completely eradicate large established tumors in CD8+ T cell-dependent manner

Irfan Baki Kilic[1], Petra Weberova[1], Derek VanDyke[2], Milada Sirova[1], Katerina Kubesova[1], Charina S. Fabilane[2], Vladyslav Mazhara[1], Kathy Liu[2], Blanka Rihova[1], Jamie B. Spangler[2], Marek Kovar[1]

[1]Institute of Microbiology of the Czech Academy of Sciences, Prague, Czech Republic; *[2]Departments of Biomedical Engineering and Chemical and Biomolecular Engineering and Program in Molecular Biophysics, Johns Hopkins University, Baltimore, MD 21218, United States*

Purpose: We found recently that complexes of IL-2 and anti-IL-2 mAb selectively stimulating $CD25^+$ cells (i.e. CD25-biased IL-2co) surprisingly possess antitumor activity, particularly in combination with immune checkpoint inhibitors (ICIs) despite robust Treg cell expansion. Thus, we decided to evaluate a panel of CD25-biased IL-2-based immunocytokines (IC) with different requirements for CD25 expression levels to stimulate IL-2-responsive cells. ICs consist of IL-2 linked through flexible oligopeptide $(Gly_4Ser)_7$ to the light chain of anti-IL-2 mAb (or irrelevant anti-FITC mAb representing a control IC) thus mimicking IL-2co both structurally and functionally but without drawbacks like excess of either IL-2 or Ab and potential dissociation leading to off-target effects. The purpose of this study was to investigate the stimulatory activity of various ICs for antigen-primed $CD8^+$ T cells and other immune cell subsets and their antitumor activity in combination with ICIs.

Methods: Stimulatory activity of CD25-biased IL-2-based ICs for antigen-primed $CD8^+$ T cells was investigated via OT-I $CD8^+$ T cell adoptive transfer experiments. The expansion of various immune cell populations and T-cell phenotypes were evaluated via flow cytometry. Antitumor activity of IL-2-based ICs in combination with ICIs (anti-PD-1 and anti-CTLA-4 mAbs) was studied in CT26 and MC38 tumor models.

Results: Y33 IC demonstrated remarkable potential to drive the expansion of antigen-primed $CD8^+$ T cells though a weaker than control IC. However, Y33 IC showed superior activity to induce the expression of effector molecules in antigen-primed $CD8^+$ T cells with limited stimulation of Treg cells. Y33 IC plus ICIs significantly prolonged survival and completely cured most CT26 or MC38 tumor-bearing mice without any sign of toxicity (body weight and temperature, pulmonary oedema). Depletion of $CD8^+$ T cells considerably reduced the antitumor activity of Y33 plus ICIs, indicating that $CD8^+$ T cells were the predominant immune population for therapeutic effect.

Conclusion: CD25-biased IL-2-based ICs may represent a promising tool for cancer immunotherapy, particularly in combination with ICIs.

Introducing SequiMACS technology: pioneering multi-cell isolation in single complex blood samples

Rebecca Königsmark[1], Hassan Ahmed[1], Christian Keßel[1], Philipp Steinbrück[1], Susanne Höher-Peters[1], Vanessa Brühl[1], Christin Donner[1], Stefano Vergani[1], Gregor Winkels[1], Ermanila Dhana[1], Lotta Räty[1], Christian Dose[1], Jonathan Fauerbach[1]

[1]*Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Germany*

Purpose: Immunomagnetic cell isolation plays a pivotal role in studying specific cell populations of the innate and adaptive immune system which are crucial in elucidating immunological mechanisms. However, existing methods are restricted to isolate one target population at a time, necessitating sample splitting and thus compromising mainly on cell yield and recovery and limiting studies on autologous derived cells. At Miltenyi Biotec, we address this gap by introducing a novel technology, '*SequiMACS*®', which allows for the simultaneous labeling and isolation of multiple cell types from a single complex sample to optimize cell isolation workflows, target cell yields, and cell recoveries.

Methods: SequiMACS® technology is an extension from the previously developed StraightFrom®REAlease® approach, where now multiple release systems can be combined to label and isolate target cells from complex samples thanks to Miltenyi's unique MACS columns. In this study, we demonstrate the efficacy of SequiMACS® by co-isolating CD3+ T cells and CD19+ B cells from human whole blood. The isolated cells were subjected to various downstream applications including cell culture, activation, and expansion. Furthermore, single-cell sequencing of TCR and BCR, was conducted to illustrate how co-enriching multiple cell populations from the same cell sample could optimize the immune profiling of cell subsets.

Results: Our results showcase high purities and recoveries achieved through the co-isolation of CD3+ T cells and CD19+ B cells from human whole blood using SequiMACS® technology. By sequentially eluting the target cells from a single MACS® column, we were able to maintain the integrity and functionality of the isolated cells, enabling robust downstream applications.

Conclusion: The SequiMACS® technology represents a significant advancement in immunomagnetic cell isolation, offering a smart workflow solution for classical multi-cell isolation from single complex specially in quantity-limited blood samples. By optimizing the use of precious samples and streamlining the isolation process, SequiMACS® holds promise for accelerating research in cancer immunology and other fields reliant on limited starting materials and precise cell isolation techniques (e.g. Chimerism Analysis from Pediatric patients).

Antitumoral activity of bacterioruberin, a rare carotenoid from haloarchaea, in solid tumor models

Andrés Baeza-Morales[1], Miguel Medina-Garcia[1], Carolina Pujalte-Satorre[1], Sandra Pascual Garcia[1], Pascual Martinez-Peinado[1], Ana Belen Lopez-Jaen[1], Alicia Navarro-Sempere[1], Yolanda Segovia-Huertas[1], María Magdalena García-Irles[1], Rosa María Martínez Espinosa[1], Jose Miguel Sempere-Ortells[1]

[1]*University of Alicante, San Vicente del Raspeig, Spain*

Purpose: Carotenoids, extensively researched for their anticancer properties, act as antioxidants by scavenging ROS and RNS, thereby preventing DNA, lipid, and protein oxidative damage. They also modulate gene expression and signalling pathways related to cell growth, differentiation, inflammation, and immune response enhancement. Additionally, certain carotenoids induce apoptosis, inhibit angiogenesis, and disrupt cell cycle progression in cancer cells.

Bacterioruberin (BR), an unusual carotenoid sourced from extremophilic haloarchaea, among others microorganisms, exhibits significantly higher antioxidant capacity compared to well-studied classical carotenoids, suggesting antitumor potential. Previous results from our group demonstrate that BR triggers death of cells from hematological tumoral but not healthy cells. The primary objective of this research is to investigate the therapeutic potential of BR addressing solid tumors employing A549 lung carcinoma epithelial cell line. These cells are used as a model for non-small cell lung cancer (NSCLC), which constitute about 80% to 85% of lung cancers.

Methods: *In vitro* experiments were conducted using incremental doses of BR (0-75 µg/ml), and its effects were assessed through various assays. These included the evaluation of cell toxicity (MTT; 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide), proliferation (CFSE-DA; (5[6]-carboxyfluorescein diacetate succinimidyl ester), apoptosis (YO-PRO-1/Propidium Iodide), and cell cycle alterations (Propidium Iodide), through flow cytometry analysis. Morphological changes associated with apoptosis were also examined using fluorescence microscopy (dual acridin orange/ethidium bromide staining).

Results: At the highest concentrations of BR, a decrease in A549 proliferation of more than 50% was observed. On the other hand, the compound induced apoptosis in a dose-dependent manner, with apoptosis rates increasing significantly from the dose of 9.375 µg/ml. The highest dead cell population was obtained after treatment with the dose of 75 µg/ml.

Conclusion: These results could indicate the potential of bacterioruberin as a promising therapeutic option, making it an attractive candidate for further research and potential development of bacterioruberin-based therapies. Further investigations are needed to elucidate the underlying mechanisms responsible for bacterioruberin's antitumoral effects.

Viral infections for cancer immunotherapy

Yeaji Kim[1], Yong Woo Jung[1]

[1]*Korea University, Sejong, South Korea*

Purpose: Cancer is a worldwide problem that needed to be solved; therefore, many researchers have been tried to reinvigorate exhausted T cells. Despite of these efforts, the treatment of cancer has not been conquered due to the deficiency of tumor antigens and the expression of immune suppressive molecules that inhibit the anti-tumor immune responses by tumor-specific T cells. To overcome these problems, we hypothesized that tumor cells deliberately infected with viruses present viral antigens to activate memory T cells, and that these T cells then kill infected tumors.

Methods: To address this hypothesis, we administered B16F10 melanoma cells subcutaneously into naïve mice containing LCMV-specific P14 memory CD8 T cells followed by intratumoral LCMV infections. These mice were infected with LCMV intratumorally to examine the survival and immune response mounted by memory T cells.

Results: First, we found that these tumor cells were infected by intracellular staining of viral nucleoprotein, and the survival of virus-infected tumor-bearing mouse increased 3 times compared to control. Second, the frequencies and numbers of P14 cells in the spleen, tumordraining lymph nodes, and tumors increased in virus-infection group compared to controls until D10 pi, suggesting that memory T cells recognized viral infections. Finally, we investigated any possible immune escape mechanisms by measuring the levels of cytokines in tumors by using ELISA.

Conclusion: Taken together, the development of strategy of virus-specific memory CD8 T cells targeting tumor cells with viral infections would be major key of noble cancer immunotherapy.

Checkpoint molecules on Antigen-Loaded Extracellular Vesicles modulate their anti-tumoral effects in a mouse model of melanoma

Loïc Steiner[1], Loes Teeuwen[1], Annemarijn Offens[1], Gözde Güçlüler Akpinar[1], Daniel Martinez Martinez[1], Jesse Kuipers[1], Jules Mazouin[1], Benedict Chambers[1], Susanne Gabrielsson[1]

[1]*Karolinska Institute, Stockholm, Sweden*

Extracellular Vesicles (EVs) have been tested in humans as cancer immunotherapy, but the treatment needs improvement. EVs secreted by bone marrow derived dendritic cells (BMDCs) have been shown to induce an antigen-specific immune response in mice and, when loaded with tumor-specific antigens, significantly delay tumor growth and recruit immune cells to the tumor site. Our previous work investigated the combination of BMDC EV treatment with checkpoint blockade therapy (anti PD1 or anti PD-L1 antibodies) and showed a synergistic effect with EVs. As the BMDC EVs contain both PD1 and PD-L1, we speculated that EVs from PD1 or PD-L1 knock out (KO) mice would induce stronger anti-tumor responses than WT EVs.

Mice were immunized with WT, PD1 KO and PD-L1 KO BMDC EVs, and all EV-injected groups showed a similar number of antigen-specific CD8 T cells detected in the spleen. However, following *ex vivo* restimulation of the splenocytes, OVA specific CD8 T cells from the PD1 and PDL-1 KO EVs were found to be more potent than the WT treatment.

In contrast, when EVs were injected as tumor therapy in a mouse melanoma model, WT EVs performed better than the two knock outs in delaying tumor growth. All the EV treatments induced a potent anti-tumor response by recruiting several immune cell types at the tumor sites, but the absence of checkpoint molecules on the EVs dampened the antigen specific response and altered the antibody response elicited against the tumor antigen. This contrasts with earlier findings in tumor-derived EVs, where exosomal PD-L1 has been shown to inhibit immune responses to the tumor.

Taken together, we have confirmed that BMDC EVs loaded with antigen are potent immune stimulators and promising tools for immunotherapy. Additionally, the checkpoint molecules present on theses EVs may play a functional role in immune activation and are important in eliciting a strong antigen specific anti-tumor response. Our results also highlight the need to further investigate the PD1/PD-L1 axis in cancer therapy.

Phenotypic analysis of cytokine-induced killer cells (CIK): identification of receptors involved in their functional capacity

Fakhri Hassouneh[1;2], Nelson López-Sejas[2], Alejandra Pera Rojas[1;3], Carlos Blanco-Benitez[4;5], Rafael Solana Lara[1;3], Raquel Tarazona[2]

[1]Immunology and Allergy, Maimonides Biomedical Research Institute of Cordoba (IMIBIC), Cordoba, Spain; *[2]Immunology Unit, Department of Physiology, University of Extremadura, Cáceres, Spain*; *[3]Department of Cell Biology, Physiology, and Immunology. University of Córdoba, Cordoba, Spain*; *[4]Department of Cell Biology, Faculty of Sciences, University of Granada, Campus Fuentenueva, Granada, Spain*; *[5]Department of Genomic Medicine, Pfizer-University of Granada-Andalusian Regional Government for Genomics and Oncological Research (GENYO), PTS, Av. de la Ilustración 114, Granada, Spain*

Cytokine-induced killer cells (CIK) cells are a heterogeneous group of immune effector cells exhibiting a mixed T- and natural killer (NK) cell-like phenotype, obtained by in vitro incubation of human peripheral blood mononuclear cells (PBMC) with interferon (IFN)-γ, interleukin (IL)-2, and anti-CD3 monoclonal antibody. Their cytotoxic capacity is mainly attributable to $CD3^+CD56^+$ cells and it is not restricted by the major histocompatibility complex (MHC), allowing them to recognize virus-infected or malignant cells in the absence of MHC. The regulation of CIK cell function by inhibitory and activating receptors is a crucial aspect of immune regulation and phenotype characterization is essential to understand their functional properties and optimize their use in cancer therapy. In this study, CIK cells were cultured and expanded from PMBC of healthy donors with the addition of IFN-γ, IL-2, and anti-CD3 antibody for 21 days. The phenotype of CIK cells has been characterized, before and after the expansion, to determine the expression of activating and inhibitory receptors. The results show that the majority of CIK cells obtained at the end of expansion are CD8+ and express the TCR-alpha/beta. There was a significant increase in the activating/costimulatory receptors DNAM-1 and NKG2D, while the most expressed inhibitory receptors were TIM-3 and LAG-3. Furthermore, we found a significant increase in CD6, Fas, and Perforin expression. On the contrary, a significant decrease was observed in the expression of KIR2D and NKp80. Analysis of CIK function showed that CD3 and to a lesser extent NKG2D play a role in redirected degranulation and cytokine production. Inhibitory receptors also regulate the functional capacity of these cells. In summary, the results support that advances in the phenotype and functional analysis of CIK cells are critical for the development of effective immunotherapies for cancer treatment.

Programmed death-ligand 1 Expression on T Lymphocytes is Associated with β2-microglobulin Levels in Treatment-naïve Patients with Chronic Lymphocytic Leukaemia

Zekhethelo Mkhwanazi[1], Aviwe Ntsethe[1], Bongani Nkambule[1], Tawanda Nyambuya[2], Phiwayinkosi Dludla[3]

[1]School of Laboratory Medicine and Medical sciences, College of health sciences, University of KwaZulu-Natal, Durban, South Africa; *[2]Department of Health Sciences, Faculty of Health and Applied Sciences, Namibia University of Science and Technology, Windhoek, Namibia*; *[3]Biomedical Research and Innovation Platform, South African Medical Research Council, Tygerberg, Cape Town, South Africa*

The aberrant expression of co-inhibitory proteins is well-documented in patients with chronic lymphocytic leukemia (CLL), where βeta 2 microglobulin (β2M) serves as a key prognostic marker for patients treated with chemotherapy and chemoimmunotherapy. Nevertheless, the predictive value of β2M as a biomarker in effectively identifying the efficacy of immune checkpoint inhibition therapy in untreated patients with CLL remains unexplored. This study aimed to evaluate T cell-mediated responses to immune checkpoint inhibition in untreated patients with CLL. Furthermore, we investigated correlations between immune checkpoint expression on T helper and cytotoxic T cells; and β2M status. We assessed immune checkpoint expression on T cells from patients with CLL using flow cytometry. In addition, we measured baseline β2M levels using enzyme-linked immunosorbent assay (ELISA) protocol. Soluble immune checkpoint proteins; including PD-1, PD-L1, and cytotoxic T lymphocyte antigen-4 (CTLA-4) were quantified using a multiplex assay. After adjusting for age and sex, β2M levels strongly correlated with soluble PD-1 ($r = 0.65$, $p = 0.022$), and the surface expression of PD-L1 ($r = 0.60$, $p = 0.036$) on T lymphocytes. The expression of PD-1, PD-L1, and CTLA-4 was increased following T cell activation with PMA ($p<0.05$). Our results revealed no significant differences in the expression of PD-1, PD-L1, and CTLA-4 following inhibition with PD-1/PD-L1 blocking antibody. Overall, these findings suggest that immune checkpoint profiling in patients with CLL and the association between β2M and the PD-1/PD-L1 axis may be useful in identifying patients that may benefit from PD-1/PD-L1 checkpoint-based therapies. Additionally, PD-1/PD-L1 upregulation on T cells is linked to markers of disease progression, highlighting the role of β2M in inhibiting T cell responses in CLL patients. Monitoring β2M levels in patients with CLL may provide valuable insights into patient responses to immunotherapy targeting the PD-1/PD-L1 axis.

Developing new and effective strategies for adoptive T- cell therapy in pediatric gliomas

Or Zohar[1], Maria Castro[2], Adi Anaki[3], Rachela Popovtzer[3], Dinorah Friedmann-Morvinski[1]

[1]Tel Aviv University, Tel Aviv, Israel; *[2]University of Michigan Medical School, Michigan, United States*; *[3]Bar Ilan university, Ramat Gan, Israel*

Tumors of the central nervous system (CNS) are the most common form of childhood malignancy, and remain the leading cause of cancer-related morbidity and mortality among children. Cancer immunotherapy holds a lot of potential as a targeted therapy designed with high affinity to locate specifically the tumor cells and act directly on them, however, its applicability in the context of gliomas seems limited, in part, by the lack of ubiquitously expressed tumor antigens. our studies identified a previously uncharacterized biomarker, a mitochondrial protein that is highly expressed in pediatric gliomas that holds potential for serving as a novel CAR target with a dual function for cancer immunotherapy in pediatric gliomas.

The aim of this project is to contribute to the state of art of immunotherapy in pediatric gliomas. This will be done in different directions, First by screening different pediatric models that potentially express our novel biomarker, second by improving the efficacy of our specific CAR-T cells enabling monitoring their pathway and biodistribution utilizing gold nanoparticles (GNPs). Lastly, by Integrating CAR-T administration with targeted inhibitors to investigate potential synergistic effects against pediatric gliomas.

We have developed elegant immunocompetent mouse models of pediatric brain tumors by cloning mutations/fusions found in human pediatric patients into Cre/loxP-inducible lentiviral vectors. We validated the expression of our novel antigen on the surface of different pediatric models by using flow cytometry analysis. Next, we generated specific CAR-T cells against this antigen and validated their specificity and functional activity. This was done by evaluating the ability to stimulate the engineered T cells and their target killing capacity. Untransduced (UT) lymphocytes were used as controls in all the experiments. Notably, while the specific CAR-T cells were able to exert their cytotoxic effect, proliferate and secrete IFN-g when co-cultured with glioma cells, UT T cells showed little to no response. Altogether, these results support the potential anti-angiogenic effect of these CARs.

We are currently assessing the efficacy of these CAR's *in vivo* using our pediatric models. In addition we will monitor the CAR-T cell migration and infiltration (biodistribution) using gold nanoparticles (GNPs) that can be tracked using CT screening.

Purpose: Cytokine-induced memory-like (CIML) NK cells are generated by *in vitro* culture with a combination of IL-12, IL-15 and IL-18. These CIML NK cells possess optimal characteristics for cancer immunotherapy, such as longer lifespan and increased cytotoxicity. Based on CD16 expression, this study aims to characterize two subsets of CIML NK cells phenotypically and functionally.

Methods: NK cells were isolated from healthy donor buffy coats and stimulated overnight with IL-12/15/18 at concentrations of 10ng/mL, 1ng/mL, and 50ng/mL, respectively. Following stimulation, NK cells were cultured with IL-15 (1ng/mL) for 7 days. Phenotypic and functional analysis of CIML NK cell subsets based on CD16/CD56 expression was done by flow cytometry. In addition, CD16+CD56+ and CD16−CD56+ subsets were sorted via FACS for high-throughput multiplexed quantitative proteomics. Statistical comparison of FACS analyses included non-parametric Friedman and Durbin-Conover test. The Benjamini-Hochberg False Discovery Rate (FDR) correction was applied for proteomic analysis, considering peptides/proteins exhibiting FDR<0.05 as significantly different.

Results: Phenotypic analysis of CIML NK cells revealed significant differences between the CD16+CD56+ and CD16−CD56+ subsets. CD16−CD56+ cells exhibited higher expression of activating receptors, increased Granzyme B production, and reduced expression of inhibitory receptors compared to CD16+CD56+ cells. In response to melanoma cell lines, CD16−CD56+ NK cells exhibited higher degranulation (CD107a/b+) compared to CD16+CD56+ cells. Additionally, proteomic profiling identified 35 proteins out of 4750 showing differential expression between the CD16+CD56+ and CD16−CD56+ subsets. Among these, 22 were significantly decreased and 13 were significantly increased in the CD56+CD16+ NK subset (FDR<0.05). Relevant proteins such as Granzymes, CD273, CD39, CD158b, and Fc receptors were identified in this comparative analysis.

Conclusion: In summary, our research offers a thorough characterization of *in vitro*-expanded CIML NK cells in terms of CD16 expression. We found that CIML NK cells with a CD16−CD56+ phenotype exhibit a greater degranulation capacity against tumor cells. Finally, our analysis identified potential NK cell biomarkers that could enhance their clinical efficacy.

Purpose: Glioblastoma (GB) is the most common primary brain tumor, characterized by a highly immunosuppressive tumor microenvironment (TME). While CAR-NK cells targeted against HER2 have shown activity in several murine glioma models, effect in advanced tumors was limited. IFNγ secreted by CAR-NK cells contributes to PD-L1 upregulation and suppression of intratumoral T-cell activity. Tumor-targeted Adeno-associated viral vectors, such as HER2-AAVs, coding for immunocheckpoint inhibitors (ICIs), are a promising tool to achieve a specific intratumoral ICI therapy. This avoids the lack of therapeutically active ICI concentrations or side effects, drawbacks of systemic ICI therapy. Here, we evaluated the effects of combination immunotherapy with HER2-specific CAR-NK cells (NK-92/5.28.z) and HER2-AAVs in preclinical GB models.

Methods: The used AAVs encode an anti-PD-1 immunoadhesin (aPD-1) and are targeted against HER2 with designed ankyrin repeat proteins (DARPins). The immune response and the modulation of the TME are currently characterized with highplex multi-color flow cytometry, multispectral histology and NanoString RNAseq.

Results: HER2-expression levels correlated with HER2-AAV mediated gene transfer in GB cells. After transduction, secreted aPD-1 effectively bound its target on PD-1 expressing cells. aPD-1 efficiently disrupted the PD-1/PD-L1 axis, leading to re-activation of T-cells. CAR-NK mediated tumor cell lysis was not impaired by AAV-transduction. aPD-1 was detected at high intratumoral and low systemic concentrations after local injection of HER2-AAVs into tumor grafts in vivo. Combination therapy significantly prolonged survival in subcutaneous and orthotopic GL261 and Tu2449 immunocompetent mouse models, resulting in complete tumor control in several animals.

Conclusion: Local combination therapy with CAR-NK cells and HER2-AAVs encoding aPD-1 is a promising immunotherapeutic strategy for GB, with potentially enhanced efficacy and reduced side effects.

Potential of inhibition of NLRP3 inflammasome in enhancement of immunotherapy in prostate cancer

Kateřina Kalkušová[1], Dmitry Stakheev[1], Pavla Táborská[1], Jiřina Bartůňková[1], Daniel Smrž[1]

[1]*Department of Immunology, Second Faculty of Medicine, Charles University and Motol University Hospital, Prague, Czech Republic*

Purpose: The NLRP3 inflammasome is a crucial innate immune pathway. However, there is expanding evidence of its role in cancer cell biology. The increased expression of the NLRP3 inflammasome has been found in several malignancies and is associated with worse prognosis, a higher rate of tumor growth, and an immunosuppressive tumor microenvironment. Moreover, increased expression of INLRP3 has been associated with resistance to several chemotherapeutics and anti-PD-1 checkpoint inhibitors. Current studies show that chemoresistance can be overcome by inhibition of NLRP3. In this study, we investigated whether a pharmacological inhibition of NLRP3 inflammasome activation could enhance anti-tumor immune responses and and decrease tumor resistance to immunotherapy.

Methods: A selective small-molecule inhibitor, MCC950, was used to inhibit the NLRP3 activation. Cancer cell lines PC3 and LNCap transfected with fluorescent protein were treated with MCC950, and subsequently co-cultivated with PBMCs or lymphocytes from prostate cancer patients. The immune rejection was analyzed by cancer cell fluorescent intensity using fluorescent microscopy. Additionally, cell surface markers and cytokine production were evaluated by flow cytometry. The immunogenicity of MCC950-treated cancer cells was also evaluated using monocyte-derived dendritic cells, prepared from peripheral blood monocytes and loaded with cancer cell lysate.

Results: Our findings reveal that inhibition of the NLRP3 inflammasome by MCC950 has the potential to enhance antitumor immune responses by promoting cancer cell immunogenicity. Furthermore, NLRP3 inhibition leads to reduced immunosuppressive signalling and cytokine production, such as PD-L1 downregulation and decreased release of IL-8, thereby decreasing the cancer cell resistance to antitumor immune responses. Additionally, we demonstrated that dendritic cells loaded with lysate from MCC950-treated cancer cells promoted the proliferation of $CD8^+$ T cells, suggesting its potential as a booster of dendritic cell-based vaccines.

Conclusion: Our findings revealed that targeting NLRP3 inflammasome could sensitize tumor cells to immunotherapy and might enhance antitumor effector functions of ex vivo-produced dendritic cells for cancer immunotherapy.

Towards the deciphering of immunological mechanisms of tumor immunotherapy-induced cardiotoxicity

Chiara Catalano[1;2], Marinos Kallikourdis[3;4]

[1]Department of Biomedical Sciences, Humanitas University, Pieve Emanuele (MI), Italy; *[2]Adaptive Immunity Laboratory, IRCCS Humanitas Research Hospital, Rozzano (MI), Italy*; *[3]Department of Biomedical Sciences, Humanitas University, Pieve Emanuele (MI), Italy*; *[4]Laboratory of Translational Immunology, IRCCS Humanitas Research Hospital, Rozzano (MI), Italy*

Immune checkpoint inhibitors (ICI) changed the landscape of cancer therapy but in 1% of the cases their use is associated with immune-related adverse events, such as fulminant myocarditis. ICIs are antibodies that block negative regulators of the immune response of T lymphocytes, including cytotoxic T lymphocyte associated protein 4 (CTLA-4), programmed cell death protein-1 (PD-1), and PD-ligand 1 (PD-L1). Seminal studies of patients with melanoma who died from fulminant myocarditis after combined treatment with anti-PD1 \ PDL1 and anti-CTLA4, identified infiltration of T cells into the myocardium suggesting that T cells are involved in ICI-associated myocarditis.

In order to investigate how T cells are linked to cardiac dysfunction in ICI myocarditis, we have set off to characterize the immune-phenotype of these patients. We set up and optimized a 34 parameter-panel for flow cytometry on peripheral blood samples (PBMC) enabling us to assess the activation state of T cell subsets, especially CD8.

For all patients we perform high sensitivity enzyme-linked immunosorbent assays (ELISA) in order to evaluate biochemical markers that are indicators of myocardial injury, such as ST2, atrial natriuretic peptide (ANP), NT- proBNP and Cardiac Troponin I (cTnI).
Our study could shed light into the immunological basis of ICI-induced cardiovascular toxicities.

the Effect of aberrant N-glycosylation of PD-L1 on the potency of anti-PD-1 treatments

Bar Kaufman[1], Nofar Erlichman[2], Tsipi Meshel[2], Adit Ben-Baruch[2], Moshe Elkabets[1], Angel Porgador[1]

[1]Ben-Gurion University of the Negev, Beer Sheva, Israel; *[2]Tel Aviv Univesity, Tel Aviv, Israel*

Immune checkpoint inhibitors (ICIs) have transformed the landscape of cancer therapy, yet the variability in patient response underscores the need for deeper mechanistic insights. This study investigates the impact of PD-L1 glycosylation on the efficacy of anti-PD1/PDL1 ICIs and introduces the Immune-Checkpoint Artificial Reporter (IcAR) technology for assessing ICI potency.

Cell lines were engineered to express wildtype PD-L1 and variants with single glycosylation site mutations (N35A, N192A, N200A, N219A), as well as a quadruple mutant (Nx4). Functional binding assays using IcAR-PD1 were conducted to evaluate the interaction between PD-L1 mutants and clinically relevant PD1/PDL1 ICIs.

While single glycosylation mutations showed comparable binding affinity to wildtype PD-L1, complete N-glycosylation site removal significantly diminished both staining intensity and functional binding. Notably, the N35A mutation exhibited a pronounced impact on the blockade efficacy of ICIs, particularly evident in Nx4 mutants where inhibition was absolute across varying concentrations (2.5 to 40 μg/mL).

Anti-PDL1 ICIs demonstrated consistent blockade of PD-1/PD-L1 interaction across all mutants, while anti-PD1 ICIs showed compromised efficacy, especially against glycosylated PD-L1, notably at the N35 site.

These findings elucidate the intricate relationship between PD-L1 glycosylation and ICI response, providing valuable insights into mechanisms of immunotherapy resistance and potential strategies for patient stratification. The introduction of IcAR technology represents a novel approach for assessing ICI potency in clinical settings, promising to advance precision immunotherapy strategies.

The influence of the metabolic phenotype of CD8+ T cells on immunotherapy response in patients with non-small cell lung cancer (NSCLC)

Sze Ying Tan[1], Ella Kearney[2], Saoirse Flanagan[1;3], David O'Reilly[4], Jarushka Naidoo[4], Catríona Dowling[1]

[1]Royal College of Surgeons in Ireland, Dublin, Ireland; *[2]Trinity College Dublin, Dublin, Ireland*; *[3]University of Limerick, Limerick, Ireland*; *[4]Beaumont Hospital, Dublin, Ireland*

Non-small cell lung cancer (NSCLC) accounts for nearly 85% of lung cancer cases and is the leading cause of cancer-related death worldwide. Immune checkpoint blockade (ICB) inhibitors have shown promising results in cancer treatment. Yet, a significant proportion of patients with NSCLC do not respond optimally to these therapies due to factors such as individual differences in immune response, tumour characteristics, and the tumour microenvironment (TME), which can influence how the immune system recognises and targets cancer cells.

Within the harsh TME, $CD8^+$ T cells are forced to undergo metabolic adaptations to sustain their survival and functionality. Therefore, the TME is recognised as a metabolic barrier to $CD8^+$ T cells, limiting their effector functions. It has been demonstrated that the metabolic mechanisms of $CD8^+$ T cells have important implications for the therapeutic efficacy of ICB. However, the specific metabolic changes within $CD8^+$ T cells that drive differential ICB response in NSCLC remain largely unknown. In this study, we aim to examine the metabolic profile of $CD8^+$ T cells isolated from patients pre and post ICB treatment.

Single Cell ENergetIc metabolism by profiling Translation inHibition (SCENITH) is a newly developed flow cytometry-based method to functionally profile single cell metabolism *ex vivo* and *in vitro*. By using SCENITH, imaging, and CRISPR, we aim to identify metabolic vulnerabilities that hamper $CD8^+$ T cell anti-tumour immunity and ultimately influence ICB response.

In short, the findings from this research will reveal the underlying metabolic mechanisms that influence treatment response variability and potentially paving the way for personalised immunotherapeutic strategies. Insights into these metabolic alterations could also lead to the development of targeted interventions, such as metabolic modulators or combination therapies, to augment the efficacy of ICB treatment in patients with NSCLC. This study signifies a critical step towards advancing precision medicine in cancer immunotherapy, offering new avenues to optimise ICB treatments and improve clinical outcomes for patients with NSCLC.

Immunomodulatory effect of ferric/nickel nanoparticles in vitro

Lenka Rajsiglova[1;2], Dmitry Stakheev[1;3], Kateřina Krausová[1;2;3], Pavol Lukáč[1;2], Paolo Tenti[1;2], Michal Babic[4], Daniel Smrz[1;3], Luca Vannucci[1]

[1]Institute of Microbiology of the CAS, Prague, Czech Republic; *[2]Faculty of Science, Charles University, Prague, Czech Republic*; *[3]Department of Immunology, Second Faculty of Medicine, Charles University and Motol University Hospital, Prague, Czech Republic*; *[4]Institute of Macromolecular Chemistry AS CR, v.v.i., Prague, Czech Republic*

Introduction: Ferric nanoparticles are small carriers composed of iron oxide (Fe_2O_3). Due to their unique properties, they have been exploited for biomedical applications, including magnetic resonance imaging (MRI), hyperthermia, immunomodulatory treatments for cancer and many others. However, their cytotoxic and immunomodulatory therapeutic effects deserve to be explored further.

Methods: In our study, we evaluated the direct toxic effect of FN (ferric - nickel) NPs (nanoparticles) on CT26 (murine colorectal adenocarcinoma) and 3T3 (murine fibroblast) cell lines *in vitro*. Next, we tested the immunomodulatory potential of the NPs, assessing if pre-treatment of CT26 with FN NPs could affect the response (activation/ maturation/ polarization) of various immune cells *in vitro*.

Results: In our experiments, FN nanoparticles showed dose-dependent toxic effect and increased apoptotic rate in the CT26 cancer cell line, while the effect was lower in the 3T3 fibroblast cell line. According to the preliminary data from the immunomodulatory evaluation - where bone marrow derived dendritic cells (BMDCs) were pulsed and maturated with the lysates of CT26 or CT26 pre-treated with FN NPs – no change was observed in the expression of BMDCs´ maturation markers regardless of the FN NPs pre-treatment. Yet, when these BMDCs were mixed with T cells and re-stimulated with live CT26 cells later, the production of IFN-γ and TNF-α by the T cells was increased in the FN NPs pre-treated group (BMDCs pulsed with FN NPs pre-treated CT26 lysate).

Conclusions: FN NPs were able to produce significant direct cytotoxic effect on murine CT26 cell line, while this effect was lower in the 3T3 fibroblast cell line. Additionally, preliminary experiments showed that pre-treatment of CT26 cells with FN NPs improved the T cell immune response against the CT26 cell line suggesting an enhancement of their antigenicity.

Expression relationship of Nectin-2 and immune checkpoint molecules in pancreatic cancer patients

Mualla İlknur Gündüz[1], Rukiye Abanoz[1], Melek Gunindi Korkut[1], Berkay Yahşi[1], Nalan Akyürek[2], Füsun Özmen[1]

[1]Hacettepe University Cancer Institute, Ankara, Turkey; *[2]Gazi University faculty of medicine, department of pathology, Ankara, Turkey*

Purpose: Checkpoint inhibitors such as anti-CTLA-4, anti-PD1 and anti-PDL-1 are used in the treatment of various cancers. However, they cannot be used in pancreatic cancer due to the lack of PDL-1 expression. Nectin-2 is a molecule that acts as a ligand for TIGIT, PVRIG and DNAM-1, which are checkpoint molecules of immune cells. Its role and targetability in pancreatic cancer are not fully known.The aim of this study is to cross-sectionally analyze the expression levels of Nectin-2 and its ligand receptors TIGIT, PVRIG, DNAM-1.

Methods: In our study, the expressions of Nectin-2, CD8, TIGIT, PVRIG, DNAM-1, PD-1, PD-L1, LAG3, TIM3, VISTA, KI-67 molecules were examined in tumor tissues of 131 patients diagnosed with pancreatic cancer.

Results: Nectin-2 was not expressed in undiseased pancreatic tissue, whereas it was expressed in 30.5% of tumor tissues. PD-1 and PD-L1 expression was not observed in any of the patients. In the group with low density of CD8 TILs, the number of patients with negative Nectin-2 expression was higher than the number of patients with positive expression. In 32 patients with positive expression of Nectin-2, KI-67 proliferation marker was highly expressed. In the patient group where Nectin-2 was not expressed, the number of patients showing TIGIT expression increased. PVRIG and DNAM-1 were also not observed in the absence of Nectin-2. Patients without Nectin-2 expression had a higher number of patients without LAG3 and TIM3 expression. Nectin-2 was observed to be significantly underexpressed in stages 3 and 4 of pancreatic cancer. When the relationship between TIGIT receptor and the expression of PVRIG and DNAM-1 molecules was analyzed, a negative relationship was found and it was statistically significant. There was a positive correlation between LAG3 expression and TIM3 expression. Lenf node metastasis was also significantly increased in patients with positive LAG3, TIM3 and VISTA expressions. Expression levels of VISTA molecule showed a significant difference in clinical stage 3.

Conclusion: These data suggest that there may be a close relationship between Nectin-2 expression and the function of CD8+ cells. Further studies are needed to explain the mechanism of this relationship and to demonstrate the targetability of Nectin-2.

Assessing immune checkpoints on NK cells and the potential for immune checkpoint inhibition to reverse NK cell exhaustion in Metastatic Melanoma Patients

Jack Behan[1], Eimear Mylod[1], Clair Gardiner[1], Fergal Kelleher[2]

[1]Trinity Biomedical Sciences Institute, Dublin, Ireland; *[2]St James Hospital, Dublin, Ireland*

Introduction: Metastatic melanoma (MetM) is an aggressive form of skin cancer that unlike early stage melanoma, cannot be treated with surgical resection. The discovery of immune checkpoints inhibitors (ICIs) have become a new standard of care for treating patients with MetM. The expression of many immune checkpoints on NK cells have been confirmed. We set out to assess the expression of ICIs on NK cells of MetM patients and propose that targeting such ICIs for blockade could restore NK cells cytotoxic activity and cytokine production, thus further potentiating the overall anti-tumour response.

Methods: Peripheral mononuclear blood cells were isolated from healthy donors and MetM patients. The ICIs TIM-3 PD-1, TIGIT and LAG-3, metabolic markers and components of the tumour driving TGFβ-GARP signalling axis where fluorescently labelled and assessed on NK cells ex vivo by flow cytometry. Similarly, interferon-γ and granzyme B where assessed in vitro. NK cell cytokine production and cytotoxicity from MetM patients were assessed post-blockade of the ICIs TIM-3, PD-1, TIGIT and LAG-3 on NK cells.

Results: NK cells from MetM patients appear to have increased TIM-3, LAG-3 and PD-1 expression in comparison with healthy donors. MetM patients also appear to show decreased Interferon-γ and granzyme B production in comparison with healthy donors post overnight treatment with IL-12/15. CD69 expression is also significantly increased in MetM patients compared to healthy donors. Expression of TIGIT in MetM appears to have varying expression amongst healthy donors and patients.

Conclusions: Our data shows that NK cells of MetM patients exhibit some characteristics of immune exhaustion with TIM-3, PD-1 and LAG-3 expression increased and interferon-γ and Granzyme B production decreased. NK cells from MetM patients also have greater activation in comparison with healthy donor. We set out to further assess if immune checkpoint inhibition can restore patient Interferon-γ and Granzyme B expression to a similar level seen in healthy donors and reverse NK cell exhaustion which could elucidate its potential as a targeted checkpoint for MetM.

Identifying vulnerabilities to immune checkpoint inhibitors of oncogene-addicted non-small cell lung cancer subgroups

Inés Díaz-Cano[1;2], José Gracia[1], Patricia Cozar[1], Belén Revuelta[1], Nuria Carrizo[1], Juan Dubrot[3], Luis Paz-Ares[1;2;4], Itziar Otano[1;2]

[1]H12O-CNIO Lung Cancer Clinical Research Unit, Health Research Institute Hospital 12 de Octubre (imas12)/ Spanish National Cancer Research Center (CNIO), Madrid, Spain; *[2]Spanish Center for Biomedical Research Network in Oncology (CIBERONC), Madrid, Spain*; *[3]Solid Tumors Program, Division of Oncology, Center for Applied Medical Research (CIMA), University of Navarra, Pamplona, Spain*; *[4]Departments of Medicine and Physiology. School of Medicine. Complutense University, Madrid, Spain*

Purpose: Even though the treatment with PD-(L)1 axis blockers induces tumor response in approximately 20% of unselected patients with advanced NSCLC, patients harboring EGFR alterations have poor outcomes with anti-PD-(L)1 antibody. Targeted therapy with tyrosine kinase inhibitors is the standard of care for patients with advanced-stage EGFR-mutant. However, resistance to kinase inhibitors is almost inevitable.

EGFR-mutant NSCLCs typically have a low TMB, low levels of $CD8^+$ T cells and natural killer cell infiltration, a limited T cell receptor repertoire and abundant infiltration of Treg cells, which might account for the poor efficacy of ICIs of this genomic subtype. We propose to investigate potential vulnerabilities and opportunities to overcome primary resistance to ICIs conferred by oncogene addiction in these patients.

Methods: In order to identify mechanisms involved in the restricted immune response of this subgroup we are performing a sub-genome-scale *in vivo* CRISPR/Cas9 screening. Murine cell lines were derived from the genetically-engineered mouse model of EGFR mutant lung cancer bearing exon 19 deletions or the L860R missense mutation. Genetically modified cell lines with the CRISPR/Cas9 library will be implanted subcutaneously into the flank of immunocompetent mice. A group of mice will then receive ICI treatment at different days post-tumor challenge and sgRNA abundances between the different mouse groups will be compared.

Results: Both oncogenic EGFR mouse cell lines were sensitive to an EGFR-specific TKI, showing a decrease in phospho-Y1068-EGFR. These results demonstrate the oncogenic dependence on EGFR signaling for growth.

In addition, EGFRdel19 or EGFR-L860R tumors injected subcutaneously were resistant to anti-PD1 and/or anti-CTLA-4 blocking antibodies, similar to the lack of response to human EGFR mutant NSCLC to immunotherapy.

Nowadays, we are conducting the *in vivo* sub-genome-scale screens and quality control analyses indicated excellent screen performance. Indeed, the vast majority of sgRNAs were well represented in all conditions and recovered within replicates.

Conclusion: We expect to identify new resistance mechanisms that could result in novel treatment strategies for these NSCLC subgroups. The identification of these targets will provide the opportunity to reprogram the tumor microenvironment and to improve the efficacy of immunotherapy in a subset of patients with lung adenocarcinoma.

Signatures of response to CD19 CAR-T-cells in diffuse large B-cell lymphoma

Luisa Ohlmeier[1;2;3], Jens Löber[2], Corinna Grunert[1;2], Antonia Busse[1;2;3], Björn Chapuy[2;3]

[1]Max-Delbrück-Center for Molecular Medicine in the Helmholtz Association (MDC), Berlin, Germany; *[2]Department of Hematology, Oncology and Tumorimmunology, Charité - Universitätsmedizin, Berlin, Germany*; *[3]German Cancer Consortium (DKTK), Partner Site Berlin, and German Cancer Research Center (DKFZ), Heidelberg, Germany*

Diffuse large B-cell lymphoma (DLBCL) is the most common aggressive lymphoma and is clinically and molecularly a heterogeneous disease. Using whole exome sequencing, we recently identified 5 genetic subtypes of DLBCL that provided novel insight into the biology and prediction of prognosis and identification of combination targeted therapies (Chapuy et al. Nat Med 2018). CD19-directed adoptive T-cell therapy with chimeric antigen receptor (CAR)-T cells is the standard of care treatment for refractory and or early relapsed DLBCL. While the advent of CAR-T-cells significantly improved overall survival of patients, still approximately 50% of patients relapse and eventually succumb to their disease. Hence, understanding the mechanisms of resistance to CART-cell therapy reflects an unmet medical need. Here, we explore the role of the molecular heterogeneity of DLBCL towards response to CD19-CAR T-therapy. To capture the molecular heterogeneity, we selected a representative panel of 13 DLBCL cell lines reflecting the genetic subtypes. CD19 as an important biomarker for interaction of CD19-CAR-T with the target cell, was shown to be highly varying in protein and surface expression between the different cell lines. A co-culture assay with CD19-CAR-T cells revealed strong differences in cytotoxicity and T-cell activation, ranging from 10 to 90 % killing. Overall, we noted that the strongest biomarker of response is the CD19 expression. Indeed, we noted a correlation of CD19 epitope expression on the surface to sensitivity of CAR-T-response. Currently, we are performing additional mechanistic experiments to understand additional signatures of response and resistance.

Development of ProsVac-INCAN: an mRNA vaccine against prostate cancer

Blanca Torres[1], Dora Emma Vélez Uriza[1], Miguel Ángel Jiménez Ríos[1], Greco Hernández Ramírez[1]

[1]*National Institute of Cancer, Mexico City, Mexico*

Background: In 2020, The World Health Organization (WHO) reported that in men, prostate cancer (PCa) was the second most common type of cancer and fifth cause of death from cancer in the world, and its incidence is expected to increase by at least 50% in the next decades. In the last three years, the COVID-19 pandemic promoted the development of mRNA-based vaccines. This technology can also drive the development of novel treatments for other diseases due to its flexibility, productivity, non-genomic integration and low costs, along with the potential to induce both humoral and cell-mediated immunity.

Purpose: Our goal was to identify immunogenic epitopes from tumor associated antigens (TAAs) reported in the literature as related to the development and progression of prostate tumors to generate a therapeutic vaccine.

Methods: We used a 3-step, *in silico/in vitro/in vivo* approach to identify HLA-restricted, immunogenic epitopes derived from tumor-associated antigens (TAAs) previously reported as overexpressed in PCa, such as the prostatic acid phosphatase (PAP), prostate-specific membrane antigen (PSMA), Anterior Gradient 2 (AGR2), New Gene Expressed in Prostate (NGEP) and ERG, a component of the TMPRSS2:ERG gene fusion that occurs in about 50% of PCa cases. We designed longer epitopes that exhibited *in silico* cytotoxic and helper function through activation of CD8/CD4 T lymphocytes. Currently, predicted peptides are being tested in 9-week-old C57BL/6 mice for immunogenicity. The anti-tumor effects of epitope-specific cytotoxic lymphocytes are tested against human prostate tumor cell lines. The recognition capacity of the antibodies generated in mice will be tested on human tumor samples taken by biopsy.

Results: Immunogenic peptides will be chosen as vaccine mRNA molecules and injected into lipid nanoparticles in mouse models that develop prostate cancer. We propose to combine the vaccine with immune-checkpoint inhibitors to evaluate synergy.

Conclusion: Our findings will provide proof of concept for mRNA-based vaccines that are tailored to the tumor's molecular profile, and lay the ground for future development of mRNA cancer vaccines for clinical use.

Dendritic cell targeting using a DNA multiepitope vaccine against EGFR for active breast cancer immunotherapy

Gretel Alvarez Escalante[1], Mariana de Lima Stein[1], Luiz Severino da Silva[1], Silvia Beatriz Boscardin[2], Elaine Guadelupe Rodrigues[1]

[1]Federal University of Sao Paulo, Sao Paulo, Brazil; [2]Sao Paulo University, Sao Paulo, Brazil

Purpose: DNA vaccines are a promising approach to cancer treatment. Active specific immunotherapy is a pivotal strategy to treat EGFR-positive tumor cells. EGFR overexpression appears to be associated with reduced overall survival and disease-free survival in breast cancer patients. The low immunogenicity of DNA vaccines in humans can be overcome by optimizing constructs. Previous works have shown that DNA vaccine targeting dendritic cells induced an immune response to the targeted antigen.

Methods: For this reason, we aimed to generate a highly optimized DC- targeting DNA multiepitope breast cancer vaccine against the overexpressed target EGFR. In silico construction included several CTL, CD4+ e CD8+ T lymphocytes epitopes. To enhance immunogenicity and increasing antigen presentation, sequences of a single chain Fv antibody (scFv) specific for the DC endocytic receptor DEC205 were attached with a linker to the N-terminal of the EGFR epitopes. Computational assessments were performed on scDEC205-EGFR fusion protein for antigenicity, allergenicity and physicochemical properties. Refined 3D constructs were subjected to structural B-cell epitope prediction. Validation through in vitro and in vivo experiments were done. BALB/c mice were intramuscularly immunized three times with 100ug of plasmid DNA encoding either scDEC205-EGFR; after first dose they were challenged with murine mammary adenocarcinoma 4T1 cells. Immune response assessment were accomplished using flow cytometry.

Results: Overall, the results suggest therapeutic potential for scDEC205-EGFR DNA vaccine against triple negative breast cancer. The vaccine constructs was sequenced and showed 100% identity in the nucleotide sequence aligned with the murine EGFR cDNA. This vaccine displayed the capacity to control primary tumor development, increase DC frequency and expression of MHC II molecules after specific-stimulation with EGFR peptide pool, decrease systemic levels of TNFα, and increase frequency of TIL.

Conclusion: In this research, a new active immunotherapy strategy for triple negative breast cancer treatment were constructed by linking specific EGFR protein epitopes for helper and cytotoxic T lymphocytes to sequences of a scFv antibody targeting DC endocytic receptor DEC205. Its capacity to modulate immune responses in vivo indicating potential efficacy. Further studies are recommended to study the scDEC205-EGFR DNA vaccine effect in solid tumors overexppressing EGFR.

Characterization of hypoxanthine phosphoribosyltransferase 1 (HPRT1) mutated Hodgkin lymphoma cells

Mohammad Amomirza[1], Ines Volkmer [1], Alexander Emmer [2;3], Martin Staege[1]

[1]Martin Luther University Halle-Wittenberg, Department of Paediatrics I, Halle, Germany; *[2]Martin Luther University Halle-Wittenberg, Department of Neurology, Halle, Germany*; *[3]AKH-Celle, Department of Neurology, Celle, Germany*

Purpose: hypoxanthine-aminopterin-thymidine (HAT)-sensitive tumour cells can be used for delivery of tumour associated antigens to antigen presenting cells. For this purpose we established a HAT-sensitive variant of the Hodgkin lymphoma cell line L-428 and characterized the hypoxanthine phosphoribosyltransferase 1 (HPRT1) sequence from these cells.

Methods: by repeated treatment with 8‘-azaguanine (8AG), we established a HAT-sensitive variant of the Hodgkin lymphoma cell line L-428. Gene expression analysis of wild type (L-428wt) and 8AG resistant (L-428agr) cells was assessed by RNAseq. The HPRT1 cDNA sequences from L-428wt cells and L-428agr cells was cloned into mammalian expression vectors and used for transfection of the HPRT-deficient fibroblast cell line 1306. HPRT1 expression was tested by quantitative reverse transcription-polymerase chain reaction (qRT-PCR). Viability of cells in the presence or absence of 8AG or HAT was assessed by flow cytometry and ATP assays. Mixed lymphocyte/tumour cell cultures (MLTC) were used for analysing the effect of HAT on the lymphoma cells in the context of immune stimulation.

Results: L-428agr cells showed resistance against 8AG but high sensitivity for treatment with HAT, whereas L-428wt cells were resistant to HAT and sensitive for 8AG. By RNAseq analysis we identified a new mutation in the HPRT1 gene of L428agr cells. Transfection of the HPRT1 cDNA from L-428wt cells into 1306 cells reverted the sensitivity profile of these cells from 8AG resistance to HAT resistance. In contrast, transfection of the HPRT1 variant from L-428agr cells had no effect on drug sensitivity, indicating that this mutant is enzymatically inactive. Treatment of MLTC with HAT resulted in suppression of L-428agr cell growth whereas lymphocyte growth was not suppressed, resulting in net increase of T cells in these MLTC.

Conclusion: we identified a new mutant of the HPRT1 gene in 8AG resistant Hodgkin lymphoma cells. The established HAT sensitive lymphoma cells might be an interesting tool for immunotherapeutic applications, e.g. for in vitro stimulation of lymphoma-reactive T cells or for fusion with dendritic cells.

Induction of mucosal immunity by different therapeutic HPV16 vaccination approaches

Ann-Katrin Schlosser[1;2], Kathrin Wellach[1;2;3], Philipp Uhl[4], Armin Kübelbeck[4], Angelika Riemer[1;3]

[1]Immunotherapy and Immunoprevention, German Cancer Research Center (DKFZ), Heidelberg, Germany; *[2]Faculty of Biosciences, Heidelberg University, Heidelberg, Germany*; *[3]Molecular Vaccine Design, German Center for Infection Research (DZIF), Partner Site Heidelberg, Heidelberg, Germany*; *[4]Institute of Pharmacy and Molecular Biotechnology, Heidelberg University, Heidelberg, Germany*

Persistent infection with high-risk types of the human papillomavirus (HPV) causes cancer in both women and men and accounts for approximately 5% of cancer cases worldwide. HPV16 is by far the most important cancer-causing high-risk type. Many therapeutic vaccines targeting HPV16-associated malignancies have shown to be highly effective in preclinical studies but lacked effectiveness when tested in human patients. To overcome this discrepancy, our group developed model systems that resemble the human system more closely. We established two orthotopic HPV16-dependent tumor models in MHC-humanized mice, which are located in the mucosa of the female genital tract and the base of the tongue, respectively. These models allow testing of different vaccine platforms containing clinically relevant HLA-A2-restricted epitopes against tumors at sites of natural infection. In first vaccination studies, we identified two vaccine platforms either consisting of amphiphilic constructs or silica nanoparticles (SiNP) that both successfully induced systemic $CD8^+$ T cell responses. SiNP were found to produce more reproducible results due to their robust synthesis procedure, which is why we focused on those in subsequent experiments. By comparing vaccinations with $CD8^+$ alone or in combination with $CD4^+$ T cell epitopes, it could be shown that the addition of $CD4^+$ T cell epitopes enhances vaccination efficacy. As mucosal tissues, such as in the female genital tract, are not readily accessible by systemic immune cells, we further focus on inducing a strong local immune response in the mucosa. Our approaches include different administration routes and prime-pull approaches in order to pull systemically induced T cells into the vaginal mucosa. The most promising vaccination strategies, as determined by these analyses, will be tested for efficacy by assessing orthotopic tumor shrinkage/elimination. Taken together, these experiments will be a crucial step in the preclinical assessment of new therapeutic HPV vaccine formulations. The obtained results will provide important insights for the design of clinical trials for therapeutic HPV vaccination.

KG, Bergisch Gladbach, Germany*

Immunotherapy has shown promising results in selected types of cancer, but its efficacy remains limited in pancreatic ductal adenocarcinoma (PDAC). Nanoparticles (NPs) can incorporate immunomodulating components, inducing a potent immune response. As mesothelin (MSLN) is a tumor-associated antigen overexpressed in PDAC, we evaluated the effect of MSLN nanovaccine therapy given at different time points in a syngeneic orthotopic KPC-PDAC mouse model. The NPs were successfully taken up by dendritic cells in vitro and were found in inguinal lymph nodes 24 h after subcutaneous injection into male C57BL/6 mice. Nanovaccine re-stimulation of splenocytes from vaccinated mice led to increased levels of IFN-γ in vitro when compared to splenocytes from mice treated with the NP control. Higher levels of MSLN-specific IgG antibodies were detected in the serum of mice treated with nanovaccine compared to that of control mice. Three vaccination regimens were tested, a prophylactic scheme that included vaccination before tumor induction and two therapeutic schemes, involving early and late vaccination after tumor cell inoculation. MSLN nanovaccination led to an inhibition of KPC tumor progression and metastasis and induced higher CD8+ T cell infiltration in the tumor that developed in response to prophylactic and early therapeutic schedules, but not in a later vaccination approach. Although the nanovaccine treatment elicited higher humoral and cellular antigen-specific responses in tumor-bearing mice in both vaccination strategies, the therapeutic vaccination also increased the expression of exhaustion markers in CD8+ T cells. Our results support the relevance of an MSLN-based nanovaccine as a new immunotherapy treatment for PDAC and propose an innovative way of vaccine delivery by the use of NPs. This project has received funding from the European Union's Horizon 2020 research and innovation program under the Marie Skłodowska-Curie grant agreement No 861190–PAVE.

Mapping the Effect of PD1 Immunoreceptor on T-cell Receptor Signalling

Martina Kreileder[1], Myriam Nabhan[1], Donagh Egan[1], Muhammad Zainul Arifin[1], Vadim Zhernovkov[1], Kieran Wynne[1], Anisha Solanki[2], Rajat Varma[2], Paul Chariou[2], Ian Barrett[2], Claus Bendtsen[2], Simon Dovedi[2], Viia Valge-Archer[2], Donal Brennan[1;3], Walter Kolch[1]

[1]Precision Oncology Ireland, Systems Biology Ireland, University College Dublin, Dublin, Ireland; *[2]AstraZeneca, Cambridge Biomedical Campus, Cambridge, United Kingdom*; *[3]Catherine McAuley Research Centre Mater Misericoridae University Hospital, Dublin, Ireland*

Tumour cells can suppress immune cell activation by engaging immune checkpoints (ICs), such as PD1 on T-cells. Targeting these receptors with IC inhibitors (ICIs) can stimulate the anti-tumour immune cell activity. Clinical trials exploiting ICIs however show only poor success (response rates <15%).

While T-cell receptor (TCR) signalling is well described, little is known about IC signalling. The aim of our study is to map PD1 signalling to better understand its role in controlling T-cell activation in order to improve ICI efficacy.

Using quantitative mass spectrometry we mapped the signalling complexes formed by PD1 in T-cells under different conditions, e.g. in T-cell lines with TCR activation and TCR + PD1 activation. The proteomics analysis was complemented by phosphoproteomics, to directly look at signalling events, and transcriptomics to include the regulation on a transcriptional level. Multiomics analysis allowed us to delineate pathways that control the regulation of T-cell (de)activation.

Our analysis from TCR activated cells identified potential novel interactors of PD1, such as EZR and MSN. Proteins with similar binding profiles were assigned to clusters using Uniform Manifold Approximation and Projection analysis. Seven clusters were upregulated in PD1 expressing cells compared to control and functional analysis showed an enrichment of immune cell signalling related terms in PD1 expressing cells. Ingenuity Pathway Analysis further identified pathways related to T-cell activation including ‘RHOA Signalling’, ‘Actin Cytoskeleton Signalling’ and ‘Glycolysis’. Integrating the whole-cell proteomics and phosphoproteomics data and subsequent UMAP analysis identified a PD1 cluster enriched in immune signalling, supporting the findings of the interactomics data. Analysis of the phosphoproteomics data revealed a set of phosphorylated transcription factors (TFs). Linking these TFs to potential target genes observed in the transcriptomics data include IL3, CXCL8 and TFN, suggesting that TFs in the phosphoproteomics data from TCR stimulated T-cells regulate target genes related to signalling of immune cells.

In conclusion, our data suggests that the sheer expression of PD1 impacts TCR signalling. Stimulating PD1 with its ligand PD-L1 will give insights into how active PD1 signalling regulates T-cell (de)activation. A deeper mechanistic understanding of ICs will help to improve ICIs application in patients in the clinics.

Engineered albumin as an effector negative scaffold for tailored design of long acting antibody fragment fusions

Fulgencio Ruso-Julve[1;2;3], Siri Aastedatter Sakya[1;2;3], Anette Kolderup[1;2;3], Elias Tjärnhage[4], Sopisa Benjakul[1;2;3], Jeannette Nilsen[1;2;3], Stian Foss[1;2;3], Devin Sok[5], Inger Sandlie[6], Jan Terje Andersen[1;2;3]

[1]Department of Pharmacology, University of Oslo, Oslo, Norway; *[2]Department of Immunology, Oslo University Hospital Rikshospitalet, Oslo, Norway*; *[3]Precision Immunotherapy Alliance (PRIMA), University of Oslo, Oslo, Norway*; *[4]Institute of Clinical Medicine, University of Oslo, Oslo, Norway*; *[5]Department of Immunology and Microbial Science, The Scripps Research Institute, La Jolla, CA, United States*; *[6]Department of Biosciences, University of Oslo, Oslo, Norway*

The pharmacological effect of many protein-based biologics is limited by brief target exposure due to a short plasma half-life. A solution to this is to genetically fuse such biologics to the Fc region of IgG, which will prolong their longevity by increasing their molecular size above the kidney threshold as well as allow binding to the half-life regulator FcRn. However, Fc fusions may interact with other effector molecules and induce unwanted immune responses. Importantly, FcRn also binds albumin via a non-overlapping binding site and provides it with a long plasma half-life. While the Fc region is an N-glycosylated homodimer, albumin is a non-glycosylated single polypeptide that is effector negative. This is an advantage when the aim is to block a biological target. Here, I will discuss how knowledge about the relationship between FcRn and its ligands can be explored in the design of new formats that combine elements from antibodies with that of albumin as a strategy to achieve improved pharmacokinetics of antibody fragments or mimics.

Mapping BTLA Immunoreceptor Signalling Pathways in T-cells

Myriam Nabhan[1], Martina Kreileder[1], Donagh Egan[1], Vadim Zhernovkov[1], Anisha Solanki[2], Rajat Varma[2], Paul Chariou[2], Ian Barrett[2], Claus Bendtsen[2], Simon Dovedi[2], Viia Valge-Archer[2], Donal Brennan[1;3], Walter Kolch[1]

[1]Precision Oncology Ireland, Systems Biology Ireland, University College Dublin, Belfield, Ireland; *[2]AstraZeneca, Cambridge Biomedical Campus, Cambridge, United Kingdom*; *[3]Catherine McAuley Research Centre Mater Misericoridae University Hospital, Dublin, Ireland*

Purpose: In recent years, immune checkpoints (ICs) have become major therapeutic targets in the treatment of malignancies with the successful development and approval of IC blockers (ICBs). ICBs prevent the interaction of ICs on T-cells with their ligands, therefore relieving T-cell suppression and promoting anti-tumour functions. However, responses are quite variable between cancers and patients and can be limited in many cancers. Understanding the mechanisms by which ICBs mediate their effects is key to defining ways to improve their efficacy. However, little is known about the signalling of ICs and the molecular modulations that can occur in T-cells following IC blockade. In this work, we focus on BTLA (B and T-lymphocyte attenuator), an IC that has become of interest as a novel promising target for cancer immunotherapy.

Methods: Two different commercially available anti-BTLA antibodies were used to pull-down BTLA in T-cell lines overexpressing the IC. Using quantitative mass spectrometry (qMS), we mapped the signalling pathways and inferred specific complexes formed by BTLA.

Results: The use of different anti-BTLA antibodies (binding to different BTLA epitopes) reveals distinct and overlapping populations of potential BTLA interacting proteins. Our analysis identified the BTLA known interactor PTPN11 (SHP-2) as well as other potential interactors involved in T-cell activation and cell adhesion, such as CD3E, ITGAL, ICAM3, NOTCH1 and IL-22. Reactome pathway analysis further identified pathways related to T-cell activation, including ‘PD1 signalling’, ‘Costimulation by the CD28 family’ and ‘STAT5 activation’. Other pathways related to ‘RUNX3 signalling’ and ‘Pre-NOTCH signalling’ were also identified. Complementing the interactomics data with whole and phospho-proteomics and transcriptomics delineates the pathways used by BTLA to induce T-cell suppression.

Conclusion: In conclusion, our data suggests that BTLA may block TCR activation by sequestering its downstream signalling proteins, therefore promoting T-cell suppression. A deeper mechanistic understanding of BTLA and its inhibition would help improve its application in the clinical setting.

Integrating Seahorse real-time bioenergetics and click-uptake metabolic fluxes to unlock metabolic heterogeneity

Sakshi Sankhla[1], Maxim Nosenko[1], David Finlay[1]

[1]*Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland*

The detailed metabolic analysis that has advanced the field of immunology involve techniques that provide metabolic data from a pooled population of cells resulting in the loss of heterogeneity within the cell population. This is a major limitation of these techniques as immune cell populations usually show a high degree of heterogeneity in terms of functional outputs. Our aim is to unlock the heterogeneity of cell populations analysed for real time core metabolic flux using Seahorse technology.

This project harnesses the collective power of Seahorse XF Analyzer, click-uptake and Novocyte flow cytometer to enable complementing the bioenergetic metabolic measurements obtained using XF Analyzer of immune cell populations (cellular rates of energy production, relative contribution of glycolysis and mitochondrial activity, maximal mitochondrial bioenergetic capacity) with single-cell information related to the rate of nutrients uptake and rate of protein synthesis using flow cytometry and facilitated by the novel series of nutrient analogues obtained by post-uptake labelled using click chemistry technology. The core advance in our approach is to use biorthogonal, or 'click' chemistry to attach a fluorophore to the nutrient after it has been transported into the cell. This strategy avoids the pitfalls and flaws of other uptake assays using fluorescent-labelled nutrient-derivatives such as 2-NBDG. We introduced a number of optimizations to allow for complementary click-uptake in the Seahorse workflow, including program optimization, fixation, and cell detachment for flow cytometry. Using this approach we aim to characterize mixed populations of immune cells with reported metabolic heterogeneity, such as splenocytes and peritoneal cells of mice, challenged with LPS or PolyI:C.

Altogether, the results of this project will allow for complementary bulk and single-cell metabolic analysis in one sample, which can be employed for both basic research as well as in clinics.

This project is supported by Agilent ACT-UR program, grant ID # 4867.

Inflammatory cytokines and chemokines are synergistically induced by co-culture of corneal epithelial cells and neutrophils in the presence of particulate matter

Yasuhiro Yoshida[1], Zirui Zeng[1], Duo Wang[1]

[1]*University of Occupational and Environmental Health, Japan, Kitakyushu, Japan*

Purpose: Ocular exposure to particulate matter (PM) causes local inflammation; however, the influence of neutrophils on PM-induced ocular inflammation is still not fully understood.

Methods: In this study, we constructed a system to investigate the role of PM in ocular inflammation using a co-culture of human corneal epithelial cells (HCE-T) and differentiation-induced neutrophils (dHL-60).

Results: To investigate whether HCE-T directly endocytosed PM, we performed holographic analysis, which showed endocytosis of PM in HCE-T. Cytokines and chemokines produced by HCE-T were measured using ELISA. HCE-T treated with PM produced IL-6, IL-8, which were inhibited by N-Acetyl-L-cysteine (NAC), suggesting the involvement of ROS. Co-culture with dHL-60 enhanced the production of IL-6, IL-8, and MCP-1. This suggests an inflammatory loop involving intraocular cor-neal epithelial cells and neutrophils. These cytokines and chemokines are mainly regulated by NF-κB. Therefore, the co-culture system was examined in the presence of an IKK inhibitor known to downregulate NF-κB activity. IKK inhibitors dramatically suppressed the production of these fac-tors in co-culture supernatants.

Conclusion: The results suggest that the inflammatory loop observed in co-culture is mediated through ROS and the transcription factor NF-κB. Thus, the co-culture system is considered a valuable tool for an-alyzing complex inflammation.

Characterization of a directed-evolution–generated mutant form of alpha1-antitrypsin

Tomer Eliyahu[1]

[1]*Ben Gurion University of the Negev, Beer Sheva, Israel*

Background: Human alpha1-antitrypsin (AAT) is a 394-amino acid glycoprotein integral to the modulation of inflammation and tissue protection. Its upregulation during inflammatory states underscores its therapeutic potential for injury-driven pathologies. AAT is pivotal in epithelial barrier repair, influencing cell migration, survival, and macrophage differentiation. Recent investigations reveal multifaceted functions beyond its canonical serine-protease inhibition, implicating interactions with diverse binding partners. Compared to other species, humans have a relatively degenerate form of AAT. Using back-to-consensus and directed evolution approaches, we identified sites on its surface that appear to vary from most other animals. For example, human AAT has a lysine residue at position 243, while most other animals have either aspartate, glutamate or a serine residue at that position. By in-vitro screening of stimulated macrophage responses, functionally superior point-mutated recombinant versions of AAT were selected. Based on this multifaceted process, an alternative form of the molecule has been generated, rhAAT^{MJ6}. It includes, e.g., a K243D mutation.

Aim: Establish an experimental framework for a comprehensive comparison between rhAAT^{WT} and rhAAT^{MJ6}; gain understanding of novel structure-function properties of AAT.

Methods: Biological process directed outcomes will be compared between rhAAT^{WT} and rhAAT^{MJ6} treatments across epithelial repair models, both in-vitro and in-vivo, as well as cell migration, cell survival, and differentiation of macrophages to the M2-like phenotype. Molecular profile of rhAAT^{MJ6} will be examined in relation to its half-life and binding partners. Based on study data, modified versions of the molecule will be formulated and challenged experimentally in-vivo.

Results: According to an epithelial gap repair assay, rhAAT^{MJ6} outperformed rhAAT^{WT} in human lung and kidney cell lines. In-vivo, using a tympanic membrane perforation model, treatment rhAAT^{MJ6} has led to a faster recovery than clinical-grade AAT.

Conclusion: The preliminary findings serve as a foundation for investigating the study hypothesis. Ongoing and planned experiments are anticipated to unveil new insights into the structure-function relationship of AAT, specifically in regions beyond the protease-binding domain. These findings hold significant clinical promise for addressing various unmet medical needs, particularly for potential topical applications in conditions involving epithelial injury, such as tympanic membrane perforation and corneal injuries.

Background: *Escherichia coli* A0 34/86 (EcO83) is a commercially available probiotic bacterium used to prevent nosocomial infections in newborns. We have previously found that intranasal administration of EcO83 reduces experimental allergic airway inflammation in mice. All bacteria produce extracellular vesicles (EVs) in the form of nanoscale, bilayered structures packed with proteins, lipids and nucleic acids. EVs play a multifaceted role in bacterial communication, pathogenesis and interaction with the host immune system. Recently, we isolated EVs from EcO83 (EcO83-EVs) and showed that they reduce ovalbumin-induced allergic airway inflammation in mice. The exact mechanisms of interaction between the airways and EcO83-EVs were previously unknown.

Methods: We isolated (ultracentrifugation), purified (density gradient) and characterized (dynamic light scattering, transmission electron microscopy, cryo- electron microscopy, atomic-force microscopy, and biochemical characterization of cargo) EcO83-EVs. We investigated the interaction of EcO83-EVs with the human airways by proteomic analysis of primary nasal epithelial cultures treated with EcO83-EVs. We investigated EcO83-EVs-specific gene expression in the nasal-associated lymphoid tissue (NALT) and lungs of mice, as well as the uptake of EVs by lung cells. Finally, we investigated TLR4-induced signaling pathways and nitric oxide (NO) production in mouse macrophages activated by EcO83-EVs.

Results: Purification of EcO83-EVs resulted in the enrichment of membrane and fimbrial proteins. EcO83-EVs contain proteins, LPS and RNA, but no detectable DNA. EcO83-EVs induce the expression of proteins related to oxidative stress and inflammation in human primary nasal epithelial cultures. In mice treated intranasally with EcO83-EVs, the pattern of gene expression in the NALT and lungs was similar. In the lung, intranasal administration of EcO83-EVs leads to the recruitment of neutrophils, but only macrophages effectively take up EcO83-EVs. Mechanistic studies of the interaction between macrophages and EcO83-EVs have shown that EcO83-EVs induce NO in a TLR4-dependent manner and upregulate the NFκβ signaling pathway.

European Journal of Immunology Clinical-Basic-Translational

Conclusion: In this study, we show that EcO83-EVs of the probiotic EcO83 interact with host´s airway cells and induce inflammatory and oxidative stress responses. EcO83-EVs are potent modulators of immune responses and, due to their non-viable status, offer a safe alternative to the use of whole bacteria in the treatment of allergic diseases.

The BiST of Burden: Harnessing biased STING agonists to enhance the resolution of inflammation and limit tissue fibrosis

Nofar Ben Jasher[1], Sergei Butenko[1], Uzma Saqib[1], Sagie Schif-Zuck[1], Amiram Ariel[1]

[1]*University of Haifa, Haifa, Israel*

Stimulator of IFN Genes (STING) is a cytosolic DNA sensor that plays a central role in host protection against pathogens upon binding of DNA-derived ligands. STING primarily acts by controlling the transcription of type I interferons (IFNs) and pro-inflammatory cytokines. Notably, STING can be inhibited or activated pharmacologically to control STING-associated pathologies. 5, 6-Dimethylxanthenone-4-acetic Acid (DMXAA) is a pharmacological activator of murine STING that induces IFN-β and its affected genes. Here, we report that macrophages from DMXAA-treated mice engulfed significantly higher numbers of apoptotic cells ex vivo, and exhibited enhanced reprogramming reflected by an increased IL-10 and reduced inflammatory cytokine secretion upon LPS exposure. Macrophage reprogramming was significantly hampered in STING and IFN-β-deficient macrophages. Furthermore, we found used virtual docking and batch screening to identify biased STING agonists (BiSTs) that enhanced IL-10 and IFN-β production by splenocytes while inhibiting TNFα. One of these compounds, termed Biased STING agonist (BiST) 2.1, also induced the STING pathway in vivo and in human macrophages. Finally, we found BiST 2.1 to enhance the resolution of liver fibrosis induced by CCl_4. Thus, our findings indicate that STING can be harnessed to drive IFN-β-mediated IL-10 secretion by resolution phase macrophages and consequently shape macrophage function to enhance the resolution of inflammation and treat fibrotic disorders

Antiapoptotic and cryoprotective effect of the carotenoid Bacterioruberin on peripheral blood mononuclear cells

Miguel Medina-Garcia[1], Pascual Martinez-Peinado[1], Alicia Navarro-Sempere[1], Yolanda Segovia-Huertas[1], Sandra Pascual Garcia[1], Andrés Baeza-Morales[1], Carolina Pujalte-Satorre[1], Ana Belen Lopez-Jaen[1], María Magdalena García-Irles[1], Rosa María Martínez Espinosa[1;2], Jose Miguel Sempere-Ortells[1]

[1]University of Alicante, San Vicente del Raspeig, Spain; *[2]I.M.E.M. RAMON MARGALEF (IMEM), San Vicente del Raspeig, Spain*

Purpose: During the last few years, multiple studies have demonstrated the immunomodulatory properties of diverse natural carotenoids, highlighting their impact on the immune system, and revealing flattering results. In fact, a promising pigment known as bacterioruberin (BR), although discovered many years ago, has recently come into the spotlight showing more efficiency in its biological functions compared to those studied to date. Taking all this into account, the objective of this study was to analyze the antiapoptotic and cryoprotective effects of BR on peripheral blood mononuclear cells (PBMCs).

Methods: PBMCs were isolated from healthy donors using a density gradient centrifugation technique. Once isolated, two different experiments were performed to observe the possible antiapoptotic and cryoprotective effect of BR. First, PBMCs were cultured in 96-well plates at a concentration of 100 000 cells per well, with different concentrations of BR, ranging from 0 to 75 µg/ml, and incubated at 37°C and 5% CO_2. After 48 hours, apoptosis was induced using UV light and cells were incubated for another 24 hours. Moreover, isolated PBMCs from different healthy donors were cryopreserved at a concentration of 500 000 cells/ml with the same BR concentrations mentioned above and stored in liquid nitrogen for seven days. Acridine orange and ethidium bromide dyes were used for visualization of live, dead, and apoptotic cells by fluorescence microscopy and propidium iodide and YO-PRO-1 iodide for the analysis by flow cytometry.

Results: In the UV apoptosis-induced cultures of PBMCs, higher percentages of cells were still viable in the presence of low concentrations of BR as compared to the control (70% vs. 40%, respectively). On the other hand, increased percentages of alive cells were also observed when cryopreserved with lower concentrations of BR, compared to control conditions (90% vs. 80% respectively).

Conclusion: These results show that bacterioruberin can act as both an antiapoptotic and cryoprotective agent and may provide a basis for its use as a new therapeutic agent.

Nanotechnology-enhanced photodynamic therapy for remodeling the tumor microenvironment in colorectal cancer

Austeja Butkute[1;2], Agata Mlynska[1;3], Evelina Kazlauske[1;3], Simona Steponkiene[1]

[1]National Cancer Institute, Vilnius, Lithuania; *[2]Vilnius University, Vilnius, Lithuania*; *[3]Vilnius Gediminas Technical University, Vilnius, Lithuania*

Purpose: Colorectal cancer (CRC) is a complex disease characterized by a diverse tumor microenvironment comprising immune and non-immune components, with macrophages being the most abundant tumor-infiltrating cells that exhibit distinct phenotypic states. However, owing to the remarkable plasticity of macrophages, their polarization status is dynamic and can be modified by integrating multiple signals from the neighboring milieu. The dynamic interplay between tumor cells and macrophages plays a critical role in shaping the immunomodulatory properties of the tumor microenvironment, affecting tumor progression and therapeutic responses. Moreover, the impact of both conventional and innovative therapies on the tumor microenvironment, where immune cells, including macrophages, play a crucial role, is often overlooked. This study aims to explore the nanotechnology-enhanced photodynamic therapy and drug-based strategies for targeting macrophages in the microenvironment of CRC.

Methods: A novel theranostic nanocomplex, composed of quantum dot and a photosensitizer, previously shown to accumulate in human skin mesenchymal cells, was tested for its efficacy in targeting human macrophages and CRC cell lines in co-culture. The induced transcriptomic changes, reflecting macrophage polarization state, were compared to the gene expression profile induced by several small molecule inhibitors, designed for targeting the stemness pathways.

Results: Under light excitation, the theranostic photodynamic nanocomplex effectively induced cell death across all colorectal cancer cell lines, irrespective of their molecular subtype. Importantly, the nanocomplex exhibited uniform accumulation and demonstrated no dark toxicity, while also avoiding transcriptome alterations in the CRC cells. Macrophages responded to conditioned media from nanocomplex-treated CRC cells by downregulating their M2-related gene expression and upregulating the M1-related gene expression, suggesting the potential repolarization from protumoral M2 type to the antitumoral M1 type. Stemness inhibitors demonstrated ambiguous effects on macrophages, inducing changes in gene expression associated with both M1 and M2 phenotypes, and allowing for further combination of several treatment strategies for obtaining the desired response.

Conclusion: Novel therapeutic approaches, such as theranostic photodynamic nanoparticles or stemness inhibitors, can act as immunomodulatory agents for repolarizing M2-like macrophages towards an antitumor phenotype. These findings justify further investigations to explore potential combination therapies for improved clinical outcomes in CRC treatment.

Exploring the dynamics of the surface proteins of exosomes and the repertoire of peptides presented by their human leukocyte antigen class I molecules

Jaxaira Maggi[1], Montserrat Carrascal[1], Joaquin Abian[1], Daniel Closa[2]

[1]Biological and Environmental Proteomics Group, IIBB-CSIC, Barcelona, Spain; *[2]Dpt. Experimental Pathology, IIBB-CSIC, Barcelona, Spain*

Background: Exosomes (exos) are nanometer-sized extracellular vesicles released by cells and implicated in cell-to-cell signaling. Although they are often viewed primarily as transporters, and their cargo has been extensively studied, there is limited information regarding two aspects potentially related to their biological functions: (i) the influence of the microenvironment on the protein corona that covers their surface, and (ii) the characterization of the repertoire of peptides presented by their human leukocyte antigen (HLA)-class I molecules.

Objectives: Here, we aimed to analyze changes in the corona of exos under inflammatory conditions and to examine their HLA-I immunopeptidome.

Methods: Exos were isolated from a pancreatic cancer cell line and incubated with ascitic fluid (PAAF) as an inflammatory stimulus. For proteomic analysis of the corona, both untreated and PAAF-treated exos were pre-digested, 100 kDa-filtered, trypsin-digested, and analyzed by liquid chromatography coupled to mass spectrometry (LC-MS/MS). For immunopeptidomic analysis, HLA-I/peptide complexes were immunoprecipitated from both cells and exos, and peptide sequencing was performed by high-resolution LC-MS/MS.

Results: We identified sixty-six proteins that were upregulated on the corona of PAAF-incubated exos. Many of these proteins were also found in PAAF, suggesting that PAAF-derived proteins became attached to the exos corona after incubation. Gene-ontology enrichment analysis of these proteins revealed their involvement in the regulation of molecular and biological functions. Additionally, the HLA-I peptide repertoire of exos was compared with that of the originating cells. Although there was not complete overlap, most sequences exhibited a length consistent with HLA-I peptidomes and displayed high theoretical affinity.

Conclusion: Our findings provide valuable insights into the dynamics of the protein corona on exos under inflammatory conditions. The attachment of microenvironment-related proteins may influence their biological function, potentially extending inflammation to distant target cells. Furthermore, the immunopeptidome presented by exos offers a new source of peptides that could trigger an immune response complementary to their cell of origin. This information could be instrumental in developing novel therapeutic strategies for cancer and inflammatory-based pathologies, for which the role of exos has been widely proposed.

Innate lymphoid cells (ILCs) are pivotal for maintaining tissue homeostasis under steady-state conditions and in inflammation. These cells function as a fundamental bridge between innate and adaptive immunity, alongside innate-like T cells (ILTCs), the unconventional T lymphocytes that rapidly respond to non-pepitde antigens. Recently, a cytotoxic subset of ILTCs has been identified in the context of tumor surveillance. Despite originating from αβ- TCR and γδ-TCR lineages, cytotoxic ILTCs exhibit a myriad of characteristics akin to ILCs and bear a striking resemblance to a subset of tissue-resident ILC1s originally described in the liver and in the salivary gland with cytotoxic properties. In this study, we discovered large numbers of cytotoxic ILC1s and ILTCs in breast tissue emerging during the phases of pregnancy and lactation. Using high dimensional flow cytometry and single-cell transcriptomics, we found that cytotoxic ILC1s and ILTCs share a wide array of phenotypic and functional features including Natural Killer (NK) cell-related receptors, residency markers and high levels of Granzymes B and C, implying a high cytotoxic potential. Furthermore, cytotoxic ILC1s and ILTCs are dependent on the transcription factor Hobit for their development and acquisition of the cytotoxicity program. Given their phenotypic similarity, we hypothesize that cytotoxic ILC1s and ILTCs share their location in the mammary niche and cooperate in regulating physiological processes of pregnancy and lactation, as well as in providing protection against threats such as viral infection. Our study will offer valuable insights into the pathophysiological properties of cytotoxic ILC1s and ILTCs, providing a foundation for their potential application in immunotherapeutic strategies.

Calcium Macrophage differentiation and maintenance depends on oxidative phosphorylation and fatty acid consumption

Syamantak Basu[1], Supriya Murthy[2], Isabel Karkossa[3], Kristin Schubert[3], Manuela Rossol[1]

[1]Brandenburg University of Technology, Cottbus-Senftenberg, Senftenberg, Germany; *[2]Division of Rheumatology, University of Leipzig, Leipzig, Germany*; *[3]Helmholtz Centre for Environmental Research, Leipzig, Germany*

The differentiation of monocytes into calcium-macrophages is initiated by increased extracellular calcium and phosphate concentrations, the formation of calciprotein particles (CPPs), and the uptake of CPPs via macropinocytosis in the absence of additional growth factors. Calcium macrophages are characterised by their needle-like shape, high osteopontin production, and a pro-inflammatory cytokine response to lipopolysaccharide (LPS).

The aim of this study was to characterize the metabolic state of resting and LPS-activated calcium-macrophages and to identify the nutrients necessary for macrophage differentiation.

Monocytes were isolated from the blood of healthy human donors and subsequently differentiated into calcium-macrophages, GM-CSF-macrophages, or M-CSF-macrophages for 7 days. The metabolic state was analysed using the Seahorse analyser.

Resting calcium-macrophages use oxidative phosphorylation over glycolysis as their main source of energy. However, activation of calcium-macrophages with LPS induced a metabolic shift towards increased glycolysis and decreased oxidative phosphorylation. Blockade of glucose, fatty acid, or glutamine consumption revealed a strong dependency of calcium-macrophages on fatty acid consumption. Accordingly, the glucose concentration in cultures of calcium-macrophages was unchanged after 7 days of differentiation, whereas the glucose concentration in cultures of GM-CSF-macrophages and M-CSF-macrophages was decreased. The differentiation of monocytes into calcium-macrophages in culture media with and without glucose, amino acids, or fatty acids revealed a decreased elongation factor (EF) when fatty acids were not available. When two nutrients were removed simultaneously, monocytes differentiated to calcium-macrophages only when fatty acids were present. Glucose or amino acids alone were not sufficient to sustain calcium-macrophage differentiation. Proteomic analysis revealed a strong upregulation of FABP3-5 in comparison to GM-CSF-macrophages and M-CSF-macrophages.

In conclusion, calcium-macrophages strongly depend on fatty acid consumption and oxidative phosphorylation, both during the differentiation process and after maturation.

The involvement of Neutrophil Extracellular Traps in Necrotizing Enterocolitis: Exploring the role of Neutrophils and their interaction with other immune cells in different organoid models

Laura Blum[1], Deirdre Vincent[1], Julia Elrod[1], Michaela Klinke[1], Jasmin Knopf[1], Michael Boettcher[1]

[1]*Department of Pediatric Surgery, University Medical Center Mannheim, University Heidelberg, Mannheim, Germany*

Purpose: Necrotizing enterocolitis (NEC) is a leading cause of mortality in premature infants, but its exact cause remains unclear. Impaired immune responses, particularly neutrophil recruitment and neutrophil extracellular traps (NETs) formation, play a central role. Macrophages exhibit heightened pro-inflammatory responses and can degrade NETs. Various organoid models, including Transwell models and advanced 3D-printed microfluidic models, are used to study NETs' role in NEC and their interaction with epithelial cells and macrophages.

Methods: Intestinal organoids were generated from healthy and NEC tissue, co-cultured with immune cells and stimulated with LPS. Various assays such as MPO-SytoxGreen staining, NETs immunofluorescence, ELISA and Western blot were used to evaluate NETs formation and immune responses. FACS staining panels were used to profile inflammation. Coated Transwell inserts facilitated the establishment of intestinal monolayer models and enabled the investigation of neutrophil recruitment, inflammatory profiles and apoptosis/necrosis of epithelial cells. In addition, a microfluidic model with a vasculature enabled live cell imaging to study the interactions between immune cells during NEC development.

Results: LPS stimulation led to a significant increase in neutrophil recruitment, which was particularly pronounced in NEC organoids compared to healthy organoids. NEC cultures showed a clear upregulation of TLR4 expression after LPS stimulation. The immune profiles differed between the groups, with the healthy organoids showing strong cytokine secretion, while the NEC organoids showed reduced cytokine levels, suggesting immune dysregulation. Healthy tissue exhibited increased epithelial cell wall necrosis after LPS stimulation, with NEC organoids showing the highest levels, especially after co-cultivation. In addition, increased NET formation was observed in LPS-stimulated organoid cultures. Collagen-coated Transwells facilitated the formation of an organoid monolayer and increased experimental versatility by allowing access to both the apical and basal sides of the intestine.

Conclusion: Our organoid models mimic conditions in the intestine and show increased neutrophil recruitment and NET formation in NEC with LPS stimulation, as well as increased TLR-4 expression. LPS induces inflammatory responses and NEC-like lesions, emphasizing the complexity of the disease. Altered cytokine profiles and increased epithelial cell necrosis highlight the dysregulation of the immune system in NEC.

The metabolic profile of plasmacytoid dendritic cells from patients with systemic sclerosis

Beatriz Ferreira[1;2], Carolina Mazeda[3;4;5], Eduardo Dourado[3;4;6], Ana Rita Prata[3;4], Rafael Argüello[7], Iola Duarte[2], Philippe Pierre[1;7], Catarina Almeida[1]

[1]iBiMED - Institute of Biomedicine, Department of Medical Sciences, University of Aveiro, Aveiro, Portugal; *[2]CICECO - Aveiro Institute of Materials, Department of Chemistry, University of Aveiro, Aveiro, Portugal*; *[3]Rheumatology Department, Unidade Local de Saúde da Região de Aveiro, Aveiro, Portugal*; *[4]Aveiro Rheumatology Research Centre, Egas Moniz Health Alliance, Aveiro, Portugal*; *[5]EpiDoc Unit, Nova Medical School, NOVA University Lisbon, Lisbon, Portugal*; *[6]Rheumatology Research Unit, Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal*; *[7]Aix Marseille Univ, CNRS, INSERM, CIML, Centre d'Immunologie de Marseille-Luminy, Marseille, France*

Purpose: Plasmacytoid dendritic cells (pDC) are innate immune cells specialised in rapidly producing large amounts of type I interferon (IFN), playing an important role in anti-viral immune responses, and in different autoimmune diseases, such as systemic sclerosis (SSc). In fact, pDC are key to the onset and development of fibrosis in SSc, and a recent paper suggested that dysregulation of the tricarboxylic acid (TCA) cycle contributes to the type I IFN signature observed in these patients. However, the metabolic profile of pDCs from SSc patients remains to be elucidated. Thus, our study aimed to apply advanced techniques to characterise the metabolic profile of these cells.
Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from blood of healthy donors and SSc patients. SCENITH, a single-cell flow cytometry-based method, was applied to infer the metabolic profile of circulating pDCs, which were identified as $CD304^+$ Lin^-, and analysed at steady-state and upon stimulation with CpG A. Toll-like receptor (TLR)9 activation by CpG A was confirmed by staining for S6 phosphorylation.

Results: Circulating pDCs were analysed in samples from 10 healthy donors and 14 SSc patients. pDCs from anti-centromere antibody-positive (ACA^+) patients displayed higher mitochondrial dependence and lower glycolytic capacity than those from anti-topoisomerase I antibody-positive (ATA^+) patients. Furthermore, pDCs from both ACA^+ patients and those with limited cutaneous SSc (lcSSc) showed a stronger response upon CpG A stimulation than cells from ATA^+, anti-RNA polymerase III antibody-positive (ARA^+) or diffuse cutaneous SSc (dcSSc) patients.

Conclusions: Our results suggest that pDCs from ACA^+ patients rely more on oxidative phosphorylation (OXPHOS) and are more responsive to external stimuli. These findings point to the possible contribution of the metabolic profile of pDCs for the SSc clinical course, unveiling new possible targets for therapeutic approaches.

Monocytes drive myofibroblast contraction in a 3D skin model used to understand fibrosis in systemic sclerosis

Djúlio Zanin da Silva[1;2], Nienke van Kooten[1], Theogiannis Papadimitriou[1], Daphne Dorst[1], Birgitte Walgreen[1], Elly Vitters[1], Peter van der Kraan[1], Martijn van den Bosch[1], Arjan van Caam[1], Marije Koenders[1]

[1]Radboud University Medical Center, Experimental Rheumatology, Nijmegen, Netherlands; *[2]Ribeirão Preto Medical School, University of São Paulo, Basic and Applied Immunology Graduate Program, Ribeirão Preto, Brazil*

Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by vasculopathy, fibrosis, and immune dysregulation. In SSc pathogenesis, circulating monocytes can be recruited to the skin and differentiate into macrophages, activating resident fibroblasts. However, how these cells exert their functions is not fully understood. Here, we investigated the role of monocytes in mediating (myo)fibroblast contraction and activation using an innovative 3D collagen hydrogel model.

Methods: For our 3D skin model we cocultured human primary dermal fibroblasts with either peripheral blood mononuclear cells (PBMCs) or CD14+ monocytes in a 3D collagen type 1 hydrogel. Subsequently, monocyte-driven tissue contraction was measured over time. We performed immunostainings for CD68, fibroblast activation protein (FAP), and alpha-smooth muscle actin (α-SMA) to evaluate cells activation. To investigate the signaling pathways involved, we measured transcription factor-driven luciferase production using reporter constructs in the same dermal fibroblasts. The activity of the following reporter constructs was determined after 24 hours: Sis-Inducible Element (SIE); SMAD-Binding Element (SBE); Nuclear Factor of Activated T-cells 5 Response Element (NFAT-5), and NFκB Response Element (NFκB).

Results: After 60 hours of co-culture, hydrogel plugs containing fibroblasts + monocytes displayed a strong contraction, seen by a (approx. 80-90%) decrease in the area of the plugs. Hydrogels containing only fibroblasts did not contract. Hydrogels with fibroblasts + monocytes contracted as fast as fibroblasts + PBMCs, but depletion of CD14+ cells from PBMCs slowed down contraction, showing that monocytes might strongly activate fibroblasts. The expression of FAP and α-SMA by fibroblasts also increased in monocyte-containing hydrogels, as well as CD68 expression, indicating enhanced monocyte differentiation/activation into macrophages by fibroblasts. Evaluating which intracellular pathway leads to fibroblast activation, we observed that SIE and NFκB reporter fibroblast constructs were strongly elevated in the presence of monocytes. Enhanced TGF-β activity using the SBE reporter was not observed. Together, our results suggest that inflammatory mediators may contribute to the monocytes-driving myofibroblast contraction.

Conclusion: This study highlights the importance of monocytes and the SIE and NFκB intracellular signaling pathways in (myo)fibroblast contraction in a 3D skin model, contributing to understanding the basic mechanisms of these cells in SSc skin fibrosis and thickness.

Systemic immune response to cold exposure is linked to γδ T cells dynamics

Daniel Vasek[1], Peter Holíček[2;3], František Galatík[4], Veronika Somova[1], Natalie Fikarova[1], Michaela Hájková[1], Martin Převorovský[1], Jitka Žurmanová[4], Magdalena Krulova[1]

[1]Department of Cell Biology, Faculty of Science, Charles University, Prague, Czech Republic; *[2]Sotio Biotech, Prague, Czech Republic*; *[3]Department of Immunology, Charles University, 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic*; *[4]Department of Physiology, Faculty of Science, Charles University, Prague, Czech Republic*

Purpose: This study aims to investigate the systemic immune response during cold acclimation in a model subjected to short-term or long-term mild cold exposure, with a focus on understanding the interplay between cold exposure, neural signaling, immune response, and thermogenic regulation.

Methods: A rat model was utilized to examine the effects of short-term or long-term mild cold exposure. Additionally, a group of regular cold swimmers was included to provide human relevance. Various parameters were measured, including activation of brown adipose tissue, adipose tissue cytokine production, systemic immune response (including leukocyte proportions, activation status, and cytokine production), and the involvement of γδ T cells using flow cytometry, ELISA, and qPCR. RNA-seq was employed to elucidate the mechanisms by which γδ T cells participate in the response to cold. Furthermore, rats exposed to cold were challenged with a Pam2CSK4 (Toll-like receptor 2 agonist) to assess modulation of the immune response.

Results: One-day cold exposure triggered a stress response characterized by cytokine production in white adipose tissue, subsequently activating brown adipose tissue and inducing thermogenesis. Systemic immune response analysis revealed the pivotal role of γδ T cells in the broader response to cold adaptation. RNA-seq analysis provided further insights into the mechanisms underlying the involvement of γδ T cells. Additionally, the challenge with a Toll-like receptor 2 agonist showed significant modulation of the immune response in cold-exposed rats. Moreover, experiments performed on human volunteers confirmed the role of γδ T lymphocytes also in the human organism exposed to cold.

Conclusion: This study sheds light on the complex relationship between cold exposure, neural signaling, immune response, and thermogenic regulation. The findings significantly contribute to our understanding of the physiological acclimation that occurs in response to cold exposure, emphasizing the importance of γδ T cells in orchestrating the immune response during cold adaptation.

Despite the success of the BNT162b2 mRNA vaccine, molecular mechanisms by which the BNT162b2 vaccine stimulates immune responses still remain not completely elucidated. In the course of analysis of CD8+T cells in individuals undergoing BNT162b2 coronavirus disease 2019 (COVID-19) vaccination, we observed in peripheral blood a sizable fraction of the CD8+ T cell pool expressing CD16. Expression of CD45RA in the absence of CCR7, CD28 and CD27 was the dominant pattern among the increased CD16+CD8+ T cells, consistent with TEMRA phenotype and thus a terminally differentiated status. This T cell subset expressed a wide array of classical Natural Killer cell-associated activating and inhibitory receptors as well as intracellular effector molecules, thus showing a distinct phenotype different from other effector CD8+ T cells and more similar to NK cells. CD16+CD8+ T cells were also characterized by interferon gamma (IFN-γ) response gene transcripts and stimulation through CD16 and other classical NK cell innate receptors could elicit a vigorous functional response. Remarkably, both CD16 and NKp30 were specifically upregulated by IL-15 stimulation on NKp80+ CD8+ T cells and engagement of NKp80 in combination with CD16 resulted in a synergic effect for their effector functions. On the other hand, CD16+ CD8+ T cells show a high expression of the inhibitory receptor GPR56, capable to limit their activation via CD16. These data indicate that terminally differentiated CD8+ effector T cells, upon BNT162b2 COVID-19 vaccination, could acquire NK cell characteristics, including Antibody-dependent cellular cytotoxicity (ADCC) and innate receptor-associated cytotoxicity. Thus, BNT162b2 COVID-19 vaccination provides an additional large fraction of ADCC-capable effector cell pool, endowed with innate functions and therefore able to potentially counteract a much wider array of diseases.

Development of the first primary mucosal mast cell model

Louise Battut[1]

[1]*INSERM IRSD UMR1220, Toulouse, France*

Purpose: Active players in the innate immune system, mast cells monitor tissues by responding to various signals from their environment. Their cytoplasm is filled with granules containing pre-formed inflammatory mediators, ready for rapid release through degranulation. There are two main subtypes of mast cells, associated with distinct anatomical niches: connective-tissue mast cells (CTMC) and mucosal mast cells (MMC). These cells differ in origin, location, phenotype, granule composition and functionality. However, the study of MMCs is hampered by the lack of pertinent experimental model.

Methods: We generated primary murine MMC from bone marrow precursors sequentially cultured in two media enriched in key cytokines found in successive sites of MMC ontogeny.

Results: This model summarizes *in vitro* the key features of tissue MMCs, mimicking original phenotype, granular composition and functions.

Conclusion: This model will provide a convenient tool to better investigate MMC responses to various signals involved in pathophysiological processes.

Ankylosing Spondylitis-Specific Isotype Immunoglobulin Glycan Profile Reveal Unique Inflammatory Responses of PMA-Differentiated THP-1 Macrophages

Hui-Ling Chiang[1], Ning-Sheng Lai[1], Ming-Chi Lu[1;2], Chien-Hsueh Tung[1], Chih-Chia Yu[2], Yu-Ling Huang[3], Yi-Ling Ye[3]

[1]Division of Immunology, Allergy and Rheumatology, Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Chiayi, Taiwan; *[2]Department of Medical Research, Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Chiayi, Taiwan*; *[3]Department of Biotechnology, National Formosa University, Yunlin, Taiwan*

Purpose: Ankylosing spondylitis (AS) poses a multifaceted challenge owing to its intricate autoinflammatory mechanism, involving both innate immune cells and innate-like immune cells in the inflammatory process. Additionally, although various inflammatory mediators have been implicated in this disease, the mechanisms underlying their expression remain ambiguous. The primary objective of this study is to analyze the inflammatory responses of PMA-differentiated THP-1 macrophages when exposed to AS or healthy control (HC) SIIg, elucidating their unique expressions.

Methods: SIIg were isolated from the serum of individuals with AS and healthy controls (HC) using affinity and gel filtration chromatography. The N-linked glycans of SIIg were enzymatically cleaved using PNGase F to remove glycosylation. The molecular weights of SIIg and deglycosylated SIIg were determined using Western Blot analysis. PMA-differentiated THP-1 macrophages were then stimulated with AS or HC SIIg, either treated or untreated with PNGase F, for 24 hours. The supernatants collected from these cultures were analyzed for the expression of TNF-α and IL-10 using ELISA, and a comprehensive cytokine analysis was performed using the Human XL cytokine array.

Results: In the ELISA analysis, it was observed that the AS group displayed a higher IL-10/TNF-α ratio following 24-hour stimulation compared to the HC group. The comprehensive cytokine analysis revealed increased expressions of many inflammatory mediators in the AS group at the 24-hour mark. Molecular weight estimation indicated larger sizes of N-glycan SIIg in both AS and HC samples compared to deglycosylated SIIg. Moreover, lacking N-glycan SIIg stimulation of THP-1 macrophages resulted in decreased TNF-α and IL-10 expressions compared to stimulated by SIIg N-glycan.

Conclusion: The findings from this study support the clinical hypothesis, emphasizing the significance of N-linked glycosylation on SIIg from both AS and HC individuals in driving inflammation in THP-1 macrophages. Particularly noteworthy is the cytokine comprehensive analysis, which identified several pivotal inflammation-related molecules linked to AS. These results provide a platform for exploring the intricate interplay between glycosylated immunoglobulin and macrophage cytokine expression, thereby establishing a groundwork for future investigations into AS pathogenesis and the potential development of therapeutics.

Dissecting monocyte metabolic reprogramming to SARS-CoV-2 vaccination in people living with diabetes

Emma Jones[1], Nicholas Oliver[1], Harald Sourij[2], Margarita Dominguez-Villar[1]

[1]*Imperial College London, London, United Kingdom*; [2]*University of Graz, Graz, Austria*

Respiratory viral infections have been clinically linked with higher susceptibility to infection and more severe pathogenesis in people with type 1 diabetes (T1D), however it is not well understood what mechanisms are responsible for this. Hyperglycaemia, a hallmark characteristic for people with diabetes, has been associated with an impaired innate immune response to infection. Additionally, it is poorly understood how chronically elevated levels of a major fuel source, such as glucose, affects the tightly regulated relationship between cellular metabolism and the functional capacity of the immune system during respiratory viral infections. As such, people with diabetes are placed in high-risk categories for vaccination prioritisation strategies despite conflicting evidence regarding the longevity and magnitude of responses for these patients. Thus, we have deeply dissected the metabolic reprogramming observed in monocytes of the innate immune system in people with diabetes, in the context of mRNA SARS-CoV-2 vaccination.

Using clinical PBMC samples from the COVAC-DM study, we compared the metabolic rewiring that occurs upon vaccination in $CD14^+$ monocytes in 4 cohorts of patients: people with type 1 or 2 diabetes and glucose levels either above or on target, as defined by HbA1c values. Samples were taken from participants before vaccination, 7-14 days before their 3rd vaccination and 14 days after their 3rd vaccination. Using Met-flow for single-cell metabolic analysis, our results reveal distinct differences between the global metabolic phenotype of monocytes between healthy and diabetic groups as well as between groups with differing levels of glucose control. Metabolic flux through the glycolysis pathway and TCA cycle is elevated in individuals with T1D compared to healthy individuals before vaccination; maintained throughout the primary vaccination schedule and in response to vaccination. Additionally, individuals with poorly controlled glucose levels had significantly higher metabolic flux through the TCA cycle which is heavily involved in anabolic metabolism and energy production. Decreased metabolic flux through the anaerobic glycolysis pathway was also observed in individuals with T1D in response to vaccination. Determining the vaccine response in these diabetic cohorts will aid understanding into predictors of vaccine response and help ascertain the contribution of glucose control for effective immune responses.

Rheumatoid Arthritis monocytes and monocyte-derived macrophages are more inflammatory, less endocytic but display distinct TET expression and differentiation potential compared to Psoriatic Arthritis

Success Amaechi[1;2], Megan Hanlon[1;2], Dumitru Anton[1;2], Mary Canavan[1;2;3], Sonia Sundanum[2], Carl Orr[2], Douglas Veale[2], Viviana Marzaioli[1;2], Ursula Fearon[1;2]

[1]*Molecular Rheumatology Department, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland*; [2]*EULAR Centre for Arthritis and Rheumatic Diseases, St Vincent University Hospital, University College Dublin, Dublin, Ireland*; [3]*School of Biochemistry & Immunology, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland*

Purpose: RA and PsA share various pathogenic features, while also displaying significant differences at the clinical, cellular, and molecular levels. We investigate the inflammatory capacity of RA and PsA monocytes and monocyte-derived macrophages (Mo-MACs), in addition to other effector functions.

Methods: $CD14^+$ monocytes from peripheral blood mononuclear cells PBMCs) were isolated, then assessed following *ex vivo* LPS stimulation. Mo-MACs were generated via 7-day stimulation with M-CSF (50ng/mL) and polarised to M1 and M2. Inflammatory responses (IL-6, IL-1b, TNF-a, CXCL9-11, SLAMF1-7) were assessed by real-time PCR (RT-PCR). Frequency of monocyte subsets and expression of activation (CD40) and macrophage signature markers (CD64, CD163, CD206, SLAMF7) were assessed by flow cytometry. Endocytosis assays were performed on monocytes and Mo-MACs. Demethylation genes TET1-3 were assessed by RT-PCR. Finally, $CD14^+$ monocytes were cultured with a methylation activator (budesonide), and pro-inflammatory responses assessed.

Results: Significant increases in LPS-induced IL-6, IL-1b and CXCL9-11 expression were observed in RA vs PsA monocytes (all $p<0.05$). Expression of SLAMF1, 2 and 7 were significantly increased in LPS-induced RA and PsA monocytes vs HC, with SLAMF4 significantly decreased (all $p<0.05$). The increased pro-inflammatory response of LPS-stimulated monocytes was paralleled by significantly decreased endocytic capacity, especially for RA ($p<0.01$). RA and PsA Mo-MACs retained the hyper-inflammatory phenotype of their precursor cell. Expression of IL-6, CXCL9 and CXCL11 were significantly higher in RA Mo-M1 (all $p<0.05$), while IL-1b was higher in PsA ($p<0.05$). Heightened SLAMF7 expression was observed for RA Mo-M1 ($p<0.05$), with SLAMF2 significantly increased in PsA ($p<0.05$). Endocytic capacity was reduced in RA vs PsA Mo-M0. RA and PsA PBMCs exhibited decreased classical but increased intermediate monocyte frequencies vs HC. Expression of CD40, CD64, CD163, CD206 and SLAMF7 were higher in PsA classical and intermediate monocytes vs RA. Increased TET2 expression in RA monocytes ($p<0.05$) and TET3 in PsA ($p<0.05$) were observed. Budesonide decreased IL-6 and TNF-a expression in *ex vivo* LPS-stimulated monocytes.

Conclusion: RA $CD14^+$ monocytes and Mo-MACs are inherently more pro-inflammatory than PsA, though PsA monocytes appear more activated and primed for Mo-MAC differentiation. The distinct inflammatory pre-programming of monocytes may also involve altered epigenetic mechanisms.

Polyherbal formulation NOQ19 Modulates Human Macrophage Polarization and Function

Asli Korkmaz[1;2], Duygu Sag[1;2;3]

[1]Department of Genomic Sciences and Molecular Biotechnology, Izmir International Biomedicine and Genome Institute, Dokuz Eylul University, Izmir, Turkey; *[2]Izmir Biomedicine and Genome Center, Izmir, Turkey*; *[3]Department of Medical Biology, Faculty of Medicine, Dokuz Eylul University, Izmir, Turkey*

Purpose: *NOQ19* is a new medicinal polyherbal formulation containing 19 ingredients derived from 13 different medicinal plants. While there is limited research on *NOQ19*, both pre-clinical and clinical investigations have shown that the herbs in *NOQ19* separately have many beneficial effects such as antiviral, antibacterial, antifungal, antioxidant, antidiabetic, and cough suppressant. *NOQ19* has been licensed by the Indian state ministry of Ayush for managing mild to moderate COVID-19 due to its promising outcomes in clinical studies. However, the impact of *NOQ19* on the immune system is not known. Here, we report a detailed analysis of the impact of *NOQ19* on polarization and function of primary human macrophages.

Methods: Human peripheral blood monocyte-derived macrophages were either left untreated or pre-treated with 500 μg/mL *NOQ19* extract for 2 h. Then they were polarized into M1(LPS, IFNγ), M2a(IL-4), or M2c(IL-10) macrophages for 22 h. M1 and M2 polarization markers were analyzed by RNA-seq, qPCR, flow cytometry and ELISA. Moreover, phagocytosis capacity of macrophages was analyzed using pHRodo conjugated heat-killed *Staphylococcus aureus* bioparticle.

Results: Our data showed that *NOQ19* increased the expression of the M1 markers IL-1β, CCL5, CXCL5, NOTCH3, and C3, while decreasing the expression of the M2 markers CD163, IL-10, MS4A6A, SELENOP and F13A1 at mRNA level. Furthermore, the surface expression of the M1 marker CD64 and the M2 markers CD200R, CD209 and CD163 was decreased in M0, M2a and M2c macrophages. While *NOQ*19 did not induce the production of TNF, IL-12(p70) or IL-1β, it decreased the levels of secreted IL-10 and TGF-β in polarized and unpolarized macrophages. Lastly, *NOQ19* treatment decreased the phagocytic capacity of both polarized and unpolarized macrophages.

Conclusion: *NOQ19* modulates human macrophage polarization and phagocytic function with a downregulation of receptors which are known to have distinct roles in phagocytosis. Recent studies indicate that CD209 may serve as a potential new entry receptor for SARS-CoV2 by facilitating endocytosis. Thus, *NOQ19* could be a promising new supplement to modulate macrophage polarization and function for the treatment of viral infections, such as SARS-CoV-2.

Impact of exogenous and endogenous CD40L on macrophage responses to IL-4

Ignacio González-Alayón[1], Mariana Suárez-Martins[1], Cecilia Casaravilla[1], Stephen J. Jenkins[2], Conor Finlay[3;4], Pedro Papotto[3], Judith E. Allen[3], Alvaro Diaz[1]

[1]Área Inmunología, Departamento de Biociencias (Facultad de Química) and Cátedra de Inmunología, Instituto de Química Biológica (Facultad de Ciencias), Universidad de la República, Uruguay, Montevideo, Uruguay; *[2]Centre for Inflammation Research, Queens Medical Research Institute, University of Edinburgh, Edinburgh, United Kingdom*; *[3]Lydia Becker Institute of Immunology and Inflammation, School of Biological Sciences, Faculty of Biology Medicine and Health, University of Manchester, Manchester, United Kingdom*; *[4]Trinity Translational Medicine Institute, Trinity College Dublin, Dublin, Ireland*

The impacts of CD40-CD40L interactions on type 2 immunity are incompletely understood. While exogenous CD40 agonists bias responses towards the type 1 arm, the induction of most Th2 responses requires CD40-CD40L, suggesting that exogenous agonist delivery does not imitate endogenous CD40L signals. DC function is impacted by endogenous CD40L both expressed by antigen-specific $CD4^+$ T cells and delivered/sensed in the absence of specific interaction. We are examining these issues with a focus on macrophages, which respond to the type 2 cytokine IL-4 by expressing M(IL-4) markers, including RELM-α and Ym1/Chil3, and proliferating. *In vitro*, exogenous soluble CD40L (sCD40L) inhibited expression of RELM-α but had weak or nil inhibitory effects on expression of Ym1/Chil3 by resident or recruited peritoneal cavity or bone marrow-derived macrophages. The known inability of macrophages to proliferate in response to IL-4 *in vitro* was not rescued by sCD40L. Endogenous CD40L was detected under basal conditions in the peritoneal cavity only in $CD4^+$ T cells, mostly intracellularly but also at the cell surface. *In vivo*, interactions with CD40-expressing cells limit cell-surface CD40L expression by bulk $CD4^+$ cells. Such CD40-CD40L interactions may also generate tonic signaling on CD40-expressing cells including macrophages. Endogenous CD40L in the absence of antigen presentation did not influence RELM-α expression by peritoneal macrophages or allow their IL-4-driven proliferation *in vitro*, even in a "forced" system in which CD40 KO splenocytes were used as a source of $CD4^+$ cells expressing abundant cell-surface CD40L. Blocking endogenous CD40L *in vivo* in the context of IL-4 injection did not alter up-regulation of RELM-α or Ym1 by resident peritoneal macrophages, but caused a modest decrease in macrophage proliferation. In preliminary experiments, CD40 KO peritoneal macrophages transferred into IL-4-injected WT mice up-regulated RELM-α and Ym1 and proliferated similarly to transferred WT macrophages, suggesting no impact on these responses of basal endogenous CD40L detected directly by macrophages. In sum, exogenous CD40L antagonizes some macrophage responses to IL-4, whereas endogenous CD40L appears not to influence macrophage responses to IL-4 in the absence of antigen presentation. We are now extending this analysis to the antigen-specific interaction context. Funding: ICGEB; CSIC, CAP and ANII (Uruguay); Wellcome Trust.

Truncating mutations in NFKB1 lead to decreased expression of CCDC22 and COMMD proteins thereby enhancing inflammatory response

Kristiina Silventoinen[1], Katariina Nurmi[1], Goncalo Barreto[1], Kari K. Eklund[2]

[1]*University of Helsinki, Helsinki, Finland*; [2]*Helsinki University Hospital, Helsinki, Finland*

Copper-metabolism Murr1 domain proteins (COMMD1–10) and coiled-coil domain-containing proteins (CCDC22, CCDC93) form a CCC complex that participates in endosomal recycling of diverse transmembrane proteins. Of these, CCDC22 is highly conserved, and it has been shown to act as a scaffold for COMMD proteins. CCDC22 together with COMMD1 are also known to regulate the NF-κB signaling. CCDC22 acts as an NF-κB activator by degrading IκB, and COMMD1 suppresses NF-κB by regulating its ubiquitination. Despite their known role in regulation of NF-κB, a key inflammatory transcription factor, understanding of CCDC22 and COMMD protein's role in immune signaling is limited. We recently described patients with loss-of-function variants of *NFKB1*. These patients suffer from severe sterile soft tissue inflammations, and their macrophages show overactivation of the NLRP3 inflammasome and type I interferon response caused by defective autophagic degradation of proteins in these signaling cascades. We employed transcriptome and proteome analysis to study the impact of truncating *NFKB1* variant (p.R157X) in THP-1 cell line. In transcriptomics p.R157X variant carrying THP-1 cells express decreased levels of *CCDC22*, and proteomics data shows downregulation of multiple COMMD proteins. To study the effect of CCDC22 alone, we silenced CCDC22 in wild type THP-1 cells and activated them with LPS, which led to increased secretion of IL-1β. Silencing of CCDC22 increased the expression of *IL1B* and *IFIT2*, and reduced expression of *NFKBIA* as analyzed by qPCR. Overall, CCDC22 silencing led to similar RNA expression pattern as observed in p.R157X variant carrying cells. To confirm the transcriptomic findings from THP-1 cell line, we analyzed *CCDC22* expression in *NFKB1* variant-carrying patients and found that expression of CCDC22 is reduced also in patient cells. Truncating mutations in NFKB1 cause decreased expression of CCDC22 and COMMD proteins which promotes proinflammatory state. Our research investigates a potential new role of CCC complex in immune dysregulation.

Macrophages activation upon phagocytosis of structurally different antigens

Asta Luciunaite[1], Milda Norkiene[1], Aurelija Zvirbliene[1]

[1]*Life Sciences Center, Vilnius university, Vilnius, Lithuania*

Macrophages phagocytose various pathogens and are activated during this process. Macrophage response to viral antigens is insufficiently explored, especially inflammation-related signalling pathways. One of inflammatory pathways is inflammasome activation. NLRP3 inflammasome can be activated by many factors, including lysosomal damage. Previously, we showed that VP1-derived virus-like particles (VLPs) of human KI and MC polyomaviruses (PyVs) induce NLRP3 inflammasome activation in macrophages and this might define phagocytosis profile. Moreover, KIPyV and MCPyV VLP-induced cell activation was of different intensity. We aimed to study the relation of phagocytosis to cell activation.

We investigated phagocytosis of VLPs in comparison to that of *E. coli* and amyloid-beta oligomers (Aβ). VLPs and *E. coli* were labelled with pHrodo dye being fluorescent in lysosomes, while Aβ were labelled with FAM fluorophore. To detect intracellular Aβ-FAM signal, cell surface signal was quenched with Trypan blue. Human macrophages derived from THP-1 cell line were treated with these particles for 3 and 24 h, then stained for inflammation marker CD86 and CD83, and analysed by flow cytometer.

We observed different phagocytosis pattern of investigated particles. MCPyV VLPs were phagocytosed at the highest intensity. We identified cell populations engulfing low to high levels of particles. The distribution of these populations were different for each particle type, indicating variant phagocytosis process of investigated particles. Comparing the uptake of VLPs, we detected co-stimulatory molecules CD86 and CD83 on cell surface only in the case of MCPyV VLPs showing the differences in cell activation profile. MCPyV VLPs are large homogeneous particles while KIPyV VLPs are of heterogeneous size. The differences in sequence of MCPyV and KIPyV VP1 could also influence cell activation.

In conclusion, we demonstrated that the structurally distinct particles are engulfed differently and this is related to macrophage inflammatory response.

Modulation of macrophage inflammatory response by Polyherbal formulation Kabasura Kudineer choornam

Duygu Unuvar[1], Asli Korkmaz[1;2], Duygu Sag[1;2;3]

[1]Izmir Biomedicine and Genome Center, Izmir, Turkey; *[2]Department of Genomic Sciences and Molecular Biotechnology, Izmir International Biomedicine and Genome Institute, Dokuz Eylul University, Izmir, Turkey*; *[3]Department of Medical Biology, Faculty of Medicine, Dokuz Eylul University, Izmir, Turkey*

Purpose: *Kabasura kudineer choornam (KKC)* is a new polyherbal formulation containing 15 different ingredients. These ingredients have been separately shown to have anti-inflammatory, anti-pyretic and anti-bacterial properties. *KKC* has high binding affinity and interactions with SARS-CoV-2 spike protein shown in *in-silico* studies and exhibits good anti-viral properties against SARS- CoV-2 shown in a few clinical studies. However, the effect of *KKC* on macrophage polarization is not known. Here, we report a detailed analysis of the impact of *KKC* on the polarization of primary human monocyte-derived macrophages.

Methods: Human peripheral blood monocyte-derived macrophages (M0 macrophages) were either left untreated or pre-treated with 500 μg/mL *KKC* extract for 2 h. Then they were polarized into M1 (LPS, IFNγ), M2a (IL-4), or M2c (IL-10) macrophages for 22 h. M1 and M2 polarization markers were analyzed at mRNA level by qPCR and at protein level by flow cytometry and ELISA. Lastly, phagocytosis capacity of macrophages was analyzed using pHRodo conjugated heat-killed *Staphylococcus aureus* bioparticle.

Results: *KKC* extract treatment decreased the surface expression of the M1 marker CD64 (FcγRI) and increased the surface expression of the M2 markers CD200R, CD209, and CD163 in both polarized and unpolorized macrophages. Although, the mRNA expression of TNF, IL-12(p70), IDO1, IL-1β and TGF-β was increased; only the secretion of TNF was induced after KKC treatment.

Interestingly, the M2 cytokine IL-10 showed a unique pattern of response; a decrease in mRNA expression but increase in secretion in M0 and M2a macrophages, while the opposite response was observed in M1 and M2c macrophages. Lastly, *KKC* extract treatment decreased the phagocytic capacity of both polarized and unpolarized macrophages.

Conclusion: In conclusion, KKC extract modulates macrophage inflammatory response and could be a potential supplement for the treatment of infectious and inflammatory diseases.

Long live the macrophages – memantine as cellular youth elixir?

Veljko Blagojević[1], Ivana Ćuruvija[1], Ivana Anđelović[1], Marko Vasić[1], Radmila Miljković[1], Ivana Prijić[1], Biljana Bufan[2], Jasmina Djuretić[2]

[1]Institute of virology, vaccines and sera "Torlak", Belgrade, Serbia; *[2]Faculty of Pharmacy, University of Belgrade, Belgrade, Serbia*

Memantine is an uncompetitive NMDA antagonist, blocking the ionic channels of NMDA receptors, influencing the Ca^{2+} metabolism. This drug is clinically used for treating Alzheimer's disease, and there have been studies on animal models covering a variety of disease models and tissues, including the heart, liver and brain. Results presented here are from a peculiar observation made in the following study: female Dark Agouti rats of two ages (young – 3 months, and old – 24 months) were fed a memantine solution (60 mg/kg body weight/day for 7 consecutive days) through oral gavage from the first day after experimental autoimmune encephalomyelitis was induced, and were sacrificed on day 8 (inductive phase of disease). We confirmed the effects of systemic memantine application through histological analysis – livers of young control group rats showed signs of steatosis, which was ameliorated in the treated group; rats from both old and young control groups showed signs of liver mononuclear infiltration, which was absent in all rats from treated groups, regardless of age. However, the curious unexpected result was of a technical nature – peritoneal macrophages isolated from the rats showed substantially greater viability even 11 days after the experiment. Memantine had a stronger effect on peritoneal cells of young rats – the peritoneal cell yield was two times lower in the memantine treated group, the percentage of $CD45RA^+$ peritoneal B-cells was substantially higher than in the control group, and 11 days post-experiment there were 3 times more live macrophages ($CD11b^+CD163^+$). Macrophages are usually short living cells upon extraction from tissues, and these results may point in a direction of an intrinsic mechanism for longevity of macrophages and potentially other cells expressing the NMDAR. Since memantine is known to block extravasation of blood mononuclear cells into peripheral tissues, it is possible that the dynamic of peritoneal cells replenishment has been disturbed. The implications of our observations are unclear and further research will be need to establish the full scope of possibilities it unlocks, however we feel confident that memantine could be the proverbial shamrock for macrophages, bringing them long and happy lives.

Macrophages are pivotal in tissue homeostasis and inflammatory responses, and they may reversibly alter their function in response to environmental cues. Macrophages are abundant in solid tumors, but it remains controversial whether they promote or inhibit tumor growth. The aim of the present study is to elucidate the potential of macrophages for cancer immunotherapy. For this purpose, we have used non-activated or activated mouse bone marrow-derived macrophages (BMDM) and human macrophages differentiated from monocytes. The macrophages have been tested in mouse models of cancer and in co-cultures with cancer cells. Mice injected subcutaneously with colon carcinoma cells alone, or non-activated macrophages in combination with cancer cells developed tumor. In contrast, injection of the activated macrophages together with cancer cells completely inhibited tumor growth. Upon rechallenge with cancer cells, the mice exhibited delayed tumor growth compared to naïve mice, suggesting that the initial co-injection of activated macrophages with cancer cells induced prolonged immunity. In vitro, mouse or human cancer cells in co-culture with non-activated macrophages proliferate to the same extent as the cancer cells grown alone. In contrast, activated macrophages efficiently killed cancer cells. Imaging by holotomography revealed that cancer cells (human breast cancer and melanoma) show typical morphological features of apoptosis when co-cultured with activated macrophages. Finally, we have observed that in a tumor-on-chip, T cells migrate into a 3D environment consisting of cancer cells and activated macrophages embedded in collagen. These results suggest a new strategy for cancer immunotherapy, based on the activation of tumor-associated macrophages.

Staphylococcal enterotoxins influence the monocyte transcriptional profile and shape subsequent macrophage differentiation

Claudia Arasa Cuartiella[1], Manuel Mata Forsberg[1], Khaleda Rahman Qazi[1], Eva Sverremark Ekstrom[1]

[1]*Department of Molecular Biosciences, The Wenner-Gren Institute, Stockholm University, Stockholm, Sweden*

Staphylococcal enterotoxins (SE) are superantigens produced by *Staphylococcus (S.) aureus*. SE crosslink the MHC-II on antigen presenting cells (APCs) with the T cell receptor, triggering a polyclonal T cell response. Although APCs are the first cells to encounter SE and direct the subsequent T cell response, very little is known regarding the effects SE have on APC activation. Our aim is to investigate how the enterotoxin SEA is affecting monocytes in the presence and absence of other cell types, and the effects that encountering SEA will have in the resulting differentiated macrophages.

We have stimulated human peripheral blood mononuclear cells (PBMC) or isolated monocytes with SEA. Upon stimulation, we collected the monocytes or differentiated them into macrophages and exposed them to polarizing conditions. The cells were collected, and we analyzed their gene expression, surface markers and protein secretion using RNAseq, flow cytometry and ELISA respectively.

Our results show that upon treatment with SEA, monocytes within the PBMC population differentiate into an HLA-DR^{high} and an HLA-DR^{low} population between 8 and 16 hours after stimulation. Furthermore, in the absence of T cells, SEA-treated monocytes show a similar transcriptional pattern as unstimulated cells, but they upregulate T cell-attracting chemokines such as CXCL-9, -10 and -11.

We also observed that macrophages derived from SEA-primed monocytes are phenotypically different to those that have not encountered the toxin, with decreased HLA-DR and activation markers CD80 and CD86, as well as diminished expression of the M2 markers CD163 and CD206 in both M1 and M2 polarizing settings. Altogether, our results suggest that interaction with SEA may influence the monocytic antigen presenting capacity and subsequent macrophage function. This could potentially lead not only to disrupted T cell activation to other antigens and the breaking of T cell tolerance, but also affect macrophage functions such as wound healing and phagocytosis.

Quantitative proteomic analysis of natural dendritic cell subsets

Simon O'Shaughnessy[1], David Finlay[1]

[1]*School of Biochemistry and Immunology, Trinity College Dublin, Dublin, Ireland*

Background: Dendritic Cells are the primary antigen presenting cells of the immune system and thus bridge the gap between innate and adaptive immunity. DC are a family of ontologically related subsets that exist across a range of maturation states. However, the molecular mechanisms that underpin the division of labour between these subsets and maturation states are not fully characterised. In recent years, cellular metabolism has been shown to be intricately linked to DC fate and function. We hypothesis that metabolism is a key determinant of DC subset specific functions. Furthermore, nutrients are the fuels of metabolism and are thus key mediators of DC function. However, how nutrients effect cDC is unexplored poorly understood.

Methods: We isolated splenic conventional DC1 and DC2 from mice that were either treated with PBS or ODN-CpG for 18h *in vivo*. Total protein was extracted from whole cell pellets and subjected to quantitative proteomic analysis. Statistical analysis was performed to investigate the metabolic proteome and nutrient sensing machinery of immature (PBS) and mature cDC (CpG) subsets.

Results: Herein, we reveal that primary mouse spleen cDC1 and cDC2 have distinct metabolic proteome features that correlate with function. We show that upon activation cDC metabolic proteins do not significantly change after 18h of stimulation. We find that cDC1 and cDC2 differentially express amino acid transporters. In particular, cDC1 have elevated expression of the system-L amino acid transporter, SLC7A5 whose activity was found to regulate anabolic signalling in cDC1s by controlling the activity of the kinase mTORC1. Additionally, pharmacological targeting of SLC7A5 transport was shown to modulate cDC1 cross-presentation.

Conclusion: This study quantifies the absolute protein expression of cDC1 and cDC2. cDC have subset specific metabolic proteome features that underpin their functions. Amino acid transport through SLC7A5 was found to be a cDC1 specific regulator of function. We propose that this is an evolutionary mechanism to support enhanced T cell activation. This data paves the way for future work to investigate the subsets specific nutrient requirements of DC and to identify molecular mechanisms to target these features therapeutically.

Mitochondrial fission-inducible lipid droplets in macrophage antimicrobial responses.

Karoline Raven[1], Syeda Farhana Afroz[2], James Curson[1], Ronan Kapetanovic[3], Robert Parton[1], Matthew Sweet[1]

[1]Institute for Molecular Bioscience (IMB), The University of Queensland (UQ), Brisbane, Australia; *[2]Penn State University College of Medicine, Hershey, United States*; *[3]INRAE, Nouzilly, France*

Mitochondria and lipid droplets (LDs) are recognised for their important roles in innate immunity, with both organelles contributing to inflammatory signalling and bacterial killing by macrophages. Mitochondria are highly dynamic organelles, changing their state from a fused network (fusion) to undergoing fragmentation (fission), with this process affecting cellular metabolism. LDs are vital in cellular metabolism and have a role in inflammatory signalling and direct antimicrobial responses. Mitochondria and LDs interact during cell metabolism, demonstrating that these organelles have an intimate relationship. This study aimed to investigate the relationship between mitochondrial fission and LDs in macrophage antimicrobial responses. Here we have demonstrated that the Toll-like receptor 4 (TLR4) agonist lipopolysaccharide (LPS) induced mitochondrial fission and LD synthesis in both murine and human macrophages. To determine whether there is a functional link between mitochondrial fission and LD formation in murine macrophages, LPS-inducible mitochondrial fission was genetically or pharmacologically inhibited by targeting the fission-promoting GTPase DRP1. Both regimes abrogated LPS-induced LD formation, suggesting that LPS-inducible mitochondrial fission drives LD formation. Signalling mechanisms driving LPS-inducible LDs are poorly understood. One potential candidate is the lysine deacetylase HDAC7 which is required for TLR-inducible mitochondrial fission. LPS-inducible LD formation was abrogated by either genetic or pharmacological targeting of HDAC7. Whereas overexpression of HDAC7 in primary macrophages was sufficient to induce both mitochondrial fission and LD formation in a basal state. In bacterial infection studies, challenge with *Escherichia coli* (*E. coli*) increased both mitochondrial fission and LD formation. Interestingly, infection with *Salmonella enterica* serovar Typhimurium (*S.* Typhimurium) didn't induce fission but induced LD formation, indicating a potential form of pathogen manipulation. Finally, whereas LPS-inducible fission and LD formation required HDAC7, these responses occurred independently of HDAC7 in macrophages responding to bacterial challenge. These data further support a connection between mitochondrial fission and LD formation and suggest that distinct mechanisms can initiate inducible fission and LD formation, depending on the nature of the stimulus. Collectively, my data suggest that the antimicrobial effects of mitochondrial fission in macrophages may be mediated by inducible production of antibacterial LDs.

MTADV 5-MER peptide suppresses lung fibrosis of a mouse model and inhibits human fibroblasts biological functions by targeting of SAA, which fuels fibrosis

David Naor[1]

[1]*Hebrew University of Jerusalem, Tel Aviv, Israel*

Focusing on therapy of chronic inflammations, we have reported in our previous communication (J Autoimmune. 2021 Nov; 124:102713) that a 5-MER peptide (5-MP; Methionine, Threonine, Alanine Aspartic Acid, Valine (MTADV) attenuates the pathology of animal models of Rheumatoid Arthritis, Crohn's Disease/Ulcerative Colitis and Multiple Sclerosis. In this report we described the ability of 5-MP to alleviate the lung inflammation and fibrosis of Bleomycin-induced fibrosis (BIF), a mouse model of human Idiopathic Pulmonary Fibrosis (IPF). All these maladies share Serum Amyloid A, that fuels chronic inflammation and fibrosis. In our previous communication we presented evidence that 5-MP targets SAA and consequently interferes with formation of SAA oligomers and aggregated fibrils, which are involved in chronic inflammations and fibrosis *in vivo* and in release of pro-inflammatory cytokines *in vitro*. In this report we focus, as indicated above, on the suppressive effect of 5-MP on fibrosis *in vivo*, and on fibroblast biological functions *in vitro*. Inflammation-induced quantitatively uncontrolled biological activities of fibroblasts and monocytes generate fibrosis, stressing the linkage between inflammation and fibrosis. The last is much less responsive than inflammation to medical intervention. Indeed, we found that 5-MP inhibits mRNA expression of pro-inflammatory cytokines (IL-6 IL-1β, TNFα) in fibroblasts and monocytes and their release from SAA-activated corresponding cells. Furthermore, the *in vitro* growth potential of fibroblasts was suppressed following their incubation with 5-MP, which explains the ability of the peptide to suppress the fibroblast proliferation-dependent fibrosis *in vivo*. In conclusion 5-MP displays therapeutic potential in lung fibrosis-associated diseases, which face unmet remedy at present.

IFN-γ induced plasticity in human alveolar macrophages can be resolved with IL-10: Implications for macrophage plasticity as a therapeutic target for tuberculosis

Olivia Sandby-Thomas[1], Zara Davies Harold[1], Dearbhla Murphy[1], Sharee Basdeo[1], Donal Cox[1], Joseph Keane[1]

[1]*Trinity College Dublin, Dublin, Ireland*

Background: Alveolar macrophages (AM) are the most prevalent immune cells in the lung and the first line of defence against invading pathogens. However, AM are also the primary host cell of *Mycobacterium tuberculosis* (Mtb) in the lung. Interferon-γ induced Th1 mediated immunity is crucial to control pulmonary infections. IFN-γ induces the human AM to become more inflammatory and metabolically active which is thought to improve pathogen clearance. There is a paucity of data on the whether human AM can revert to a homeostatic state after activation by Th1 cytokines such as IFN-γ.

We wanted to investigate if the human AM can revert to a homeostatic regulatory phenotype post treatment with IFN-γ. Furthermore, we wanted to examine the ability of AM that have resolved Th1 inflammation, to respond to Mtb.

Methods: To model plasticity and resolution of inflammation *in vitro*, human AM and monocyte derived macrophages (MDM) were treated with IFN-γ for 24 h, to mimic an inflammatory lung environment. Macrophages were subsequently treated with IL-10 for 48 h. Activation marker expression was determined using flow cytometry. Metabolic profiles were assessed by Seahorse metabolic-flux analysis and PCR. To examine functional responses, AM were stimulated with Lipopolysaccharide (LPS), irradiated H37Rv (iH37Rv) or Mtb lysate and cytokine production was quantified by ELISA. Alternatively, macrophages were infected with Mtb, lysed and colony forming units were quantified.

Results: IFN-γ increased expression of CD40 and HLA-DR by human AM, subsequent IL-10 stimulation only reduced HLA-DR surface expression. IFN-γ treated AM stimulated with LPS, iH37Rv or Mtb lysate had increased TNF and IL-1β production which was attenuated by IL-10 treatment. IFN-γ primed IL-10 treated AM had increased glycolysis and oxidative phosphorylation compared to controls, suggesting metabolic control of homeostasis in human AM. Additionally, IFN-γ primed IL-10 treated AM have a better ability to control intracellular Mtb growth. Similar results were observed in MDM.

Conclusion: IL-10 can revert AM to a homeostatic state after IFN-γ which may mechanistically require increased metabolic activity. The data also suggests that the resolution of inflammation in the macrophage may also play a critical role in killing Mtb from the lung.

Limosilactobacillus reuteri regulate the monocyte transcriptome and functional macrophage polarization

Khaleda Rahman Qazi[1], Manuel Mata Forsberg[1], Ludwig Lundberg[2], Stefan Roos[2], Eva Sverremark Ekstrom[1]

[1]Molecular Biosciences The Wenner-Gren Institute, Stockholm University, Stockholm, Sweden; *[2]BioGia AB, Stockholm, Sweden*

Background: Species from the bacterial genera *Lactobacillus (L.)* are among the first gut colonizers that play a vital role to built-up healthy immune system. In the neonatal gut, they are known to have beneficial health effects, and their presence has been associated with protection against allergy. We have previously demonstrated how lactobacilli-derived factors (secretome) suppress pro-inflammatory T cell responses and that this activity was mediated via monocytes/DCs.

Aim: To investigate the effect of lactobacilli-derived secretome on the human primary monocyte transcriptome, differentiation to M1 (proinflammatory-like) and M2 (anti-inflammatory-like) macrophages and their functional responses.

Methods: Human monocytes purified from peripheral blood were exposed to the secretome from *Limosilactobacillus (L.) reuteri* for 24 hours. mRNA was isolated and subjected to RNA sequencing. Also, macrophages were generated under different growth conditions *in vitro*, and further exposed to the secretome from *L. reuteri* for 48 hours. The cells were analyzed for cell surface expression of M1/M2 characteristics, i.e. HLA-DR, CD80, CD86, CD163, CD206, and PDL-1 by flow cytometry and cell-culture supernatant were analyzed for the detection of TNF, sCD14, sCD163, IL-6, IL-10, IL-19, IL-1RA, and G-CSF by ELISA. Functional analysis was conducted by coculturing macrophages with the autologous T cells.

Results: Preliminary results from transcriptome analyses of *L. reuteri*-treated monocytes indicate a strong effect on many protein-coding genes. Among others, there was a strong down-regulation of several genes in the MHC class II antigen processing pathway, but also the induction of several non-coding RNAs, some with described regulatory functions. For macrophage differentiation, there was a general dampening of both M1 and M2 phenotypic characteristics but a tendency to upregulate PDL-1 and CD14 on M2 macrophages. Furthermore, LR secretome preferentially elicited immunomodulatory cytokines such as IL-10, sCD163 and G-CSF on M2 conditioned macrophages. Moreover, LR treated macrophages suppressed the autologous T cell responses.

Conclusion: *L. reuteri* induce a broad transcriptional gene activity in monocytes with a clear reduction of the antigen presentation pathway in both monocytes and differentiated macrophages, which could have implications for their capacity to modulate lymphocyte functions and towards therapeutic approaches.

Platelets as possible biomarker candidates to differentiate between neurodegenerative disorders. Platelets as possible biomarker candidates to differentiate between neurodegenerative disorders.Platelets as possible biomarker candidates to differentiate between neurodegenerative disorders.Platelets as possible biomarker candidates to differentiate between neurodegenerative disorders.

Noelia Arias Gonzalez[1], Marc Boigues[1], Marco antonio Fernandez- Sanmartin[2], Katrin Beyer[3], Eva Martínez Cáceres[1]

[1]Division of Immunology, LCMN, Germans Trias i Pujol University Hospital and Research Institute, Badalona, Barcelona, Spain; *[2]Flow cytometry platform. Research Institute Germans Trias i Pujol, Badalona.4Department of Neurosciences, Research Institute Germans Trias i Pujol, Badalona., Barcelona, Spain*; *[3]Genomics and Transcriptomics of Synucleinopathies" (GTS-Group) en Germans Trias i Pujol Research Institute (IGTP), Barcelona, Spain*

Platelets (PLTs) have recently been recognized as immunoregulatory elements that modulate immune responses with an increasing evidence of their role in the pathogenesis of neurodegenerative disorders. Alzheimer's disease (AD), Parkinson's disease (PD) and Lewy body dementia (DLB) are complex diseases that usually overlap in their neuropathological manifestations preventing a correct clinical diagnosis and management of the disease.

The aim of this project was to explore the interaction of PLTs with other immune cells in these different neurodegenerative disorders and determine the usefulness of PLTs as possible biomarkers. Sixty-six individuals from Germans Trias i Pujol Hospital were analyzed in this pilot study. The percentage of PLTs (CD41+CD61+) attached to T lymphocytes (CD3+CD4+, CD3+CD8+), B lymphocytes (CD19+), monocytes (CD14+), and theiractivation grade (CD25+/ CD68+) were measured in peripheral blood by flow cytometry.

Results revealed an increase in the percentage of PLTs attached to CD4+ and CD4+ CD25+ T lymphocytes in PD compared to DLB(p=0,0186) (p=0,0317). A similar result was obtained with CD19+ B lymphocytes attached to PLTs in CTRL(p=0,0233), PD (p=0,0038) and AD (p=0,0386) compared to DLB. In the same tendency an increase was also observed in the percentage of PLTs attached to CD8+ T lymphocytes in PD compared to DLB (p=0,0132).

Moreover, the percentage of PLTs attached to CD14+ monocytes was higher in AD (p=0.0164) and CTRL(p=0,0384) compared to DLB as well. However, the expression of the activator marker CD68 in monocytes was higher in DLB compared to AD (p=0,0044).

The percentage of PLTs attached to B lymphocytes, CD4+T lymphocytes and monocytes could be a promising biomarker to discriminate between PD, DLB and AD. Moreover, it seems that there is a tendency of a decrease percentage of immune cells attaches to PLT in DLB. This difference should be further explored as a tool for the differential diagnosis between DLB and PD at early disease stages, as it is still very difficult to differentiate them. A correct diagnosis and treatment is crucial to improvethe quality of life of these patients. Further studies with higher number of participants are needed to validate these results.

High production of IL-12p70 by human dendritic cells stimulated with combinations of pattern-recognition receptor agonists

Brian Christopher Gilmour[1], Alexandre Corthay[1;2;3], Inger Øynebråten[1;2]

[1]Tumor Immunology Lab, Department of Pathology, Oslo University Hospital, Oslo, Norway; *[2]Hybrid Technology Hub – Centre of Excellence, Institute of Basic Medical Sciences, University of Oslo, Oslo, Norway*; *[3]Institute of Clinical Medicine, University of Oslo, Oslo, Norway*

The cytokine IL-12p70 is crucial for T helper 1 (Th1) polarization and the generation of type 1 immunity required to fight cancer and pathogens. Therefore, strategies to optimize the production of IL-12p70 by human dendritic cells (DCs) may significantly improve the efficacy of vaccines and immunotherapies. However, the rules governing the production of IL-12p70 remain obscure. Here, we stimulated pattern recognition receptors (PRRs) representing five families of PRRs, to evaluate their ability to elicit high production of IL-12p70 by monocyte-derived DCs. We used ten well-characterized agonists and stimulated DCs *in vitro* with either single agonists or 27 different combinations. We found that poly(I:C), which engages the RNA-sensing PRRs TLR3 and MDA5, and LPS which stimulates TLR4, were the only agonists that could elicit notable IL-12p70 production when used as single ligands. We identified six different combinations of PRR agonists, all containing either the TLR3/MDA5 agonist poly(I:C) or the TLR7/8 agonist R848, that could synergize to elicit high production of IL-12p70 by human DCs. Five of the six combinations also triggered high production of the antiviral and antitumor cytokine IFNβ. Overall, the tested PRR ligands could be divided into three groups depending on whether they triggered production of both IL-12p70 and IFNβ, only one of the two, or neither. Thus, combinations of PRR agonists were found to increase the production of IL-12p70 by human DCs in a synergistic manner, and we identified six PRR agonist combinations that may represent strong adjuvant candidates, in particular for therapeutic cancer vaccines.

NFAT is important for NK cell maturation and function

Xiaoli Lou[1], Yin Xiao[1], Cristina Chiarolla[1], Snigdha Majumder[1], Nadine Hundhausen[1], Boutaina El kenz[1], Benjamin Lunz[1], Friederike Berberich-Siebelt[1]

[1]*Institute of Pathology, University of Wuerzburg, Würzburg, Germany*

Purpose: With the key aim to block false T-cell activity, patients receive cyclosporine A (CsA) or tacrolimus (FK506). However, other cell types like natural killer (NK) cells will be affected, too. Both drugs inhibit the enzymatic activity of the phosphatase calcineurin (CN), which primarily but not exclusively dephosphorylates and activates transcription factors of the *nuclear factor of activated T-cells* (NFAT) family. In T cells, CN is activated upon engagement of the T-cell receptor with a subsequent increase in intracellular Ca^{2+} and NFAT nuclear translocation. Here, NFAT proteins directly translate antigen recognition signals into altered gene expression. NK cells possess several receptors, known or predicted to increase intracellular Ca^{2+} as well. In addition, NK cells – like T lymphocytes – express NFATc1, c2 and c3.

Methods: Initially, mice harboring the *Nfatc1eGFP* reporter mice were exploited to verify NFATc1 expression in NK cells of different organs. *Nkp46iCre.YFP*$^{fl/fl}$ were utilized to ascertain the efficacy and specificity of the Cre recombinase system specifically within NK cells. Subsequently, mice with the *Nkp46iCre.Nfatc1*$^{fl/fl}$ and/or *Nfatc3*$^{fl/fl}$ genotype as well as *Nfatc2*$^{-/-}$were employed. Flow cytometry analysis was conducted to assess NK cell maturation and function.

Results: The *Nfatc1eGFP* reporter mice testified that at least NFATc1 is highly expressed and activated in NK cells of the bone marrow, secondary lymphoid organs as well as lung and liver. The *Nkp46iCre.YFP*$^{fl/fl}$ mouse model confirmed the precise targeting by NKp46 iCre solely to NK cells, i.e. without affecting other immune cell populations including $CD4^+$ and $CD8^+$ T cells. Mice with NFAT-deficient NK cells exhibited an increased proportion of NK cells in more mature stages compared to wild-type mice. Furthermore, these NFAT-deficient mice demonstrated reduced levels of inflammatory cytokines such as IFN-γ, but heightened expression of cytotoxic molecules such as granzyme B alongside with their killing capacity measured by CD107a expression.

Conclusion: These findings suggest that NK-specific deletion or inhibition of NFAT supports the anti-inflammatory effect it has on T cells but preserves late NK-differentiation stages with their cytotoxic activity.

Immune excitation of hematopoietic stem cells

Roi Gazit[1]

[1]*Ben-Gurion University Of The Negev, Beer Sheva, Israel*

Hematopoietic Stem Cells (HSCs) are the source of blood and immune cells. During everyday healthy life, HSCs are mostly quiescent in the bone marrow. Following inflammation, HSCs can gain activation, presumably accelerating the generation of the needed blood and immune cells. Surprisingly, however, our knowledge regarding the ability of various pathogens' to perturb HSCs is minimal. Moreover, the early- and late-effects of such activation are only beginning to reveal.

We had first revealed surface markers of immune-activated HSCs. Utilizing improved identification of activated HSCs provide us with molecular insights, and better ability to follow the process dynamically. We recently found that HSC's activation is much faster and broader than previously thought -- evident as early as 2 hours for both Stem- and progenitor-cells. The response is systemic, highly sensitive, and dose-dependent down to a surprisingly low amounts of stimulant. Interestingly, other recent studies challenge the concepts of HSCs' contribution to emergency hematopoiesis, highlighting further interests.

Chronic activation may deplete HSCs' potency and increase the risk of malignancies. We find extraordinary impact following prolonged bacterial infection in mice, and even more exciting ability for recovery following clearance of the pathogen. Single-cell analysis let us novel insights into molecular states of naïve, potent-less, and recovered HSCs.

Changing concepts of hematopoiesis are fundamental for the generation of new immune cells through health and disease. New data will allow for preserving the potency for a longer and healthier life.

Evaluation of NK cell anti-tumor activity by detection of subcellular nitric oxide in response to BCG treatment

Inmaculada Ruiz Lorente[1], Lourdes Gimeno Arias[2], Alicia López Abad[3], Maria Victoria Martínez Sánchez[1], Diana Ceballos Francisco[1], Francisco Galindo Honrubia[4], Pedro López Cubillana[3], Alfredo Minguela Puras[1]

[1]IMIB-Arrixaca (Immunology Service), Murcia, Spain; *[2]Universidad de Murcia-IMIB, Murcia, Spain*; *[3]University Hospital Virgen de la Arrixaca (Urology Service), Murcia, Spain*; *[4]Universitat Jaume I (Quimica Organica Department), Castellón, Spain*

Purpose: BCG therapy induces a local inflammatory response that is associated with an immune response capable of eradicating residual tumour cells. NK cells play a central role; however, not all patients achieve a response. NKG2A ligands, HLA-B leader peptides presented in HLA-E with dimorphism at position -21 (threonine -T- vs. methionine -M-), impact the survival of bladder cancer patients. Preliminary results from our series show that "M" ligands are associated with poor survival in patients undergoing chemotherapy but with very good survival in patients under BCG, particularly in patients with concurrent KIR2DL5.

Methods: We evaluate whether the M/T ligands could have an impact on nitric oxide production of NK cells from healthy donors and bladder cancer patients in response to BCG. The method used was described in PM 34821904, with the antibody panel: CFSE-FITC, CD45-APC-Cy7, CD3-BV786, CD4-APC, CD16-V450, CD56-PeCy7, CD8-BV605.

Results: In the presence of KIR2DL5, MT patients performed better clinically in the first 3 years of BCG treatment than TT patients. The proportion of patients in whom strong nitric oxide production is induced in NK cells after BCG stimulation is much higher in KIR2DL5+ genotypes. BCG stimulation in both KIR2DL5+ genotypes (TT and Mx) induces a much stronger nitric oxide response in NK-bright cells and CD8+ and CD4+ T cells ($p<0.05$) than in TT genotypes.

Conclusion: Preliminary results from in vitro assays have given us a glimpse that NK cell activation with BCG is associated with higher rates of nitric oxide secretion in M/KIR2DL5+ genotypes, which would explain their better response to BCG therapy. In contrast, the genotypes with the best response to BCG therapy show the worst survival curves in patients with infiltrating tumours who do not receive BCG therapy, and who may have benefited from BCG therapy.

Dengue virus exploits secretory autophagy mechanisms to promote viral dissemination by human dendritic cells

Anusca Rader[1;2;3], Alexandra Cloherty[1;2], Kharishma Patel[1;2], Tracy-Jane Eisden[1;2;4], Sterre van Piggelen[1;2], Renee Schreurs[1;2;3], Carla Ribeiro[1;2;3]

[1]Amsterdam UMC, University of Amsterdam, Department of Experimental Immunology, Amsterdam, Netherlands; *[2]Amsterdam institute for Immunology and Infectious Diseases, Amsterdam, Netherlands*; *[3]Amsterdam Gastroenterology Endocrinology Metabolism, Amsterdam, Netherlands*; *[4]Amsterdam UMC, Vrije Universiteit Amsterdam, Department of Medical Oncology, Cancer Center Amsterdam, Amsterdam, Netherlands*

Dengue virus (DENV), transmitted by infected mosquitoes, is a major public health concern, with half the world's population at risk for infection. Recent decades have increasing incidence of dengue-associated disease alongside growing frequency of outbreaks. Although promising progress has been made in anti-DENV immunizations, post-infection treatment remains limited. Dendritic cells (DCs) are amongst the first human cells to encounter DENV upon injection into the skin mucosa, and thereafter promote systemic viral dissemination. Autophagy is a vesicle trafficking pathway involving the formation of cytosolic autophagosomes, which engulf the cargo for subsequent lysosomal degradation. Recent reports have highlighted the extensive manipulation of autophagy by DENV for viral replication. However, the temporal profiling of autophagy activity and function of autophagy vesicles in DENV infection of human primary DCs remains elusive. Herein, we demonstrate that mechanisms of autophagosome formation and extracellular vesicles (EVs) release have a pro-viral role in DENV dissemination by DCs. We show that DENV exploits early-stage ULK1/ATG16L1-dependent autophagy mechanisms to establish infection in primary human DCs. DENV replication enhanced autophagosome formation in DCs, and intrinsically-heightened autophagosome biogenesis correlated with relatively higher rates of DC susceptibility to DENV. Furthermore, our data demonstrates targeting of viral replication intermediates to autophagosomes, while productive DENV infection institutes a block at the late degradative stages of autophagy in infected DCs but not in uninfected bystander cells. We identify for the first time that approximately one-fourth of DC-derived CD9/CD81/CD63+ EVs co-express canonical autophagy marker LC3, underscoring the relevance of secretory autophagy in DC-mediated intercellular communication. Notably, we demonstrate that DENV hijacks host exocytosis pathways leading up to the release of viral RNA-laden EVs, including extracellular LC3+ autophagy vesicles, by human DCs for viral dissemination to other recipient target cells. Taken together, our study highlights intersections between autophagy and secretory pathways during viral infection, and puts forward cytosolic autophagosome accumulation and release of infectious EVs populations as host determinants of DC-mediated DENV infection in humans. Host-directed therapeutics targeting autophagy mechanisms and EV biogenesis thus have potential to enhance DC-driven resistance to DENV acquisition and thereby limit viral dissemination by initial human target cells following mosquito-to-human transmission of DENV.

IL-2 drives glucose flux through glycolysis and the PPP

Conor de Barra[1], Karen Slattery[1], Geraldine O'Connor[2], Clair Gardiner[1]

[1]Trinity College Dublin, Dublin, Ireland; *[2]University of Central Lancashire, Preston, United States*

Purpose: NK cells are important lymphocyte effector cells that kill cancer cells and virally infected cells. NK cells are activated by cytokines, including IL2, which cause a metabolic reprogramming of the cells towards increases in both glycolysis and oxidative phosphorylation. An alternative TCA-like cycle has previously been shown to be important in *in vitro* expanded murine NK cells. The goal of this work was to undertake an unbiased approach in terms of tracing glucose metabolism in human primary NK cells that were activated for 18 hours with IL2.

Methods: For this study isolated NK cells were left untreated or stimulated with IL-2 (500IU/ml) and cultured with universally labelled glucose to map fate of that glucose in these cells and to measure that relative abundance of metaboilites that are derived from imported glucose. The overall metabolic profile of the NK cells was carried out using metabolomics, while extracellular and intracellular pyruvate and lactate concentrations were determined using commercially available assays.

Results: NK cells utilised glucose for glycolysis and IL2 increased this modestly. There was little evidence of TCA cycle use under these conditions; however, there was evidence to support glucose shuttling into the pentose phosphate pathway (PPP). It was interesting to note that NK cells secreted pyruvate, that has been metabolised from labelled glucose, both at rest and stimulateed with IL-2, in addtion to lactate. This was confirmed by blocking the MCT 2 transporter, via the selective inhibitor VB-124, which reduced the amount of pyruvate in the supernatant.

Conclusion: NK cells metabolised glucose through a variety of pathways including glycolysis and the PPP. The evidence for active secretion of pyruvate by NK cells is of note, as it contrasts reported increased rates of OxPhos in IL-2 stimulated NK cells. Our current research is investing the reason or potential role of pyruvate secretion in NK cells.

miRNA content in subpopulations of NK cell-derived extracellular vesicles connects to different functional activity

Miriam Aarsund[1], Yunjie Wu[1], Tirill Marie Trøften Hagen[2], Kimberly Schell[3], Amanda Sudworth[1], Rachel Crossland[3], Marit Inngjerdingen[1]

[1]*Department of Pharmacology, University of Oslo, Oslo, Norway*; [2]*Oslo Metropolitan University, Oslo, Norway*; [3]*Translational and Clinical Research Institute, Newcastle University, Newcastle-upon-Tyne, United Kingdom*

NK cells release extracellular vesicles (EVs) in response to cytokine stimulation or receptor engagement. These vesicles contain cytolytic proteins, and can induce apoptosis of a wide range of cancer cells. The EV secretome is heterogeneous, and we previously showed that NK cells release distinct vesicles originating from the plasma membrane or from intracellular sources. Only the intracellularly-derived EVs mediate apoptosis of cancer cells. To further understand how these vesicles target and kill cancer cells, we profiled the miRNA expression in EV subpopulations derived from both primary human NK cells and the NK-92 cell line via the NanoString hybridization platform and quantitative PCR. EVs were harvested from NK cells cultured in IL-15 or a combination of IL-12/IL-15/IL-18 for 48 hrs in serum-free culture. We found that miR-22-3p, miR-129-5p, miR-382-3p, and miR-3140-5p appeared enriched in EVs derived from the plasma membrane, while there was an enrichment of miR-16-5p, miR-19b-3p, miR-20a/20b-5p, miR-23a-5p, miR-29b-3p, miR-142-3p, miR-181a-5p, and miR-630 in internally-derived cytotoxic EVs. No major differences were observed when comparing the different cytokine treatments. Bulk, unfractionated EVs were also harvested from primary NK cells activated through the CD16 receptor, and these EVs showed an overlapping profile with the fractionated, internally derived cytotoxic EVs. Target prediction analysis suggested that miRNAs enriched in cytotoxic EVs converge on genes related to apoptosis and TGF-β receptor signaling, and we further show that the cytotoxic EV subpopulation specifically reduced expression levels of *BCL2*, *RICTOR* and *TGFBR1* in the HCT-116 colon cancer cell line. Subjecting HCT-116 cells to miR-16-5p and miR-19b-3p led to increased apoptosis compared to scrambled controls, as well as reduction of *RICTOR*. To conclude, our data indicate that cytotoxic NK-EVs can target cancer cells through miRNA-mediated modulation of anti-apoptotic pathways.

Dissection of neutrophil heterogeneity in glioblastoma

Lucia Zotti[1;2], Francesca Albano[1;2], Eleonora Pace[1], Laura Giordano[1], Simone Puccio[1], Pasquale Persico[1], Matteo Simonelli[1;2], Massimo Locati[1;3], Raffaella Bonecchi[1;2]

Diffuse gliomas are severe brain tumors accounting for 30% of central neural system malignancies. Glioblastoma multiforme (GBM) is one of the most severe form with a very poor prognosis. Its heterogeneity and immunosuppressive nature are the principal causes of failure of different therapeutic approaches, including immunotherapy. Despite the common occurrence of neutrophilia in GBM patients, our understanding of the interplay between neutrophils and cancer remains limited.

The aim of the study is to delineate the phenotype and maturation state of circulating neutrophils, clarifying their role in the tumor microenvironment (TME).

From the analysis of 70 sera of HGG patients we observed no differences in the levels of IL-17 and CCL2, while CXCL8 levels were increased in GBM patients compared to healthy controls. According to these evidence, we choose to focus on the CXCL8-CXCR2 axis to deeper elucidate the role of neutrophils in HGG tumor and find new potential therapeutic approaches.

Our observations revealed high levels of circulating neutrophils in patients with poorer prognosis. However, the neutrophil maturation and activation states emerged as critical factors, indicating that patients with a higher number of immature neutrophils exhibited longer survival. Experiments are ongoing to understand the interplay of immature neutrophils with GBM.

To better investigate the role of neutrophils in this context, we set up an in vivo model of glioma, by the orthotopic injection of the glioma cell line GL261 in WT and neutropenic (CSF3R KO) mice. Our results showed a better survival of CSF3R KO mice compared to WT, suggesting a pro-tumoral role of neutrophils. To further elucidate these findings, we are performing in vivo experiments using the SB28 glioma cell line, known for better recapitulating the immune profile found in human patients.

Further studies are necessary to deepen our understanding of the role of neutrophils in the biology of brain cancer, paving the way for novel therapeutic approaches.

This study is supported by Italian Association for Cancer Research AIRC HFR072 and Ricerca finalizzata KMN242.

Role of PTX3 in Staphylococcus aureus-induced sepsis

Raffaella Parente[1], Francesco Scavello[1], Giada Cassanmagnago[2], Giacomo Iapichino[3], Maria Rita Fumagalli[1], Arianna Felicetta[1], Martina Tagliaferro[3], Alessia Giordano[4], Sonia Valentino[1], Sarah Mapelli[1], Gainluigi Condorelli[1;5], Maurizio Cecconi[3;5], Alessandro Protti[3;5], Dominique Missiakas[6], Cecilia Garlanda[1;5], Alberto Mantovani[1;5;7], Andrea Doni[1]

[1]Humanitas Clinical and Research Center IRCCS, Milan, Italy; *[2]Mario Negri Pharmacological Research Institute IRCCS, Milan, Italy*; *[3]Dept. of Anesthesia and Intensive Care Units, IRCCS Humanitas Research Hospital, Milan, Italy*; *[4]Dept. of Veterinary Medicine and Animal Sciences, University of Milan, Milan, Italy*; *[5]Humanitas University of Milan, Milan, Italy*; *[6]Department of Microbiology, University of Chicago, Chicago, United States*; *[7]The William Harvey Research Institute, Queen Mary University of London, London, United Kingdom*

Background. Sepsis is associated with dysregulated coagulation and impaired fibrinolysis resulting in disseminated intravascular coagulation (DIC), which contributes to multi-organ damage and mortality. PTX3 is a humoral pattern recognition molecule of the innate immune system, which interacts with defense fibrinogens amplifying effector functions of the innate immunity. By interacting with fibrin and plasminogen (Plg), PTX3 regulates injury-induced thrombotic responses and promotes fibrinolysis. In human sepsis, PTX3 is a marker of severity and prognosis, and is associated with altered coagulation parameters.

Objective. To define the role of PTX3 in fibrinolysis in the thrombotic response associated with *Staphylococcus aureus* (SA)-induced sepsis.

Methods. Models of SA-induced sepsis in *Ptx3* targeted mice, 2P-IVM and confocal microscopy, multi-plexed histology, bioinformatic analysis.

Results. In mouse SA-induced sepsis, PTX3-deficiency was associated with increased susceptibility to infection, bacterial dissemination, early abscess formation in major organs with increased fibrin deposits and thrombosed vessels, and death. Circulating parameters of coagulation and multi-organ dysfunction indicators were increased in PTX3-deficient mice, whereas levels of D-dimer were decreased. PTX3 expression was restricted to aorta, lung and heart, associated with PDGFRa^+ mesenchymal cells. PTX3 interacted with Plg in blood and was associated with fibrin deposits in damaged organ parenchyma, SA abscesses and vascular thrombi. In bone marrow chimeric mice, PTX3 resistance to SA was totally dependent on non-hematopoietic cells. The phenotype was recapitulated in *Cre*-inducible mice with selective *Ptx3* deletion in PDGFRa^+ cells. Use of agents targeting coagulation molecules or boosting fibrinolysis rescued the phenotypes.

Conclusion. PTX3 is involved in SA-induced hemostatic response, possibly through regulation of the thrombotic response by promotion of fibrinolysis. These results will be instrumental for the development of PTX3 as a prognostic and therapeutic target in sepsis.

Optimizing bronchoalveolar lavage yield in infectious disease immunology research: a comprehensive review

Hamida Diab[1]

[1]*University Badji Mokhtar -Annaba, Annba, Algeria*

Bronchoalveolar lavage (BAL) is a valuable tool in infectious disease immunology research, providing insights into the local immune response within the respiratory tract. However, optimizing the yield from BAL samples in human participants presents several challenges that must be addressed to maximize the utility of this technique. This abstract offers a comprehensive review of strategies for optimizing BAL yield, focusing on sample collection, processing, and analysis methodologies.

Effective sample collection techniques are crucial for obtaining high-quality BAL specimens. Proper patient preparation, bronchoscope insertion, and lavage fluid recovery are essential steps to minimize contamination and maximize sample yield. Additionally, the choice of lavage fluid and the volume instilled can impact the quantity and quality of recovered cells and soluble mediators.

Optimizing sample processing protocols is equally important for preserving cellular integrity and minimizing artifacts. Standardized procedures for cell isolation, viability assessment, and storage conditions help ensure reproducibility and reliability of experimental results. Furthermore, innovative techniques such as flow cytometry, multiplex cytokine assays, and transcriptomic analysis offer valuable insights into the immune profile of BAL samples.

Infectious disease immunology research often requires specialized analyses to elucidate host-pathogen interactions and immune responses. Integration of BAL data with clinical and microbiological parameters allows for a comprehensive understanding of disease pathogenesis and progression. Moreover, longitudinal studies and comparative analyses across different patient populations enhance the generalizability and translational relevance of findings.

Despite its utility, BAL sample collection in human participants poses ethical and logistical considerations that must be carefully addressed. Informed consent, patient safety, and adherence to ethical guidelines are paramount in conducting BAL procedures. Collaboration between clinicians, researchers, and regulatory bodies is essential for navigating these complexities and ensuring ethical conduct of research involving human participants.

In conclusion, optimizing the yield from BAL in infectious disease immunology research requires a multifaceted approach encompassing sample collection, processing, and analysis. By employing standardized protocols, leveraging advanced methodologies, and adhering to ethical principles, researchers can maximize the utility of BAL samples and advance our understanding of respiratory immune responses in health and disease.

Loss of TLR2 signalling slows retinal degeneration in mouse models of disease

Rachel Dalton[1;2], Ema Ozaki[1;2], Natalie Hudson[3], Matthew Campbell[3], Sarah Doyle[1;2]

[1]Trinity College Dublin, Department of Clinical Medicine, Dublin, Ireland; *[2]Trinity College Institute of Neuroscience, Dublin, Ireland*; *[3]Smurfit Institute of Genetics, Trinity College Dublin, Dublin, Ireland*

Purpose: Age–related macular degeneration (AMD) is the leading cause of blindness in the developed world, estimated to effect 180 million people worldwide. Despite this staggering figure there are few therapeutic options available to patients. Our aim is to use newly characterised mouse models that recapitulate features of AMD and examine the role of TLR2 in this disease progression.

Methods: Claudin 5 (Cldn5) is a tight junction protein that is highly expressed at the inner blood retina barrier. We have shown that suppression of Cldn5 in mice provided a high cholesterol diet can induce dry AMD pathology. Here, we induce Cldn5 deficiency through the use of Cldn5 shRNAs and the Cre-LoxP system. Using these models we investigate the effect of inhibiting TLR2 signalling. TLR2 plays a key role in the innate immune response, however, overactivation of TLR2 can contribute to disease pathology by causing chronic inflammation. Previously we have shown that inhibiting TLR2 is protective against oxidative – damage induced retinal degeneration in an acute model of retinal degeneration. Here we investigate the effect of TLR2 or MyD88 deficiency in this AMD mouse model.

Results: Cldn5 deficient mice show evidence of degeneration in the light absorbing layer of the retina, in addition to mononuclear phagocyte infiltration. The complement membrane attack complex (MAC) is a key effector of the immune system and MAC formation is increased in the choroid of AMD patients. Our findings show increased MAC formation in the retinas of Cldn5 deficient mice. TLR2 deficient mice present with a less severe phenotype, with the light absorbing layer of the retina more intact, and significantly less MAC deposited. Loss of TLR2 signalling also altered the dynamics of mononuclear phagocyte infiltration. Migration assays and chemokine receptor expression suggests TLR2 activation increases immune cell infiltration in this model.

Conclusion: TLR mediated signalling will trigger a robust inflammatory response in the eye. Our findings support the idea that overactivation of the innate immune response is a significant contributor to AMD pathogenesis. Inhibiting TLR2 signalling pathway may represent a powerful target for prevention of RPE degeneration.

Dietary fibre and its metabolites regulate alveolar macrophage transcriptional landscape and alter bone marrow progenitor phenotype

Aishat Azeez[1]

[1]*University College Dublin, Dublin, Ireland*

Inflammatory cells play a major role in the pathogenesis of pulmonary disease. Metabolites from dietary-fibre fermentation, mainly short chain fatty acids (SCFA), can alter alveolar macrophage phenotype and reduce inflammatory cell infiltration through modulation of gene expression. However, they can also affect macrophage progenitor cells from the bone marrow altering the phenotype of bone marrow derived alveolar macrophage that are often present in the lung during inflammation.

Aim: Upon treatment of mice with high-fibre diet (HFiD) and low-fibre diet (LFiD), we aimed to sequence broncho-alveolar (BAL) cell-derived RNA and identify differentially expressed genes *in vivo*. We investigated potential role of SCFA on gene expression in murine alveolar macrophages (MH-S) *in vitro* in homeostasis and inflammation. We also derive bone marrow macrophage (BMDM) from HFiD and LFiD fed mice and investigate effects on polarization.

Method: Cells from mice BALF were processed for RNA sequencing and data mapped to reference genome library by GENEWIZ to obtained differentially expressed genes. MH-S cells was treated with SCFA in homeostasis, LPS and hypoxia induced inflammation and q-PCR to assess gene expression. BMDM from mice fed HFiD and LFiD were polarized, and M1 and M2 markers were assessed using q-PCR.

Result: Alveolar macrophages from mice treated with HFiD and LFiD showed 680 differentially expressed genes, HFiD mice showed upregulation/downregulation of genes (such as NFKBiα, SOCS3) and chemokines that are associated with pathways of ‘resolution of inflammation’ and ‘recruitment and chemotaxis of phagocytes. *In vitro* analysis of SCFA treated MH-S mimic *in vivo* gene expression in homeostasis, while SCFA exhibit differential modulation of genes in LPS, and hypoxia induced inflammation showing condition dependent protective effects. HFiD skewed BMDM towards anti-inflammatory M2 macrophage.

Conclusion: HFiD affects inflammatory cells *in vivo* through modulation of gene expression. We demonstrated that SCFA (acetate, butyrate, and propionate) constitute for this affect through alveolar macrophage as seen *in vitro*. A diet lacking fibre (LFiD) predisposes mice to increased susceptibility to inflammation when challenged with injurious insults.

The effect of Th1 and Th2 cells on properties and transcriptomic profile of mare endometrial stromal cells – an in vitro study

Anna Wójtowicz[1], Agnieszka Sadowska[1], Tomasz Molcan[2], Dawid Tobolski[3], Graca Ferreira-Dias[4;5], Anna Szóstek-Mioduchowska[1]

[1]Department of Reproductive Immunology and Pathology, Institute of Animal Reproduction and Food Research of Polish Academy of Sciences, Olsztyn, Poland; *[2]Laboratory of Molecular Biology, Institute of Animal Reproduction and Food Research of Polish Academy of Sciences, Olsztyn, Poland*; *[3]Department of Internal Diseases with Clinic, Faculty of Veterinary Medicine, University of Warmia and Mazury, Olsztyn, Poland*; *[4]Faculty of Veterinary Medicine, CIISA - Centre for Interdisciplinary Research in Animal Health, University of Lisbon, Lisbon, Portugal*; *[5]Associate Laboratory for Animal and Veterinary Sciences (AL4AnimalS), Lisbon, Portugal*

Purpose: Fibrotic diseases cause about 45% of global premature deaths, yet their molecular mechanisms remain incompletely understood, leading to a lack of effective treatments. Results of recent studies indicate, that Th1 and Th2 cells may play an important role in modulating processes important in the development of fibrosis. However, whether and how these cells affect the key cells for the development of fibrosis – fibroblasts – hides many secrets. In our study, we utilize fibroblasts isolated from mare endometria, providing a non-traditional model of spontaneously occurring fibrosis known as endometrosis. Endometrosis involves fibrosis formation around endometrial glands and in stroma, adversely affecting endometrial structure and function. To better comprehend the role of Th1 and Th2 cells at fibrotic sites, we aimed to assess their impact on the viability, proliferation, and transcriptomic profile of mare endometrial fibroblasts.

Methods: To obtain Th1 and Th2 conditioned media (CM), Th naive cells were isolated from mare's (n=5) peripheral blood and differentiated *in vitro* into Th1 and Th2 cells. Then, mare endometrial fibroblasts (n=4) were isolated, cultured and treated with Th1-CM or Th2-CM for 48 hours. The proliferation and viability of fibroblasts were determined using BrdU and MTT, respectively, while the transcriptomic profile was determined using NGS followed by bioinformatic analyses.

Results: The proliferation and viability of fibroblasts increased after treatment with Th1-CM and Th2-CM ($p<0.05$). The treatment of fibroblasts with Th1-CM and Th2-CM resulted in 2140 and 1033 differentially expressed genes (DEGs; $p_{adj}<0.05$, $log2FC\geq1.0/log2FC\leq-1.0$), respectively. Further functional analysis using the KEGG database revealed, that DEGs identified exclusively after Th1-CM treatment enriched cytokine-cytokine receptor interaction, calcium, and PI3K-Akt signaling pathways. DEGs identified after both Th1-CM and Th2-CM enriched, among others, ECM-receptor interaction, cell cycle, protein digestion and absorption, and JAK-STAT signaling pathway, while Th2-CM changed DEGs enriched the AGE−RAGE signaling pathway.

Conclusion: Th1 and Th2 cell secretome enhances proliferation, viability, and alters transcriptome of mare endometrial fibroblasts, impacting processes linked to fibrosis development. This highlights the necessity for more research to fully grasp their mechanisms and potentially modulate them to mitigate fibrosis development.

The disease with a thousand faces: what's neutrophils' portrait?

Sandrine Huot[1;2], Paul R. Fortin[1;2;3], Cynthia Laflamme[1;2], Philippe Tessier[1;2], Martin Pelletier[1;2], Marc Pouliot[1;2]

[1]Centre de recherche du CHU de Québec-Université Laval, Québec, Canada; *[2]Centre ARThrite-UL, Québec, Canada*; *[3]CHU de Québec-Université Laval - Département de médecine, Québec, Canada*

Purpose: Systemic lupus erythematosus, also referred to as "the disease with a thousand faces", is an autoimmune disease hallmarked by a plethora of autoantibodies, interferon-signature, high levels of immune complexes, dysregulation of soluble factors in circulation, and neutrophils with altered phenotypes. While lupus neutrophils might exhibit inherent detrimental traits, we hypothesized that factors present in the circulation of people with lupus could also be responsible, at least in part, for these alterations. Thus, we investigated the influence of the "lupus environment" on the neutrophils' viability and activation level to understand better what causes the abnormalities observed in lupus neutrophils.

Methods: Blood samples from lupus patients and healthy volunteers were analyzed by flow cytometry for viability and expression of surface markers of interest. Neutrophil-enriched suspensions, freshly isolated from healthy volunteers, were stimulated with serum samples from lupus patients, and apoptosis was monitored in real-time. Plasma from both groups were subjected to multiplex analysis to measure a selection of over thirty analytes. Analytes exhibiting the most significant alterations were identified as lupus-relevant soluble factors. Finally, healthy volunteers' whole blood and isolated neutrophils were stimulated with the lupus-relevant soluble factors or with heat-aggregated IgGs, an antigen-free model of immune complexes, before flow cytometry analysis.

Results: Lupus neutrophils showed significant alterations in the expression of surface markers of the immune complex response, adhesion, complement regulation, and degranulation. These neutrophils also displayed reduced viability and increased apoptosis at 4 hours. Stimulation of normal neutrophils with lupus serum increased apoptosis. Lupus-relevant soluble factors were identified as IL-1β, CXCL12/SDF-1, CCL5/RANTES, CCL2/MCP-1, CXCL10/IP-10, IL-7, and calprotectin. Together, these factors altered neutrophil viability with similar trends to those observed in lupus neutrophils. Stimulation with heat-aggregated IgGs largely reproduced trends in surface marker expression observed in lupus.

Conclusion: This study identifies factors that can alter the viability and the phenotype of lupus neutrophils. Ongoing studies focus on how such alterations can contribute to the implication of neutrophils in the progression of "the disease with a thousand faces".

Circulating levels of Low Density Granulocytes and cell-free DNA as predictors of cardiovascular disease and bone deterioration in SLE patients

Uxía Tobío Parada[1;2], Ana Suárez Díaz[1;2], Javier Rodríguez-Carrio[1;2], Aleida Martínez-Zapico[2;3], Ángel I. Pérez-Álvarez[2;4], Silvia Suárez[2;3], Luis Caminal-Montero[2;3], Patricia López[1;2]

[1]Department of Functional Biology, Immunology Area, Faculty of Medicine, University of Oviedo, Oviedo, Spain., Oviedo, Spain; *[2]Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Oviedo, Spain., Oviedo, Spain*; *[3]Department of Internal Medicine, Hospital Universitario Central de Asturias, Oviedo, Spain*; *[4]Department of Neurology, Hospital Universitario Central de Asturias, Oviedo, Spain*

Purpose: To evaluate the predictive value of low-density-granulocytes (LDGs) for the development of cardiovascular disease (CVD) and/or bone deterioration (BD) throughout the disease course of Systemic Lupus Erythematosus (SLE). Considering the high SLE-LDG capacity to form Neutrophil Extracellular Traps (NETs), circulating levels of cell-free DNA (cirDNA) were tested as an LDG-associated biomarker to identify SLE patients at risk of CVD and BD.

Methods: The frequency of total blood LDGs, as well as the $CD16^{neg}CD14^{neg}$ (nLDG) and $CD16^{pos}CD14^{low}$ (pLDG) subsets, was quantified by flow cytometry in 33 controls and 144 SLE patients. The serum levels of cytokines and bone metabolites were analysed by immunoassays. Total cirDNA and relative amounts of mitochondrial (mtDNA) and nuclear (nDNA) cell-free DNA were measured by fluorometry or qPCR in plasma from a subgroup of 117 patients and 23 controls at enrolment. All the parameters were analysed in relation to the development of CVD and BD in a six-year prospective study.

Results: Increased blood SLE-nLDGs at enrolment were associated with prospective CVD development (pCVD) and the presence of BD. The levels of cirDNA were also increased in patients, especially those presenting traditional CV-risk factors or subclinical atheromatosis, and were directly correlated with C-reactive protein levels, the erythrocyte sedimentation rate, the neutrophil count and triglyceride levels, thus supporting their use as CVD biomarkers. Similar to nLDGs, the nDNA concentration could predict the development of pCVD in SLE. Finally, patients presenting BD during the follow-up period had the highest levels of sclerostin and RANKL, which correlated with the frequency of circulating LDG subsets, cirDNA and/or nDNA.

Conclusion: Our findings highlight the potential role of immature-LDG expansion as a predictor of CVD and BD in SLE evolution and suggest that altered haematopoiesis could underlie both comorbidities in these patients. The present results also support the quantification of cirDNA levels as a surrogate marker of LDGs in clinical practice.

Whole-brain light-sheet and live-cell microscopy to investigate the role of Gαi2 and Gαi3 in cerebral ischemia-reperfusion injury

Ragini Kushwaha[1;2], Bernd Nuernberg[1], Bettina Weigelin[2], Sandra Beer-Hammer[1]

[1]*Institute of Pharmacology, Experimental Therapy and Toxicology, Tuebingen, Germany*; [2]*Werner Siemens Imaging Center, Tuebingen, Germany*

Aim: The project aimed to develop workflows to investigate Gαi2 and Gαi3 isoforms in neutrophils in cerebral ischemia-reperfusion injury using live-cell imaging and whole-brain light-sheet microscopy.

Background: Stroke-induced tissue damage results from two main mechanisms, ischemia and reperfusion injury. Reperfusion mediates an inflammatory response, accompanied by neutrophil infiltration. Non-canonical signalling, mediated by Gαi2 and Gαi3 isoforms, ameliorates reperfusion injury in myocardial tissue, but their role in regulating neutrophil recruitment to infarcted brain tissue remains unclear.

Method: Chemotaxis towards fMLP and CXCL2 gradients was monitored in *Gnαi2*-deficient neutrophils using Ibidi chemotaxis chambers and manual cell tracking. To simulate reperfusion injury in brain, we used the transient middle cerebral artery occlusion model (tMCAO). Immediately following reperfusion, brains were harvested, stained with a 5-marker antibody panel, and rendered transparent using a modified Ethyl Cinnamate-based tissue clearing protocol for 3D reconstruction by light-sheet microscopy.

Results: The genetic ablation of *Gnai2* in neutrophils affected their chemotaxis towards fMLP and CXCL2 in 3D collagen matrices. Interestingly, ablation of *Gnai2* had no impact on the total track length or total distance travelled but eliminated the directed migration of neutrophils towards the chemotactic gradient. To test if *Gnai2*-deletion affects neutrophil infiltration into inflamed brain tissue, we established a whole-brain tissue clearing and light-sheet microscopy workflow to quantify neutrophil infiltration following reperfusion injury after tMCAO with single cell resolution. 3D reconstructions of whole brains were analysed for neutrophil infiltration (Ly6G) and PNC formation (Ly6G – CD42b) in relation to vessel and tissue damage detected by Iba-1 (microglia), wheat germ agglutin (WGA, perfused vessels) and CD31 (all vessels). Ischemic and reperfused brain regions could be clearly delineated based on the WGA/CD31 signal, revealing microglia-covered vessels but sparse neutrophil infiltration immediately after reperfusion.

Conclusion: In summary, genetic ablation of *Gnai2* in neutrophils disrupts directed chemotaxis towards fMLP and CXCL2 in 3D collagen matrices without altering overall motility. Additionally, we established a multiplexed antibody panel and tissue clearing workflow to investigate the effects of Gαi2 on neutrophil infiltration into reperfused brain tissue.

Zymosan-induced trained innate immunity in mice aggravates myocardial infarction

Patricia Kleimann[1], Pascal Bouvain[1], Zhaoping Ding[1], Ulrich Flögel[1], Sebastian Temme[2]

[1]*Department of Molecular Cardiology, Düsseldorf, Germany*; [2]*Department of Anaesthesiology, Düsseldorf, Germany*

Introduction: Zymosan has been used to induce trained innate immunity (TII), which can support the immune response against infectious diseases, but could also exaggerate cardiovascular diseases (CVDs). Here, we investigated the impact of zymosan-induced TII (zTII) on inflammatory and functional consequences after myocardial infarction (MI) in mice.

Methods: C57BL/6 mice were stimulated twice (day -7, -4) with zymosan (or PBS as control) before induction of MI (50 min ischemia/reperfusion). Noninvasive magnetic resonance imaging (MRI) was conducted to assess cardiac function and infarct size (late gadolinium enhancement, LGE). Perfluorocarbon nanoemulsions (PFCs or fluorescently labelled ^{A488}PFCs) were injected intravenously. Immune cell counts and cellular PFC uptake were analyzed by flow cytometry.

Results: Flow cytometric analysis of immune cells in blood, spleen, and bone marrow after zTII revealed increased numbers of neutrophils and monocytes on day 0. Induction of MI (day 0) led to an increased infarct size as well as a reduced ejection fraction (EF) on day 1 in zTII mice. Follow up monitoring of cardiac function by MRI showed a reduced EF and higher end-systolic/-diastolic volume after four weeks. Interestingly, injection of PFCs - which are avidly taken up by phagocytic immune cells that accumulate in inflamed lesions - revealed a significantly reduced ^{19}F signal in the infarcted heart and bone marrow in zTII mice on day 2 post MI. Analysis of immune cell counts showed slightly elevated neutrophil counts in the heart and bone marrow of zTII treated mice. Flow cytometric in vivo and in vitro analyses revealed that PFC uptake by phagocytic immune cells of zTII mice was strongly reduced but could only partly be explained by direct zymosan stimulation.

Conclusion: We show that zTII leads to an increased infarct size and a worse outcome after MI. Reduced ^{19}F signals in the infarcted heart and bone marrow are due to strongly reduced PFC uptake. We conclude that zTII induces functional alterations of phagocytic immune cells, which can be noninvasively detected by ^{1}H/^{19}F MRI, and which may be relevant for the onset, progression and healing after MI or other CVDs.

Immune cell activity during anti-TNF treatment in patients with psoriasis and psoriatic arthritis

Aleksandra Petrovic[1], Victoria Marie Samuelsen[1], Richard Davies[1], Anders Krogh Aarebrot[1], Tim Holmes[1], Irene Sarkar[1], Brith Bergum[2], Roland Jonsson[1], Lene Frøyen Sandvik[3;4], Silje Michelsen Solberg[1;3], Silke Appel[1;2]

Background: Psoriasis is a chronic, inflammatory skin disease characterized by a dysregulated immune response and systemic inflammation. Up to one-third of patients with psoriasis have psoriatic arthritis (PsA). Targeted treatment with antibodies neutralizing tumor necrosis factor (TNF) can ameliorate both diseases. We here explored the impact of long-term infliximab treatment on the composition and activity status of circulating immune cells involved in chronic skin and joint inflammation.

Methods: Immune cells were analyzed by multicolor flow cytometry. We measured markers of immune activation in peripheral blood mononuclear cell (PBMC) populations in 24 infliximab-treated patients with psoriasis/psoriatic arthritis compared to 32 healthy controls.

Results: We observed a significant decrease in the frequency of both peripheral natural killer (NK) cells and their subset $CD56^{dim}CD16^{+}$ NK cells in PsA compared to healthy controls and patients with psoriasis. The latter had a strong positive correlation with psoriasis area and severity index (PASI) in these patients, while $CD56^{bright}CD16^{-}$ NK cells were negatively correlated with PASI. In addition, we observed an upregulation of $CD69^{+}$ intermediate $CD14^{+}CD16^{+}$ and $CD69^{+}$ classical $CD14^{+}CD16^{-}$ monocytes in PsA and increased activity of $CD38^{+}$ intermediate $CD14^{+}CD16^{+}$ monocytes in patients with psoriasis. Compared to healthy controls, psoriasis patients demonstrated shifts of the three B cell subsets with a decrease in transitional $CD27^{-}CD38^{high}$ B cells.

Conclusions: Our exploratory study indicates a preserved pathophysiological process including continuous systemic inflammation despite clinical stability of the patients treated with infliximab.

Sources of contributed support: The flow cytometry analysis was performed at the Flow Cytometry Core Facility, Department of Clinical Science, University of Bergen, Norway. The role of Neutrophil Extracellular Traps in Epidermolysis Bullosa Acquisita

Sripriya Murthy[1], Markus Thieme[1;2], Marie Louise Mueller[1], Lasse Kroeger[1;2], Christian Sadik[1;2]

[1]*University of Luebeck, Luebeck, Germany*; [2]*University Hospital Schleswig Holstein, Luebeck, Germany*

Purpose: Epidermolysis bullosa acquisita (EBA) is an autoimmune blistering disease (AIBD) clinically characterized by erosions and blisters. EBA is caused by autoantibody against type VII collagen, and its skin lesions feature a marked infiltration of neutrophils into the dermis. Release of reactive oxygen species (ROS) and neutrophil extracellular traps (NET) are among the effector functions of neutrophils which contribute to tissue damage and the resulting inflammation in AIBD. NET formation has been shown to be dependent on ROS generation by NADPH oxidase and chromatin decondensation relying upon the enzymes peptidylarginine deiminase 4 (PAD4), neutrophil elastase (NE), and myeloperoxidase (MPO). This study examines the role of these key players in EBA.

Methods: To provide preclinical proof for the role of neutrophil effector functions during the disease, a mouse model for bullous pemphigoid (BP)-like EBA was utilized. *In vitro,* the study was conducted using bone marrow derived neutrophils stimulated with immune complexes (IC). WT controls were compared to *Rab27a*$^{-/-}$, *Mpo*$^{-/-}$, *NE*$^{-/-}$, and *Padi4*$^{-/-}$ mice.

Results: While WT mice displayed the expected disease progression, and lesional skin stained positive for Ly6G and CitH3, indicating the involvement of NETs, *Mpo*$^{-/-}$ mice were completely protected and did not develop skin lesions or show signs of neutrophil infiltration. Absence of PAD4 or Rab27a did not alter disease severity. *In vitro,* absence of Mpo and Rab27a correlated with a significant reduction in ROS release, NET formation, and leukotriene B_4 (LTB_4) release. These differences were not observed in the absence of NE or PAD4. The specific role of MPO in the inhibition of ROS and formation of NETs could be confirmed by use of PF-1355, a mechanism-based inhibitor of MPO.

Conclusion: Taken together, our results provide evidence that among the various key players of NET formation, MPO plays a crucial role in EBA. The mode of action may be attributed to the inhibition of two disease driving forces, ROS release and NET formation, and release of LTB_4.

Investigating the autoimmune response in myocarditis and myocardial infarction

Adam B. Lokman[1], Maria-Alexa Cosma[1], Sarah J. R. Sigal[1], Christophe Ravaud[1], Paul R. Riley[1]

[1]*Institute of Developmental and Regenerative Medicine, University of Oxford, Oxford, United Kingdom*

Purpose: Autoimmunity is becoming a more recognised sequalae following myocardial infarction(MI), where exposure of the adaptive immune system(AIS) to released cardiac antigens exacerbates the inflammatory response. This leads to detrimental remodelling and ultimately heart failure(HF). This phenomenon is more pronounced when an underlying inflammatory disorder is present (ie.myocarditis). We have previously shown in mouse models that specific enhancement of cardiac lymphatics post-MI improves cardiac function, partly due to clearance of innate immune cells (macrophages and dendritic cells(DCs)) from the heart. The interplay between the innate and AIS in this context, however, is poorly understood. We have determined the profiles of adaptive immune cells in mice post-MI that spontaneously develop myocarditis due to T-cells specifically expressing functional receptors to cardiac antigen alpha-myosin heavy chain(αMHC;TCRM) and have begun to manipulate their interactions in draining lymph nodes to prevent T-cell activation and autoantibody production through targeted lymphatic-based clearance from the injured heart.

Methods: Permanent ligation of the left anterior descending artery was performed on anaesthetised wild-type(WT) BALB/c mice or TCRM mice (8-12 weeks). For sham controls, surgical procedure was equivalent minus ligation. The heart and mediastinal lymph nodes(MLN) were harvested 7-days post-MI(7dpi) for processing.

Results: 7dpi, significant enlargement of the heart was observed in MI models versus sham for both mouse groups. A significant inflammatory response was observed in hearts of TCRM mice, especially following MI – with a 4-fold increase in conventional-type 2 DCs(cDC2s) and 5-fold increase in effector CD4+ T-helper cells(eTh) compared to WT. The autoimmune response was elevated in MLNs of TCRM mice – with a 2-fold increase in both cDC2s and eTh, and a trending increase in plasma B-cells compared to WT.

Conclusion: Our studies to-date confirm that activated DCs migrate from the injured heart to MLNs resulting in activation of the AIS and recycling of auto-activated T-cells back to the heart. This is further augmented in the TCRM background sensitised to αMHC. Studies are ongoing to determine how precocious enhancement of cardiac lymphangiogenesis post-MI may traffic immature, non-antigen presenting DCs to blunt crosstalk with T-cells in MLNs, preventing the autoimmune component of chronic MI/HF.

Obesity comprises tissue repair by altering type 2 immunity

Lea Semmler[1], Inaya Hayek[1], Andrea Deinzer[1], Christian Schwartz[1;2]

[1]*Institute of Microbiology – Clinical Microbiology, Immunology and Hygiene; Universitätsklinikum Erlangen and Friedrich-Alexander-University (FAU) Erlangen-Nürnberg, Erlangen, Germany*; [2]*FAU Immunomedicine (FAU I-MED), Erlangen, Germany*

Purpose: Obesity represents an evolving global health concern. In addition to well-known comorbidities like cardiovascular diseases and metabolic diseases, obesity is associated with impaired wound healing and drastic changes to the immune cell homeostasis resulting in a constant low-grade type-1/-17-dominated inflammation in both the adipose tissue and the periphery. Therefore, we hypothesize that the impaired wound healing response during obesity is due to a disruption of the type 2 immune response.

Methods: In order to investigate the immune-mediated tissue repair response during obesity, transient lung damage in control-diet fed and high-fat diet-induced obese mice was induced using *Nippostrongylus brasiliensis* infection or papain treatment. Different stages of tissue repair (early damage, acute immune response and late wound healing) were investigated using flow cytometry to characterize infiltrating immune cells, histological analysis for the evaluation of the wound healing progress and ELISAs to evaluate immune cell functionality.

Results: Characterization of immune cells participating in wound healing revealed changes during early immune responses in the lung comparing control-diet fed and high-fat diet-fed animals in both models. In particular, major changes in T cell and macrophage polarization as well as granulocyte recruitment in obese animals were observed. Notably, the acute immune responses in the lung led to long-lasting changes in the immune cell composition within the abdominal white adipose tissue (WAT). ILC2, dendritic cells, eosinophils as well as Th2 cell numbers were still altered long after the primary immune response against the helminth had subsided and the infection was cleared. Similar long-term effects were detected in the WAT immune cell compartment of papain-treated mice.

Conclusion: In summary, our study highlights the detrimental effects of obesity on immune cell behaviour that contribute to compromised tissue regeneration in mice. Long-term effects in the immune cell composition of WAT might be an interesting basis for investigation of subsequent tissue repair and associated immune responses. In our future investigations, we aim to translate these findings with clinical samples obtained from persons living with and without obesity.

Modulating effect of astaxanthin in mouse model of osteoarthritis

Blagovesta Todorova[1], Nikolina Mihaylova[1], Andrey Tchorbanov[1]

[1]*Institute of Microbiology, Bulgarian Academy of Sciences, Sofia, Bulgaria*

Purpose: As one of the most common arthropathies – osteoarthritis (OA) is age related, slowly progressive, condition, affecting more than 240 million people worldwide. The physical manifestations of OA include pain, stiffness, locomotor restriction, bony enlargement, swelling of affected joints, impaired function. Moreover, wear and tear on the joints resulted in bone remodeling, osteophyte formation, fibrosis hyperplasia of the synovial membrane, and damage or loss of articular cartilage. The currently used therapies include pain relieving medicines, non-steroidal anti-inflammatory drugs, and topical therapies. The aim of the study is to investigate the anti-inflammatory and anti-arthritic effects of Astaxanthin (ASTA), a natural keto-carotenoid classified as a xanthophyll, in the collagenase-induced mouse model of osteoarthritis (CIOA).

Methods: Balb/c mice were injected intra-articularly with Collagenase type IA for induction of osteoarthritis. The animals were treated with 40mg/kg ASTA *per os* daily. The effect of the ASTA therapy was evaluated by FACS analysis of synoviocytes, splenocytes, and macropahages, the differentiation of bone marrow-derived osteoclasts and osteoblasts, and the histological assessment of histopathological alterations.

Results: The daily suplementation of 40mg/kg ASTA leads to the reduction of osteoarthritis-associated joint histological manifestations, and improvement of the knee joint remodeling process, confirmed by the evidence of the formation of multinucleated osteoclast-like cells and osteoblasts. The flow cytometry analysis showed a reduction in pro-inflammatory immune cell subtypes.

Conclusion: The animals fed with ASTA showed improved disease symptoms and positive effects on the control and restriction of the disease progression. The results show the potential of the ASTA as the supplement to the main therapy of patients with osteoarthritis.

This study is funded by the Bulgarian National Science Fund with grand № КП-06-Н33/8 - 16.12.2019.

The impact of miR-21 on epithelial intercellular junctions influencing gut inflammation and barrier repair

Kevin Mercurio[1], Sinéad Corr[1;2]

[1]Moyne Institute of Preventive Medicine, Trinity College Dublin, Dublin, Ireland; *[2]APC Microbiome Ireland, University College Cork, Cork, Ireland*

Purpose: Inflammatory bowel disease (IBD) is an autoimmune disease of chronic inflammation along the gastrointestinal tract. In the gut, intestinal epithelial cells (IECs) react to changes in the gut environment impacting the abundance of gut microbes, thus affecting gut permeability via key barrier points like intercellular junctions. These tactics can be regulated by microRNAs, short nucleotides that bind to target mRNA and impact protein synthesis. Of focus to this project is microRNA-21 (miR-21), an oncomiR upregulated in IBD and previously shown to target epithelial tight junctions like occludin and Zo-1, thereby increasing barrier dysfunction. However, the molecular mechanisms underlying this phenotype of barrier permeability and repair via intercellular junctions remain inconclusive.

Methods: To evaluate the impact of colitis on direct and indirect miR-21 targets *in vivo*, WT and constitutive knockout mice (miR-21$^{-/-}$) were subjected to DSS-induced colitis. In addition, to assess the consequence of selective miR-21 modulation, we employed an *in vitro* system using the human adenocarcinoma cell line Caco-2 to model the intestinal epithelium. Tissue samples and cell lysates underwent molecular analyses for differential gene expression (qRT-PCR) and protein abundance (fluorescence microscopy) of intercellular junction components.

Results: We show *in vivo* that both basal and dextran sulfate sodium (DSS)-inflamed colonic tissue from miR-21$^{-/-}$ mice have greater expression levels of several tight and adherens junction genes compared to wild type controls, and these were upregulated in other murine intestinal regions. Interestingly, fixed colonic tissue from miR-21$^{-/-}$ mice showed elevated levels of E-cadherin at the top of intestinal crypts. Further isolating IECs from healthy miR-21$^{-/-}$ mice demonstrated an upregulation of claudin-4. Additionally, we demonstrate *in vitro* that selectively modulating miR-21 levels impact the levels of junction components in a predictable manner.

Conclusion: miR-21 plays a regulatory role over IEC intercellular junctions, which dictate paracellular transport, cell adhesion and cell-cell communication. Modulating the levels and function of E-cadherin and tight junction proteins can reduce susceptibility to inflammation and improve mucosal barrier repair during IBD. Importantly, this work elucidates the negative impact of miR-21 over the stability and protection provided by the gut epithelium.

Purpose: Infertility is considered a major problem of the modern-day life with up to 12% of couples affected worldwide. Inflammation-induced testicular damage plays a substantial role in the rising prevalence of infertility. Disappointingly, conventional therapies, often employed during the inflammatory stage, fail to rescue fertility, highlighting the need for pioneering interventions like cell therapy. We have identified Sertoli cells (SCs) as a promising candidate. SCs are crucial for the nourishment, support, and development of sperm cells within the testicular niche. Recently, we have confirmed that SCs possess stem cell-like properties including their immunomodulatory function.

Methods: In this study, we employed an *in vivo* mouse model of acute lipopolysaccharide-induced inflammation and analysed the potential of intravenously administered SCs to alleviate testicular inflammation. Flow cytometry was used to assess the phenotypes of infiltrating and resident myeloid cells. The presence of pro- and anti-inflammatory cytokines in the serum and testicular homogenate was assessed by ELISA. Furthermore, computer-assisted sperm analysis (CASA) and immunohistochemistry were utilized to assess the germ cell quality along with the morphology of the testes.

Results: Intravenously administered SCs showed anti-inflammatory activity *in vivo*. They showed a distinctive migratory pattern, and preferentially accumulated within the testes and liver. Administration of SC resulted in reduced neutrophil infiltration but maintained macrophage population within the testis. Furthermore, the expression of MerTK on testicular macrophages was upregulated. Most importantly, the administration of exogenous SC into an inflammatory model exhibited protective effects on sperm cells, restoring their motility and preserving the physiological morphology of the testes.

Conclusion: Our research provides compelling evidence for the therapeutic effectiveness of SC transplantation in mitigating testicular damage induced by acute inflammation. Hence, highlighting the potential of cell therapies as a novel targeted intervention for male infertility.

Dysregulation of type 2 immune responses and microbiota in patients with obesity

Jule Gawor[1], Inaya Hayek[1], Christian Schwartz[1;2]

[1]*Institute of Microbiology - Clinical Microbiology, Immunology and Hygiene; Universitätsklinikum Erlangen and Friedrich-Alexander-University (FAU) Erlangen-Nürnberg, Erlangen, Germany*; [2]*FAU Immunomedicine (FAU I-MED), Erlangen, Germany*

Purpose: Obesity, as one of the most important medical challenges worldwide, is a well-known risk factor for the development of many comorbidities, such as hypertension, diabetes mellitus, or cancer. Moreover, people with obesity (PWO) are more prone to develop surgical wound infections, which can become chronic due to impaired wound healing responses representing severe postoperative complications. Importantly, obesity is associated with a chronic low-grade local and systemic inflammation as well as alterations in gut microbiome composition, both of which affect proper immune function. We therefore hypothesise that tissue repair and wound healing are -at least in part- caused by changes of the microbiome and the altered type 2 immune response in PWO.

Methods: Blood and stool samples were collected from PWO before and after bariatric surgery and analysed in comparison to lean, healthy individuals. To assess alterations in the immune response, the frequencies of different immune cell populations were analysed by flow cytometry. Macrophages, T cells and eosinophils were isolated and cultured to examine polarization capacity, proliferation status and functionality by using qPCR and ELISA. To detect differences in the gut microbiome, stool samples were examined by 16S rRNA metagenomic analysis. We also analysed microbiome and immune cell composition of visceral adipose tissue from PWO and lean controls undergoing reflux surgery in regard to inflammatory conditions.

Results: We observed important changes in composition, functionality and interaction of immune cells, when comparing blood and stool samples from lean and obese individuals. In particular, T cell and macrophage polarisation as well as eosinophil activity were affected by obesity. We have analysed the effects of bariatric surgery and subsequent weight loss on various cell subsets both systemically and locally in adipose tissue. Additionally, we examined the composition of the gut microbiome. Our findings suggest a direct relationship between the loss of specific gut microbes and low-grade tissue inflammation in PWO.

Conclusion: Our results indicate that both the microbiome and polarization capacity and activation are altered in PWO, which may lead to impaired immunity and wound healing. Thus, our data contribute to a deeper understanding of the microbiome-immune axis to avoid surgical site infections.

Orthotopically transplanted organoids closely recapitulate human colonocytes in vivo

Annika Hausmann[1], Frederik Post[2], Andreas Mund[2], Casper Steenholdt[3], Ole H. Nielsen[3], Matthias Mann[2], Kim B. Jensen[1]

[1]reNEW - NNF Center for Stem Cell Medicine, Copenhagen, Denmark; [2]NNF Center for Proteome Research, Copenhagen, Denmark; [3]Herlev Hospital, Copenhagen, Denmark

The intestinal epithelium plays a central role in human health and disease, and several chronic inflammatory disorders associate with a weakened epithelial barrier. The organoid model allows the cultivation, expansion and analysis of non-immortalized intestinal epithelial cells and has been instrumental in studying epithelial behavior in homeostasis and disease. Recent advances in human organoid transplantation into mouse and human lay the base for models to study human epithelial cell behavior within the intestinal tissue context, and promise novel therapeutic approaches for diseases such as short bowel syndrome and inflammatory bowel disease. It remained unclear how organoid transplantation into the colon would affect epithelial phenotypes and protein expression, which is key to assess the suitability of this model to study human epithelial cells *in situ* and as a therapeutic approach. To address this, we employed Deep Visual Proteomics, which utilizes AI-guided cell classification on high-resolution images, microdissection, and high-sensitivity proteomics, on human colonic epithelial stem and differentiated cells *in vivo*, upon transplantation *in situ*, and organoids cultured *in vitro*. We find that organoids transplanted into the murine colon closely resemble human intestinal epithelial cells *in vivo* compared to organoids grown *in vitro*, indicating that organoid culture induces a transient shift in epithelial phenotypes, which is reversible upon reintroduction into the mucosa. Phenotypic differences between epithelial cells *in vitro* and *in situ*/*in vivo* were largely driven by hallmarks of high proliferation and lower functional differentiation in organoids due to culture conditions. Taken together, we demonstrate that transplanted epithelial cells *in situ* represent a physiological, relevant model for studying functional aspects of mature colonocytes compared to the organoid model.

Lymphatic emigration of pro-tolerogenic human epidermal Langerhans cells after tick feeding and tick-borne pathogen transmission

Lisa Kleissl[1;2], Johanna Strobl[1;2], Michiel Wijnveld[3], Sophie Müller[1], Sophie Weninger[2], Aglaja Kopf[1;2], Sally Connolly[4], Laura Marie Gail[1;2], Christian Freystätter[5], Mateusz Markowicz[6], Herbert Strobl[4], Hannes Stockinger[3], Georg Stary[1;2]

[1]CeMM Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria; *[2]Department of Dermatology, Medical University of Vienna, Vienna, Austria*; *[3]Institute for Hygiene and Applied Immunology, Center for Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria*; *[4]Otto Loewi Research Center, Chair of Immunology and Pathophysiology, Medical University of Graz, Graz, Austria*; *[5]Department of Plastic and Reconstructive Surgery, Medical University of Vienna, Vienna, Austria*; *[6]Austrian Agency for Food and Health Safety (AGES), Vienna, Austria*

Langerhans cells (LCs) are the first antigen presenting cells that respond to environmental stimuli including pathogens and may induce immunity or tolerance at the epidermal skin barrier. Here, we investigate the migration and polarization patterns of human LCs in response to clinical and experimental tick bite as well as skin infection with *B. burgdorferi* (acute Lyme borreliosis) using flow cytometry, functional assays, multi-color imaging and single-cell RNA sequencing.

We observed strong emigration of epidermal LCs after tick feeding on human skin and in an *in vitro* experimental tick bite model using tick saliva (TS) injection. Consequently, LCs were increased in the dermis, especially in proximity to dermal lymph vessels. Upon tick bite, LCs over-expressed the migration marker CXCR4 and the lymph node homing molecule CCR7, indicating their capability for lymph node homing. In line with this, LCs stimulated with TS showed increased potential to emigrate from epidermal sheets and invade towards collagen gels supplemented with the CCR7-ligand CCL19. Similarly, acute Lyme borreliosis skin harbored activated LCs expressing CXCR4 and CCR7. Interestingly, monocyte-derived LCs exposed to TS or infected with *B. burgdorferi* exhibited a tolerogenic phenotype characterized by the upregulation of the transcription factors IDO1 and IRF4, when compared to uninfected cells. In contrast, LCs exposed to *S. aureus* infection induced a strong immunogenic response. This could be verified by single-cell RNA sequencing of patients with Lyme borreliosis, where lesional LCs exhibited increased expression of *IRF4, IDO1* and *IL4I1* compared to LCs from healthy skin of the same individuals. Accordingly, when co-cultured with autologous, naïve CD4+ T cells, moLCs pulsed with TS or *B. burgdorferi*, skewed T cell polarization towards regulatory T cells indicating impaired adaptive immune response.

Collectively, our results indicate that tick-feeding induces emigration of LCs to the lymphatic system and a skewed T cell polarization by tolerogenic LCs, which may result in impaired adaptive immune response to tick-borne pathogens. These findings explain the low immunogenic response and high transmission rates of Lyme disease and other tick-borne infections observed in human skin.

Targeting NPM1 epigenetically reprograms macrophage metabolism to facilitate post-infarction cardiac repair

Sheng Zhang[1;2], Zhenzhen Zhan[3]

[1]Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; *[2]Tongji University School of Medicine, Shanghai, China*; *[3]Shanghai Institute of Transplantation, Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China*

Background: Reparative macrophages play a crucial role in limiting excessive inflammatory responses and promoting cardiac repair after myocardial infarction (MI). Thus, timely and proper transitions of macrophage phenotypes are essential for effective wound healing post-MI. Nonetheless, the mechanisms that governing this transformation are not well-defined.

Objectives: To explore the function and mechanisms of macrophage NPM1 in orchestrating cardiac repair post-MI.

Methods: Peripheral blood mononuclear cells (PBMCs) were collected from healthy individuals and patients with MI to analyze NPM1 expression and its correlation with prognostic indicators of MI. A mouse strain with macrophage-specific knock-out of NPM1 was developed to observe the effect of NPM1 deficiency. Metabolomic profiling was used to analyze the influence of NPM1 deletion on metabolic patterns. Transcriptomic sequencing combined with Cut&Tag was used to analyze the epigenetic mechanisms by which NPM1 regulates macrophage metabolic remodeling.

Results: Firstly, we found that the expression of NPM1 in the PBMCs of MI patients was higher compared to that in healthy individuals, and it showed a positive correlation with indicators of prognosis. Deleting NPM1 specifically in macrophages significantly lessened cardiac fibrosis, encouraged angiogenesis, enhanced cardiac performance, and prevented ventricular remodeling in mice with MI. Additionally, the elimination of NPM1 promoted the reparative phenotype and function of macrophages by increasing mitochondrial oxidative phosphorylation and reducing glycolytic pathways. Mechanistically, NPM1 was observed to bind directly to the promoter region of *Tsc1*, recruiting KDM5b to diminish H3K4me3 modifications, suppressing TSC1's transcriptional activity, blocking mTOR signaling activation, and leading to metabolic reprogramming in macrophages. Both antisense oligonucleotides targeting NPM1 and inhibitory agents against NPM1 showed significant protective effects on cardiac repair following MI.

Conclusion: Our findings indicate that NPM1 participates in the metabolic reprogramming and phenotypic transition of macrophages after MI through epigenetic mechanisms, impeding the repair of cardiac injury and the recovery of cardiac function.

SLAMF7 expression of peripheral monocytes in patients with rheumatoid arthritis

Hannah R. Spatzier[1], Kathrin Rothe[1], Laurin Braune[1], Anne-Marie Glimm[1], Phuong Nguyen[1], Olga Seifert[1], Marco Krasselt[1], Matthias Pierer[1], Ulf Wagner[1]

[1]*University of Leipzig, Department for Endocrinology, Nephrology and Rheumatology, Leipzig, Germany*

Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease of unknown etiology and a complex pathogenesis. Ongoing inflammation results in phenotypic and functional alterations of various immune cell populations. SLAMF7 (also known as CRACC), a typical nk cell receptor, can induce a stimulatory or inhibitory signal in the cell and thereby regulate immune cell functions. For RA monocytes, SLAMF7 has been shown to support activation and induce inflammation, but the SLAMF7-specific function of monocyte subpopulations, classical (CD14+CD16-), intermediate (CD14+CD16+) and non-classical (CD14-CD16+), are not known so far.

Methods: RA Patients and healthy donors (HD) were recruited and clinical parameters, e.g. serum C-reactive protein (CRP) levels and anti-citrullinated protein antibodies (ACPAs) levels were assessed. Disease activity score 28 was determined to evaluate disease activity. Peripheral blood mononuclear cells (PBMCs) were isolated and CD14/CD16 and SLAMF7 expression was determined by flow cytometry. For functional in-vitro assays, monocytes were isolated and stimulated with and without SLAMF7-specific antibody and analyzed for cytokine production using ELISA.

Results: First results show a general decreased SLAMF7 expression on RA monocytes (n=19) compared to healthy controls (n=22). Within the subpopulations, SLAMF7 is mainly expressed on CD16+ non-classical monocytes in RA as well as in HD (mean: 57,8 % and 53,3 % SLAMF7+), but the SLAMF7 expression level was significant lower on CD16+ RA than CD16+ HD monocytes. Furthermore, The increased frequencies of SLAMF7+CD16+ monocytes are associated with age in HD (n=22; r=0,37), but not in RA. However, in RA, frequencies of SLAMF7+CD14+ monocytes are associated with high disease activity (n=15,r=0.63; p=0.01).

Conclusion: We are the first to show a SLAMF7 expression on peripheral blood monocyte subpopulations. SLAMF7+ is mainly expressed of CD16+ monocytes, which seems to be a feature of a healthy aging process that is disturbed in RA. In contrast, frequency of SLAMF7+CD14+ classical monocytes are associated with high disease activity. Because SLAMF7+ monocytes might play a stimulatory role, blocking of SLAMF7 in RA could avoid inflammatory processes.

The Fibrin-derived Peptide Bβ15-42 (FX06) Protects Human Pulmonary Endothelial Cells Against COVID-19-Triggered Cytokines

Zhiran Wang[1], Vadim Zhernovkov[1], Kevin Wu[1], Dmitrii Lebedev[1], Kieran Wynne[1], Alfonso Blanco[1], Jeremy Simpson[1], Margaritha M. Mysior[1], Petra Wülfrot[2], Walter Kolch[1], Günther Eissner[1]

[1]UCD, DUBLIN, Ireland; *[2]F4 Pharma, Vienna, Austria*

Objectives: Coronavirus disease 2019 (COVID-19), caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), has been a major health emergency since 2019. Endothelial dysfunction is a hallmark of COVID-19, which leads to severe illness, i.e. multi-organ failure, coagulopathy, and death. FX06, a fibrin-derived peptide naturally occurring in the human body, formerly known as $B\beta_{15-42}$, protects the vasculature in myocardial ischemia-reperfusion in animal models and clinical trials. Therefore, it is a promising therapeutic candidate for endothelial complications like capillary leak in COVID-19 and other forms of acute respiratory disorders. This project aims to investigate *in vitro* whether FX06 can help to prevent COVID-19 progression.

Methods: To mimic the inflammatory status of COVID-19, cells from a human pulmonary endothelial cell line (ECs) were treated with a cytokine cocktail comprised of ten different cytokines or chemokines at concentrations found in COVID-19 patients' serum profiles. ECs were cultured under both static and shear stress/laminar flow conditions and treated with the cytokine cocktail for 24h, in the absence or presence of FX06 for 2h.

Results: Under both static and shear stress conditions, the COVID-19-triggered cytokine cocktail increased the adhesion and migration of Peripheral Blood Mononuclear Cells (PBMCs) through the endothelial monolayer. This deleterious effect was significantly reduced by FX06. FX06 was shown to mitigate the cytotoxic activity of CD8+ T cells, which increases upon cytokine treatment. Interestingly, FX06 did not protect ECs from cytokine-triggered apoptosis and necrosis, suggesting that restoration of vascular integrity is caused by cytoskeletal reorganisation rather than cellular rescue. Cytokines promote RhoA expression and actin polymerisation, while FX06 treatment reverses cytokine-induced RhoA overexpression and causes morphological changes in F-actin (stress) fibres. Additionally, FX06 restores continuous VE-cadherin/CD144 distribution on the EC surface after disruption by the cytokine cocktail.

Conclusions: FX06 shows great potential in reducing vascular leakage to protect the endothelium against the proinflammatory effect of COVID-19-triggered cytokines. The investigation of immunological markers in ECs will further advance our understanding of the mechanism of action of FX06 and its potential to counteract systemic endothelial inflammation and disease progression.

ICOS/ICOSL/OPN in tissue repair: enhancing wound healing with ICOS-Fc treatment

Foteini Christaki[1], Deepika Pantham[1], Amirabbas Ghasemi[1], Reza Abouali[1], Umberto Dianzani[1], Ian Stoppa[1]

[1]*Univerisy of Piemonte Orientale, Novara, Italy*

Background/Purpose: ICOS is a T cell co-stimulatory receptor that binds ICOSL expressed on various cell types. ICOSL also binds osteopontin (OPN), acting as both extracellular matrix protein and cytokine. ICOSL triggering by ICOS or OPN exert different, often opposite, effects on the cell expressing ICOSL, modulating cell migration, angiogenesis and inflammation. In tumours, activation of ICOSL by ICOS-Fc, a recombinant protein comprising the extracellular portion of ICOS fused with IgG1 Fc domain, inhibits cell migration, metastatization and angiogenesis. OPN-triggered ICOSL activation yields contrasting outcomes. Recently, we found that ICOS-Fc improves wound healing in normal skin, enhancing angiogenesis and modulating inflammatory infiltrate. The aim of this work was to extend the analysis to include mice deficient in either ICOS, ICOSL, or OPN, as well as those dually deficient in ICOS/ICOSL, ICOS/OPN, or ICOSL/OPN.
Methods: Skin wounds were induced in C57BL6/J wild type (WT) and the knockout mice cited above (n=4–7 mice per condition-experiment). Mice were treated locally with either PBS or ICOS-Fc and wound healing was monitored for 10 days. Some mice were sacrificed from day 1 to 4 for histological and molecular analyses.
Results: In comparison to WT mice, ICOS-, ICOSL-, OPN- and ICOS/ICOSL -/- dual deficient mice exhibited impaired wound healing, whereas wound healing appeared normal in mice dually deficient in ICOS/OPN or ICOSL/OPN. Treatment with ICOS-Fc ameliorated healing in all mice strains except for those lacking ICOSL (i.e. ICOSL-, ICOS/ICOSL-, ICOSL/OPN -/-). More specifically, the treatment enhanced fibroblast migration, angiogenesis, and immune cell migration on day 3 and day 4 in WT mice and all single knock out mice, without increasing collagen deposition.
Conclusion: These data show that the ICOS/ICOSL/OPN network is involved in wound healing. Surprisingly, healing is defective in the mice carrying an unbalanced mechanism, but not in those whose system is completely unfunctional (i.e. ICOS/OPN and ICOSL/OPN deficient mice). Overstimulation of ICOSL by ICOS-Fc improves healing in all mice expressing ICOSL by exerting effects different from those exerted in tumours.

Characterising potential tissue-protective roles of the BTNL-γδ T cell axis in relation to dietary tissue stress

Vivien Mülheims-Kohlhaas[1], Cara Brown[1], Adrian Hayday[1]

[1]*Francis-Crick Institute, London, United Kingdom*

The intestinal Butyrophilin-like (BTNL)-γδ T cell axis appears highly conserved: human BTNL3+BTNL8 expressed by colonocytes regulates Vγ4+ intraepithelial lymphocytes (IEL), while Btnl1+Btnl6 expressed by mouse enterocytes selects and maintains Vγ7+ IEL. Consistent with IEL being tissue-protective, BTNL3/8 hypomorphism is a risk factor for human inflammatory bowel disease (IBD) severity. Given that high fat intake also disposes to IBD, we hypothesise that dietary stress is a major stimulus triggering the tissue-protective response of the BTNL-gd axis so as to limit progression to severe inflammatory disease. This hypothesis is further supported by evidence from mice that γδ T cells regulate dietary adaptation. Based on this, we are developing a new mouse model of IBD based upon the potential synergy of high-fat diet (HFD) and hypomorphism at the BTNL-γδ T cell axis. Currently, we are examining the impact of HFD on the epithelial expression of BTNL (and other) molecules and on the immunophenotypic and transcriptomic status of Vγ7+ IEL. Thereafter, the physiologic impact of combined defects in the BTNL-γδ T cell axis and HFD, respectively, will be assessed.

Deregulated pIgR contributes to steatotic liver disease via systemic IgA accumulation

Dragana Rajčić[1], Constanze Höbinger[1], Tim Hendrikx[1]

[1]*Department of Laboratory Medicine, Medical University of Vienna, Vienna, Austria*

Purpose: While IgA is the predominant antibody in the gut where it plays a crucial role in mucosal immunity, increased systemic IgA titers have been shown to propagate steatotic liver diseases (SLD). Yet, the mechanism that contributes to increased circulatory IgA during SLD is currently unknown. Given that IgA levels are regulated by the polymeric immunoglobulin receptor (pIgR), transporting it across intestinal epithelium and hepatic canaliculi, our aim was to elucidate the function of pIgR-dependent IgA secretion in the context of steatohepatitis.

Methods: IgA and *pIgR* levels were determined in different segments of the gut-liver axis of wild-type mice fed chow or methionine- and choline-deficient (MCD) diet for 4 weeks to induce murine SLD. Further, IgA was assessed in serum and stool of biopsy-proven metabolically-associated SLD (MASLD) patients. Next, wild-type (*Wt*) and *pIgR*-deficient (*pIgR*$^{-/-}$) mice, as well as *Wt* and *pIgR*$^{-/-}$ mice transplanted with IgA-deficient bone marrow, were fed MCD diet to investigate the causal role of IgA accumulation during *pIgR*-deficiency in steatohepatitis.

Results: Increased systemic IgA in murine steatohepatitis correlated with reduced *pIgR* expression in the liver, suggesting dysfunctional hepatic IgA secretion. In contrast, increased *pIgR* in colonic epithelium reflected higher fecal IgA, indicating site-specific IgA regulation by pIgR during SLD. In line, MASLD patients displayed increased serum and stool IgA compared to controls, which positively correlated with fibrosis. Furthermore, MCD-fed *pIgR*$^{-/-}$ mice, having higher circulatory IgA compared to their *Wt* littermates, developed more liver inflammation and injury accompanied with increased infiltration of neutrophils and macrophages Elevated neutrophil elastase in liver, as well as higher plasma LPS levels were present in *pIgR*-deficient mice, indicating increased bacterial translocation and NETosis. Importantly, transplantation of bone marrow lacking IgA ameliorated hepatic neutrophil infiltration and injury in *pIgR*$^{-/-}$ mice.

Conclusion: We identified a dysfunctional pIgR-mediated IgA secretion as novel mechanism contributing to steatohepatitis.

Development of a novel pathotype-specific therapeutic strategy for osteoarthritis by targeting synovial macrophage subpopulations

Anaïs Cardon[1], Nicolas Gaigeard[1], Lola Le Vaillant[1], Julien De Lima[1], Claire Vinatier[1], Denis Waast[1;2], Benoit Le Goff[1;3], Frédéric Blanchard[1], Virginie Escriou[4], Jerome Guicheux[1], Marie-Astrid Boutet[1;5]

[1]Nantes Université, Oniris, CHU Nantes, INSERM, Regenerative Medicine and Skeleton, RMeS, UMR 1229, Nantes, France; *[2]Department of Orthopaedics, CHU Nantes, Nantes, France*; *[3]Department of Rheumatology, CHU Nantes, Nantes, France*; *[4]UTCBS, CNRS, INSERM, Université Paris Descartes, Sorbonne-Paris-Cité, Chimie ParisTech, PSL Research University, Paris, France*; *[5]Centre for Experimental Medicine & Rheumatology, William Harvey Research Institute and Barts and The London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom*

Osteoarthritis (OA) is the most common rheumatic disease affecting over 500 million of people worldwide. Incurable and debilitating joint disease, OA leads to cartilage degradation, bone remodelling with the formation of osteophytes, meniscal alterations, and synovitis, with only symptomatic treatments available. Synovitis has been shown to play an important role in OA initiation and progression. Our group recently identified that OA synovium could be stratified into three different pathotypes, based on a precise histopathological analysis of the synovial cellular infiltration, namely pauci-immune (PI), diffuse-myeloid and lympho-myeloid (LM). Importantly, macrophages represent the most abundant synovial immune population observed in the three pathotypes (Boutet et al., OAC, 2023).

We hypothesized that the fine characterisation of macrophage subpopulations in each pathotype could lead to the development of pathotype-specific macrophage targeting strategies and provide novel personalized therapeutic approaches for OA patients, contributing to giving the “right drug to the right patient”.

Therefore, we collected OA synovial tissues from patients who underwent total knee replacement surgery and selected samples from PI, DM and LM pathotypes (n=3/pathotype), as well as 2 non-OA controls. We performed single-cell RNA sequencing of the $CD45^+$ cells dissociated from these tissues to characterise macrophage subpopulations and we developed a lipoplex-based targeting strategies of these cells.

The single-cell RNA sequencing data revealed 13 distinct macrophage populations. Those macrophage subpopulations were differently represented in the OA synovium compared to control non-OA synovial tissues, as well as across OA pathotypes. We identified *SPP1*$^+$, *LYVE1*$^+$ and *TREM2*^{low} macrophages as respectively enriched in the PI, DM and LM pathotypes. To individually target those pathotype-specific macrophage populations, we selected relevant genes in each population, based on bioinformatic approaches, and developed specific lipoplexes containing a mix of siRNA and mRNA to either reduce or promote their expression. We confirmed the biodistribution of lipoplexes *in vitro* and *ex vivo* on synovial explants, as well as their effective modulation of gene expression.

Overall, this strategy will help better characterise OA pathophysiology and, applied to OA murine models, could ultimately bring the proof of concept that the pathotype-specific modulation of synovial macrophage populations would contribute to prevent OA development.

Modulation of lung tissue remodelling induced by Mycobacterium tuberculosis infection by anti-fibrotic drugs

Deborah L W Chong[1], Julia Kutschenreuter[1], Jon S Friedland[1]

[1]*Institute for Infection and Immunity, St George's, University of London, London, United Kingdom*

Purpose: Up to 52% Tuberculosis (TB) patients exhibit tissue remodelling after recovery from *Mycobacterium tuberculosis* (*Mtb*) infection, which is characterised by expression of pro-fibrotic transforming growth factor-β1 (TGFβ1) and collagen deposition by lung fibroblasts. Tissue remodelling is mediated by matrix metalloproteinase-1 (MMP-1), a collagenase that is significantly increased in TB patient plasma. Mechanisms driving fibrosis in TB are ill-defined and the efficacy of anti-fibrotic drugs in reversing TB-driven tissue remodelling are unknown.

Methods: Human monocytes were infected with *Mtb* at a multiplicity of infection of 1, for 24 h. Filter-sterilised supernatant from *Mtb*-infected (CoMtb) or un-infected monocytes (CoMCont) were used to stimulate primary human lung fibroblasts (PHLF) to investigate intercellular networks driving tissue remodelling. Collagen expression was quantified by immunofluorescence microscopy and secreted TGFβ1 and MMP-1 measured by ELISA. To investigate the effect of anti-fibrotic drugs on TB-induced tissue remodelling, PHLF were pre-treated with Nintedanib (a tyrosine protein kinase inhibitor) or Pirfenidone (a pyridinone derivative) for 30 min prior to CoMtb stimulation.

Results: At 72 h, CoMtb stimulation of PHLF significantly increases TGFβ1 secretion compared to CoMCont (149.2±5.7 vs. 106.7.0±2.0 pg/ml, $p<0.05$). Pre-treatment of PHLF with Nintedanib significantly decreases TGFβ1 secretion in a dose-dependent manner, with maximal inhibition observed with 1 μM Nintedanib ($p<0.05$). Pre-treatment of PHLF with Pirfenidone has no effect on TGFβ1 secretion at any tested concentrations (1-100 μM). Nintedanib and Pirfenidone significantly suppress TGFβ1-induced collagen expression from PHLF by 14.0% and 24.4% respectively. However, Nintedanib or Pirfenidone pre-treatment of PHLF has no significant effect on CoMtb-induced collagen expression. However, both Nintedanib and Pirfenidone pre-treated PHLF secrete significantly decreased MMP-1 in response to CoMtb compared to CoMCont stimulation (both $p<0.0001$).

Conclusions: These data demonstrate that primary human lung fibroblasts adopt a tissue remodelling phenotype in response to *Mtb*-induced immune activation secreting TGFβ1 and MMP-1. Nintedanib and Pirfenidone significantly reduced MMP-1 secretion and tyrosine kinase inhibition also decreases TGFβ1 secretion, consistent with blockade of tissue remodelling. Such host-directed therapies may potentially improve outcomes in TB patients.

Financial support: New lecturer start-up grant awarded to Dr Deborah Chong from St George’s, University of London.

Mesenchymal stem cell extracellular vesicles attenuate dendritic cell maturation.

Fiona Buckley[1], Pamina Contreras Kallens[1], Meadhbh Brennan[1]

[1]*University of Galway, Galway, Ireland*

Purpose: In inflammatory states, dendritic cells infiltrate bone tissue and activate T cells, increase osteoclast differentiation, and subsequently increase bone resorption and destruction. Therefore, the control of dendritic cell maturation is imperative to potentiate repair. The concept of mediating tissue regeneration using transplanted mesenchymal stem cells was primarily based on the early hypothesis that the cells would engraft and differentiate, to replace damaged tissue. However, low engraftment rates and poor survival remain a barrier for exploitation of the multi-potency of mesenchymal stem cells. Despite this, tissue regeneration is still potentiated. These observations gave rise to the developed hypothesis that mesenchymal stem cells faciliate tissue regeneration via a paracrine method, through secretion of soluble factors and extracellular vesicles. Extracellular vesicles are secreted membrane bound nano-vesicles that contain proteins, lipids, ribonucleic acid (RNA) and deoxyribonucleic acid (DNA). Extracellular vesicles are found in most biological tissues and are involved in cargo transfer between cells. It is hypothesized here that mesenchymal stem cell extracellular vesicles are phagocytosed by dendritic cells, and this subsequently attenuates dendritic cell maturation.

Methods: Extracellular vesicles were isolated from the conditioned media of the D1 ORL UVA mesenchymal stem cell line. Immature dendritic cells were differentiated from C57BL/6 bone marrow monocytes in the presence of granulocyte-macrophage colony-stimulating factor (GM-CSF). Dendritic cell maturation was induced via lipopolysaccharide (LPS) and CpG oligonucleotide stimulation. Mature dendritic cells were subsequently treated with mesenchymal stem cell extracellular vesicles and maturation was assessed via flow cytometry and cytokine analysis.

Results: Mesenchymal stem cell extracellular vesicles are characterised by size, protein content, morphology and flow cytometry. Mesenchymal stem cell extracellular vesicles are phagocytosed by dendritic cells, and this is potentiated by LPS CpG oligonucleotide stimulation. Mesenchymal stem cell extracellular vesicles reduce the surface marker expression of CD80, CD83, CD86, CD40, MHC II and CCR7 on LPS CpG oligonucleotide-stimulated dendritic cells. Secretion of IL-12 and TNF-α from these dendritic cells is also reduced post-extracellular vesicle treatment.

Conclusion: Mesenchymal stem cell extracellular vesicles attenuate maturation in LPS CpG oligonucleotide-stimulated dendritic cells.

IL-10 and Gal-3 expression is linked to reduced ulcerative colitis severity in patients with metabolic syndrome

Irfan Corovic[1], Ivan Jovanovic[1], Bojana Simovic Markovic[1], Isidora Stanisavljevic[1], Aleksandar Djukic[2], Natasa Zdravkovic[3], Milena Jurisevic[4], Marina Jovanovic[3]

[1]Center for Molecular Medicine and Stem Cell Research, Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia; *[2]Department of Pathophysiology, Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia*; *[3]Department of Internal Medicine, Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia*; *[4]Department of Pharmacy, Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia*

Purpose: Ulcerative colitis (UC) is defined as a chronic inflammatory condition affecting the gastrointestinal tract, marked by alternating phases of remission and flare-ups. UC is linked with a variety of coexisting conditions, with metabolic syndrome (MetS) being notably prevalent among them. Despite this association, the connection between UC and MetS remains poorly understood. Consequently, our study aims to investigate the influence of MetS on the severity and the immunopathology of UC, both locally and systemically.

Methods: Eighty-nine patients with newly diagnosed and histologically confirmed UC were divided into two groups based on ATP III criteria for MetS: those with UC only and those with UC and MetS. The severity of UC was assessed for each participant using clinical, endoscopic, and histological scoring systems. Concentrations of inflammation mediators were measured in serum and fecal supernatants of UC patients using commercially available ELISA kits. Additionally, the phenotypic and functional characteristics of immune cells in the colon tissue were determined using flow cytometry.

Results: Patients with both UC and MetS exhibited a milder form of the disease, as confirmed by significantly lower endoscopic, clinical, and histological scores, characterized by higher levels of the immunosuppressive cytokine IL-10 in serum and Gal-3 in fecal content, compared to patients with UC only. Moreover, serum ratios of TNF-α/IL-10, IL-6/IL-10, and IL-17/IL-10 were significantly lower, whereas fecal ratios of Gal-3/TNF-α and Gal-3/IL-17 were significantly higher in patients with both UC and MetS. Additionally, a higher percentage of CD56+ NK cells and CD4+ Th cells producing IL-10, as well as a higher percentage of CD3+CD56+ NKT cells and CD8+Foxp3+ Tregs expressing Gal-3, were found in the lamina propria of patients with both conditions compared to those with UC only.

Conclusion: MetS might mitigate colon inflammation by altering the local immune response to enhance the activity of immunosuppressive cells and molecules. The increase in systemic IL-10 and local Gal-3 production could serve as a mechanism to limit inflammation and the resulting tissue damage in UC.

Investigating innate immune mechanisms in dental pulp repair

Huda Alsalamin[1], Katherine Feeney[1], Catherine Fulton[1], Imad About[2], Fionnuala Lundy[1], Ikhlas El Karim[1], Yvonne Dombrowski[1]

[1]*Queen's University Belfast, Belfast, United Kingdom*; [2]*Aix-Marseille University, Marseille, France*

Introduction: The tooth is composed of several tissues, enamel, dentin, and pulp which is considered the innermost layer. It is a highly vascularised tissue that is responsible for the tooth vitality, sensation, and defence. Whenever it is inflamed either due to bacteria (e.g., in caries) or due to trauma, this inflammation is referred to as pulpitis. Irreversible pulpitis is linked to NLRP3 inflammasome-mediated inflammation. Inflammasomes mediate inflammation and may also play a role in tissue repair and regeneration, a function which is currently not well understood.

We recently demonstrated using a co-culture model that when odontoblasts, the cells responsible for dentin formation, die, they induce differentiation and proliferation of dental pulp cells (DPCs) in an NLRP3 inflammasome-mediated manner. This induces mineralization required for new dentin production suggesting repair of the damaged tooth.

Aim/Purpose: This study aims to determine the underlying mechanisms of inflammasome-mediated dentin regeneration.

In addition, we aim to determine the cell types responsible for inflammasome activation, as well as determining the response of the other cells to inflammasome activation.

Methods: Healthy dental pulp from immature third molars was exposed to bacterial PAMPs and extracellular danger signals to mimic inflammation. The inflammatory response was determined by ELISA and qPCR, inflammasome-positive cells were identified by fluorescent immunocytochemistry and pyroptosis was measured by LDH release. Alternatively, DPCs were cultured in a co-culture model with macrophages.

Results: IL-1β release and cytotoxicity were negligible in DPCs when exposed to NLRP3 activators, suggesting that DPCs do not form active NLRP3 inflammasomes directly. In preliminary results we found that NLRP1 and AIM2 were upregulated in DPCs following inflammatory stimuli in vitro.

Conclusion: Macrophages are the key immune cells in pulpitis, and we have previously shown that DPCs respond to IL-1β in vitro. Using an in vitro pulpitis co-culture model, we will next investigate whether macrophage-derived IL-1β mediates dental pulp cell differentiation.

Future work will identify the role of NLRP1 and AIM2 inflammasomes in pulpitis with the aim to find novel targets that could be used to modulate the destructive inflammation in pulpitis towards regenerative outcome.

Immunomodulatory capacity of large and small apoptotic bodies derived from human bone marrow mesenchymal stromal cells: An in-vitro investigation

Jiemin Wang[1], Seyedmohammad Moosavizadeh[1], Manon Jammes[1], Abbas Tabasi[1], Trung Bach[1], Aideen Ryan[2], Thomas Ritter[1]

[1]*REMEDI, University of Galway, Galway, Ireland*; [2]*Discipline of Pharmacology and Therapeutics, University of Galway, Galway, Ireland*

Background: Mesenchymal stromal cell (MSC) apoptosis was reported required for their therapeutic function including immunodulation. In our previous study, MSC-derived apoptotic bodies (ApoBDs) also exhibit immunomodulatory potency. However, compared with small extracellular vesicles, there is a dearth of literature to elaborate on the preparation, characterization and biological properties of ApoBDs.

Purpose: This project aims to prepare highly efficient and safe ApoBDs and evaluate their immunomodulatory potential in vitro.

Methods: ApoBDs were collected from the conditioned medium (fetal bovine serum-free) staurosporine-induced apoptotic human MSCs. The 3,000 g and 16,000 g centrifuged speed was performed to isolate large and small ApoBDs, respectively. ApoBDs were collected and characterized comprehensively. In their surface marker characterization, we characterized the surface proteins which were verified expressed or not in their parental MSCs. Then, the ApoBDs were incubated with peripheral blood mononuclear cells and macrophages respectively to investigate their in-vitro immunomodulatory capacity.

Results: Two sets of ApoBDs were harvested which differed in size. The large ApoBDs were about 700 nm and small ApoBDs were about 500 nm. Both ApoBDs expressed CD90, CD44 and CD73 which were verified positive in their parent MSCs. Similarly, PD-L1, CD11b and HLA-DR were expressed lowly in both ApoBDs and their deriving MSCs. Then, ApoBDs were incubated with peripheral blood mononuclear cells. We found that both ApoBDs inhibited allogeneic T-cell proliferation but the large ApoBDs were more effective. Next, in ApoBDs/macrophage incubation assays, both ApoBDs can polarize M1 macrophages towards M2-like phenotype with large ApoBDs being more effective in upregulating the expression of CD163. Besides, large ApoBDs were easier to be phagocytosed by macrophages as detected through flow cytometry analysis and immunocytochemistry images. Finally, the in-vitro safety of both ApoBDs was verified well as no toxicity was observed using staurosporine.

Conclusion: The staurosporine-induced ApoBDs are safe and exhibit immunomodulatory potential in vitro. Compared with small ApoBDs, large ApoBDs are more effective in inhibiting T-cell proliferation and M2 polarization. ApoBDs could be useful in future studies replacing cell therapies with MSCs.

Intravenous immunoglobulins: A new therapeutic option for cryptogenic organizing pneumonia?

Daniel Albert Mendoza Bravo[1], Ivan Garcia De La Torre[1], Celia Ferrez Hernández[1], Vivian Lizeth Stewart DelCid[1], Elena Manterola Navarro[1], Jhonnathan Adrian León Valdiviezo[1], Rafael Rodriguez Ramos[1], Ana De Andres Martin[1]

[1]*Hospital Universitario Ramon y Cajal, Madrid, Spain*

Purpose: Cryptogenic organizing pneumonia (COP) is a rare form of idiopathic interstitial pneumonia in which granulation tissue obstructs the ducts and alveolar spaces with chronic inflammation occurring in the adjacent alveoli for which no etiologic agent is found.

The standard treatment for COP is high-dose corticosteroids to reduce the inflammatory process. Approximately 50% of patients with NOC treated with corticosteroids experience disease recurrence.

For recurrent cases and severe infiltrative COP, different immunosuppressive treatments have been tried, such as Rituximab, aziatropine, mycophenolate, cyclophosphamide, all of them with low effectiveness.

The purpose of this work is to present a new therapeutic option for these patients that in our experience demonstrates promising results.

Methods and results: The first is a 60-year-old man with a history of chronic lymphocytic leukemia treated with Venetoclax-Obinutuzumab, who completed the 6 cycles of obinutuzumab. The patient required several admissions due to exacerbations of his cryptogenic pneumonia, with increasing worsening of respiratory function, even requiring home oxygen therapy for the most part. that you are requested to join the waiting list for a lung transplant.

The second is a 53-year-old man with clonal lymphocytosis B being monitored by hematology without active treatment. It begins with symptoms of fever and weight loss with CT images where lung lesions suggestive of NOC and bronchial lymphadenopathy are observed

The third is a 65-year-old patient with a history of non-Hodgkin's lymphoma treated with autologous hematopoietic stem cell transplantation and rituximab who 4 years later has multiple admissions due to exacerbations of cryptogenic organizing pneumonia (COP). With poor response to treatment, it is proposed to join the waiting list for a lung transplant.

The 3 patients received treatment with intravenous immunoglobulins at a dose of 600 mg/kg every 3 weeks, presenting both clinical and radiological improvement with disappearance of the lung lesions, so they were removed from the transplant list.

Conclusion: There are only 10 cases reported in the medical literature of NOC successfully treated with immunoglobulins, so this should be considered as another option for patients who present NOC that relapses to immunosuppressive treatment

Immune cell interaction in Pulmonary Arterial Hypertension

Olaya Esparta[1], Konrad Rosskopf[2], Panja Böhm[3], Konrad Hoetzenecker[3], Grazyna Kwapiszewska[1;4], Leigh Marsh[1;4]

[1]Otto Loewi Research Centre, Medical University of Graz, Graz, Austria; *[2]University Clinic for Blood Group Serology and Transfusion Medicine at Medical University of Graz, Graz, Austria*; *[3]Medical University of Vienna, Division of Thoracic Surgery, Vienna, Austria*; *[4]Ludwig Boltzmann Institute for Lung Vascular Research, Graz, Austria*

Pulmonary arterial hypertension (PAH) is a cardiovascular disease characterised by a high mean pulmonary arterial pressure of >20 mmHg at rest and a low survival rate. It is associated with chronic inflammation, lung vascular remodelling and vasoconstriction that ultimately leads to heart failure and death. Immune cell infiltration is a hallmark of PAH, and emerging evidence suggests that gamma-delta T (gdT) and plasmacytoid dendritic cells (pDC), with pro-inflammatory and cytotoxic effects, could play a crucial role in the transition to a chronic inflammatory environment.

Therefore, we aim to investigate how gdT and pDC cell populations interact with each other and with the structural cells from all layers of the pulmonary arteries (PAs) and ultimately their contribution to vascular remodelling in PAH.

The methodology consists of immune cell isolations from human healthy buffy coats with magnetic beads, direct co-culture system of gdT and pDC with human primary pulmonary arterial smooth muscle cells (hPASMC) isolated from healthy and PAH lungs, multi-colour flow cytometry, fluorescent microscopy and qPCR.

Our results have shown significant downregulation in activation (CD25) and cytotoxic markers (CD8 and CD56) in gdT and L-selectins (CD62L) in pDC cells, as well as downregulation in extracellular matrix components (Col4A1), cell adhesion (periostin) and upregulation of chemoattractants (CCL4) in hPASMC. These results indicate a potentially unknown homeostatic role of these immune cells on hPASMC.

Even though these results are promising, cellular behaviour in the vascular wall is controlled by the interaction of multiple cell types, which is not possible to replicate in 2D cell culture. Therefore, future experiments will include a 3D human immune cell-blood vessel organoid with induced pluripotent stem cells (iPS) together with gdT and pDC cells to ultimately understand their role in vascular remodelling in PAH.

The tricarboxylic acid cycle regulates fibroblast-driven tissue remodelling via hypoxia-inducible factor 1α during Mycobacterium tuberculosis infection

Ramla Cusman[1], Julia Kutschenreuter[1], Deborah L W Chong[1], Jon S Friedland[1]

[1]*Institute for Infection and Immunity, St George's University of London, London, United Kingdom*

Background: *Mycobacterium tuberculosis* (*Mtb*) causes extensive lung tissue remodelling, driven by matrix metalloproteinases (MMPs). Fibroblasts are a major source of MMPs in a monocyte-dependent network during *Mtb* infection. Metabolic pathways including the tricarboxylic acid (TCA) cycle, which produces many intermediate compounds, may modulate innate immune responses. Itaconate is a key TCA cycle derivative, which regulates the transcription factor, hypoxia-inducible factor 1α (HIF1α), that drives pro-inflammatory responses in tuberculosis (TB). We investigated the role of itaconate in regulating fibroblast-dependent tissue remodelling and inflammation during *Mtb* infection.

Methods: Primary human lung fibroblasts (PHLF) were treated with 4-octyl itaconate (4OI, a cell permeable derivative of itaconate) for 1 h prior to stimulation with conditioned media from *Mtb*-infected monocytes (CoMTb). MMP-1 (a collagenase), MMP-3 (an MMP-1 activator) and IL-1β secretion, and gene expression were measured by ELISA and qRT-PCR respectively. Functional MMP activity was quantified using the EnzChek™ Collagenase Assay Kit which fluoresces upon collagen degradation. HIF1α protein expression in PHLF was measured at 4-48 h by western blot.

Results: PHLF pre-treated with 4OI upregulated CoMTb-induced MMP-1 and MMP-3 secretion in a dose-dependent manner at 24, 48 and 72 h. The maximal effect was observed with 100 μM 4OI at 72 h when PHLF MMP-1 secretion increased from 156.9 to 232.6 ng/ml (p=0.0002) and MMP-3 concentrations increased from 425.9 to 529.3 ng/ml (p<0.0001). IL-1β secretion was also upregulated with 4OI pre-treatment from CoMTb-stimulated PHLF (286.9 vs. 592.8 ng/ml, p=0.0002). Furthermore, *mmp1* gene expression in PHLF stimulated with CoMTb was increased in response to 4OI treatment ($p=0.034$). Increased collagen degradation was observed from CoMTb-stimulated PHLF pre-treated with 4OI when compared to CoMTb stimulation alone ($p=0.0006$). Lastly, CoMTb stimulation induced HIF1α protein expression in PHLF from 8 h onwards, which was increased with 4OI pre-treatment.

Conclusion: Itaconate, which modulates the TCA cycle, increases *Mtb*-dependent MMP-1, MMP-3 and IL-1β secretion and gene expression in human monocyte-fibroblast networks in TB, as well as upregulation of HIF1α expression in fibroblasts. Specific TCA cycle metabolites may represent potential targets for host-directed therapies to limit inflammation and tissue destruction in TB.

Investigating the impact of ECM-based biomaterials in macrophage-mediated tissue regeneration.

Sinead O'Rourke[1;2], Giovanni Gonnella[1;2], Josephine Wu[1], Gabriela Soares Kronemberger[1], Aisling Dunne[2;3], Daniel Kelly[1;2]

[1]School of Engineering, Trinity College Dublin, Dublin, Ireland; *[2]Advanced Materials and BioEngineering Research, Dublin, Ireland*; *[3]School of Biochemistry, Immunology, Trinity College Dublin, Dublin, Ireland*

Purpose: Osteoarthritis (OA), is a degenerative disease, stemming from initial injuries or defects of the joint. The immune response, largely mediated by innate immune cells macrophages, greatly dictates disease progression and patient outcome following joint replacement. As a result, modulation of macrophage response has become an attractive therapeutic target to improve tissue regeneration and implant longevity following surgery.

There is now ample evidence which demonstrates how biomaterial design can be used to modulate macrophages in vivo, steering cell phenotype from a destructive pro-inflammatory state to a more favourable pro-regenerative phenotype.

Previous work from the Kelly lab has highlighted that the use of biomaterials derived from mammalian extracellular matrix promotes a hybrid phenotype in primary human macrophages. It is the aim of this study to further characterise this response, and furthermore compare the response of macrophages to ECM derived from distinct tissue sources of the joint including articular cartilage, tendon, and bone.

Methods: Primary human macrophages were treated with ECM derived from porcine bone, tendon, and articular cartilage. Macrophage phenotype was characterised using PCR, ELISA, and western blotting. Metabolic profile of macrophages in response to ECM was also characterised using extracellular flux Seahorse assays. Regenerative potential of ECM-treated macrophages was assessed using indirect co-culture with human MSCs using conditioned media from ECM-treated macrophages.

Results: Results of this study show that musculoskeletal ECM promotes a distinct hybrid phenotype in primary human macrophages, exhibiting markers of both classical and alternative activation. ECM was also shown to limit LPS activation of macrophages, limiting glycolytic capacity of LPS-treated macrophages, as well as pro-inflammatory cytokine production. Finally, Articular-cartilage ECM was shown to drive specific growth factor expression in macrophages, conducive with cartilage regeneration. This result was confirmed with conditioned media experiments, whereby conditioned media from ECM-treated macrophages was shown to promote robust chondrogenesis of human MSCs.

Conclusion: This work builds on previous studies regarding ECM-based scaffolds, further exemplifying the immunomodulatory potential of ECM-based biomaterials, while also highlighting how tissue source can further tune the immune response.

Phosphodiesterase 4 regulates monocyte-dependent fibroblast activity in Mycobacterium tuberculosis (Mtb) infection

Sharenja Ratnakumar[1], Deborah L W Chong[1], Joanna Porter[2], Jon S Friedland[1]

[1]*St George's, University of London, London, United Kingdom*; [2]*University College London, London, United Kingdom*

Purpose: Tuberculosis (TB) infects around a third of the world's population and even after recovery, up to 94% patients have clinically significant lung fibrosis. Fibrotic lung tissue is characterised by the increased presence of differentiated fibroblasts expressing α-smooth muscle actin (αSMA) and excessive deposition of extracellular matrix proteins. During *Mycobacterium tuberculosis (Mtb)* infection, cyclic adenosine monophosphate (cAMP) is a key regulator of the interface between inflammation and fibrosis and modulated by nucleotide phosphodiesterases (PDE). PDE4 (subtypes A-D) are highly upregulated during TB and so we investigated the hypothesis that PDE4-dependent events drive the development of chronic fibrosis in TB.

Methods: Primary human lung fibroblasts (PHLFs) were stimulated with media, 1 ng/ml TGFβ (positive control), or media from *Mtb*-infected monocytes (CoMTB) or from un-infected monocytes (CoMCon) for 72 h. Expression of αSMA was detected by immunofluorescent microscopy and DAPI nuclear co-staining; quantification of αSMA mean stain area was assessed using ImageJ software. Supernatants were collected at 72 h and profibrotic mediators PDGF-BB and TGFβ quantified by ELISA. RNA was extracted and cDNA reverse transcribed for qRT-PCR analysis of *pde4a-d* expression.

Results: PHLFs treated with CoMTB but not CoMCon enhanced αSMA expression compared to media alone, leading to differentiation into myofibroblasts, a key effector cell in fibrosis ($p=0.011$). CoMTB-stimulated PHLFs secrete significantly more PDGF-BB than fibroblasts treated with CoMCon (73.63pg/ml vs. 35.85 pg/ml, $p<0.01$). CoMTB-stimulated PHLFs secrete increased concentrations of TGFβ1 compared to PHLFs stimulated by CoMCon (748.8 pg/ml vs 552.0 pg/ml, $p<0.05$). Stimulation of PHLF with CoMTB results in upregulation of *pde4a-d*, compared to CoMCon ($p<0.05$ in all subtypes). Pre-treatment of PHLF with PDE4 inhibitor decreases PDE4 mRNA expression and TGFβ secretion.

Conclusion: Fibroblasts activated by Mtb-infected human monocytes secrete pro-fibrotic mediators in a PDE4-dependent manner. PDE4 may be a potential target for host directed therapy in TB treatment, thus reducing the mortality and morbidity associated with TB disease.

Comparative Effects of Vitamin C, Curcumin and Sambucus nigra Extract on Cell Viability & Cytokine Levels of Cigarette Exposed Lung Epithelium Cell Culture

A. Eren Ozkaya[1], Hanife Sevgi Varli Ma[2], Aysegul Yabaci Tak[1], Nelisa Turkoglu Lacin[2], Fatmanur Karakose Okyaltirik[1]

[1]*Bezmialem Vakif University, Istanbul, Turkey*; [2]*Yildiz Technical University, Istanbul, Turkey*

Introduction: Cigarettes contain harmful chemicals leading to diseases like lung cancer and coronary artery diseases, causing 1 in 10 deaths globally. Smoking depletes antioxidants crucial for immune function. Inflammation, involving cytokines, is a natural defense. Antioxidants like Sambucus nigra, Curcumin, and Vitamin C reduce oxidative stress. However, higher doses of Vitamin C may have a potential pro-inflammatory aspect, revealing a complex relationship between antioxidants and inflammation. Study aims to investigate mutual effects of Vitamin C, Curcumin and Sambucus nigra in lung epithelium cells.

Methods: Human lung epithelium (BEAS-2b) cells were cultured in T25 flasks until 90% confluence at 37°C. Cigarette Smoke Extract (CSE) was prepared for cell interaction. TNF-α and IL-6 cytokine levels from CSE-stimulated cells were measured using ELISA kits. Vitamin C, Sambucus nigra, and curcumin effects were tested through MTT analysis at varying concentrations. CSE-treated cells were supplemented with antioxidants, and cytokine levels were assessed with ELISA kits. Statistical analysis was performed.

Results: After 24 hours of incubation with various Cigarette Smoke Extract (CSE) concentrations, the highest (41% viability) was chosen for subsequent stages. Human lung epithelium cells, stimulated with the CSE for 24 hours, showed high Interleukin 6 levels (28.97) and high but insignificant TNF-alpha levels (6.96). Antioxidant exposure for 24, 48, and 72 hours with 5 different concentrations of each compound yielded varying viability percentages. In the Vitamin C groups, cell viability increased as the dose decreased. Curcumin & S. nigra groups showed overall low viability. Seven groups were selected for cytokine level analysis, and IL-6 or TNF-alpha stimulation was not measured.

Conclusion: Substances' impact on cells depends on dose and exposure duration. Higher vitamin C doses correlated with lower cell viability, indicating potential pro-inflammatory effects. Sambucus nigra and Curcumin consistently showed low viability rates. Adjusting doses in future studies may clarify healing effects. Cigarette smoke uniquely increased TNF-α cytokine levels, revealing its inflammatory effects, while other substances suppressed inflammation, reducing cytokine levels.

Keywords: Cigarette smoke, Cell viability, Cytokine, Antioxidant

Characterization of Fibroblast-like Synoviocytes isolated from the synovial fluid of Juvenile Idiopathic Arthritis patients

Simone Pelassa[1], Federica Raggi[1], Chiara Rossi[1], Federica Briasco[1], Chiara Artale[1], Marco Gattorno[1], Angelo Ravelli[2], Alessandro Consolaro[1], Maria Carla Bosco[1]

[1]UOC Rheumatology and Autoinflammatory Diseases, IRCCS Istituto Giannina Gaslini, Genova, Italy; *[2]Scientific Direction, IRCCS Istituto Giannina Gaslini, Genova, Italy*

Purpose: The role of Fibroblast-like Synoviocytes (FLS) in Juvenile Idiopathic Arthritis (JIA) is still unclear. FLS have been mostly investigated in the synovial membrane (SM-FLS) or synovial fluid (SF-FLS) of adults rheumatic patients or in murine models of arthritis . In SM, two different subsets of FLS were identified: the lining (LL) and sublining (SL), involved in chartilage degradation or the orchestration of immune responses, respectively. FLS seem to retain multipotent capacity and are able to differentiate into a chondrocyte-like phenotype. The characterization of different FLS subtypes and multipotent properties have never been assessed in JIA patients.

Methods: 10 JIA patients with active disease were enrolled in the study, Cells were isolated from SF by adherence. Skin fibroblasts (sFB) from 4 healthy donors were used as controls. Cytofluorimetric analysis was carried out after staining with anti-CD45, CD34, PDPN, THY antibodies. Gene expression was quantified by RT-PCR under both basal and pro-inflammatory conditions (LPS or TNFα). Chondrogenic differentiation was obtained by culturing pelleted cells in differentiation or normal medium for 28 days, fixed, and stained with Alcian Blue.
Results: Citofluorimetry showed that the majority of SF-FLS cells present a phenotype similar to that of the SM-FLS of the SL region of adult arthritis patients, specifically $CD45^{-}$,CD34-,$CD90^{+}PDPN^{+}$. RT-PCR analysis showed that SF-FLS expressed higher mRNA levels of HAS-1, BMP4, and Aggrecan genes than sFB. LPS stimulation induced high mRNA expression of the pro-inflammatory molecules,IL1β, IL6, IL8, CCL5, respect to metalloproteasis (MMP1, MMP3) supporting the hypothesis of SF-FLS involvement in immune response rather than in tissue degradation. FLS also demonstrated to be able to differentiate into chondrocytes-like tissues when cultured in differentiation medium, as showed by the Alcian-Blue staining Assay.

Conclusion: Results demonstrated that SF-FLS from active JIA patients exhibit a phenotype similar to that of FLS in the sublining SM of adult arthritis patients and might play a role in the inflammation within the joint. Furthermore, SF-FLS ability to differentiate in chondrocytes-like cells suggest the potential of these cells as a model for the study of chondrocytes in JIA and for the predictionof disese severity.

Teucrium montanum extract ameliorates collagen-induced arthritis in rats

Biljana Bufan[1], Mirjana Marčetić[2], Jasmina Djuretić[3], Ivana Ćuruvija[4], Veljko Blagojević[4], Dragana Božić[1], Violeta Milutinović[2], Jelena Sopta[5], Jelena Kotur-Stevuljević[6], Nevena Arsenović-Ranin[1]

[1]Department of Microbiology and Immunology, University of Belgrade – Faculty of Pharmacy, Belgrade, Serbia; *[2]Department of Pharmacognosy, University of Belgrade – Faculty of Pharmacy, Belgrade, Serbia*; *[3]Department of Pathobiology, University of Belgrade – Faculty of Pharmacy, Belgrade, Serbia*; *[4]Department of Research and Development, Institute for Virusology, Vaccines and Sera "Torlak", Belgrade, Serbia*; *[5]Institute of Pathology, University of Belgrade – Faculty of Medicine, Belgrade, Serbia*; *[6]Department of Medical Biochemistry, University of Belgrade - Faculty of Pharmacy, Belgrade, Serbia*

Purpose: Traditional herbal plants attract atention as potential therapeutics in the treatment of arthritis. *Teucrium montanum* L. (TM) is a widely distributed plant in almost all Mediterranean countries. The therapeutic potential of TM extract is insufficiently examined, but its composition implies potential anti-inflammatory effect. We tested amelorating effects of TM extract on rheumatoid arthritis (RA), in rat collagen-induced arthritis (CIA) model.

Methods: Phytochemical analysis of TM methanol extract was performed using LC-DAD-ESI-MS. Female *Dark Agouti* rats were immunized with bovine type II collagen (CII) in incomplete Freund`s adjuvant to induce CIA. CIA rats were treated with TM extract daily *per os* (100 or 200 mg/kg) from day when the first signs of disease started. Clinical evaluation of CIA was performed by scoring and histological analysis. Phenotypic and functional characteristics of splenocytes and draining lymph nodes (dLNs) cells were analyzed by flow cytometry. Cytokine levels in supernatants from hind paw tissue culture, and IgG CII-specific antibodies level in blood were determined by ELISA.

Results: TM extract contained phenylethanoid glycosides, mainly verbascoside, phenolic acids, flavonoid and iridoid glycosides. Applied TM extract doses significantly reduced arthritic score and severity of ankle joint inflammation in CIA rats. This was accompanied by the more pro-oxidant profile in serum, and shifted pro-inflammatory (TNF-α and IL-6) and anti-inflammatory (IL-10) cytokines balance toward later in paws of treated rats. This was in conjunction with less inflammatory phenotype of dLN and spleen CD11b+ cells (monocytes/macrophages) judged by their lower expression of CD86, MHCII, and TLR-4, and lower production of TNF-α and IL-1β. The frequency of TCR+ cells, and IL-17- and IFN-γ- producing CD4+ cells were lower in dLNs and spleen, while frequency of regulatory CD4+CD25+FoxP3+ cells was higher. The lower frequency of CD45RA (B cells) in dLNs and spleen was accompanied with lower levels of serum anti-CII antibodies in treated rats.

Conclusion: These findings suggest, for the first time, that TM extract effectively ameliorated clinical presentation of RA in model of rat CIA, and that this therapeutic effect may be associated with its immunoregulatory/anti-inflammatory action.

Modulating Human Macrophage Metabolism through the Glycolytic Enzyme PKM-2 for the Generation of Bone Regenerative Extracellular Vesicles

Cansu Gorgun[1;2], Brenton Cavanagh[3], David Hoey[2;4;5], Annie M Curtis[1;4;5]

[1]Curtis Clock Laboratory, School of Pharmacy and Biomolecular Sciences (PBS), RCSI, Dublin, Ireland; *[2]Trinity Centre for Biomedical Engineering, Trinity Biomedical Sciences Institute, Trinity College, Dublin, Ireland*; *[3]Cellular and Molecular Imaging Core, RCSI, Dublin, Ireland*; *[4]Advanced Materials and Bioengineering Research Centre, Trinity College Dublin & RCSI, Dublin, Ireland*; *[5]Tissue Engineering Research Group (TERG), RCSI, Dublin, Ireland*

Purpose: The extracellular vesicles (EVs) from pro-inflammatory (M1) and anti-inflammatory (M2) macrophages play crucial roles in terms of bone regeneration. These macrophage phenotypes are dependent on intracellular metabolic pathways such as glycolysis of which the enzyme Pyruvate-kinase M2 (PKM2) is essential. Macrophages switch from M1 to M2 during the bone healing process. Thus, we postulated that we could generate a hybrid M1/M2 macrophage through targeting PKM2, and that their EVs may provide an effective new strategy for bone healing.

Methods: For this aim, primary human macrophages were treated with different concentrations of the PKM2 allosteric activator (DASA-58) before inducing a pro-inflammatory phenotype with LPS (100 ng/mL) + IFN-gamma (20 ng/mL) and compared to LPS + IFN-gamma (M1) or IL4 (20 ng/mL) + IL13 (10 ng/mL) (M2) alone. Metabolic profiling was conducted using Seahorse XF-analyzer, and expression of M1 and M2 markers along with inflammatory and pro-angiogenic markers relevant to bone healing were assessed. EVs were separated and their angiogenic potential was evaluated *in vitro* using tube formation assays with HUVECs.

Results: The activation of PKM-2 in macrophages prior M1 stimulation led to upregulated mRNA levels of *IL10*, *VEGF* and *COX2*, along with downregulation of *CXCL10* and *CD38* expression, as well as reduced IL-6 secretion compared to M1 controls. EVs obtained from PKM-2 re-programmed human macrophages significantly enhanced tube formation in HUVECs compared to M1 controls.

Conclusion: We have shown for the first time that DASA-58 modulates human macrophage metabolism with hybrid features of both pro-inflammatory and anti-inflammatory markers, leading to the production of EVs capable of enhancing tube formation, a critical first step in terms of bone healing. This highlights the link between macrophage metabolism and EV generation, suggesting potential therapeutic strategies for promoting bone healing. Further studies will explore the biological activity of these regenerative EVs in various *in vitro* settings, such as osteogenesis and immune response, prior to incorporating them into a novel biomaterial for localized delivery in an *in vivo* model of large bone defects.

Intermittent actuation decreases the presence of neutrophils in the pericapsular region of implanted biomaterials.

Hannah Prendeville[1], Niamh A. Ward[1], Garry Duffy[2;3], Eimear Dolan[1]

[1]Department of Biomedical Engineering, University of Galway, Galway, Ireland; *[2]Anatomy and Regenerative Medicine Institute (REMEDI), University of Galway, Galway, Ireland*; *[3]Advanced Materials and BioEngineering Research Centre (AMBER), Trinity College Dublin, Dublin, Ireland*

Background: The Foreign Body Response (FBR) is a complex cascade of inflammatory and fibrotic events that occur in the presence of a foreign object, such as implantable biomaterials. Innate immune cells including neutrophils recognise the foreign material and orchestrate the FBR, leading to the formation of a hypopermeable, fibrous capsule around the device, which is detrimental to its function and long-term durability. We have previously shown that cyclic inflation and deflation (intermittent actuation (IA)) of an implanted device interferes with the progression of the host FBR, resulting in a significant reduction in fibrous capsule thickness. However, the immunological mechanisms by which IA interferes with the FBR are not fully understood.

Methods / Results: Given that neutrophils play a key role in initiating the inflammatory response to implanted biomaterials, we hypothesised that IA affects neutrophil recruitment to the pericapsular region. To test this, devices were implanted subcutaneously in mice and actuated for 5min every 12hrs. Immunofluorescent staining of Ly-6G at the pericapsular region showed that IA significantly reduced the presence of neutrophils 5-days post-implantation, compared to non-actuated control devices. We next established an *in vitro* model to further understand the neutrophil response to IA and investigate if IA alters neutrophil survival and function. Owing to their short lifespan *in vitro*, primary neutrophils are challenging to culture. Therefore, we established a protocol to differentiate neutrophil-like cells from the acute promyelocytic leukaemia cell line, HL-60. HL-60s were cultured with 1.3% DMSO for 7-days and expression of neutrophil markers were monitored by flow cytometry. DMSO did not affect cell viability and significantly increased the expression of CD16, CD11b and CD66b, indicating successful differentiation into neutrophils. Neutrophils will be cultured on devices which will be actuated daily for 5-days. We will examine if IA affects neutrophil survival, cytokine (TNF and IL-10) and Reactive Oxygen Species production.

Conclusions: Results from this project will better our understanding of the mechanisms by which IA interferes with the cellular coordination of fibrosis. Defining this process has critical implications for understanding the host response to implantable biomaterials and how modulation of neutrophils may have important long-term consequences on the FBR.

Butyrate, tributyrin, and high-fiber diet: improving inflammation in acute and chronic psoriasis

Roberta Sagiorato[1], Beatriz Burger[1], Vitória Gaspar[1], Isabela Baccarin[1], Isabela Grego[1], Hosana Rodrigues[1]

[1]*Unicamp, Limeira, Brazil*

Purpose: Psoriasis is a chronic disease characterized by T cell activation and keratinocyte hyperproliferation. Butyrate is being studied for its potential therapeutic effects on immunological diseases, however, its impact on psoriasis remains unclear. This study aimed to investigate the effects of oral administration of butyrate, trybutirin and a high-fiber diet on experimental psoriasis.

Methods: In a chronic psoriasis model, male C57BL/6 mice were induced with psoriasis by applying an imiquimod-based cream for 6 consecutive days, followed by reapplication from day 21 to day 26. Mice were either given 150 mM butyrate in drinking water or orally administered with 3 g/kg tributyrin (a pro-drug of butyrate) through gavage from day 7 to day 28. In another model, animals were fed a high-fiber diet (25% inulin), starting 7 days before imiquimod application and continuing until the final day of the protocol. In an acute psoriasis model, mice were induced with psoriasis by applying an imiquimod-based cream for 5 consecutive days while simultaneously receiving 150 mM butyrate in drinking water. Skin thickness, body weight, water and food intake, spleen area and weight, and gene expression of resident memory T cell (TRM) markers in the skin were assessed. Statistical analyses were performed using one-way or two-way ANOVA followed by Bonferroni's post-test ($p < 0.05$) (CEUA: 6059-1/2022).

Results: Topical application of imiquimod mimicked psoriatic inflammation (increased skin thickness, redness, and peeling, increase in spleen area and weight) compared to the control group. Treatment with butyrate reduced skin thickness, redness, and scaling in both chronic and acute psoriasis models. The gene expression of CD103, a T_{RM} marker, was reduced at the 28th of the protocol in butyrate-treated animals. Tributyrin or a high-fiber diet also showed some benefits in alleviating psoriatic inflammation, although the effects were not as pronounced as pure butyrate.

Conclusion: Butyrate, tributyrin and high-fiber diet treatment had beneficial effects on psoriatic inflammation. Butyrate led to a reduction in skin thickness and modulated the expression of T_{RM} markers, specifically decreasing CD103 expression. These findings suggest that butyrate may have immunomodulatory properties that can attenuate the activation of T_{RM} cells in psoriasis.

Unravelling stem cell destiny: calcineurin-NFAT axis in early stem cell commitment and immune exclusion

Stefano Cozzi[1], Laura Marongiu[1], Marco Galli[1], Giulia Stucchi[1], Giuseppe Rocca[1], Anna Celant[1], Ilaria Fontana[1], Alessia Donato[1], Metello Enzo Innocenti[1], Francesca Granucci[1]

[1]*University of Milano-Bicocca, Milan, Italy*

The Nuclear Factor of Activated T Cells (NFAT) is a family of transcription factors composed of 5 members, four of which (NFATc1-4) are regulated by calcineurin (CN), a calcium-dependent phosphatase. Our group shed light on additional non-inflammatory roles of this transcription factor in dendritic cells. The aim of this work is to unveil how NFAT activation modulates early stem cell commitment and differentiation while exploring new tissue-dependent mechanisms of immune system alertness towards cell proliferation.

We investigated two tissues with distinct regenerative capabilities: the brain, characterized by slow regeneration, and the small intestine/colon, known to be highly proliferative. *In vitro*, we infected neural stem cells with a lentivirus carrying a CN inhibitor (iCN), while *in vivo*, we conducted intracranial injections targeting the ventricular-subventricular zone (V-SVZ) with the same virus. To assess if this mechanism extends to the small intestine/colon system, we utilized mice with inducible inhibition of NFAT in $LGR5^+$ stem cells, predominantly found in intestinal and colon crypts. We also employed 2 models of disease: Parkinson's disease (PD), for the brain system, and dextran sulfate sodium (DSS)-induced colitis.

When NFAT-CN interaction is inhibited, there is an expansion of the neural stem cells in resting condition both *in vitro* and *in vivo*. Furthermore, we showed that this expansion can ameliorate a damage induced by PD. This phenotype is also conserved in the small intestine and colon where there is an expansion of $LGR5^+$ cells leading to tissue elongation. Consistent with our previous findings, this expansion of stem cells can mitigate colitis damage induced by DSS. We also found that NFAT regulates a checkpoint phase mediated by the immune system.

In summary, we propose that NFAT is involved in an early phase of stem cell differentiation, controlling directly or indirectly adult stem cell differentiation and immune system surveillance on activated progenitor cells.

Extracellular vesicles produced by interleukin 4 polarized macrophages suppress atherosclerosis by reprograming Ly6Chi monocytes that improve efferocytosis

Ngan Khanh Vu[1;2;3], Tuan Anh Phu[2;3], Martin Ng[2;3], Alex Gao[2;3], Robert L. Raffai[2;3]

[1]School of Medicine, University College Cork, Cork, Ireland; *[2]Division of Vascular & Endovascular Surgery, Department of Surgery, University of California San Francisco, San Francisco, United States*; *[3]Northern California Institute for Research and Education, San Francisco, United States*

Purpose: Extracellular vesicles (EVs) produced by IL-4-polarized macrophages (Mϕ) suppress inflammation by communicating immunometabolic signaling to recipient immune cells and adipocytes. The purpose of this study was to examine transcriptional responses sensitive to IL-4-polarized Mϕ EVs among circulating Ly6C^{hi} monocytes that could suppress atherosclerosis in hyperlipidemic mice.

Methods: EVs were produced by culturing THP-1 macrophages with IL-4 and purified using cushioned-density gradient ultracentrifugation. Twenty-week old male LDL-receptor deficient mice fed high-fat diet for 16 weeks were treated given intraperitoneal infusions of 10e^{10} THP1-IL4 EVs or sham 3-weekly for 6 weeks. Circulating Ly6C^{hi} monocytes were collected using a cell sorter and extracted RNA was examined using NanoString nCounter Autoimmune and Metabolic gene panels. Plasma cytokines were detected with a V-Plex Meso Scale assay. Atherosclerosis was assessed by detecting myeloid cell subsets in enzymatically digested aortae as well as oil red O positive lesions and Sirius Red collagen staining in the aortic root. Efferocytosis was examined both *in vitro* and *ex vivo* by exposing THP1-IL4 EVs or sham-treated bone marrow-derived macrophages and peritoneal macrophages with CFSE-labeled apoptotic Jurkat cells.

Results: THP1-IL4 EVs caused reduced signaling pathways controlled by MAPK, PI3K, TLR and inflammasomes among Ly6C^{hi} monocytes. We identified reduced levels of Casp-1, Nlrp1a, as well as Aim2, all recognized to drive atherosclerosis including in JAK2^{vf} clonal hematopoiesis. Furthermore, THP1-IL4 EVs upregulated metabolic pathways involved in arginine metabolism, IDH1/2 activity, redox stress control, nucleotide salvage, mitochondrial respiration, and fatty acid oxidation. In contrast, they reduced pathways involved in glucose transport, hypoxia, KEAP-NRF2 pathway and tryptophan metabolism. Control of these pathways in Ly6C^{hi} monocytes contributed to reduced levels of IL-1β, IL-6, IFNγ and TNFα in plasma, as well as CD45^{+} aortic myeloid cells and oil red O positive aortic lesions. This also led to plaque stabilization as noted by increased collagen deposition and reduced necrotic core volumes. *In vitro* and *ex vivo* studies of macrophages treated with THP1-IL4 EVs supported their capacity to enhance efferocytosis.

Conclusions: IL-4-polarized Mϕ EVs communicate profound transcriptional reprogramming to Ly6C^{hi} monocytes, suppressing their propensity to accelerate atherosclerosis while benefitting their ability to contribute to atheroma remodeling and stabilization.

Purpose: Rheumatoid arthritis (RA) affects approximately 1% of the global population, causing significant morbidity and disability. Despite advances in treatment options, many patients experience suboptimal responses to therapy and decreased quality of life. Inflammation-induced activation of osteoclasts, exclusive bone-resorbing cells of hematopoietic origin, mediates joint destruction and systemic bone loss in RA. We previously characterized highly osteoclastogenic human osteoclast progenitor (OCP) population within the classical monocyte subset (CD45+CD15-CD3-CD19-CD56-CD11b+CD16-CD14+CCR2+), present in the inflamed periarticular tissues as well as among peripheral blood mononuclear cells. As Notch signaling is implicated in hematopoietic cell differentiation and activation, we investigated the effect of Notch modulation on OCP activity in RA.

Methods: Upon Ethical approval, mononuclear cells from peripheral blood and periarticular tissue were collected from RA patients and controls. Expression of Notch pathway components were analyzed in sorted OCPs using flow cytometry and qPCR. In addition, Notch receptors and ligands were assessed in periarticular tissue by immunohistochemistry. Osteoclasts and macrophages were differentiated from common progenitor monocyte subset in vitro using RANKL and/or M-CSF respectively, under stimulation by immobilized Notch ligands, with or without addition of neutralizing anti-Notch 1 antibodies.

Results: Substantial proportion of OCPs within peripheral blood and periarticular mononuclear cells of RA patients express Notch receptors. Moreover, we observed lower gene expression of Notch 1 and 2 receptors in OCPs from RA as well as negative association between Notch 1 and 2 expression with RA activity score DAS28. Differentiating osteoclasts increasingly expressed Notch 3 and DLL1 mRNA. In vitro stimulation of osteoclastogenic cultures by Notch ligands showed that JAG1 and DLL1 inhibited osteoclast formation in a dose dependent manner, whereas neutralizing anti-Notch 1 antibodies partially ameliorated that inhibition. Moreover, macrophages differentiated from the same monocyte progenitor subset were also functionally regulated by Notch signaling, with DLL1 acting to suppress phagocytosis but enhance antigen-presenting potential.

Conclusion: Notch axis is involved in the negative regulation of OCP differentiation and activity, therefore modulation of Notch signaling may serve as an important complementary approach to reduce bone resorption in arthritis.

Dexamethasone and mRNA co-loaded Lipid Nanoparticles (LNPs): A Synergistic Approach for Efficient mRNA Delivery and reduced pro-inflammatory Cytokine Secretion in immunological cells

Rocio Gambaro[1], Ignacio Berti[1;2], María-José Limeres[1], Malin Svensson[1], Silvia Fraude[1], Paula Calderon[1], Ana Pena Vaquero[1], German Islan[1;2], Stephan Gehring[2]

[1]Children´s Hospital, University Medical Center Mainz, Mainz, Germany; *[2]CINDEFI (UNLP-CONICET), La Plata, Buenos Aires, Argentina*

Purpose: The objective of this work is to develop two LNP formulations with the ability to efficiently express a reporter mRNA and co-deliver an anti-inflammatory drug (Dexamethasone, DX) in Human peripheral blood mononuclear cells (PBMCs). LNPs-mRNA/DX could reduce the secretion of pro-inflammatory cytokines and attenuate the side effects of repetitive LNPs administration.

Methods: LNPs were optimized by modifying the helper lipids and replacing the 25% of cholesterol with DX, to obtain two different lipid mixes: LM1-DX (ALC-0315/DSPC/Cholesterol/ALC-0159/DX) and LM2-DX (ALC-0315/DOPE/Cholesterol/ALC-0159/DX). LNPs without DX were also prepared (LM1 and LM2). The LNPs were generated using the microfluidic platform and characterized in terms of size, polydispersity and Z potential by Dynamic Light Scattering and mRNA encapsulation efficiency (EE) by fluorescence assay. Transfection efficiencies of LNPs delivering a reporter mRNA (Luciferase) to PBMCs were determined. The release of cytokines induce by different LNP formulation was measured in the supernatant of PBMCs by cytometric bead array. *In vivo* biodistribution in C57BL/6J mice after i.m injection of the LNP formulations was performed.

Results: Stable LNPs-DX were obtained with a mean size around 120 nm, highly homogeneity (PDI less than 0.05) and Zeta potential values close to neutrality. High mRNA EE (95-100%) was achieved. The LNPs efficiently delivered *Luciferase* mRNA to PBMCs with relative luciferase levels higher than $5x10^5$ for LM1-DX and LM2-DX. Cytokine release was evaluated after stimulation of PBMCs with LNPs for 24 h. While LM1 and LM2 LNPs induced an increase in interleukin-1β (IL-1β), tumor necrosis factor-α (TNF-α), and monocyte chemoattractant protein-1 (MCP-1) levels, the respective LNPs-DX strongly reduced 3 to 5 times the cytoquines levels. The biodistribution assay showed that LM1-DX and LM2-DX mostly distributed in the liver, while LM2-DX also exhibited luciferase signal in spleen and limph nodes.

Conclusion: The results demonstrate that LNPs co-loaded with mRNA and anti-inflammatory drug could be considered as effective carriers for transfection of human primary immune cells and reduction of pro-inflammatory effects. Furthermore, LNPs showed differences in biodistribution. These formulations showed more tolerogenic properties with lower pro-inflammatory activity and could be potential candidates for the reduction of adverse effects in the treatment of metabolic diseases.

Role of macrophage migration inhibitory factor (MIF) on mesenchymal stromal cell (MSC) therapeutic efficacy in acute lung injury

Ian Hawthorne[1;2], Courteney Tunstead[1;2], Evelina Volkova[1;2], Hazel Dunbar[1;2], Claudia C. dos Santos[3], John G. Laffey[4;5], Karen English[1;2]

[1]Cellular Immunology Lab, Department of Biology, Maynooth University, Maynooth, Ireland; *[2]Kathleen Lonsdale Institute for Human Health Research, Maynooth University, Maynooth, Ireland*; *[3]Keenan Research Center for Biomedical Research, St. Michael's Hospital, Toronto, Canada*; *[4]Anesthesia and Intensive Care Medicine, School of Medicine, College of Medicine Nursing and Health Sciences, University of Galway, Galway, Ireland*; *[5]Anesthesia and Intensive Care Medicine, Galway University Hospitals, Saolta University Hospitals Groups, Galway, Ireland*

Purpose: Human mesenchymal stromal cells (MSCs) rely on specific inflammatory disease microenvironments in order to carry out their anti-inflammatory actions *in vivo*. One of the barriers to the success of MSC therapy is the inability to identify potential responders. Macrophage migration inhibitory factor (MIF) has been previously shown to act as a mediator sustaining the pulmonary inflammatory response in acute respiratory distress syndrome (ARDS). This study evaluates the role of MIF in ARDS pathophysiology and how it may be used to predict MSC therapy outcomes.

Methods: To investigate the role of MIF in ARDS humanised MIF mice were subjected to an LPS-induced acute lung injury model. Mice with either the low-expressing MIF promoter polymorphism ($CATT_5$), or the high-expressing MIF promoter polymorphism ($CATT_7$) or wild type (WT) littermate controls were anesthetised by isoflurane, and 2mg/kg LPS (*E.coli* - O111:B4) or PBS control was instilled intratracheally. 4 hours after LPS challenge, human bone marrow-derived MSCs were administered intravenously. Mice were sacrificed 48 hours post LPS challenge and the bronchoalveolar lavage fluid was obtained. Pro-inflammatory cytokines, total protein content and immune cell populations were evaluated.

Results: Mice containing the high-expressing MIF allele ($CATT_7$) exhibit a more severe phenotype with increased clinical score, elevated levels of pro-inflammatory cytokines and greater immune cell infiltration following LPS challenge compared to the low MIF expressing $CATT_5$ and WT groups. Furthermore, $CATT_7$ mice displayed increased lung permeability. Interestingly, BM-MSCs were more efficacious in the $CATT_7$ mice where they significantly reduced inflammatory markers and abrogated immune cell infiltration.

Conclusion: These data demonstrate how disease microenvironments can affect MSC therapeutic efficacy and identifies MIF as a potential biomarker for MSC success.

Time-Dependent Modulation of Peritoneal Adhesion Post-Abdominal Surgery: The Role of PAD2 in Regulating neutrophil extracellular traps and macrophage extracellular traps

Yuqing Lu[1], Elrod Julia[1], Jasmin Knopf[1]

[1]*University Medical Center Mannheim, Heidelberg University, Mannheim, Germany*

Purpose: This study investigates the inhibition of Peptidylarginine Deiminase 2 (PAD2) as a therapeutic strategy to mitigate peritoneal adhesions resulting from past surgeries, focusing on its effects on Neutrophil Extracellular Traps (NETs) and Macrophage Extracellular Traps (METs) formation inhibition.

Methods: Utilizing a peritoneal adhesion model in C57BL/6 mice, this study assessed the impact of various pharmacological inhibitors on NET and MET at post-operative days 3 and 21, exploring their roles in adhesion formation. Inhibitors tested included Pad2in1 (PAD2), DNase1 and DNase1L3 (extracellular DNA), BMS-P5 (PAD4), Alvestate (Neutrophil elastase), AZD5069 (CXCR2 antagonist), Disulfiram (Gasdermin D), Na11 (NOX-2 for ROS-dependent NETs), and Metformin (HMGB1). Evaluation methods comprised HE staining, immunohistochemistry for NET/MET markers, and immunofluorescence for detailed NET/MET visualization. Macroscopic grading of adhesions was performed using the Leach and Nair grading systems.

Results: PAD2 inhibition significantly reduced adhesion severity, especially in the prolonged post-operative phase (21-day model). The efficacy of PAD2 inhibition in reducing NET and MET formation in both, the early phase (3-day model) and late phase (21-day model), contributed to this reduced adhesion severity.

Conclusion: Targeting PAD2 presents a promising approach to reducing peritoneal adhesions post-abdominal surgery. By modulating both NET and MET pathways, PAD2 inhibition offers a nuanced therapeutic strategy that addresses the complex temporal dynamics of adhesion formation. This underscores the importance of considering the timing of intervention in the development of post-surgical care protocols, suggesting a new avenue for improving patient outcomes following abdominal surgery.

To stress... To resist? The power of stress responses in sepsis

Katia Jesus[1], André Barros[1], Elsa Seixas[1], Luís F. Moita[1;2]

[1]*Instituto Gulbenkian de Ciência (IGC), Oeiras, Portugal*; [2]*Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal*

Restoration of organismal homeostasis after an insult requires a balanced response by two arms of host defence: disease tolerance and resistance. Disease tolerance refers to mechanisms involved in tissue protection from damage caused by inflammation, whereas resistance mechanisms aim to kill and clear out the pathogen that triggered the inflammatory condition.

Inducing stress responses can initiate disease tolerance mechanisms, as our lab previously demonstrated (DOI: 10.1016/j.immuni.2020.09.011). In a severe murine sepsis model, we showed increased survival and less tissue damage upon treatment inducing mild mitochondrial stress. However, the protective mechanisms initiated by stress responses have not been systematically studied. This work focuses on understanding the impact of stress responses on resistance and tolerance mechanisms.

For this, we optimized a mild murine sepsis model to allow monitoring for 5 days. Within this period, pathogen load, immune phenotyping and damage markers were assessed by colony forming unit assays, flow cytometry, histopathology and circulating damage markers quantification, respectively. Mixed effects models, with experiments as random effect, were performed using R software.

So far, we have found a significant pathogen burden decrease of at least 30% in treated animals compared to controls, starting at 72h post-infection and treatment. Culminating in complete pathogen clearance in some organs of treated animals at 120h, with control mice still showing considerable pathogen loads. These observations support the hypothesis that mild mitochondrial stress also triggers pathogen clearance, a hallmark of resistance responses. Furthermore, we found significant differences in adaptive and innate immune cell populations, associated with the treatment of septic animals. Interestingly, the effects of mitochondrial stress appear to be cell-specific: treatment reduced lymphocyte activation whilst, in parallel, increasing innate immune cells. We hypothesize these changes could be underlying protective mechanisms.

Our results show that mild mitochondrial stress can improve resistance mechanisms and tolerance in septic mice. Furthermore, our data suggests that mild mitochondrial stress could be a potential strategy for fine-tuning the type and quality of immune responses. Understanding how mitochondrial stress contributes to homeostasis restoration could inform the development of therapeutic approaches to life-threatening conditions characterized by dysfunctional immune responses.

Neutrophil subsets and their functions in the development of periodontitis

Banndith Cheat[1;2], Jérôme Bouchet[1], Marjolaine Gosset[1;2], Véronique Witko-Sarsa[3], Catherine Blanc[4]

[1]URP 2496, BRIO Lab, UFR'Odontologie, Faculté de Santé, Université Paris Cité, Montrouge, France; *[2]Service de médecine bucco-dentaire, Hôpital Charles-Foix, AP-HP, Ivry-sur-Seine, France*; *[3]Inserm U1016-CNRS UMR8104, Institut Cochin, Paris, France*; *[4]UMS37 Faculté de Médecine, Sorbonne Université, Paris, France*

Periodontitis is a highly prevalent chronic inflammatory disease triggered by the oral dysbiosis, whith *Porphyromonas gingivalis* considered a key stone pathogen. Neutrophils, the most abundant immune cells found in periodontal lesions, play a crucial role in periodontal health and disease. Recent data suggests that neutrophils are differentially distributed in periodontal lesions of experimental periodontitis models, exhibiting differential expression of pro-inflammatory markers, which may indicate distinct subtypes of neutrophils involved in the pathogenesis of periodontitis. This study aims to identify predictive neutrophil phenotypes and determine their functions in periodontitis onset and progression.

Experimental periodontitis was induced on 2 groups of wild-type (WT) mice using ligatures soaked with or without *P. gingivalis.* The ligatures were placed into the palatal sulcus of the first maxillary right molar, while the intact left molars served as control. Alveolar bone resorption was monitored by micro-CT before, during, and at the end of the experiment. All mice were sacrificed for histological and immunostaining analysis. In addition to periodontitis mice model, gingival tissue and saliva samples from periodontitis patients were analyzed using mass imaging cytometry (Hyperion) and spectral flow cytometry (Cytek).

In ligature-induced periodontitis, the presence of *P. gingivalis* modulates the expression of neutrophil serine proteases-expressing cells in connective tissue and along alveolar bone crest, with a differential expression of cathepsin G, neutrophil elastase, and PR3 observed. The multiplex analysis of neutrophils purified from saliva revealed a differential expression of markers related to maturation, activation, survival, and phagocytosis between healthy individuals and those with periodontitis, indicating a pro-inflammatory profile in the latter. We identified the overexpression of neutrophil serine proteases in tissue from periodontitis patients. Deeper analysis of neutrophils distribution and phenotypes showed fewer PMNs in non-inflamed tissue and strong patches of PMN infiltrates, with differential expression of key markers and enzymes (CD16, myeloperoxidase, cathepsin G, neutrophil elastase, etc.) according to their localization, indicating different functions and levels of maturation.

The preliminary data of the present study indicates evidence of different subtypes of neutrophils with distinct functions involved in the development of periodontitis.

Attenuation of apoptosis and inflammation in oral lichen planus patients after low level laser therapy

Milena Draganova[1], Maria Mutafchieva[1], Svitlana Bachurska[2], Georgi Tomov[1], Plamen Zagorchev[1]

[1]Medical University-Plovdiv, Plovdiv, Bulgaria; *[2]Department of Clinical Pathology, National Oncology Hospital, Sofia, Bulgaria*

Oral lichen planus (OLP) is a T-cell-mediated chronic inflammatory disorder that affects the oral mucosa. The control of symptomatic OLP includes different therapies but a permanent cure is not yet available. Although topical steroids are the first-line treatment, alternative strategies for management are required. Low-level laser therapy (LLLT) is an innovative approach for OLP patients that improves wound healing and decreases inflammation.

The study aimes to determine and compare the expression of pro- and anti-apoptotic markers in patients' biopsies and TNF-α in saliva before and after LLLT treatment.

Material and methods: 20 OLP patients and underwent LLLT with a diode laser (810 nm), 3 times weekly for a month. 20 healthy donors were used as controls. The biopsies were taken before and after therapy and the expression of the markers was examined immunohistochemically. Unstimulated whole saliva was collected and the levels of TNF-α were measured by ELISA.

Results: The results from immunohistochemistry showed that p53 and caspase-3 expression were high in OLP patients and decreased after LLLT. In contrast, p63 and bcl-2 expression was absent or weak in the OLP group and slightly increased after therapy. Salivary TNF-alpha levels were significantly increased before and decreased after therapy in patients with OLP in comparison with healthy subjects.

Discussion: Based on our immunohistochemical results, the reverse correlation between p53-p63 and the lack of keratinocyte expression of bcl-2 observed in OLP patients makes keratinocyte cell death possible through a caspase cascade activation. Decreased caspase 3 and TNF-a expression after LLLT are linked with significant improvement in the symptoms and clinical signs of OLP. We showed decreased inflammation and stimulated cell survival and proliferation, counteracting in this way to the pro-apoptotic assault blamed for the tissue damage. All this determines LLLT as a useful and harmless treatment modality for OLP patients.

Immuno profile of Inflammatory bowel disease patient response to anti- TNFa therapy

Penelope Pelczar[1], Can Ergen-Behr[1], Marius Boettcher[1], Andres Machicote[1], Morsal Sabihi[1], Carolin Manthey[1], Samuel Huber[1]

[1]*I. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Tumor necrosis factor (TNF) α is a pleotropic cytokine with a potential proinflammatory capacity and has been recognized as one of the triggering cytokines in the induction of colorectal inflammation and involved in the pathogenesis of inflammatory bowel disease (IBD). As a result of this, blocking of TNF signal by anti-TNF antibodies becomes a main therapeutic strategy for severe steroid refractory or dependent IBD patients today. Clinical evidence showed that anti-TNF therapy results in an improved clinical success including a rapid disease remission, a high rate of mucosal healing, and improved quality of life in up to 70% of IBD patients. However, about 30% of IBD patients do not respond to anti-TNFα induction therapy. To provide new insights and to optimize the precision of anti-TNF strategy in patients with IBD, we designed a longitudinal study of patients who received anti-TNFα therapy. We collected biopsies before and after 12 weeks of treatment with anti-TNFα and performed single cell transcriptomic analysis with particular focus on CD4+ T cells. We further integrated our findings with 4 other published data sets to analyze individual cell activity and its interaction to other immune and non-immune cells. Our analysis provides a detailed cellular landscape of inflamed gut tissue compared to healthy or non-inflamed controls. In particular, we found that expanded intestinal T follicular helper (TFH) cells are more associated to inflamed tissue and suggest a potential link to negative response to anti-TNFa therapy. These findings shed light on the possible role of intestinal TFH cells in maintaining gut homeostasis and highlight its pivotal role to intestinal immunity in the pathogenesis of IBD.

Expression of MIR22 Host Gene in different cell populations isolated from Oligoarticular Juvenile Idiopathic Arthritis patients

Chiara Artale[1], Simone Pelassa[1], Federica Raggi[1], Chiara Rossi[1], Federica Briasco[1], Francesca Orso[2;3], Daniela Taverna[2], Marco Gattorno[1], Alessandro Consolaro[1], Maria Carla Bosco[1]

[1]UOC Rheumatology and Autoinflammatory Diseases, IRCCS Istituto Giannina Gaslini, Genova, Italy; *[2]Department of Molecular Biotechnology and Health Sciences, Molecular Biotechnology Center "Guido Tarone", Torino, Italy*; *[3]Department of Translational Medicine, University of Eastern Piedmont, Novara, Italy*

Purpose: Oligoarthritis is the most common category of Juvenile Idiopathic Arthritis (JIA). To date, no reliable biomarker of disease activity and response to treatment has been identified for this disease. Recent findings indicate a causal role for MIR22 Host Gene (MIR22HG) in the pathogenesis of adult arthritis and suggest its potential as a biomarker. No information is available on MIR22HG expression/function in Oligoarthritis. We investigated MIR22HG expression in different cell populations from peripheral blood (PB) and synovial fluid (SF) of Oligoarthritis patients at disease onset. MIR22HG putative role in Oligoarthritis was studied by assessing the association of its expression with patient clinical course after 1 year of follow up.

Methods: MIR22HG expression was analyzed by RT-qPCR in the human monocytic cell line, THP1, and in mononuclear cells isolated from both PB (PBMC) and SF (SFMC) of 30 treatment-naïve Oligoarthritis patients at onset and from PB of 10 age/gender matched healthy individuals as controls. Cells were isolated by Ficoll and separated into CD14+ and CD14- subsets using CD14+ magnetic beads. SF-derived fibroblast-like synoviocytes (FLS) were isolated from 8 patients and phenotypically characterized using anti-CD45, CD90, CD34, and Podoplanin (PDPN) antibodies. Results of MIR22HG expression analysis were associated with patient clinical parameters.

Results: We showed increased MIR22HG expression in THP1 cells upon stimulation with the proinflammatory stimuli, LPS, IFNy, and hypoxia. Higher MIR22HG expression was detected in patient-derived CD14+ compared to CD14- cells. Correlation with patient clinical data indicates different MIR22HG mRNA expression levels in CD14+ cells between patients with oligoarticular and polyarticular courses of the disease at follow up. FLS from patients were CD45-/CD90+/PDPN+, consistent with the phenotype of synovial sublining FLS involved in inflammation. MIR22HG was found expressed in FLS. Finally, we demonstrated the chondrogenic differentiation ability of MIR22HG-expressing FLS.

Conclusion: We demonstrated induction of MIR22HG expression in THP1 cells by proinflammatory stimuli in CD14+ and CD14- mononuclear cells and in FLS from Oligoarthritis patients. MIR22HG expression levels differed in CD14+ cells from patients undergoing different disease courses. MIR22HG role in the pathogenesis of Oligoarthritis and as a molecular biomarker/target for therapy will be assessed in the future.

Novel dairy fermentates have differential effects on key immune responses associated with viral immunity and inflammation

Dearbhla Finnegan[1;2], Monica Mechoud[2;3], Claire Connolly[2;4], Jamie Fitzgerald[2;3;4], Tom Beresford[2;3], Harsh Mathur[2;3], Lorraine Brennan[2;4], Paul Cotter[2;3;5], Christine Loscher[1;2]

[1]Dublin City University, Dublin, Ireland; *[2]Food for health Ireland, Dublin, Ireland*; *[3]Teagasc food research centre, Cork, Ireland*; *[4]University College Dublin, Dublin, Ireland*; *[5]APC Microbiome Ireland, Cork, Ireland*

Fermented foods and ingredients, including fermentates derived from lactic acid bacteria (LAB) in dairy products, can modulate the immune system. Here we describe the use of reconstituted skimmed milk powder to generate novel fermentates from *Lactobacillus helveticus* strains SC232, SC234, SC212, and SC210, and from *Lacticaseibacillus casei* strains SC209 and SC229, and demonstrate using in vitro assays that these fermentates can differentially modulate cytokine secretion by bone marrow derived dendritic cells (BMDCs) when activated with either the viral ligand, loxoribine, or an inflammatory stimulus, lipopolysaccharide. Specifically, we demonstrate that SC232 and SC234 increase cytokines IL-6, TNF-α, IL-12p40, IL-23, IL-27 and IL-10, and decreased IL-1β in primary bone marrow derived dendritic cell (BMDCs) stimulated with a viral ligand. In contrast exposure of these cells to SC212 and SC210 resulted in increased IL-10, IL-1β, IL-23, and decreased IL-12p40 following activation of the cells with the inflammatory stimulus LPS. Interestingly SC209 and SC229 had little or no effect on cytokine secretion by BMDCs. Additionally, the metabolite composition of these fermentates differed with SC212 having high relative concentrations of desaminotyrosine, succinate, glutamate, and lactate, while SC234 had higher relative concentrations of succinate, and lactate. Overall, our data demonstrates that these novel fermentates have specific effects and can differentially enhance key immune mechanisms that are critical to viral immune responses, or can suppress responses involved in chronic inflammatory conditions, such as Ulcerative Colitis (UC), and Crohn's disease (CD).

The care, treatment, and experiments involved in this study were approved by the Research Ethics Committee (REC) of Dublin City University (Approval DCUREC/2023/187).

Development of an ex vivo approach preserving natural hair follicles and resident immune cells in order to recapitulate hair loss-associated inflammation

Emilie Braun[1], Mathias Peries[1], Nicolas Giang[1;2], Manon Scholaert[1], Benoit Chaput[3], Nicolas Gaudenzio[1;4], Emeline Pages[1]

[1]*Genoskin, Toulouse, France*; [2]*LAAS CNRS, Toulouse, France*; [3]*Rangueil Hospital, CHU Toulouse, Toulouse, France*; [4]*Infinity INSERM, Toulouse, France*

Purpose: More than 30 years ago, Philpott et al. developed an ex vivo model enabling the survival of hair units inside a petri dish after microdissection. It is now considered as the gold standard human hair in vitro model. However, in biopsies from hair loss patients, the perifollicular region exhibits inflammation related to the infiltration of lymphocytes, macrophages and mast cells. While targeting inflammatory aspects represents a promising therapeutic approach for slowing down hair loss, new translational models with hair follicles and immune cells are lacking. Our objective is to develop an ex vivo inflammatory model maintaining hair follicles in their complex native immune environment.

Methods: We collected face lift samples after plastic surgery with all legal authorizations required from 5 donors. Natural skin biopsies with hairs were embedded in a proprietary solid matrix and maintained in chemically-defined xeno-free medium for 5 days. To reproduce local inflammation, we performed a 24h initial topical treatment with bacteria-derived LPS.

Results: Using multiplex imaging, we showed that skin-resident T cells, macrophages and mast cells were preserved in the hair follicle microenvironment in our models. Histological analysis revealed that 24h of LPS treatment did not have significant impact on tissue integrity. Using a 36-plex pro-inflammatory cytokines panel, we demonstrated that LPS treatment induced an inflammatory response in ex vivo models with increased levels of GM-CSF, IL-8 and MIP-1β. By co-immunostaining of Ki-67 and active caspase 3 post-treatment, we observed that the LPS induced a decrease in proliferation at day 2 and an increase in the percentage of apoptotic cells in the hair follicles around day 5.

Conclusion: Overall, we found that a topical LPS treatment for 24h induces an inflammatory environment associated with high levels of GM-CSF, IL-8 and MIP-1β. Importantly, both IL-8 and MIP-1β were elevated in the serum of patients with alopecia areata. LPS treatment was also associated with decreased proliferation followed by increased apoptosis of hair follicles. This model with an inflammation induced by topically applied LPS could be relevant to evaluate the efficacy of compounds for reducing scalp inflammation in a natural environment.

Prothrombotic activity of adipose tissue in patients with rheumatoid arthritis treated with JAK kinase inhibitors baricitinib or upadacitinib

Krzysztof Bonek[1], Magdalena Plebanczyk[2], Maciej Ołdak[2], Weronika Kurowska[2], Sylwia Szczygielska[1], Katarzyna Helon[1], Agnieszka Zielińska[1], Anna Felis-Giemza[3], Wlodzimierz Maslinski[2], Ewa Kuca-Warnawin[2]

[1]Department of Rheumatology, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland; *[2]Department of Pathophysiology and Immunology; National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland*; *[3]Biologic Therapy Center; National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland*

Background: Data from clinical trials indicate that patients with rheumatoid arthritis (RA) who were treated with the Janus kinase inhibitor (JAKi) had an increased risk of thromboembolic events. Since adipose tissue (AT) can secrete factors that affect coagulation and fibrinolysis, we examined the prothrombotic activity of AT in RA patients just before and after treatment with baricitinib or upadacitinib.

Materials and methods: Seventeen patients with RA were included in the study. Peripheral blood and subcutaneous AT samples were collected from patients just before the implementation of JAKi treatment and after six months of JAKi therapy. Adipose tissue explants were cultured in the presence of TNF or without TNF for 24 hours. At the end of culture, cells were harvested and supernatants were collected for mRNA and protein analyses of tissue factor (TF), plasminogen activator inhibitor (PAI) and visfatin. (Peripheral blood mononuclear cells served as a control for adipose cell mRNA expression. Concentrations of TF, PAI and NAMPT in blood plasma and AT culture supernatants were quantified by ELISA.

Results and conclusions: We found no significant differences in the levels of TF, PAI and visfatin spontaneously produced ex vivo by AT before implementation of treatment with baricitinib or upadacitinib and after treatment with either of these JAKis in all study participants. However, a significant change in the prothrombolytic activity of AT after TNF- stimulation was detected. In the presence of TNF, AT from RA patients who were treated with JAK**i** produced significantly higher levels of mRNA for TF, PAI and visfatin, as well as significantly higher levels of TF and NAMPT proteins, compared to AT samples explanted before the implementation of JAKi. In addition, a strong correlation was found between plasma levels of visfatin and TF. These results indicate that JAKi therapy may increase the sensitivity of AT to TNF, leading to increased production of prothrombotic proteins by this tissue. This may contribute to an increased risk of thromboembolic events in RA patients treated with JAKi.

A protective function of sclerosing cholangitis on inflammatory bowel disease

Tanja Bedke[1], Friederike Stumme[2], Miriam Tomczak[2], Babett Steglich[2], Rongrong Jia[2], Simon Bohmann[2], Agnes Wittek[2], Jan Kempski[2], Emilia Göke[2], Marius Boettcher[2], Dominik Reher[2], Anissa Franke[2], Maximilian Lennartz[3], Thorben Fründt[2], Sören Weidemann[4], Gisa Tiegs[5], Christoph Schramm[2], Penelope Pelczar[2], Samuel Huber[2]

[1]. Department of Medicine, Hamburg, Germany; *[2]I. Department of Medicine, Hamburg, Germany*; *[3]Institute of Pathology, Hamburg, Germany*; *[4]Center of Diagnostics, Hamburg, Germany*; *[5]Center for Experimental Medicine, Hamburg, Germany*

Purpose: There is a strong clinical association between inflammatory bowel disease (IBD) and primary sclerosing cholangitis (PSC), a chronic disease of the liver characterized by biliary inflammation that leads to strictures and fibrosis. Approximately 60-80% of people with PSC will also develop IBD (PSC-IBD). One hypothesis explaining this association would be that PSC drives IBD. Therefore, our aim was to test this hypothesis and to decipher the underlying mechanism.

Methods: Colitis severity was analyzed in experimental mouse models of colitis and sclerosing cholangitis, and people with IBD and PSC-IBD. Foxp3$^+$ Treg infiltration was assessed by qPCR and flow cytometry. Microbiota profiling was carried out from fecal samples of people with IBD, PSC-IBD, and mouse models recapitulating these diseases. Fecal microbiota samples collected from people with IBD and PSC-IBD were transplanted into germ-free mice followed by colitis induction.

Results: We show that sclerosing cholangitis attenuated IBD in mouse models. Mechanistically, sclerosing cholangitis causes an altered intestinal microbiota composition, which promotes Foxp3$^+$ Treg expansion, and thereby protects against IBD. Accordingly, sclerosing cholangitis promotes IBD in the absence of Foxp3$^+$ Treg. Furthermore, people with PSC-IBD have an increased Foxp3$^+$ expression in the colon and an overall milder IBD severity. Finally, by transplanting fecal microbiota into gnotobiotic mice, we showed that the intestinal microbiota of people with PSC protects against colitis.

Conclusion: This study shows that PSC can have protective properties on IBD and provides a comprehensive insight into the mechanisms involved in this effect.

CXCL4, CXCL4-DNA/RNA complexes and anti-CXCL4 antibodies are modulated in Systemic Sclerosis patients under Iloprost therapy

Giuseppe Ocone[1], Roberto Lande[1], Anna Mennella[1], Katia Stefanantoni[2], Raffaella Palazzo[1], Immacolata Pietraforte[3], Iliana Sciarra[2], Massimiliano Vasile[2], Valeria Riccieri[2], Loredana Frasca[1]

[1]National center for global health, Istituto Superiore di Sanità, Rome, Italy; *[2]Department of Clinical, Internal, Anesthesiological and Cardiovascular Sciences, Sapienza University of Rome, Rome, Italy*; *[3]Department of Oncology and Molecular Medicine, Istituto Superiore di Sanità, Rome, Italy*

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by vascular and immunity alterations, and skin/internal organs fibrosis. Aberrant levels of plasma CXCL4, CXCL4-RNA/DNA complexes, type I IFN (IFN-I) and anti-CXCL4 antibodies characterize SSc. These parameters influence each other: CXCL4-self-DNA/RNA are triggers of IFN-I and pro-inflammatory factors in plasmacytoid dendritic cells (pDCs) and myeloid DC (mDC), respectively, via TLR7/8/9. Anti-CXCL4 antibodies can further amplify these responses.

Methods: Here, we assessed modulation over six months time of plasma CXCL4, CXCL4-DNA/RNA complexes, anti-CXCL4 antibodies, IFN-a and TNF-a expression in a SSc cohort under the synthetic prostaglandin iloprost treatment. Responders down-regulated their disease index (EScSGAI), after six months.

Results: Anti-CXCL4 autoantibodies correlated with both IFN-a and TNF-a levels in SSc plasma. In seven patients with shorter disease duration, who significantly improved disease activity after six months, improvement coincides with decreased plasma concentrations of IFN-a, CXCL4 and TNF-a. Interestingly, iloprost efficiently blocked pDCs IFN-I production i*n vitro.*

Conclusions: This is a longitudinal pilot study that analyzes CXCL4 and related parameters modulation over time in SSc. These findings suggest a possible role of Iloprost as disease modifying drug, which may be mediated by down-regulation of the plasma CXCL4 and IFN-I levels. Since CXCL4, IFN-I and TNF-a down-modulation was more evident in SSc patients with shorter disease duration over iloprost treatment, these results warrant future investigations to address whether the early treatment with iloprost can slow or block SSc progression and complications.

USP43 promotes inflammation-driven colorectal cancer progression through stabilizing HDAC11 protein

Han Wu[1], Weilin Chen[1]

[1]*Shenzhen University, Shenzhen, China*

Purpose: Toxic substances or imbalance of intestinal flora homeostasis can easily cause intestinal barrier damage, leading to inflammatory bowel disease (IBD) and colorectal cancer. Here we demonstrated the roles of ubiquitin-specific protease 43 (USP43) in DSS-induced experimental colitis and inflammation-driven colorectal cancer.

Methods: Used DSS treatment for induction of experimental colitis and AOM/DSS treatment to induce colon cancer in Usp43 WT and Usp43 KO mice. qPCR and ELISA assay were used to detect IL-10 expression. HE staining and microscopy were used to assess colon section. Multiproteomics mass spectrometry was used to explore mechanistically relevant candidate proteins. Ubiquitination assay was used to detect proteins ubiquitination modification.

Results: Deficiency of USP43 leads to resistance to experimental colitis and colonic tumorigenesis independent of adaptive immunity, with an alteration of innate immune cytokines that IL-10 increased while IL-6 decreased. Furthermore, we found that USP43 can interacts with and stabilizes histone deacetylase 11 (HDAC11), an epigenetic repressor of IL-10. Knockout or pharmacologic inhibition of HDAC11 shows phenotypes consistent with DSS-induced colitis and AOM/DSS-induced colorectal cancer in USP43 deficient mice. Meanwhile, high levels of USP43 and HDAC11 proteins with a positive correlation were found in human colon cancers.

Conclusion: USP43 deficiency results in increased expression of anti-inflammatory cytokine IL-10 and attenuated experimental colitis and colorectal cancer in murine models. Meanwhile, USP43, as an ubiquitin-specific protease, can deubiquitinate K48-specific polyubiquitin chains of HDAC11 at the site of Lys44, thereby promoting the stability of the HDAC11 protein that represses IL-10 expression. These findings suggest critical roles of USP43-HDAC11-IL-10 axis in IBD and colorectal cancer, which serves as a potential therapeutic target.

High-fructose diet and folate insufficiency exacerbate renal inflammation in adenine-induced murine model of chronic kidney disease

Ting-Yu Chen[1], Ya-Ching Chiu[1], Jennifer Fransisca Budiman[1], Bi-Fong Lin[1]

[1]*Department of Biochemical Science and Technology, College of Life Science, National Taiwan University, Taipei, Taiwan, Taipei, Taiwan*

Purpose: A Western diet and high intake of sweetened beverages could readily result in metabolic syndrome and chronic kidney disease (CKD). Our previous study has demonstrated that folic acid deficiency enhanced inflammation and exacerbated renal fibrosis in high-fat high-fructose diet-fed mice. Therefore, this study aims to examine whether high-fructose diet and folic acid insufficiency might exacerbate renal fibrosis in adenine-induced CKD mice.

Methods: In our experimental design, 7 week-old C57BL/6 mice were divided into four groups: a control diet group (Ctrl), a high-fructose diet group (Hfru), Hfru with adenine (Hfru+ade), Hfru+ade with 2 mg/kg folate (Hfru-f+ade). Then, mice were treated with 0.1% (w/w) adenine on 22-week-old, and all groups were sacrificed on 44-week-old.

Results: The results showed significant increases in blood urea nitrogen, serum creatinine, renal fibrosis area, and immune cell infiltration in the adenine-induced groups compared to those of the control group. Furthermore, the kidney injury molecule-1 (KIM-1) was higher in the Hfru-f+ade group. In addition, TNF-α and IL-6 were significantly elevated in the spleen of the Hfru-f+ade group, and MCP-1 and TGF-β were also significantly increased in the kidneys of the adenine-induced groups.

Conclusion: These findings suggested that folate insufficiency might exacerbate fibrosis, inflammation, and the progression of CKD.

Chronic intestinal inflammation predisposes to the development of acute kidney injury

José Arimatéa de Oliveira Nery Neto[1], Victor Yuji Yariwake[1], Eloisa Martins da Silva[2], Raquel Vieira[1], Cláudia Silva Souza[1], Suemy Melim Yamada[1], João Vinícius Honório da Silva[1], Marcella Cipelli[1], Samuel dos Santos Oliveira[3], Laura Quadros-Pereira[4], Lorena Doretto da Silva[4], Niels Olsen Saraiva Camara[1], Vinicius de Andrade-Oliveira[1;4]

[1]Institute of Biomedical Sciences, University of São Paulo, São Paulo, Brazil; *[2]Division of Nephrology, School of Medicine, Federal University of São Paulo, São Paulo, Brazil*; *[3]Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, Brazil*; *[4]Center for Natural and Human Sciences, Federal University of ABC, Santo André, Brazil*

Clinical observations suggest that individuals with intestinal inflammation worse kidney function, yet the mechanisms are unexplored. Therefore, the aim of this study is to evaluate the influence of intestinal inflammation in an Acute Kidney Injury model. C57BL/6 mice were subjected to three cycles (5 days each) of 2% dextran sulfate sodium (DSS) in water with an interval of 4 days between DSS cycles. The Disease Activity Index (DAI) was determined based on weight loss, stool consistency, and rectal bleeding. The predisposition to the development of renal injury was evaluated by Ischemia Reperfusion (I/R) Injury model for 15 minutes (in our hands, this time of ischemia does not increase serological urea and creatinine levels). The frequency of immune cells was assessed by flow cytometry. Animals in the DSS group showed a reduction in colon length, greater cumulative DAI and loss of intestinal epithelial cells with inflammatory infiltrate. The DSS-treated group did not exhibit an increase in creatinine or urea in the serum. Interestingly, animals in the DSS group showed 6x higher expression of the KIM-1 gene than the control group, indicating that intestinal inflammation can generate kidney damage in absence of classical hallmarkers of kidney function. In fact, animals subjected to 15 min of I/R that did not receive DSS maintained creatine and urea levels similar to the control group. Notably, animals that previously received DSS and were subjected to 15 min of I/R showed high levels of creatinine and urea, corroborating that chronic intestinal inflammation can lead to susceptibility to the development of kidney disease. Animals that underwent I/R surgery showed an increase in the percentage of neutrophils and a reduction in B lymphocytes, regardless of DSS. Our data indicate that prior intestinal inflammation is capable of increasing susceptibility to I/R, suggesting a potential link between chronic intestinal inflammation and increased risk of AKI.

Gentamicin-induced inner ear injury: modulating immune and inflammatory responses with alpha1-antitrypsin for inner ear function preservation

Amit Amar[1], Eli Lewis[1], Sabri El-Saied[2], Tehilla Marom[1], Binyamin Kaminer[2]

[1]Ben Gurion University of the Negev, Beer Sheva, Israel; *[2]Soroka Medical Center, Beer Sheva, Israel*

Introduction: Aminoglycosides, the most known ototoxic antibiotic agent, lead to vestibular dysfunction and hearing loss. Ototoxic mechanism involves excessive inflammation, tissue damage, reactive oxygen species (ROS) and apoptotic events leading to irreparable cell damage. Currently, no clinical approach exists aside of corticosteroids, carrying controversial effects. Alpha1-antitrypsin (AAT), a circulating immune and inflammation modulating molecule, elevates during inflammation, promotes resolution, reduces ROS, and inhibits apoptosis. Moreover, AAT induces macrophages towards a resting phenotype, reducing inflammation. Present indication is genetic AAT deficiency. Mice carrying transgenic hAAT alleles ($hAAT^{+/+}$) exhibit elevated circulating hAAT, protecting from inflammatory flares. These attributes motion investigation of inner ear preservation under hAAT-rich conditions.

Aim: Characterize immunological, functional, molecular, and structural aspects of drug-induced ototoxicity under in-vivo AAT treatment routes.

Methods: A. $hAAT^{+/+}$ and heterozygote mice received daily gentamicin injections (100mg/kg, daily, 9 days, i.p). Vestibulo-cochlear functions were determined and inner ear organs collected for analysis. **B.** Wild-type mice were injected with gentamicin as described. AAT treatment introduced daily (intratympanic, systemic, simultaneous or preemptive). At day 10, vestibulo-cochlear functions were examined, animals were sacrificed; inner ear samples were analyzed for RT-PCR gene expression, paraffin embedded sections made for histological observation and explants for immunostaining.

Results: Expectedly, gentamicin caused hearing deficiency (60dB versus 20-30dB healthy threshold), and vestibular performance decline (2.6 severity score). **A.** $hAAT^{+/+}$ mice exhibited a hearing threshold 20dB better than heterozygote mice ($p=0.0004$) and a 13-fold lower vestibular score. **B.** Intratympanic AAT exhibited superior vestibular functionality than non-treatment, mean rotarod time-to-fall 101.66 sec versus 56.33 sec ($P=0.04$), alongside favorable auditory threshold. RT-PCR analysis showed lower iNOS expression and 3-fold increased IL-1Ra/IL-1β ratio amongst treated group. Additionally, negative correlation between iNOS and IL-1β in treated groups indicates pro-resolution, less aggressive inflammation. Preemptive treatment exhibited earlier and faster vestibular functions normalization, supporting AAT tissue preconditioning. Histological sections of treated mice depicted superiorly preserved organ of corti. Immunostaining for hair cell specific MYO-7 protein revealed a 4-fold increased hair cell survival within treated ears.

Conclusion: Findings support clinically relevant inner ear protection with AAT treatment. Ongoing experiments explore mechanisms and innate immune cell profile of AAT-treated inner ear compartment.

Soluble immune checkpoints as biomarkers for disease activity in large vessel vasculitis

Martina Bonacini[1], Alessandro Rossi[1], Ilaria ferrigno[1;2], Cecilia Catellani[1], Veronica Buia[1;2], Francesco Muratore[3;4], Chiara Marvisi[3;4], Carlo Salvarani[3;4], Alessandro Zerbini[1], Stefania Croci[1]

[1]Clinical Immunology, Allergy and Advanced Biotechnologies Unit, Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Reggio Emilia, Italy; *[2]Clinical and Experimental Medicine PhD Program, University of Modena and Reggio Emilia, Modena, Italy*; *[3]Rheumatology Unit, Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Reggio Emilia, Italy*; *[4]Dep. Chi.Mo.Mo, University of Modena and Reggio Emilia, Modena, Italy*

Purpose: Giant Cell Arteritis (GCA) and Takayasu arteritis (TAK) are different types of large vessel vasculitis (LVV) that share many pathological and clinical features. Both are characterized by immune cells infiltrating the large arteries leading to vessel remodeling and resulting in ischemic events. The pathogenesis is still largely unknown, and the lack of a standardized approach for disease activity definition is the most clinical need. Literature data support a role for immune checkpoints in LVV pathogenesis.

We aimed to identify soluble immune checkpoints deregulated in LVV and those able to discriminate between LVV patients in the active and remission phases.

Methods: 54 LVV patients and 37 controls were enrolled. LVV inclusion criteria: diagnosis of LVV-GCA or diagnosis of TAK; PET/CT with FDG uptake ≥2 in at least one vascular district and at least one among ESR >40 mm/h (or CRP >10 mg/L). The EULAR consensus definitions for disease activity states in LVV were used [Hellmich B., Ann Rheum Dis. 2020;79:19]. For LVV patients, plasma/serum samples were collected longitudinally during the active and remission phases. Concentrations of soluble CD137L, CD137, CD27, CTLA4, CD80, CD40, CD40L, GITR, GITRL, ICOSL, IDO, LAG3, PD1, PDL1, PDL2, TIM3, and VISTA were evaluated by a multiplex bead-based assay.

Results: The comparison between active LVV patients and controls revealed that plasmatic levels of PD-L2 were lower, while VISTA concentrations were higher in LVV patients. Instead, lower levels of ICOSL were observed in serum samples from active LVV patients. The comparison between LVV patients in different disease phases revealed that serum levels of ICOSL increased at least 1.4-fold in 14/31 patients when they transitioned from active to remission phase.

Conclusions: Soluble ICOSL, PD-L2, and VISTA could be involved in LVV pathogenesis. Monitoring the concentrations of ICOSL in serum might help to discriminate between LVV in the active and remission phase.

Founding: This study was supported by AUSL-IRCCS di Reggio Emilia, Italy and th Italian Ministry of Health, Ricerca Finalizzata (GR-2019-12370628).

Background: Systemic sclerosis (SSc) is an immune-mediated rheumatic disease characterized by microvasculopathy, immune dysregulation, and skin and visceral organ fibrosis. Although SSc is a rare disease, it presents high morbidity and mortality. Pathophysiology involves early endothelial damage, inflammatory infiltration, and a resulting fibrotic reaction. Innate immune system dysfunctions can be involved in the release of cytokines and chemokines, as well as autoantibodies, which can activate fibroblasts. These events give rise to a dysregulated remodeling of extracellular matrix (ECM) proteins, leading to organ failure. SSc pathophysiology involves the imbalance between pro-angiogenic and anti-angiogenic factors. However, evidence related to the prevalence of pro- or anti-angiogenic factors is controversial. Both pro- and anti-angiogenic factors, can be released by human neutrophils (PMNs) under inflammatory stimuli. Moreover, PMNs release Neutrophil Extracellular Traps (NETs), source of autoantigens and players in the pathogenesis of autoimmune diseases. However, little is known about the potential involvement of neutrophils in SSc. The aim of this study was to investigate the angiogenic profile and the involvement of neutrophil-related mediators and NETs biomarkers in SSc.

Methods: Serum levels of angiogenic (VEGF-A, VEGF-A_{165b}, ANGPT1, AGPT2, TGF-β), and lymphangiogenic factors (VEGF-C, VEGF-D) were measured by ELISA in 16 patients with SSc with videocapillaroscopic alterations and 22 healthy controls (HCs). Circulating levels of neutrophil-related mediators such as matrix metalloproteinase-9 (MMP9), CXCL8/IL-8, and NETs biomarkers (MPO-DNA complexes) were also evaluated by ELISA.

Results: SSc patients display higher circulating levels of angiogenic (VEGF-A, VEGF-A_{165b}, ANGPT1, ANGPT2, TGF-β) and lymphangiogenic (VEGF-D) factors compared to HCs. Interestingly, a directly proportional correlation between VEGF-A, VEGF-A165b, and ANGPT2 serum levels was also found. No differences were found in the circulating levels of VEGF-C. In addition, SSc patients display increased serum levels of neutrophil-related mediators (CXCL8/IL-8, MMP-9, and MPO) and the same levels of MPO-DNA complexes compared to HCs.

Conclusions: These preliminary results suggest that SSc patients display a peculiar profile of angiogenic and lymphangiogenic factors compared to HCs. Moreover, SSc patients show increased circulating levels of neutrophil-related and pro-inflammatory mediators (CXCL8/IL-8, MMP-9, MPO, and TNF-α) compared to HCs. A larger patient cohort is needed to confirm these data.

Genetic variants and serum levels analysis of indoleamine 2,3-dioxygenase in Behcet's disease

Ülkü Uçar[1;2], Yagmur Aydin Atalay[2], Güven Özkaya[3], Barbaros Haluk Oral[2;4]

[1]Department of Rheumatology, Antalya Research and Training Hospital, Antalya, Turkey; *[2]Department of Medicine-Immunology, Institute of Health Sciences, Bursa Uludağ University, Bursa, Türkiye, Bursa, Turkey*; *[3]Department of Biostatistics, Faculty of Medicine, Bursa Uludağ University, Bursa, Turkey*; *[4]Department of Immunology, Faculty of Medicine, Bursa Uludağ University, Bursa, Turkey*

Purpose: Behcet's Disease (BD) is a multisystemic disorder with an unknown etiology, having the highest prevalence rates in Turkey. Genetic factors, including familial aggregation, contribute significantly to its pathogenesis. Indoleamine 2,3-dioxygenase (IDO), a key enzyme in tryptophan metabolism, has been implicated in immune regulation and inflammation. IDO activity is believed to play a role in maintaining immune homeostasis by regulating T cell responses and promoting immune tolerance. Herein, this study aimed to investigate the association between IDO gene polymorphisms, serum IDO levels, and BD susceptibility in ninety BD patients and 52 healthy controls.

Methods: Genomic DNA was extracted from the patient's blood by using DNA isolation kit, and single nucleotide gene polymorphisms for IDO (rs7820268, rs10108662) and IDO-2 (rs4503083) were determined using RT-PCR together with the melting curve analysis method using fluorescence resonance energy transfer probs. Serum samples were collected for IDO and IDO-2 measurement using enzyme-linked immunosorbent assay (ELISA). In addition, clinical manifestations of BD such as oral ulcer, genital ulcer, uveitis, and neurological involvement were compared with serum IDO and IDO-2 levels of patients.

Results: Having been in Hardy-Weinberg equilibrium of all allele and genotype frequencies of patients and controls, statistical analyses revealed no significant differences in gene polymorphisms of IDO and IDO-2. On the other hand, serum IDO and IDO-2 levels were significantly lower in BD patients ($p<0.001$ and $p<0.001$, respectively), and a strong correlation was identified between IDO and IDO-2 levels ($r=0.920$, $p<0.001$). Furthermore, only serum IDO-2 levels were significantly lower in patients with a neuro-Behçet group compared to those without neurological involvement seen groups ($n=7$ and $n=83$ respectively, $p<0.001$).

Conclusion: While no significant differences were found in IDO gene polymorphisms between patients and healthy controls, serum IDO levels were notably lower in BD patients. This suggests a potential dysregulation of IDO activity in BD, possibly contributing to the proinflammatory immune response observed in the disease.

Dysregulated innate immune cell activity in children with periodic fever, aphthous stomatitis, pharyngitis, adenitis

Andy Dernstedt[1], Pauline Girard[1], Emilie Sallansonnet[1], Emma Arsac[1], Paola Fontannaz[1], Wafae Adouan[1], Sylvain Lemeille[1], Arnaud Didierlaurent[1], Géraldine Blanchard-Rohner[1]

[1]*University of Geneva, Geneva, Switzerland*

Purpose: Periodic fever, aphthous stomatitis, pharyngitis, adenitis (PFAPA) is a cyclic autoinflammatory syndrome that commonly manifests in children aged two to five years old. Immune dysregulation, rather than infections, is the leading hypothesis to the aetiology of PFAPA. Cytokine levels and infiltrates of adaptive immune cells in tonsils have previously been demonstrated during PFAPA fever flares. Since the innate immune cell phenotype is less known, our aim is to assess functionality of monocytes, dendritic cells (DCs), and NK cells in children with PFAPA compared to age-matched controls.

Method: We collected blood from children with PFAPA during and between flares (n=13), and age-matched healthy controls (n=10). Whole blood cells were used for flow cytometric characterisation of innate immune cells at baseline and after six hours stimulation with lipopolysaccharide (LPS), the toll-like receptor (TLR)7-agonist Gardiquimod, or interferon (IFN)-γ. We quantified production of the cytokines interleukin (IL)-12/23, TNFα, IFNα, IFNγ, and IP10 upon stimulations. We also performed bulk-RNA sequencing on whole blood. Finally, we isolated serum and measured systemic cytokine levels by multiplex.

Results: In line with previously observed lymphopenia during PFAPA flares, we found decreased frequencies of T cells, B cells, and most innate cells during flares, compared to controls and between flares. Cell stimulations showed increased TNFα production in DCs after stimulation with LPS and Gardiquimod in PFAPA subjects compared to controls. TNFα production was also increased in flare-free PFAPA subjects. CD14+CD16+ monocytes had also higher TNFα and IL12/23 production upon stimulation with LPS and at baseline between PFAPA flares. In serum we found increased IL-1RA, IL-15, IL-6, and IL-10 during flares. Between flares, those cytokines return to baseline but GM-CSF and IL-10 levels were lower compared to controls. Analysis of blood transcriptomics showed upregulated pathways associated with an innate antiviral response during flares, that came back to similar level than controls between flares.

Conclusion: Our initial analysis of the innate response in children with PFAPA shows that their DC and monocyte subsets may have a dysregulated responsiveness to innate stimuli. Further functional and genetic analysis of these cells could reveal pathways involved in this dysregulation and association with clinical symptoms.

Role of CD16 receptor in development of diabetes mellitus type 2

Vanna Imširović[1], Felix Wensveen[1], Bojan Polic[1], Vedrana Jelencic[1]

[1]*School of medicine Rijeka, Rijeka, Croatia*

CD16 is an activating receptor expressed on NK cells, macrophages, monocytes and neutrophils. This receptor was mostly investigated in the context of ADCC while its role in other aspects of immune responses remained poorly investigated. We noticed that mice lacking CD16 receptor have higher body weight in comparison to control animals which lead us to our hypothesis that this receptor might play a role in adipose tissue homeostasis. To investigate how CD16 mice cope with metabolic stress we used a model of obesity induced diabetes mellitus type 2 (DM2). In this model mice were fed *ad libitum* with normal diet (NCD) or high fat diet (HFD) in which 50% of calories were derived from animal fat. After 12 weeks on HFD diet mice develop insulin resistance and glucose intolerance. We noticed that CD16 deficient mice gained more weight after HFD and were more prone to development of DM2, seen from greater glucose intolerance and insulin resistance in comparison to control mice.

Characterisation of T lymphocytes in a rat model of Duchenne muscular dystrophy

Suzan Saidin[1], Valentina Taglietti[1], Frédéric Relaix[1;2]

[1]Univ Paris-Est Créteil, INSERM, U955 IMRB, Créteil, France; *[2]École nationale vétérinaire d'Alfort, IMRB, Maisons-Alfort, France*

Duchenne Muscular Dystrophy (DMD) arises from a mutation in the *dystrophin* gene on the X chromosome. The resulting absence of functional dystrophin protein results in a disorder marked by recurring and unresolving muscle damage and leads to progressive loss of musculoskeletal function. Numerous extensive studies have highlighted the role of macrophages in the context of muscle damage. However, despite the presence of other immune cell populations such as T lymphocytes in the DMD muscle, its role remains poorly understood. In this study, we aim to understand the T cell responses in the DMD muscle using a rat model of DMD. Via single cell RNA sequencing of the wildtype and DMD rats, we identified increased infiltration in absolute numbers of not only macrophages, but also neutrophils, NK, T, and B cells across the DMD diaphragm, tibialis anterior, and extraocular muscle compared to that of WT. We then confirmed this observation by flow cytometry. To further understand the functional capacity of the T cells in the context of DMD, we stimulated T cells from the spleens and popliteal lymph nodes of wildtype and DMD rats *ex vivo* and analysed their production of inflammatory cytokines by flow cytometry. Taken together, this study highlights the need for understanding the T cell responses to chronic musculoskeletal damage in DMD. This knowledge will help to reveal potential immunotherapy avenues for managing the disease progression in DMD patients.

Upregulation of DNase I in systemic lupus erythematosus: a role of mithocondrial DNA

Uxía Tobío Parada[1;2], Ana Suárez Díaz[1;2], Javier Rodríguez-Carrio[1;2], Aleida Martínez-Zapico[2;3], Silvia Suárez[2;3], Patricia López[1;2]

[1]Department of Functional Biology, Immunology Area, Faculty of Medicine, University of Oviedo, Oviedo, Spain; *[2]Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Oviedo, Spain*; *[3]Department of Internal Medicine, Hospital Universitario Central de Asturias, Oviedo, Spain*

Purpose: The inflammatory environment present in SLE and the high capacity of low density granulocytes (LDG) to induce NETosis promotes the increase of circulating cell-free DNA (cirDNA) and contributes to the formation of anti-dsDNA antibodies. The present study aims to analyze the role of DNase I, responsible for cirDNA degradation, in relation to LDG subsets and cirDNA levels in SLE.

Methods: DNase I and anti-DNase I were determined by ELISA, DNase I activity by a fluorescence-based assay, total cirDNA by fluorometry, mitochondrial/nuclear circulating DNA (mtDNA/nDNA) by qPCR and the frequency of LDG and T-cell subsets by flow cytometry in 42 controls and 144 SLE patients.

Results: Serum levels of DNase I were increased in SLE patients (p=0.040), especially in those presenting anti-dsDNA antibodies (p=0.005). However, the DNase I/cirDNA ratio was reduced in patients compared with controls, mainly in those with active disease (p=0.017). Remarkably, DNase I levels in controls correlated with mtDNA (r=0.438, p=0.012), a main component of NETs. Furthermore, SLE patients displayed increased levels of anti-DNase I antibodies (p=0.040), that correlated with the DNase I/cirDNA ratio (r=0.247, p=0.007). Thus, the upregulated levels of DNase I in SLE, probably induced by the elevated cirDNA amounts, could not be fully functional and might promote the generation of anti-DNase I antibodies. No differences were detected in DNase I activity, that was unrelated to DNase I levels. However, the DNase I activity rate (DNase I activity relative to DNase I levels) was reduced in patients, especially in those presenting anti-dsDNA antibodies (p=0.025) and correlated negatively with the amount of mtDNA in controls (r=-0.356, p=0.045) and non-active patients (r=-0.213, p=0.040). Finally, blood levels of LDGs were increased in SLE and associated directly with cirDNA, but only the mtDNA amount was linked to CD16+LDGs. DNase I activity was negatively correlated with LDGs and IFNγ expression on CD4 T-cells, but positively associated with Tang in SLE, especially in non-active patients

Conclusion: Present results highlight the relevance of the "cirDNA-NETosis-DNase I" tandem as a pathogenic mechanism directly involved in the etiopathogenia of SLE.

To BCG or not to BCG – a case against trained immunity?

Ivana Anđelović[1], Radmila Miljković[1], Ivana Ćuruvija[1], Marko Vasić[1], Marija Petrušić[1], Irena Živković[1], Veljko Blagojević[1]

Trained immunity (TI) has been a hot button issue in current immunology, and we decided to look at the understudied effect of TI on chemically induced colitis. We used BALB/c male mice, which are more susceptible to TNBS-induced colitis, and immunized them subcutaneously with BCG (TI-TNBS group) or saline (control-TNBS group). Seven days later, we induced colitis by intrarectal injection of TNBS in 50% ethanol. We observed the mice over a period of another week. Most mice in both groups did not survive, but the mice in the control-TNBS group lived significantly longer. We investigated the mice who survived in an additional study. We immunized the mice with another dose of BCG and paired them up with adequate controls (mice who didn't have colitis induced, immunized with BCG or with saline). Prior to the second immunization we isolated the PBMCs from a blood sample and analyzed them on a flow cytometer. Two days later mice were euthanized and their bone marrow, peritoneal, and PBMCs were collected and analyzed on a flow cytometer. The results showed BCG immunization causes an increase in both $CD45R^{+}CD19^{+}$ B cells and $CD4^{+}$ T cells in the circulation, however after colitis induction, the frequency of these cells is reduced in the circulation of the immunized mice compared to controls. Given that the immunized animals had a shorter lifespan after colitis induction, it is possible that the infiltration of these lymphocytes from the peripheral circulation could be a causal factor in aggravated inflammation. In the peritoneal cavity, BCG immunized animals had a greater percentage of $F4/80^{+}CD68^{+}$ macrophages, however after colitis, this ratio was reversed, which could indicate a faster depletion of resident macrophages of the peritoneal cavity, which are known to have a reparative role in visceral tissue damage. Post colitis, a greater percentage of peritoneal macrophages expressed iNOS, and the BCG vaccination did increase it slightly in the two days after immunization, compared to the control group. It was shown that TI could aggravate chemically induced colitis in mice, and our results seem to support this notion, which we will research further.

Th17-cell derived IL-22 plays a non-redundant protective role in a mouse colitis model

Antonella Fazio[1;2], Babett Steglich[1;2], Beibei Liu[1], Penelope Pelczar[1], Justus Neuendorff[1], Anissa Franke[1], Nicola Gagliani[1;2], Samuel Huber[1]

[1]Department of Internal Medicine, I. Medical Clinic and Polyclinic, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; *[2]Department of General, Visceral and Thoracic Surgery, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Purpose: The aim of this study is to investigate the role of Th17-cell derived interleukin 22 (IL-22) in patients with IBD and experimental colitis.

Methods: To understand the functional relevance of Th17-cell derived IL-22 we analysed human IBD samples, induced experimental colitis in a mouse model with Th17 cell specific deletion of IL-22 and used an *in vitro* human intestinal organoid system.

Results: We observed that $CD4^+$ T cells co-expressing IL-17A+IL-22+ were reduced in intestinal biopsies from people with ulcerative colitis (UC) with both active and inactive disease. To assess the functional relevancy of this finding, we used *Il17a*^{Cre} x *Il22*^{flox} mice and dextran sulfate sodium (DSS)-induced colitis. We found that *Il17a*^{Cre} x *Il22*^{flox} mice were more susceptible to DSS colitis compared to littermate control mice. Specifically, *Il17a*^{Cre} x *Il22*^{flox} mice showed a higher disease severity, reduced epithelial proliferation and a delayed tissue regeneration. This was associated with a dysregulation of genes involved in antigen presentation. Therefore, we exposed human-derived intestinal organoids to either IL-22, IL-17A or combination of both cytokines. Analysis on their transcriptome profiles identified cluster of genes specifically regulated by the combination of IL-22 and IL-17A. Gene ontology analysis identified biological processes related to presentation via MHC II to be upregulated in intestinal organoids stimulated by the combination of IL-17A and IL-22. We validated upregulation of MHC class II complex via flow cytometry analysis in this setting. Finally, we showed that colonic organoids promote differentiation of IL17A+IL22+ $CD4^+$ T cells via MHC class II.

Conclusion: Th17-cell derived IL-22 has a non-redundant protective role during intestinal inflammation and mucosal healing. It promotes tissue repair and induction of epithelial MHC class II, thereby further promoting $CD4^+$ T cell producing IL-17A and IL-22. These results indicate that the source of IL-22 is important. Specifically, the loss of Th17-cell derived IL-22 cannot be compensated by IL-22 produced by other cellular sources.

Treatment of experimental autoimmune uveitis and effects of probiotic supplementation

Petra Prochazkova[1], Radka Roubalova[1], Janet Jezkova[1], Miloslav Kverka[1], Aneta Klímová[2], Petra Svozilkova[2], Jarmila Heissigerova[2]

[1]*Institute of Microbiology of the Czech Academy of Sciences, Prague 4, Czech Republic*; [2]*Department of Ophthalmology, First Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, Czech Republic*

Uveitis is an intraocular inflammation affecting the iris, ciliary body, and choroid. Non-infection autoimmune uveitis is a heterogeneous disease mediated by T-lymphocytes, without clear pathogenesis. Intraocular inflammation is manifested by infiltration of cells and exudation of inflammatory proteins in various ocular structures. Current treatment is based on systemically administered corticosteroids, often combined with immunomodulators/immunosuppressants and biologics.

Purpose: To analyze which immunosuppressant has the best effects on autoimmune uveitis in mice or which treatment could be improved by prophylactic administration of probiotics. Such probiotic treatment in combination with immunosuppressive drugs could simulate the treatment modalities in human medicine

Methods: To induce experimental autoimmune uveitis (EAU), the interphotoreceptor retinoid-binding protein was subcutaneously applied to C57BL/6 mice. The severity of the EAU was assessed in vivo using an otoscope. Intensity and manifestation of intraocular inflammation were compared in mice treated with various immunosuppressants (mycophenolate mofetil, methotrexate) or corticosteroids (methylprednisolone) and control mice. To test the immunomodulatory properties of *Escherichia coli* Nissle 1917 (EcN), mice received EcN for 2 weeks before the EAU induction. Cervical and inguinal lymph nodes were used for analyses of intracellular cytokine production and immune cell phenotype by flow cytometry as well as the same analyses after the antigen-specific stimulation.

Results: The clinical severity of EAU was evaluated on day 21 and day 27 after the EAU induction. The strongest effect was observed in mice treated with methotrexate, milder but a significant effect was in mice treated with mycophenolate mofetil. The decreased severity of EAU caused by methotrexate was accompanied by a decreased proportion of CD4+ and an increased proportion of CD8+ T cells in both cervical and inguinal lymph nodes together with a decreased proportion of IFNγ+CD4+ in the lymph nodes draining the site of inflammation.

Conclusion: Live EcN protects against EAU when administered before and during its induction, suggesting EcN influences antigen presentation and T cell priming and may have a role in regulating the gut-eye axis.

A multidisciplinary approach to diagnosis and management of scleromyositis syndrome with positivity of anti-OJ, anti-PL7 and anti-Scl70 antibodies

Dhouha Krir[1;2], Imen Zamali[1;2], Samar Derbel[2;3], Mariem Marrak[1;2], Ahlem Ben Hmid[1;2], Meya Abdallah[2;3], Melika Ben Ahmed[1;2]

[1]Pasteur Institute of Tunis, Department of Clinical Immunology, Tunis, Tunisia; *[2]Faculty of Medicine of Tunis, University of Tunis El Manar, Tunis, Tunisia*; *[3]Department of Internal Medecine, Yasminet Regional Hospital, Ben Arous, Tunisia*

Background: Scleromyositis is a rare autoimmune condition that falls between the clinical spectrum of systemic sclerosis and autoimmune myositis that involves more than the overlap syndrome typically characterised by the presence of anti-PM/Scl antibodies.

Purpose: Highlight the clinical manifestations, diagnostic challenges, and therapeutic interventions associated with a rare case of scleromyositis with co-positivity of ASA (anti-OJ, anti-PL7) and anti-Scl70 antibodies.

Methods : A detailed clinical history, physical examination findings and imaging were used for the diagnosis and management of the patient. Sera samples were tested for antinuclear antibodies using both indirect immunofluorescence and immunodot assays to screen for anti-aminoacyl-transfer RNA (tRNA) synthetase and systemic scleroderma antibodies.

Results: We report the case of a 68-year-old female, with a history of dyspnea grade 2 on mMRC scale and joint pain. Physical examination reveals cutaneous sclerosis limited to the fingers not extending beyond the proximal metacarpophalangeal joint. The patient fulfilled the diagnostic criteria for AAS based on both serology, due to positive anti-PL7 and anti-OJ antibodies, and clinical manifestations, with the presence of interstitial lung disease, restrictive pattern on spirometry and arthritis. Systemic scleroderma was diagnosed based on the presence of cutaneous sclerosis along with the detection of anti-Scl 70 antibodies. This phenotype of scleromyositis was distinct for its absence of muscular involvement and severe lung disease that required an intensive therapeutic intervention with high-dose systemic corticosteroids associated to mycophenolate mofetil.

Conclusion: This clinical and immunological presentation offers valuable insights into the spectrum of scleromyositis disease. The entity may vary in severity and therapeutic response reflecting the diversity in clinical presentation and disease progression based on the specific anti-synthetase antibody involved.

Simultaneous hyperbaric oxygen therapy and antioxidant supplementation in the treatment of thermal skin injuries reduce inflammation and alter nociceptive signalling and wound healing

Nemanja Jovičić[1], Dragica Selakovic[2], Milos Krstic[2], Bojana Krstic[2], Marko Simic[2], Sara Rosic[2], Natalija Arsenijevic[3], Gvozden Rosic[2]

[1]Department of Histology and Embryology, Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia; *[2]Department of Physiology, Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia*; *[3]Department of Dentistry, Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia*

Purpose: Thermal skin injuries are a prevalent cause of skin damage. Pain is considered to be one of the most striking symptoms of a burn injury, caused by the direct effect of thermal injury, stimulation of nociceptors, and the production of mediators of inflammation. Some adjuvant approaches, such as hyperbaric oxygen therapy (HBO) and antioxidant supplementation, have been found useful in achieving therapeutic goals for primary injuries and their consequences.

Methods: As a thermal skin injury experimental model, we used two-month-old male Wistar albino rats. Thermal injuries were made with a solid aluminium bar at a constant temperature of 75 °C for 15 seconds. Hyperbaric oxygen treatment was performed in a specially constructed hyperbaric chamber for rats (HYB-C 300) for seven consecutive days (100% O2 at 2.5 ATA for 60 minutes). Antioxidant supplementation was performed with *Filipendula ulmaria* extract dissolved in tap water to reach the final concentration of 100 mg/kg b.w., for seven consecutive days. The behavioural testing was performed 24 hours after completing the protocols. The nociception assessment was performed in a hot plate test and tail flick test.

Skin tissue, spinal cords and hippocampi samples were obtained for estimation of inflammation (IL-6, TNF-α, IL-33, IL-10), apoptosis (Bax, Bcl-2), and pain control receptors (μ, δ, and κ opioid receptors; melatonin receptors – MT1 and MT2).

Results: Simultaneous administration of HBO and the antioxidant supplementation ameliorated macroscopic and histopathological characteristics of wound area and healing. Also, this therapeutic approach decreased the levels of IL-6, and TNF-α and increased the expression of the IL-33 and IL-10 as well as μ-opioid receptor, and MT1 and MT2 receptors in the wound area and spinal cord, with the consequent increase in the reaction time in behavioural testing.

Conclusion: In conclusion, the presented results allow evidence for the advantages of the simultaneous employment of HBO and antioxidant supplementation in the treatment of thermal skin injury, with special reference to the attenuation of painful sensations accompanied by this type of trauma.

Premature ageing in long-term homeless adults

Ailbhe Herity[1], Conor Reddy[1], Nicole Roche[2], Matt McElheron[3], Adam Dyer[3], Georgia Richard[1], Nollaig Bourke[3], Cliona Ni Cheallaigh[1]

[1]Trinity Translational Medicine Institute, Dept Clinical Medicine, Dublin, Ireland; *[2]School of Biochemistry and Immunology, Trinity Biomedical Sciences Institute, Dublin, Ireland*; *[3]Dept Medical Gerontology, Trinity Translational Medicine Institute, Dublin, Ireland*

Individuals in lower socioeconomic strata experience an increased burden of disease. People experiencing homelessness (PEH) exhibit extremes of poor health and psychosocial stress. Causation of these extreme disparities is complex and multifactorial, there are known effects of diet, smoking and substance abuse but other factors are also likely to play a role.

We hypothesise that homelessness may accelerate the ageing process, manifesting in poorer health and increased frailty among affected individuals. Furthermore, we believe that lifecourse psychosocial stress plays an important role in mediating accelerated ageing in PEH.

Long-term homeless individuals (n=59, F = 25.42%) aged 20-70 (μ=57) were recruited from six Dublin hostels over eight months.

65% suffered from one or more age-related disease, the most common of which was chronic hypertension. The mean age of participants with an age-related disease was 53.75. The median Clinical Frailty Score (CFS) in this cohort was 4, considered “vulnerable”. While age and CFS were strongly correlated in the housed (R = 0.62, P = 1.3e-11), PEH were as frail as the oldest housed individuals (μ = 4.1) independent of their age (r = 0.053, p = 0.69).

To characterise baseline immune status, banked plasma was analysed using a multi-plex ECLIA. Levels of eight circulating cytokines were significantly increased in homeless individuals, reminiscent of signatures associated with inflammageing and pathological chronic inflammation. Next, we will examine effects on dynamic immune responses to stimulation to investigate the functional consequences of this phenotype.

Additionally, we measured psychosocial adversity in participants, including social isolation and past trauma, which have been linked to accelerated biological ageing. 40% of homeless participants reported feeling lonely either “often” or “very often”. The average number of Adverse Childhood Experiences (ACEs) in our cohort was 4 – just 3-5% of the general housed population report 4 or more ACEs .

We conclude that homelessness is associated with psychosocial stress that may drive physiological dysregulation, including immune dysregulation. Independently, we showed that homeless individuals exhibit age-independent increased frailty and immune dysregulation. Future research will examine how psychosocial stress and immune dysregulation may mediate increases in frailty.

Serum free light chains in systemic lupus erythematosus disease

Dhouha Krir[1;2], Yousr Galai[1;2], Imen Zamali[1;2], Ahlem Ben Hmid[1;2], Raja Rekik[2], Monia Khanfir[1;3], Alia Fazaa[1;4], Habib Houman[1;3], Ahmed Laatar[1;4], Kamel Bousslema[1;5], Melika Ben Ahmed[1;2]

[1]Faculty of Medicine of Tunis, University of Tunis El Manar, Tunis, Tunisia; *[2]Pasteur Institute of Tunis, Department of Clinical Immunology, Tunis, Tunisia*; *[3]Department of Internal Medecine, La Rabta Hospital, Tunis, Tunisia*; *[4]Department of Rheumatology, Mongi Slim Hospital, Tunis, Tunisia*; *[5]Department of Internal Medecine, Mongi Slim Hospital, Tunis, Tunisia*

Background: Serum free light chains (FLC) are produced by plasma cells and serve as markers of monoclonal proliferation in plasma cell pathologies. They also reflect immune status and renal function. Recently, elevated serum FLC levels have been observed in systemic lupus erythematosus (SLE).

Purpose: This study aims to assess the relationship between serum FLC levels (kappa, lambda, and total FLC) and disease activity in SLE, comparing it with rheumatoid arthritis (RA) as another autoimmune disease model, along with healthy controls.

Methods: Twenty SLE patients and 42 age- and sex-matched rheumatoid arthritis (RA) and 20 healthy controls were enrolled. Disease activity was assessed using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) definition. Serum FLCs were quantified through a turbidimetric assay using 500 µl of stored thawed serum. Two separate measurements kappa and lambda FLC were conducted. The total FLC is equal to K+L light chains. Nonparametric tests compared FLC levels in SLE versus RA and healthy controls, as well as across different SLE disease activity levels and dsDNA antibody positivity. Correlations between FLC and SLEDAI were examined.

Results: We enrolled 20 SLE and 42 RA patients, with mean ages of 35±10 and 40± 7 years, respectively, and 15.7% and 11% men, respectively. Kappa, lambda, and total FLC levels were significantly higher in SLE compared to RA and healthy controls. FLC elevation did not correlate with anti-DNA antibody positivity or kidney damage but was significantly correlated with SLE disease activity.

Conclusion: Serum FLC levels are notably higher in SLE compared to both RA patients and healthy controls. However, to establish them as reliable markers of disease activity, further investigations with larger cohorts are imperative to ensure the generalizability of these findings.

Uncovering the role of novel protein FKBPL in obesity associated psoriasis

Ananya S. Pushpa[1], Anna Bogdanska[1], Noor Bakour[1], Stephanie Annett[1], Tracy Robson[1]

[1]*The Royal College of Surgeons in Ireland, Dublin, Ireland*

Psoriasis is a chronic inflammatory disease caused by a complex interplay between the immune system, polygenic inheritance, and environmental factors. Obesity is an important environmental factor that promotes both psoriasis development and severity as well as reducing the therapeutic response to currently available therapies. FK506-binding protein-like (FKBPL) is an immunophilin protein and a deficiency in FKBPL strongly correlates with the development of obesity in both mice and humans. FKBPL is located on chromosome 6p21, a major psoriasis susceptibility locus region (PSORS1). The overall aim of the study is to investigate the role of FKBPL in psoriasis using *in vitro* and *in vivo* models.

Female *Fkbpl*$^{+/-}$ (wild type) and *Fkbpl*$^{+/-}$ (heterozygous) mice were fed a normal chow or high-fat diet (60%) for six months and imiquimod (IMQ) cream was applied to the dorsal skin for six days to model psoriasis. Gene expression changes in the skin were measured *ex vivo* by qPCR. Similarly, *in vivo* experiments were replicated *in vitro* using Human keratinocyte (HaCat) cells. The HaCat cells were transfected with pFKBPL, rs28732176, and siFKBPL to induce overexpression and under-expression of FKBPL. Post-transfection cells were treated with TNF to mimic the psoriasis condition. Pro-inflammatory cytokine expression and DNA repair gene expression was evaluated.

In the *in vivo* IMQ model, obese *Fkbpl*$^{+/-}$ mice had significantly higher IL-1 β ($p=0.0002$, n = 6 *Fkbpl*$^{+/+}$, n = 8 *Fkbpl*$^{+/-}$) and IL-17 ($P= 0.0133$) compared to lean *Fkbpl*$^{+/-}$ mice. In invitro proinflammatory cytokine such as IL-1 β, IL-23A, TNF expression decreased when FKBPL was upregulated ($p=0.002$) similar to this, same trend was observed when FKBPL was knocked down ($p=<0.0001$). Furthermore, we investigated the DNA damage genes. Interestingly, we observed the DNA repair gene (PARP1 and CCND1) expression reduced ($p=0.0002$) when FKBPL was knocked down.

In summary, FKBPL overexpression and knockdown show the same effect on proinflammatory cytokines however the DNA repair gene expression is reduced when FKBPL is reduced. Therefore, FKBPL is a regulator of keratinocyte DNA repair, and novel target in obesity-associated psoriasis. However further experiments are required to narrow down a specific pathway.

Universidad de Guadalajara, Guadalajara, Mexico*; [4]*Doctorado en Ciencias Biomédicas., Guadalajara, Mexico*; [5]*Departamento de Biología Molecular y Genómica del Centro Universitario de Ciencias de la Salud. Universidad de Guadalajara., Guadalajara, Mexico*

Purpose: To identify the frequency of micronuclei in drug-addicted mothers and their newborns.

Methods: This cross-sectional descriptive study involved collecting 51 oral mucosa samples from drug-addicted mothers aged 16 to 39 and their neonates. Subsequently, the micronucleus assay was conducted, and the samples were stained using Giemsa-Wright. Bright-field microscopy was employed to examine 1000 cells per individual.

Results: Over 50% of pregnant women exhibited cellular inflammation and a notably high frequency of micronuclei compared to women without cellular inflammation ($P = 0.004$). Preterm newborns show a higher incidence of micronuclei than full-term newborns ($P = 0.050$).

Conclusions: Mothers who consumed drugs and their newborns exhibited a heightened frequency of cytotoxicity. We suggest that micronucleus assay shows cytotoxicity in cellular inflammation and can be considered as an early marker. Further research involving diverse populations is warranted to strengthen these findings.

A switch in macrophage ontogeny leads to increased fibrosis during aging after myocardial infarction

Tobias Weinberger[1;2], Clarisabel Garcia Rodriguez[2;3], Denise Messerer[1], Clement Cochain[4], Christian Schulz[1], Elisa Gomez Perdiguero[2]

[1]*Department of Cardiology, University Hospital, Ludwig, Munich, Germany*; [2]*Institut Pasteur, Paris, France*; [3]*Sorbonne Université, Paris, France*; [4]*Comprehensive Heart Failure Center, University Hospital Würzburg, Würzburg, Germany*

In tissues, aging is associated with structural and functional alterations that notably affect inflammatory responses to diseases and infections. This is of particular importance when assessing pathological processes at play in elderly, such as myocardial infraction. Although extensive studies have investigated the inflammatory response to myocardial infarction in young mice, much less is known concerning the influence of aging on cardiac healing and immune cell function. We here aimed at investigating the age-related alterations in macrophage populations within the aging heart and how this impacts on cardiac healing following myocardial infarction.

This was achieved by employing a combination of lineage-tracing and pulse-labelling mouse models to examine the immune cell composition at baseline and their dynamic responses to myocardial infarction in both young and aged mice. Additionally, we used single-cell RNA sequencing to delineate the differences in the transcriptomic profiles of cardiac immune cells. While macrophages emerged as the predominant immune cell population in the cardiac tissue even in aged animals, age-dependent differences were observed, including an increased proportion of recruited monocyte-derived macrophages with a proinflammatory phenotype in aged animals. Noticeably, this was associated with a reduced proportion of embryo-derived macrophages, the predominant macrophage population found in the heart of young mice under steady-state conditions. Importantly, such age-related changes in macrophage populations correlated with heightened fibrosis in the aging heart.

In aged mice, monocyte-derived macrophages recruited after myocardial infarction were found beyond the infarcted area and notably in the remote ventricular regions not directly affected by the ischemic event. This is stark contrast to young hearts, where recruited macrophages are restricted to the infarcted zone. Functionally, this basal increase in monocyte-derived macrophages and their extended recruitment in aged animals was associated with increased fibrotic scar size.

Increasing the frequency of monocyte-derived macrophages at the expense of embryo-derived macrophages in young animals before the ischemic insult was sufficient to augment fibrotic scarring post-injury, emphasizing the critical role of the immune cell composition in adverse cardiac outcomes following myocardial infarction in the elderly.

Interleukin-2 dynamically reduces interleukin-2 receptor β expression and function especially in T cells

Charline Sommer[1], Sophie Jacob[1], Tonia Bargmann[1;2], Susann Dehmel[1], Vanessa Neuhaus[1], Armin Braun[1;3], Katherina Sewald[1]

[1]*Fraunhofer Institute for Toxicology and Experimental Medicine, Hannover, Germany*; [2]*Member of the Fraunhofer Cluster of Excellence Immune-Mediated Diseases CIMD, Hannover, Germany*; [3]*Institute of Immunology, Medical School Hannover, Hannover, Germany*

Purpose: More than 40 interleukin-2 (IL-2)-based compounds are currently being tested in clinical trials to treat inflammatory diseases or cancer. However, IL-2 therapy can induce systemic inflammation, affecting multiple organs. Similar autoimmune-like symptoms are observed in patients with hypomorphic mutations in the IL-2 receptor β subunit (IL-2Rβ). We hypothesize that high-dose IL-2 (hdIL-2) decreases IL-2Rβ surface expression and reduces IL-2R signaling capacity especially in T cells but not NK cells, similar to patients with defective IL-2Rβ.

Methods: Human peripheral blood mononuclear cells (PBMCs) were continuously stimulated with 1-10,000 IU/mL IL-2 (aldesleukin) for up to 7 days. Receptor surface expression and IL-2R signaling (pSTAT5) of cell subsets were measured using flow cytometry.

Results: While IL-2Rβ surface expression remained high on CD8+ T cells and NK cells after 15 min of hdIL-2 stimulation, receptor expression significantly decreased on CD4+ T cell subsets to levels below 0.4% (vs. 2.5% for unstimulated CD4+ T effector cells [Teffs] and 26.1% for regulatory T cells [Tregs]). Prolonged IL-2 exposure (up to 7 days) reduced IL-2Rβ expression on CD8+ T cells to 0.2%. Expression on NK cells also was reduced but 55.8% of cells remained IL 2Rβ+. CD4+ and CD8+ T cells stimulated with hdIL-2 for 7 days showed lower pSTAT5 signal when re-stimulated with IL-2 than unstimulated cells (reduction in mean fluorescence intensity of 1.9-fold, 1.8-fold, and 1.7-fold for CD4+ Teffs, Tregs, and CD8+ T cells, respectively). In contrast, hdIL-2 did not impact IL-2 signaling in NK cells as pSTAT5 signaling remained unaltered upon re-stimulation with IL-2. Similarly, re-stimulation with IL-15 – also signaling through IL-2Rβ – induced significantly reduced pSTAT5 in T cells after high-dose IL-2 stimulation, while pSTAT5 in NK cells was unaltered.

Conclusion: IL-2Rβ is basically absent on hdIL-2-stimulated T cells, leading to concomitant decreases in IL-2R signaling. NK cells retained relatively high IL-2Rβ expression and IL-2R signaling. Given the resemblance of cellular characteristics of hdIL-2-stimulated cells and cells from patients with defective IL-2Rβ, impact of continuous IL-2 stimulation on IL-2R signaling should be considered in the onset of adverse events during IL-2 therapy.

Solving the Mystery of Immunomodulation in Malignant Ascites: an exploration of novel unknown immunosuppressive factors in ovarian cancer ascites, and their impact on modern immunotherapeutics.

Luke Furtado O'Mahony[1], Gulsah Albayrak[1], Mahnoor Nadeem[1], Hena Khalique[1], Len Seymour[1], Kerry Fisher[1]

[1]*University of Oxford, Oxford, United Kingdom*

Purpose: Cancer treatment has been revolutionised by the recent discovery of BiTEs (Bispecific T-cell Engagers) and other immunotherapeutics. BiTEs are bi-specific proteins that cross-link CD3 on T-cells to cancer antigens, forcing immunoactivation and cytotoxicity. Despite these advances, ovarian cancer is still predominantly treated with chemotherapy, leading to a poor prognosis. It regularly results in accumulation of peritoneal fluid called malignant ascites. By using this ascites as a model of the tumour microenvironment, we aimed to identify immunosuppressive factors preventing the functionality of modern immunotherapeutics in ovarian cancer.

Methods: Ovarian cancer patients were recruited through NHS ethics agreements. 20,000 OVCAR-3 cells were seeded into 96-well plates. T-cells were isolated from healthy donors by immunomagnetic separation, and were co-cultured with OVCAR-3 cells and EpCAM-BiTE (Epithelial Cell Adherence Molecule) for 72 hours. XTT assay was used to measure cytotoxicity and flow cytometry to measure T-cell activation markers (CD69/CD25/41BB). Chloroform precipitation was used to remove lipids from ascites, and Amicon 3kDa filters were used to remove protein. Cytokine concentrations were measured by ELISA.

Results: Nine ovarian cancer patients had ascites collected. T-cells showed significantly reduced activation and cytotoxicity in response to EpCAM-BiTE or Dynabeads when exposed to ascitic fluid. Ascitic fluid demonstrated similar pH buffering capacity to cell media, but caused heterogenous reduction in EpCAM expression on OVCAR-3 cells. Modification of ascites by removal of lipids or proteins caused a drastic increase in cytotoxicity and T-cell activation beyond normal cell media. However, analysis of previously described ascitic cytokines (IL10/IL6/TGFbeta/IFNg) showed no correlation with immunosuppression.

Conclusion: Ovarian cancer ascites induces immunosuppression of T-cells. This leads to reduced functionality of BiTEs, and likely other immunotherapeutics. This is not due to lack of nutrients or pH buffering in ascites, but rather due to immunosuppressive proteins and lipids. When these are removed, ascites becomes an immunostimulatory environment promoting BiTE-mediated cytotoxicity, representing an exciting therapeutic opportunity. Given the lack of correlation between known ascitic cytokines and immunosuppression, it is likely that this effect is mediated by novel, unknown proteins and lipids. Moving forwards, we will utilise proteolipidomics to identify these factors.

A small bispecific antibody induces HIV-1 Env-specific T-cell activation

Eudald Vehí Piqué[1;2], María Lázaro-Díez[2], Rodrigo Lázaro Gorines[3;4], Ruth Peña[2], Carlo Carolis[5], Carmen Dominguez Alonso[3;4], Luis Álvarez-Vallina[3;4], Julia G Prado[2;6;7]

[1]Universtat Autonoma de Barcelona, Cerdanyola del Vallés, Spain; *[2]IrsiCaixa, Badalona, Spain*; *[3]H12O-CNIO Cancer Immunotherapy Clinical Research Unit, Spanish National Cancer Research Centre (CNIO), Madrid, Spain*; *[4]Cancer Immunotherapy Unit (UNICA), Department of Immunology, Hospital Universitario 12 de Octubre, Madrid, Spain*; *[5]Centre for Genomic Regulation (CRG), Barcelona, Spain*; *[6]CIBER Enfermedades Infecciosas (CIBERINFEC), Instituto de Salud Carlos III, Madrid, Spain*; *[7]Institut de Recerca Germans Trias i Pujol (IGTP), Badalona, Spain*

Purpose: The introduction of antiretroviral treatment (ART) has been instrumental in controlling the HIV-1 pandemic. However, the virus persists in individuals for a lifetime in the form of a viral reservoir. The development of an HIV-1 cure is a global priority. Bispecific antibodies (bsAbs) are promising HIV-1 cure therapeutic agents to target and eliminate the viral reservoir. Here, we present a next-generation small-sized bsAb that engages T-cells by targeting both the T-cell receptor (TCR)/CD3 complex and the HIV-1 Envelope (Env) on the surface of infected cells. We evaluate the ability of the bsAb "light T-cell engager", called LiTE, to specifically bind to each cognate target and to induce Env-specific T-cell activation.

Methods: We designed LiTEs prototypes and produced them by transfection in Expi-293F cells. The binding capacity and specificity of LiTEs were assessed by ELISA with immobilized CD3 and Env and by flow cytometry in Jurkat T-cells and Env-expressing K562 cells (K562-Env). In addition, on-target, and off-target T-cell activation was studied in Jurkat T-cells and PBMC from healthy donors, using anti-CD3 IgG as a control. Cells were stained for CD4, CD8, CD25 and CD69 markers and evaluated by flow cytometry.

Results: We demonstrated specific binding of the LiTE to CD3 and Env by ELISA. In addition, antigen binding on Jurkat T-cells and K562-Env cells further validated the specificity of LiTEs towards CD3 and Env. Importantly, functional assays demonstrated the ability of the bsAb to promote on-target CD3-mediated activation in Jurkat T-cells, dependent on the presence of Env protein, as determined by a significant increase in the expression of CD69. In PBMCs, the LITE Env-specific activation was determined by a significant increase in CD69 and CD25/CD69 frequency in total $CD4^+$ and $CD8^+$ T-cells.

Conclusion: The LiTE prototype demonstrates specific binding to both targeted antigens and Env-specific T-cell activation in a dose-dependent manner. These data highlight the potential Env-targeted LiTE as immunotherapy in the context of HIV-1 infection. Further functional *in vitro* and *in vivo* experiments are required to understand the full potential of light T-cell engagers as an HIV-1 curative strategy.

Development of an in vivo suppression assay to assess Treg function

Joanne Anstee[1], Julieta Karegli[1], Michael Worwood[1], Shanthi Herath[1], Madhav Kishore[1], Bahire Kalfaoglu[1], Sim Tung[1], Courtney Grant[1], Georgios Eleftheriadis[1], Jenny McGovern[1]

[1]*Quell Therapeutics, London, United Kingdom*

Background: Regulatory T cells (Tregs) comprise an important subpopulation of T cells and play a pivotal role in maintaining homeostasis and immune tolerance. Considering their powerful ability to suppress aberrant immune responses, there has been an increasing interest in utilizing Tregs therapeutically for pathologies such as autoimmune diseases and transplant rejection. *In vivo* disease models continue to be used to generate proof of concept and safety data for Treg cell therapy. Chronic inflammation models can be long, with large treatment groups and incomplete incidence. Therefore, murine Treg production processes must be optimised, scalable and robust to minimise the risk of failure in these disease models. Although *in vitro* suppression assays have been routinely used to assess the ability of Tregs to control T cell responses, these fail to mimic complex physiological conditions and can be inconsistent indicators of function *in vivo*. Here, we propose the use of a novel *in vivo* model as a valuable tool to examine the impact of cell production processes on murine Treg function.

Methods: Congenic C57BL/6 mice were used to provide total T cells on a CD45.2 background. These were injected with or without Tregs generated from C57BL/6 mice on a CD45.1 background into irradiated NSG mice. Treg function and phenotype was monitored using tail bleeds and at endpoint blood and spleen was harvested. Analysis involved flow cytometry and cell staining with an antibody panel to quantitate and phenotype the cell populations, ultimately revealing the level of Treg function *in vivo*.

Results: T cells were co-injected with an equal dose of Tregs into NSG mice. T cell responses were significantly abrogated when compared to control animals which did not receive the Tregs, thus demonstrating Treg-mediated immune suppression of both $CD4^+$ and $CD8^+$ T cell populations. Throughout the experiment, the Treg populations were detectable and maintained over 90% FoxP3 expression, demonstrating a stable phenotype under *in vivo* conditions.

Conclusions: We have successfully developed a robust animal model which can be utilized as an *in vivo* suppression assay. The advantages of this model are that it is quick, reproducible and more physiologically relevant than *in vitro* equivalents.

Functional regulation of human lymphoid cells by IL-1R8 targeting in cancer

Roberto Garuti[1], Domenico Supino[2], Elena Magrini[2], Giovanni Pezone[2], Irene Di Ceglie[2], Andrea Mariancini[1], Silvia Carnevale[2], Laura Falcone[3], Monica Casucci[3], Joanna Mikulak[2], Domenico Mavilio[2;4], Enrico Lugli[2], Sebastien Jaillon[1;2], Alberto Mantovani[1;2;5], Cecilia Garlanda[1;2]

[1]Humanitas University, Pieve Emanuele, Italy; *[2]IRCCS Humanitas Research Hospital, Milan, Italy*; *[3]San Raffaele Scientific Institute, Milan, Italy*; *[4]University of Milan, Milan, Italy*; *[5]Queen Mary University of London, London, United Kingdom*

Purpose: Interleukin-1 Receptor 8 (IL-1R8) is a negative regulator of IL-1 and Toll-like family receptors that controls inflammation and innate and adaptive immunity. Taking advantage of IL-1R8-deficient mice, this receptor was shown to inhibit IL-18-dependent activation of Natural Killer (NK) cells against liver carcinogenesis and metastasis. We recently reported that IL-1R8 tunes CD8+ T cell tumoricidal potential in transplantable mouse models of colon carcinoma and fibrosarcoma. IL-1R8 deficiency promoted cytokine-induced responses of intratumoral lymphocytes, suggesting that IL-1R8 acts as an NK- and T-cell immune checkpoint in mouse. However, its role in human lymphocyte remains largely unexplored, as well as strategies to inhibit its function.

Methods: Using spectral flow cytometry, pharmacological and genetic targeting, and *in vivo* models, we studied the heterogeneity of IL-1R8 expression in human lymphocytes and the therapeutic impact of IL-1R8 blockade in antigen specific and antigen non-specific cell-based immunotherapy.

Results: We found that IL-1R8 is expressed in the NK-92 cell line and in primary lymphocytes from healthy donors, with high expression levels in NK and CD8+ T cells. Higher expression was observed in effector and memory subsets, suggesting a maturation-dependent upregulation of IL-1R8 in human lymphoid cells. Moreover, high levels were observed in intrahepatic NK cells and circulating lymphocytes from colorectal cancer liver metastases and B cell lymphoma patients, respectively. Pharmacological targeting of IL-1R8 increased effector functions (Granzyme B production, IFNγ secretion) in NK-92 cells and intrahepatic NK cells *in vitro*. Increased IFNγ production was observed in polyclonally activated $CD8^+$ T cells treated with an IL-1R8 inhibitor. Taking advantage of OT-I mice, we reported increased antigen-induced proliferation for IL-1R8-deficient OT-I cells *in vitro*. Coherently, the adoptive transfer of IL-1R8-deficient OT-I cells better controlled MC38-OVA tumour growth in mice. Finally, IL-1R8 was expressed by CD19 Chimeric Antigen Receptor (CAR) T cells post-infusion. CRISPR-Cas9-mediated IL-1R8 silencing in CAR-T cells improved their tumoricidal effects against Acute Lymphoblastic Leukemia.

Conclusion: Collectively, we show that IL-1R8 loss-of function using both genetic and pharmacological approaches, effectively boosts clinically relevant immune reactivity against cancer which may be exploited in adoptive cell immunotherapies.

IL-10 enhances the antitumor immunity in the orthotopic hepatocellular carcinoma mouse model by increasing CD8+T cell cytotoxicity

Chia-I Lin[1], Yu-Wen Wang[1], Yi-Wei Chiu[1], Ying-Hsuan Wu[1], Ya-Hui Chuang[1]

[1]*Department of Clinical Laboratory Sciences and Medical Biotechnology, National Taiwan University College of Medicine, Taipei, Taiwan*

IL-10, known for its immunoregulatory functions, has recently garnered attention for its anti-tumor effects. However, its role in the tumor microenvironment remains controversial due to the diverse cancer types and organ-specific conditions. Hepatocellular carcinoma (HCC) is the primary liver cancer characterized by an immunotolerogenic microenvironment. We sought to understand whether and how IL-10 functions in liver cancer under such tumor-promoting conditions. To address this issue, we utilized an adeno-associated virus to deliver IL-10 (AAV-IL-10) in an orthotopic HCC mouse model. After inoculating Hep55.1c hepatoma cell lines into the liver, mice received intravenous injections of either AAV-IL-10 or controls (AAV-mock). Two weeks post-tumor cell inoculation, we assessed tumor size and tumor-infiltrating leukocytes (TILs). Mice treated with AAV-IL-10 showed dose-dependent reductions in tumor size and significant increases in TILs, particularly $CD8^+$ T cells, accompanied by elevated secretion of effector cytokines such as IFN-γ, perforin, and granzyme B. $CD8^+$ T cells from AAV-IL-10-treated mice exhibited enhanced cytotoxicity against Hep55.1c cells compared to those from AAV-mock-treated mice. Importantly, no significant adverse effects were observed in other adjacent organs despite increased serum IL-10 levels following AAV-IL-10 injection. In addition, serum ALT was in the normal range. These findings suggested the therapeutic potential and safety of IL-10 in HCC by enhancing $CD8^+$ T cell cytotoxicity.

Induction of Resident Memory CD8+ T cell phenotypes to eliminate the HIV reservoir

Cristina Mancebo-Pérez[1], Aleix Benitez[1], Judith Grau-Expósito[1], Sebastián G. Kugel[1], Núria Massana[1], Jon Cantero-Pérez[1], Nerea Sánchez-Gaona[1], Josep Castellví[2], Laura Mañalich-Barrachina[3], Cristina Centeno-Mediavilla[3], Jordi Navarro[1], Adrià Curran[1], Vicenç Falcó[1], Maria Jose Buzon[1], Meritxell Genescà[1]

[1]Institut de Reserca Vall d'Hebron (VHIR), Department of Infectious Diseases, Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Barcelona, Spain; *[2]Department of Pathology, Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Barcelona, Spain*; *[3]Department of Obstetrics and Gynecology, Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Barcelona, Spain*

Background: The major hurdle to HIV-1 eradication in people with HIV (PWH) is the establishment of viral reservoirs. In tissues, where most of the HIV burden persists, antiviral resident memory CD8+T cells (TRM) may be critical to eliminate cellular reservoirs and transcriptionally-active HIV infected cells. Here we aimed to address the functional capacity of $CD8^+$TRM phenotypes and the control they exert on the viral reservoir.

Methods: In ART-suppressed HIV^+ women, we determined total viral DNA in blood (n=8) and cervix (n=7) and its correlation with the frequency of cervical $CD8^+$ TRM ($CCR7^-$ $CD69^+$ $CD103^+$). A functional assay was established to assess suppression of reactivated $CD4^+$T cells by cervical $CD8^+$ TRM from ART-suppressed HIV^+ women undergoing hysterectomy. Moreover, PBMC obtained from PWH were treated with cytokines to expand TRM-like phenotypes, which were subsequently exposed to Gag to determine degranulation and IFNɣ secretion by flow cytometry (n=7). An additional functional assay was established to evaluate the capacity of expanded $CD8^+$ TRM-like cells to eliminate the autologous ex vivo reactivated HIV reservoir (n=5) and to determine intact viruses after ex vivo reinfection (n=5). Last, single cell RNA sequencing was performed to determine the nature of PBMC-expanded cells after cytokine treatment.

Results: The frequency of cervical $CD8^+$TRM cells inversely correlated with proviral HIV-1 DNA in cervix (n=7; p=0.03). Gag-specific $CD8^+$TRM were rarely detected in biopsies, which was likely limited by sample size. Still, cervical $CD8^+$TRM cells from two patients with a large sample were more efficient at eliminating HIV-reactivated $CD4^+$T cells than circulating effector $CD8^+$T cells. Circulating Gag-specific $CD8^+$ T cells presented higher expression of CD107a and IFNɣ after TRM-like induction treatment with more capacity to eliminate reactivated HIV-infected cells (p=0.031). CD8+ TRM-like cells from PBMC-expanded cells were more effective at decreasing proviral intact HIV-1 DNA than other phenotypes, likely caused by an increase in cytotoxic potential of expanded clusters.

Conclusion: Our results highlight an active role of $CD8^+$ TRM phenotypes in limiting tissue viral persistence. Overall, we provide evidences that $CD8^+$TRM-like phenotypes should be potentiated to enhance control of viral persistence and identify a promising immunotherapeutic strategy to achieve control of reactivated viruses.

Apheresis characteristic impacting response to Chimeric Antigen Receptor T-cell therapy

Ivan Garcia De La Torre[1], Carlota García-Hoz Jiménez[1], Eulalia Rodríguez Martín[1], Rafael Rodriguez Ramos[1], Elena Manterola Navarro[1], José Luis Veiga González[1], Vivian Lizeth Stewart DelCid[1], Celia Ferrez Hernández[1], Daniel Albert Mendoza Bravo[1], Paula Batres Faba[1], Kyra Velázquez Kennedy[1], Roberto Pariente Rodríguez[1]

[1]*Hospital Universitario Ramón y Cajal, Madrid, Spain*

Introduction: Chimeric Antigen Receptor T-cell (CAR-T) therapy stands as a transformative advancement in cancer immunotherapy. This therapeutic modality has yielded significant rates of remission in patients afflicted with B-cell Acute Lymphoblastic Leukaemia (B-ALL), Diffuse Large B-cell Lymphoma (DLBCL), Primary Mediastinal B-cell Lymphoma (PMBCL), and Mantle Cell Lymphoma (MCL). However, despite these notable achievements, a subset of patients across these malignancies experiences relapse or recurrence. Hence, the imperative for research persists, particularly in the realm of identifying biomarkers that offer prognostic insights into patient responses.

Materials and methods: We have assembled data from 11 DLBCL patients undergoing treatment at our institution, all of them with an anti-CD19 CAR-T cell. Each patient has undergone a minimum 3-month follow-up regimen, inclusive of PET/CT scans at month +1 and month +3 post-treatment. Employing flow cytometry, we have undertaken an investigation into lymphocytic subpopulations on the day of apheresis.

Results and discussion: As of the study cut-off date on March 25, 2024, 45% of patients exhibited complete remission at the 3-month mark post-CAR-T therapy, as assessed via PET/CT imaging. Leveraging this dataset, we partitioned the cohort in two groups: those in remission (n=5) and those experiencing relapse (n=6). Upon scrutinizing the composition of T lymphocyte subpopulations during apheresis, a clear difference emerged, revealing higher percentages of central memory CD8+ T lymphocytes (CM CD8+T) in remission-afflicted patients ($P < 0.05$). There exist studies correlating the percentage and functionality of CM CD8+T cells in CAR-T cell product. Nevertheless, in our research, we identify this correlation at a significantly earlier phase of treatment. This underscores the potential of CM CD8+T cells in apheresis as a marker of treatment response, merits further research and validation.

Monitoring of immune system in CAR-T infused patients diagnosed of hematological malignancies

Raquel Bernardo[1;2], Laura Carrero[1;2], Ana Navas[1;2], Estefania García Torres[3], Concepción Herrera[3], Aurora Jurado Roger[1;2]

[1]Immunology and Allergy Research Unit, Maimonides Biomedical Research Institute of Córdoba (IMIBIC)/ University of Córdoba/ Reina Sofía University Hospital, Córdoba, Spain; *[2]Department of Immunology and Allergy, Reina Sofía University Hospital, Córdoba, Spain*; *[3]Department of Haemathology, Reina Sofía University Hospital, Córdoba, Spain*

Purpose: CAR-T cell therapy is emerging as an alternative against cancer, especially in hematological malignancies such as diffuse large B cell lymphoma (DLBCL), acute lymphoblastic leukemia (ALL), and multiple myeloma. The objective of this study was to monitor the immune system of patients treated with the commercial CAR-T products Tisagenleucel (Kymriah®) and Axicabtagene-ciloleucel (Yescarta®) at the Reina Sofía University Hospital.

Methods: Circulating level of serum cytokines (IL-6, IL-8, IL-10, MCP-1 and IP-10; CBA, Beckton and Dickinson) and IgG subclasses (Optilite, Binding Site) were measured. The proportion of $CD3^+CAR\text{-}T^+$ cells was identified by flow cytometry (Miltenyi). Additionally, a detailed cellular phenotype of CAR-T and non-CAR-T subpopulations was performed. All determinations were conducted weekly in the first month and monthly thereafter.

Results: A total of 7 patients with DLBCL (85%) or ALL (15%) were included in this study. Of them, 85% were adults (>25 years) and 15% were pediatrics (<25 years). Among all, 57% relapsed and 50% died. The Yescarta® product was applied to 5 adults, while 1 adult and the pediatric patient received the Kymriah® product. The $CD3^+CAR\text{-}T^+$ population expanded between +7d and +14d and disappeared between +2M and +4M. $CAR\text{-}T^+CD4^+$ and $CD8^+$ effector cells were the main subpopulations detected and remained over time, while central memory and naïve subpopulations were the least abundant. Th1 cells were the predominant among both $CAR\text{-}T^+$ and $CAR\text{-}T^-$ T-helper cells. Throughout the follow-up time, an inversion was detected between CAR-T $TCR\alpha\beta^+$ and $TCR\gamma\delta^+$ cells in the first month after the infusion. Cytokines reached their maximum level between +0d and +14d, matching with the expansion of CAR-T cells. Given the small cohort studied, no correlation with clinical factors were performed.

Conclusions: Immune system of patients infused with adoptive cell therapy suffers changes througout the therapy course and its monitoring could be of transcendental relevance to identify possible differences between underlying pathologies, patient categories, implemented therapies and, particularly, prognostic biomarkers.

Changes in immunological and metabolic parameters in patients with spondyloarthropathies treated with biologics

Krzysztof Bonek[1], Antonina Markowicz[2], Maciej Ołdak[2], Magdalena Plebanczyk[2], Anna Kornatka[2], Sylwia Szczygielska[1], Katarzyna Helon[1], Marek Kajfasz[3], Paulina Wydrych[3], Brygida Kwiatkowska[3], Piotr Głuszko[1], Anna Felis-Giemza[4], Ewa Kuca-Warnawin[2]

[1]Department of Rheumatology, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland; *[2]Department of Pathophysiology and Immunology; National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland*; *[3]Early Arthritis Clinic, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland*; *[4]Biologic Therapy Center; National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland*

Background: Psoriatic arthritis (PsA) and ankylosing spondylitis (AS) are chronic inflammatory disorders marked by joint inflammation, with AS additionally affecting the spine, causing stiffness and pain. PsA, associated with psoriasis, impacts joints globally, resulting in pain, swelling, and diminished mobility. Both conditions are linked to an elevated risk of metabolic syndrome, characterized by hypertension, hyperglycemia, central obesity, and dyslipidemia. The therapeutic landscape has been transformed by the advent of biologic therapies, including tumor necrosis factor inhibitors (TNFi) and interleukin-17 inhibitors (IL-17i), which target specific immunologic and metabolic pathways. This study aims to assess the immunological and metabolic effects of TNFi and IL-17i in PsA and AS patients.

Materials and Methods: We enrolled three cohorts: PsA patients receiving TNFi (n=9), PsA patients on IL-17i therapy (n=16), and AS patients treated with TNFi (n=19). Pre-treatment and follow-up blood samples were analyzed to quantify regulatory lymphocytes, Th1, Th2, Th17, and Th1/Th17 populations, along with cytokine IL-17A, Il-23, IL-26, IL-9, IL-10, IL-18, IL-18BP levels. Comprehensive clinical data were also compiled**.**

Results and Conclusion: Contrary to expectations, cytokine profiles remained unchanged across all groups. Nevertheless, a significant reduction in CD4+CD25+ lymphocyte percentages was noted in all cohorts, indicating diminished Th lymphocyte activation. Specifically, the PsA+IL-17i group showed a notable decrease in regulatory lymphocyte percentages. Metabolic effects varied by treatment and disease condition: in the PsA+TNFi group, significant reductions in LDL and increases in HDL were observed alongside DAPSA improvement, without notable changes in ESR or CRP levels. The PsA+IL-17i cohort experienced significant declines in total cholesterol, triglycerides, DAPSA, and CRP. For the AS+TNFi group, notable decreases in LDL, non-HDL, BASDAI, CRP, and ESR were documented. This evidence suggests that TNFi and IL-17i treatments not only reduce systemic inflammation but may also favorably affect metabolic parameters, including lipid profiles. However, effects vary by therapeutic agent and patient, advocating for personalized treatment strategies. These findings underscore the complex relationship between inflammation, immune response, and metabolic health in PsA and AS management, spotlighting the need for ongoing research in this interdisciplinary field.

Exploring TCR and gene expression diversity: Single cell RNA and TCR sequencing on NY-ESO-1-specific HLA-DRB3*02:02-restricted CD4+ T cells from cancer-free individuals

Berta Casanovas Albertí[1], Andrea Aran[1], Ariadna Bartoló[1], Roberto Martínez[1], Iván García-Loza[1], Alejandro Ramírez-Chacón[1], Mariona Pascal[1;2], E. Azucena González Navarro[1;2], Manel Juan Otero[1;2;3]

[1]Fundació de Recerca Clínic Barcelona (FRCB) - Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; *[2]Servei Immunologia. Centre de Diagnòstic Biomèdic (CDB) - Hospital Clínic de Barcelona, Barcelona, Spain*; *[3]Immunotherapy platform Clínic-Sant Joan de Deu. Universitat de Barcelona, Barcelona, Spain*

Purpose: Natural transgenic T-cell receptors (tTCRs) represent an emerging type of cell therapy against cancer, capable of recognizing peptides expressed both intracellularly and extracellularly. This offers a significant advantage over CAR therapy that can only target extracellular surface proteins. These surface proteins are often challenging to define as Tumor Associated Antigens (TAAs), especially in the context of solid tumors. However, it is important to acknowledge that TCR therapies against TAAs could potentially generate off-tumor on-target toxicity. To address this, our focus is on NY-ESO-1, a cancer/testis antigen expressed in various tumors but minimally in healthy tissues besided testicles. While several tTCR clinical trials have targeted NY-ESO-1, they all focused on peptide presentation to class I HLA molecules, risking HLA class I downregulation by tumor cells and loss of therapy efficacy. In contrast, our work is focused on HLA-DRB3*02:02, an HLA class II allele expressed approximately by half of the Caucasian population in a similar manner to HLA-A*02:01, for which many more studies have been performed. Our aim is to obtain specific TCRs against NY-ESO-$1_{119\text{-}143}$ presented on HLA-DRB3*02:02.

Methods: $CD4^+$ $CD25^-$ T cells isolated from 12 healthy donor PBMCs were co-cultured with NY-ESO-$1_{119\text{-}143}$-pulsed monocytes for 14 days to promote specific T cell sensitization, stimulating them at days 0, 7 and 14 with NY-ESO-$1_{119\text{-}143}$ peptide. At day 15, $CD4^+$ $CD154^+$ T cells were sorted. Then, cells underwent a 14-day expansion with feeders followed by a second $CD4^+$ $CD154^+$ T cell sorting before freezing them for further single cell isolation followed by single cell RNAseq and TCRseq.

Results: After 30 days of culture and two sorting rounds on days 15 and 30, specific $CD4^+$ $CD25^-$ T cells targeting NY-ESO-$1_{119\text{-}143}$ on HLA-DRB3*02:02 were obtained. Purity and specificity assessments utilizing CD4 and CD154 markers respectively, revealed a sustained purity of 97%, with specificity significantly enhanced after the second sorting round. Single-cell TCR sequences were successfully obtained.

Conclusion: Our study demonstrates the feasibility of obtaining specific TCRs from $CD4^+$ $CD25^-$ T cells targeting NY-ESO-$1_{119\text{-}143}$ presented on HLA-DRB3*02:02. This was achieved through our specialized protocol involving pre-sensitization and expansion of $CD4^+$ T cells.

Unveiling therapeutic potential of adoptive T-cell products in cancer treatment by integrating full spectrum flow cytometry with image-based assays

Sarah Schulenberg[1], Michelle Loeser[1], Martí Farrera-Sal[1], Jacqueline Keye[2], Candise Tat[3], Désirée Kunkel[2], Bilal A. Omer[3;4], Michael Schmueck-Henneresse[1]

[1]Berlin Institute of Health (BIH) at Charité – Universitätsmedizin Berlin, BIH Center for Regenerative Therapies (BCRT), Experimental Immunotherapy, Berlin, Germany; *[2]Berlin Institute of Health at Charité - Universitätsmedizin Berlin, Flow & Mass Cytometry Core Facility, Berlin, Germany*; *[3]Center for Cell and Gene Therapy, Texas Children's Hospital, Houston Methodist Hospital, Baylor College of Medicine, Houston, Texas, United States*; *[4]Texas Children's Cancer and Hematology Centers, Texas Children's Hospital, Baylor College of Medicine, Houston, Texas, United States*

The cancer treatment landscape is rapidly evolving with the emerging field of adoptive T-cell therapy, offering promising avenues for patients across various cancer types. Central to the success are precise assessment tools of T-cell products, particularly in solid tumor diseases entrenched within immunosuppressive microenvironments. Here, we propose a comprehensive approach aimed at evaluating the performance and conducting a thorough analysis of T-cell products, introducing a customized multicolor full spectrum flow cytometry (FSFC) panel combined with image-based assays. Our FSFC panel provides a streamlined platform for assessing T-cell composition, functional attributes, and potency, all of which are critical for the efficacy of therapy. By integrating extracellular surface markers, intracellular cytokines, and immune checkpoint molecules, we delineate the essential features of therapeutic T-cells necessary for targeting solid tumors in a single staining process. Through the integration of FSFC data with image-based assays, we can assess the performance of T-cell products and their correlation with treatment efficacy in a clinical trial focusing on solid tumor diseases. This detailed analysis uncovers disparities in the composition of patient-specific T-cell products, directly influencing their effectiveness against cancer. Ultimately, our refined methodology offers valuable insights to enhance the precision and effectiveness of adoptive T-cell therapy, thereby contributing to the ongoing advancement of cancer treatment strategies.

Isolation of a high avidity TCR targeting a newly identified epitope of a common cancer testis antigen expressed by solid tumors

Emina Sivro[1;2], Martin Klatt[1], Sefer Elezkurtaj[3], Caecilia Freund[1;2], Corinna Grunert[1;2], Ulrich Keller[1], Antonia Busse[1;2]

[1]Charité - Universitätsmedizin Berlin, Department of Hematology, Oncology and Tumor Immunology, Berlin, Germany; *[2]Max Delbrück Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany*; *[3]Charité - Universitätsmedizin Berlin, Institute of Pathology, Berlin, Germany*

Purpose: Developing T cell receptor (TCR)-based immunotherapy holds promise in cancer treatment due to its ability to target a wide range of tumor antigens, including both intracellular and extracellular antigens. Our newly identified cancer-testis antigen (CTA) is an intracellular antigen, characterized by its exclusive expression in cancer and reproductive tissues and thereby presents a promising target for cancer treatment. Our objective is to isolate a TCR specific to an HLA-A*02:01 restricted CTA epitope from the human HLA-A*02:01 negative repertoire for subsequent safety and efficacy evaluation *in vitro* and *in vivo*.

Methods: CTA expression and epitope presentation are assessed in hematological and solid neoplasms using immunohistochemistry, qRT-PCR, and mass spectrometry. TCR isolation involves co-culturing naive HLA-A*02:01 negative CD8+ T cells with antigen-presenting cells. Epitope-specific T cells are identified through multimer staining and sorted via fluorescence-activated cell sorting. Subsequent sequencing of TCR alpha and beta chains enables the identification of mutation specific TCRs. Functional avidity of TCR-transduced CD8+ T cells is evaluated by measuring IFNγ release (ELISA). Cross-reactivity is measured through the Alanine- and Glycine-Scan-Assay, and alloreactivity is assessed by co-culturing immortalized B lymphoblastoid cell lines with different haplotypes with TCR-transduced T cells.

Results: CTA expression was identified in patient samples of colorectal, breast, and head and neck cancer using immunohistochemistry and qRT-PCR. Quantification of epitope presentation was conducted via mass spectrometry in myeloma and leukemia cell lines, and PDX models of colorectal and breast cancer. To date, four potential CTA-specific TCRs with minimally murinized constant regions have been identified and synthesized, pending additional safety assessment and efficacy testing in PDX models.

Conclusion: We have discovered an undisclosed epitope of a CTA not targeted by immunotherapy thus far. From human HLA-A*02:01 negative donors, we have isolated four potential high avidity epitope-specific TCRs. Confirmation of target CTA expression and epitope presentation has been achieved across various common solid neoplasms. These findings suggest a significant therapeutic potential of our identified TCRs, offering promising prospects for a wide patient population with relapsed/refractory solid tumors in a tumor-agnostic manner.

Purpose: Psoriasis (Ps) is a multi-factorial disease with a deep inflammatory outline where genetic and certain extrinsic factors like obesity initiate and sustain psoriatic lesions. A network of cytokines intercedes inflammation and supports epidermal cell proliferation, and cytokines of adipocytes origine can enhance the autoimmune reaction. The key changes in Ps are recorded at the IL-22/IL-23/IL-17 axis level, in addition a wide range of chemokines (e.g., CXCL1, MCP-1, Eotaxin etc.) produced by keratinocytes modulates inflammation in Ps. Thus, the purpose of our work was to depict a multi-analyte cytokine/chemokine pattern in experimental Ps in relation with induced obesity as frequently associated co-morbidity.
Methods: We used an experimental imiquimod mice model of psoriatic dermatitis comprising C57 BL/6 mice (Jackson Laboratory, Bar Harbor, ME, USA), males and females (10–11 weeks). The following experimental conditions were tested: (i) the Ps group with induced psoriatic dermatitis; (ii) mice with induced obesity (Fat diet C1090-45 obesity-inducing diet with w/45% energy form fat, *Altromin International*) for ten weeks; (iii) obesity induced mice with induced Ps. A normal group of mice was runed in parallel with the treatment groups. A panel of 40 analytes were tested in mice plasma with Quantibody® Mouse Inflammation Array 1 (#QAM-INF-1, *RayBiotech*).
Results: There was a clear delineation of analytes profile regarding experimental conditions and gender mice ratio. Some of our results indicate that certain proinflammatory Th1 cytokines level (e.g., IL-15) are differently modulated by fat diet in Ps condition and registered distinct patterns for male and female mice, sustaining an enhanced proinflammatory profile in females. Analyzing the chemokines portrait in the frame of Ps combined with fat diet there it is an individualized panel closely dependent on the mice gender as we found for eotaxin, MIP-1 or MCP-1 levels.
Conclusion: Despite all the current clinical improvements Ps remains an incurable disease where new tools or new visions are to be explored to reconcile the cellular and molecular foundations with the clinical course.

A sensitive functional cell-based bioassay for the screening of different recombinant variants of soluble mouse LIGHT to be used in in vivo anti-tumor studies

Jose-Ignacio Rodriguez-Barbosa[1], Pascal Schneider[2], Maria Luisa del Rio[1]
[1]Transplantation Immunobiology and Immunotherapy Section. Institute of Molecular Biology. University of Leon, Leon, Spain, [2]Department of Immunobiology, University of Lausanne, Epalinges, Switzerland

Purpose: LIGHT binds to two receptors HVEM (TNFSFR14, CD270) and LTβR (TNFSFR3). The bidirectional interaction of HVEM/LIGHT delivers costimulatory and survival signals to T cells, whereas the engagement of LTβR by LTα1β2 and LIGHT has been involved in lymph node development and in the formation of ectopic lymphoid structures at sites of chronic inflammation. The classical approach to produce soluble recombinant proteins bound to the Fc fragment of immunoglobulin G (IgG) turned out to yield a functionally inactive mouse LIGHT protein.
Methods: To overcome this hurdle and gain insight into the preclinical potential of LIGHT as a proinflammatory cytokine secreted by tumor cells, various formats of recombinant soluble mouse LIGHT proteins were expressed in eukaryotic cells (dimeric Ig.LIGHT, trimeric FF (Flag-Foldon)-LIGHT and hexameric Ig.FF-LIGHT). These proteins were assessed for their ability to bind and engage HVEM. The different mouse LIGHT recombinant proteins were quantified in culture supernatants by a newly developed sandwich ELISA using anti-mouse LIGHT specific monoclonal antibodies.
Results: In contrast to the dimeric format of recombinant LIGHT that neither bound nor killed reporter cells, the bioactive trimeric and hexameric recombinant variants mouse LIGHT can kill reporter cells transduced with chimeric constructs containing the extracellular domain of mouse HVEM fused to the intracellular domain of the human death receptor FAS. This LIGHT-mediated cytotoxic effect was abrogated in a dose-dependent manner by antibody-mediated blockade of LIGHT.
Conclusion: In summary, this work brings a novel set of tools for the preclinical evaluation of the therapeutic potential of soluble recombinant mouse LIGHT secreted by tumor cells in the context of immune check-point blockade as an immunotherapeutic intervention to enhance the proinflammatory tumor microenvironment for effective activation of the innate and adaptive response against the tumor cells.

Transcriptional and epigenetic regulation of IL23R expression in human CD4+ T cells

Hanane Yahia[1], Ikram Mezghiche[1], Victoire Baillet[2], Daniel J. Cua[3], Raphaelle Parker[4], Lars Rogge[1], Elisabetta Bianchi[1]
[1]Immunoregulation unit, Department of Immunology, Institut Pasteur, Paris, France; *[2]Bioinformatics and Biostatistics Hub, Institut Pasteur, Paris, France*; *[3]Janssen Research & Development, Pennsylvania, United States*; *[4]Janssen Research & Development, Paris, France*

The importance of interleukin-23 (IL-23) and its specific receptor, IL-23R, in the pathogenesis of several chronic inflammatory diseases has been established, but the underlying pathological mechanisms are not fully understood. IL-23 signals via a heterodimeric receptor composed of a specific subunit, IL-23R, and the IL-12Rβ1 subunit shared with the IL-12 receptor. IL-23/IL-23R signaling has been studied, in particular, in the context of Th17 cell differentiation and function, however the mechanism controlling the expression of the *IL-23R* gene in different human lymphocyte populations remains poorly understood. Here we aim to enhance our understanding of IL-23/IL-23R biology by elucidating the transcriptional and epigenetic mechanisms controlling *IL23R* expression in human naïve T cells and thus their responsiveness to IL-23.
To define the early molecular events that lead to *IL23R* expression, we isolated naïve $CD4^+$ T lymphocytes from cord blood and stimulated them under different T helper polarizing conditions. *IL23R* expression was induced in both Th17 and Th1 cells, and among Th17 polarizing cytokines, IL-21 was necessary and sufficient to initiate *IL23R* expression in TCR-stimulated cells.
ATAC-seq profiling of the *IL23R* locus revealed accessible chromatin regions with putative regulatory function. IL-21, in the presence of TCR stimulation, induced chromatin accessibility similar to the one observed in Th17 differentiating conditions, confirming the important role of IL-21/IL-21R signaling in initiating *IL23R* gene expression. In addition, ATAC-seq footprinting highlighted potential transcription factor candidates for regulating *IL23R* expression. The role of these transcription factors was tested by siRNA-mediated downregulation and their binding to their target sequence was confirmed by DNA affinity capture assay.
Together, our data demonstrate that IL-21 plays an important role in early induction of *IL23R* in human CD4+ T cells and suggests cell subset specific regulation of *IL23R* expression.

GDF-15-Driven Macrophage Reprogramming: Impact on IL17RB Expression and Immune Tolerance

Lina Susana Silva Bermudez[1;2], Jingxuan Xu[1], Harald Klüter[1;2], Julia Kzhyshkowska[1;2]
[1]1Institute of Transfusion Medicine and Immunology, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany; *[2]German Red Cross Blood Service Baden-Württemberg – Hessen, Mannheim, Germany*

GDF-15 is a multifunctional cytokine involved in immune tolerance that is elevated in stress conditions, correlating with disease severity and survival. The role of GDF-15 in macrophages and its effects on the macrophage transcriptional program have been studied to only a limited extent. In this study, we identified the transcriptional program induced by recombinant human GDF-15 (rGDF15) on human macrophages in the presence or absence of lipopolysaccharide (LPS). Human monocytes were isolated from buffy coats by CD14+ positive selection and differentiated into M0 (non-stimulated), M1 (IFN-γ stimulated), and M2 (IL-4 stimulated) macrophages for 6 days. On day 6, macrophages were pre-treated with 50 ng/mL rGDF-15 for 1 hour, followed by a 6-hour challenge with 100 ng/mL LPS. Total RNA Seq revealed that rGDF15 altered the expression of 210 genes in M0 and of 372 in M2. rGDF15 and LPS in M0 and M2 exhibited changes in 230 and 295 genes, respectively. Gene Ontology analysis highlighted enrichment in blood vessel morphogenesis and angiogenesis pathways following rGDF-15 treatment in both M0 and M2. The top-upregulated GO terms in M0 and M2 under rGDF-15 and LPS belonged to TGF-β receptor and cytokine signaling pathways. Validation through RT-PCR and flow cytometry confirmed increased expression of IL17RB across all groups, indicating an anti-inflammatory effect mediated by rGDF-15 in macrophages. These findings highlight the ability of GDF-15 to induce a tolerogenic phenotype in human macrophages, promote angiogenesis, and modulate TGF-β signaling.

IFN-γ response by medullary thymic epithelial cell in the absence of Aire gene

Ana Carolina Monteleone Cassiano[1;2], Rute Daniela Pinto[2], Pedro Ferreirinha[2], Geraldo Passos[1], Nuno Alves[2], Eduardo Donadi[1;3]
[1]Programa de Pós graduação em Imunologia Básica e Aplicada FMRP/USP, Ribeirão Preto, Brazil; *[2]i3S – Instituto de Investigação e Inovação em Saúde, Universidade do Porto, Porto, Portugal*; *[3]Faculdade de Medicina de Ribeirão Preto-FMRP/USP, Ribeirão Preto, Brazil*

Purpose: In humans, the deficiency of the autoimmune regulator (AIRE) gene may cause several autoimmune disorders, like the autosomal recessive autoimmune polyendocrine syndrome type 1 (APS-1). Chronic mucocutaneous candidiasis (CMC) is one of the earliest and most frequent clinical manifestations of the disease. To explain the occurrence of CMC in APS-1 patients, It has been hypothesized that AIRE deficiency is associated with excessive STATI-mediated mucosal IFN-γ production by 'pathogenic' T cells, impairing the integrity of oral epithelial cells. We evaluated the IFN-γ response in the absence of Aire gene in medullary thymic epithelial cell .
Methods: The Aire WT mTEC 3.10 and the Aire$^{-/-}$ mTEC 3.10E6 cell lines were cultured as monolayers and seeded in 12 well plates and stimulated or not with IFN-γ (Thermo Fisher Scientific, Waltham, MA), maintained in culture for 3 days, the gene expression of IFN-γ receptors and GTPases that are induced by IFN-γ was evaluated by RTqPCR.
Results: Both cell lines expressed the IFNγ receptors 1 and 2 (Ifngr1 and Ifngr2). The WT presented the same pattern of Ifngr1 along the culture, nonetheless the Aire-/- overexpressed the Ifngr1 after 3 days of stimulus with IFN- γ. Regarding the Ifngr2, we observed for both cells line an increase after IFN-γ stimulation, more accentuated for the WT cells. The GTPases Irgb6, Irgm1 and Irgm3 were expressed in both cell lines. Although GTPases were increased in Aire$^{-/-}$ both cells responded to IFN-γ stimulation.
Conclusion: These findings indicate that, in this model, WT and Aire$^{-/-}$ mTECs responded to IFNγ stimulus; however, the Aire$^{-/-}$ cells presented an imbalance of the heterodimer Ifngr1/Ifngr2 expression.

The gene expression of TGF-β receptor subunits in blood is altered in relapsing-remitting multiple sclerosis and under the influence of dimethyl fumarate

Ludmiła Szewczak[1;2;3], Magdalena Kierasińska[1;2], Rafał Rola[4], Anna Karlińska[4], Katarzyna Donskow-Łysoniewska[1;5]
[1]General Karol Kaczkowski Military Institute of Hygiene and Epidemiology, Laboratory of Parasitology, Warsaw, Poland; *[2]Medical University of Warsaw, Department of Histology and Embryology, Warsaw, Poland*; *[3]University of Warsaw, Faculty of Biology, Institute of Functional Biology and Ecology, Department of Parasitology, Warsaw, Poland*; *[4]Military Institute of Aviation Medicine, Department of Neurology, Warsaw, Poland*; *[5]Lazarski University, Faculty of Medicine, Department of Experimental Immunotherapy, Warsaw, Poland*

Purpose: Relapsing-remitting multiple sclerosis (RRMS) is the most common form of multiple sclerosis. Dimethyl fumarate is one of the first-line treatment drugs used in the treatment of RRMS. The aim of the study was to determine the alterations of gene expression of TGF-β receptor subunits in blood cells and in TGF-β1 concentration in serum of patients with RRMS untreated or treated with dimethyl, compared to healthy controls.
Methods: Expression of TGFBR1, TGFBR2 and TGFBR3 genes in blood of patients and healthy donors was determined using digital droplet PCR. Serum concentration of TGF-β1 was determined using ELISA. All patients were in remission.
Results: Untreated patients had significantly lower expression of TGFBR3 gene in blood and TGF-β1 serum concentration than healthy controls. Patients treated with dimethyl fumarate had significantly lower TGFBR1 and TGFBR2 gene expression in blood than untreated patients, significantly lower TGFBR2 and TGFBR3 gene expression in blood than healthy controls and significantly higher serum TGF-β1 concentration than untreated patients.
Conclusion: This study demonstrates, changes in the expression of molecules related to TGF-β signaling under the influence of dimethyl fumarate. Dimethyl fumarate affects the Nrf2-related signaling pathway, which may also interfere with TGF-β-related signaling.

This work was supported by grants from the TEAM TECH/2017-4/22 project carried out within the TEAM TECH programme of the Foundation for Polish Science co-financed by the European Union under the European Regional Development Fund.

Changes in levels of leptin, adiponectin, chemerin and resistin in response to progressive resistance training in highly trained athletes and non-trained individuals

Olga Sierawska[1;2], Marek Sawczuk[1]
[1]Institute of Physical Culture Sciences, University of Szczecin, Szczecin, Poland; [2]Doctoral School, University of Szczecin, Szczecin, Poland

Background: Despite the old view that adipose tissue (AT) has only a storage and thermoregulatory role, it is now known to be a highly active and complex endocrine and metabolic gland. Cytokines secreted by adipocytes are important in inflammation and many pathologies, such as cardiovascular, metabolic disorders, cancer, dietary behaviour, and even mental illnesses or microbiota disorders. Adipokines can easily pass from AT into systemic circulation, so they are a valuable and readily available indicator. Individuals who regularly engage in physical activity (PA) have a more favourable adipokine profile. They have elevated levels of anti-inflammatory cytokines and reduced levels of inflammatory cytokines. In addition, PA leads to changes in the gene expression of adipokines, protein ligands, and their binding to receptors. Therefore, regular PA is essential for managing AT and adipokine-related diseases. Previous studies have shown that not all adipokines show predictable patterns in secretion in response to PA.
Purpose: We aim to analyze changes in levels of leptin, adiponectin, chemerin, resistin in response to progressive resistance training in highly trained athletes and non-trained individuals.
Methods: Venous blood samples (volume 500 μl) were collected from study participants at time points (before and after the training). Total RNA isolation and cDNA synthesis were performed to assess gene expression levels by real-time PCR (quantitative PCR, qRT-PCR). All results were standardized to the levels of GAPDH, and statistical analysis was performed.
Conclusion: Due to the varying methodologies of studies on PA, it is difficult to determine its effect on adipokine secretion subjectively. For this reason, there is a need to collect data on how different adipokines interact and to study the entire panel of major adipokines involved in developing pathologies of various systems in the human body. In addition, most studies focus on overweight/obese patients, where the adipokine panel is disrupted by excessive AT accumulation. However, there are limited studies on adipokines in regularly physically active individuals whose AT levels remain within normal limits.

Evaluating the cytokine profile in steroid naive patients with polymyalgia rheumatica

Patricia Harkins[1], Sharon Cowley[1], Robert Harrington[1], Jean Dunne[1], David Kane[1], Niall Conlon[1], Richard Conway[1]
[1]*Trinity College, Dublin, Ireland*

Purpose. Despite polymyalgia rheumatica (PMR) being the most common inflammatory rheumatic disease in those over the age of 50 years, there remains a significant unmet need for a reliable serum biomarker of disease activity, to aid the diagnosis, and the identification of disease relapse. The aim of this pilot study was to evaluate the levels of 7 serum cytokines in a cohort of newly diagnosed PMR patients.
Methods: 15 consecutive patients, who had active, untreated PMR were recruited from a fast track PMR clinic. The following circulating cytokines were then measured via ELISA using the participants serum: MCP-1(CCL2), interleukin-6 (IL-6), CXCL9 (MIG), MIP-1 alpha (CCL3), Tumour necrosis factor alpha (TNF-α), interleukin-1 beta (IL-1β) and interleukin-17A (IL-17A). The statistical analysis was performed using STATA MP Version 18.
Results: A total of 15 patients with PMR were studied (33% female; 67% male). The mean age was 71.71 (SD 5.97). In reference to defined manufacturer parameters, at diagnosis serum MCP-1 levels were elevated in 14/15 (93%), with a median level of 732.5pg/ml (571, 921). Serum IL-6 levels were elevated in 10/15 (67%) with a median level of 11.85 pg/ml (6.05, 31.8). CXCL9 was elevated in 14/14 (100%), with a median level of 2184pg/ml (1180, 3897.5). Levels of MIP-1 alpha were elevated in 4/14 (28.6%) patients, with a median level of 91.1 pg/ml (76.5, 105). IL-1β was elevated in 2/15 (13.3%) with a median level of 0.445pg/ml (0.27, 0.815). TNF-α was elevated in 1/15 (6.7%) with a median level of 15.35pg/ml (12.85, 16.8). Finally, IL-17A was only available in 6 patients, with 5/6 (83%) demonstrating increased levels, with a median IL-17A level of 3.02 (2.89,3.27).
Conclusion: Our pilot study has demonstrated the potential utility of serum CXCL-9, MCP-1 and IL-17A in the diagnosis of those with pure PMR. Our study offers the advantage of inclusion of a pure PMR cohort, who are naïve to any treatment including steroid. Our findings provide promise for future large scale prospective studies exploring the role of these cytokines in PMR, which may also facilitate a deeper understanding of the inflammatory and immune mechanisms underlying PMR pathophysiology.

Adipokines dysregulation in the dysfunctional body adipose tissue is associated with immunometabolic biomarkers increase, highlighting dyslipidemias with a greater contribution from the TG-VLDLC-APO B metabolic pathway

Jacqueline Noboa-Velástegui[1], Ana-Lilia Fletes-Rayas[2], Perla-Monserrat Madrigal-Ruiz[3], Jorge Castro Albarran[4], Sandra Luz Ruiz Quezada[3], Martha Eloisa Ramos Marquez[3], Rosa Elena Navarro Hernandez[3]
[1]Doctorado en Ciencias Biomédicas. Secretaría Académica. Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Guadalajara, Mexico*; *[3]UDG-CA-701. Inmunometabolismo en Enfermedades Complejas y Envejecimiento. Departamento de Biología Molecular y Genómica, Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Guadalajara, Mexico*; *[4]Departamento de Ciencias de la Salud y Ecología Humana, División de Desarrollo Regional, Centro Universitario de la Costa Sur, Guadalajara, Mexico*

Purpose: CCL2, chemerin, and adiponectin are adipokines with crucial roles in immunometabolism. The presence of dyslipidemias is also involved in metabolic control. Remarkably, levels of LDLc have shown controversial results regarding the obesogenic profile (adipose tissue distribution in the immunometabolism process). Our study aimed to evaluate the association of adipokines levels with the immunometabolic biomarkers in the dysfunctional body adipose tissue of individuals with obesogenic profile.
Methods: In this cross-sectional study, 230 males and females aged 20 to 59 were included and split up into three groups: reference (healthy), study (overweight/unhealthy), and comparison (overweight/healthy), based on obesogenic profile. We evaluated body fat storage and distribution using bioelectrical impedance. Immunometabolic biomarkers by routine methods. Meanwhile, insulin, chemerin, CCL2, and adiponectin-oligomers serum levels by the ELISA method.
Results: The magnitude of all adiposity parameters increased in the following order: the study group was greater than the comparison group, and this, in turn, was greater than the reference group. The comparison between the study group and the comparison and reference groups showed differences in elements of the lipid profile, mainly the TG-VLDLc-Apo B metabolic pathway and insulin resistance. C3 and C-reactive protein levels showed an increase in the study and comparison groups versus the reference group. HMW and MMW + LMW adiponectin oligomers showed a decrease in the study group compared to the reference group. The chemerin levels showed a pattern that tends to decrease in the following order: the reference group is greater than the study group, and this, in turn, is greater than the comparison group, while a reverse pattern was observed in the CCL2 levels. The CCL2-Chemerin relationship coincides with the obesogenic profile.
Conclusion: The increase in dysfunctional adipose tissue coincides with the increase in the lipid profile with a greater contribution from triglycerides-VLDLc-Apo B metabolism. We suggest that the imbalance in the adipokine scenario, which is contributed by the inflammatory process (characterized by the increase in biomarkers of subclinical inflammation), agrees with the imbalance in the immunometabolic indices.

Cross-regulation of antibody responses against viral and host proteins by commensal microbiota via molecular mimicry

Marina Bondareva[1], Pawel Durek[1], Adrian Schreiber[2], Philipp Enghard[2], Mir-Farzin Mashreghi[1], Andrey Kruglov[1]
[1]German rheumatism research centre, Berlin, Germany; *[2]Charité medical school, Berlin, Germany*

The commensal microflora provides a repertoire of antigens that elicit mucosal antibodies. In some cases, these antibodies can cross-react with host proteins, inducing autoimmunity, or with other microbial antigens providing protection against pathogens. We demonstrate that several human commensal bacteria can induce salivary anti-SARS-CoV-2 Spike IgG antibodies via molecular mimicry. In particular, S. salivarius, was recognized by SARS-CoV-2-neutralizing monoclonal antibodies and induced cross-reactive anti-Spike antibodies in mice, facilitating SARS-CoV-2 clearance. A specific S. salivarius protein, RSSL-01370, contains regions with homology to the Spike receptor-binding domain, and immunization of mice with RSSL-01370 elicited anti-Spike IgG antibodies in the serum and oral S. salivarius supplementation enhanced salivary anti-Spike antibodies in vaccinated individuals. In case of autoimmunity, we observed that pathogenic ANCA antibodies against myeloperoxidase can be induced by distinct commensal bacteria.
Altogether, our data show that distinct species of the human microbiota can express molecular mimics of viral and host proteins that contribute to human health.

Packaged Food Emulsifiers Trigger Pro-Inflammatory Activation and Disruption of the Gut Epithelial Barrier

Duygu Yazici[1], Yagiz Pat[1], Ismail Ogulur[1], Sena Ardicli[1], Sheri Simmons[2], Anthony Almada[2], Christine Avena[2], Tye Jensen[2], Manru Li[1], Yasutaka Mitamura[1], Huseyn Babayev[1], Anja Heider[1], Raja Dhir[2], Mubeccel Akdis[1], Kari Nadeau[3], Cezmi Akdis[1]

The barrier function of the epithelia is crucial for maintaining homeostasis. Environmental exposures may alter the epithelial barrier integrity and influence the development of diseases. Recent studies have shown that certain surfactants and emulsifiers damage the epithelial barriers. We investigated the effects of three commonly used food emulsifiers, sunflower-derived lecithin (SunLec), soy lecithin (SoyLec) and diacetyl tartaric acid ester of mono- and diglycerides (DATEM) on gut organoids and organs-on-a-chip and adult stem cell derived intestine-on-a-chip. All emulsifiers were examined at consumer-relevant doses using transepithelial-electrical resistance (TEER), RNA-seq, and targeted proteomics. SunLec, SoyLec and DATEM elicited a dose- and time-dependent decrease in epithelial barrier function in TEER measurement. RNA-seq analysis indicated that both lecithins upregulated the pathways of response to lipid and cell death at 6.25 mg/ml. Specifically, wound healing was upregulated with SunLec exposure, while cell migration, oxidative stress and angiogenesis pathways were upregulated with SoyLec. DATEM showed increased cell death, regulation of metabolic processes and response to oxygen-related compounds. An increase in type 2 cytokine levels such as IL-4, IL-13 and IL-33 in response to SunLec, while SoyLec induced the production of proinflammatory cytokines (IL-6, IL-18) as well as alarmins (TSLP, IL-33). DATEM induced the production of not only the alarmin, TSLP, but also proinflammatory and cell death-related proteins such as caspase 8, IL-18, DDX58 and peroxiredoxins. Irregular and heterogeneous confocal microscopy staining of ZO-1 was observed after exposure to all three emulsifiers, additionally demonstrating the disruption of the intestinal epithelial barrier. In conclusion, the present study provides direct evidence on the detrimental effects of food emulsifiers, SunLec, SoyLec and DATEM on intestinal epithelial integrity, due to extensive proinflammatory, oxidative stress, tissue healing, angiogenesis and alarmin release of the epithelial cells, namely causing epithelitis. Studies are going on to examine the epithelial damaging and inflammatory effect of emulsifiers on mice in vivo and to verify the related pathways mechanistically in human intestinal organoids using CRISPR/Cas9.

PPARβ/ inhibition enhances Mesenchymal Stromal Cell-mediated immunomodulation in the context of Acute Respiratory Distress Syndrome

Courteney Tunstead[1], Evelina Volkova[1], Hazel Dunbar[1], Ian J. Hawthorne[1], Alison Bell[2], Ritu Negi[3], Bairbre McNicholas[3], Claudia C. dos Santos[4], John G. Laffey[3], Karen English[1]
[1]Maynooth University, Kildare, Ireland; *[2]Trinity College, Dublin, Ireland*; *[3]Galway University Hospital, Galway, Ireland*; *[4]St. Michaels Hospital, Toronto, Canada*

Purpose: Mesenchymal Stromal Cells (MSCs) have been utilised in a variety of clinical trials to date, due to their immunomodulatory properties and their low immunogenicity. MSCs are known to require a pro-inflammatory stimulus in order to activate/license them. This makes them an attractive treatment for inflammatory diseases such as Acute Respiratory Distress Syndrome (ARDS); a condition in which there is an abundance of pro-inflammatory mediators available for MSC licensing. The PPARβ/*δ* nuclear receptor has been thought to impact MSC functionality. In the context of ARDS, there are many natural ligands of PPARβ/*δ* in the patient micro-environment that could bind to this ubiquitously-expressed receptor on the MSCs. We sought to investigate the impact of PPARβ/*δ* on MSC immunomodulation, specifically of human monocyte-derive macrophages (MDMs), in the context of ARDS.
Methods: Human bone-marrow-derived MSCs were seeded at a density of $1x10^5$ and stimulated with a synthetic PPARβ/*δ* agonist (GW0742) or antagonist (GSK3787) for 6hrs, followed by cytokines for a further 6hrs. The cells were sent for RNA sequencing, used in a variety of *in vitro* functional assays, or trialled in our LPS-induced Acute Lung Injury (ALI) mouse model.
Results: Our results showed that PPARβ/*δ* inhibition drastically improved MSC-immunomodulation of human MDMs, and upregulated immunomodulatory genes such as *ptgs1*, *icam1* and *ccl2*. These genes were downregulated when the cells were exposed to either the synthetic agonist, or human ARDS serum samples containing natural ligands of PPARβ/*δ*. However, when PPARβ/*δ* was inhibited prior to exposure to the ARDS serum, we could redeem the upregulation of these immunomodulatory genes. RNA sequencing datasets further highlighted the pathways that had been altered, showing clear differences in the NFkB pathway, with many NFkB-regulated genes being enhanced upon inhibition of PPARβ/*δ*.
Conclusion: PPARβ/*δ*-activation negatively impacts MSC immunomodulation, and inhibiting or removing it prior to MSC therapy, in the context of ARDS, may be beneficial.

Differential FLS populations define Rheumatoid and Psoriatic Arthritis pathotypes via their functional response to distinct immune regulators

Órla Tynan[1], Conor Smith[2], Mary Canavan[3], Achilleas Floudas[1], Aoife O'Rourke[3], Dumitru Anton[1;4], Carl Orr[4], Douglas Veale[4], Ursula Fearon[1;4]
[1]Molecular Rheumatology, Clinical Medicine, Trinity Biomedical Sciences Institute, Dublin, Ireland; *[2]Translational Immunology, Trinity Biomedical Sciences Institute, Dublin, Ireland*; *[3]Translational Immunopathology, School of Biochemistry & Immunology and School of Medicine, Trinity Biomedical Sciences Institute, Dublin, Ireland*; *[4]EULAR Centre for Arthritis and Rheumatic Diseases, St Vincent University Hospital, University College Dublin, Dublin, Ireland*

Purpose: To identify phenotypic and functional characteristics that define distinct fibroblast (FLS) populations and immune regulators in Rheumatoid Arthritis (RA) vs Psoriatic Arthritis (PsA).
Methods: ScRNAseq was performed on 88,953 RA and PsA FLS from intact synovial-biopsies and FLS populations defined by advanced bioinformatic analysis. Multiparametric flow-cytometric analysis (22-markers) was performed on RA and PsA patient synovial-biopsies to examine FLS phenotype/function. FLS were sorted into $THY1^+$ vs $THY1^-$ FLS, cultured and supernatants analysed by MSD-Multiplex assays. Following ligand-receptor interaction analysis, FLS were cultured with IL-1β (1ng/ml), TGF-β (10ng/ml) alone or in combination. Metabolic-capacity was assessed using Seahorse-XFe-technology and glycolytic markers, mitochondrial fission/fusion proteins (DRP1/MFN1/MFN2) and endoplasmic reticulum (ER) stress proteins quantified by real-time PCR and/or immunofluorescence.
Results: ScRNAseq demonstrated 11-distinct FLS populations in RA and PsA, with differential clusters frequency observed with $THY1^+$FLS dominant in RA vs $THY1^-$FLS dominant in PsA. Flow-analysis of $PDPN^+$FLS demonstrated significant increases in $HLADR^+$, YAP^+, $Cad11^+$, and $pS6^+$ FLS in RA (all-$p<0.05$), whilst CD55 was increased in PsA-FLS ($p=0.0079$). Further flow-analysis identified 6-main FLS populations. RA displayed enrichment of $THY1^+CD34^+CD55^-FAP^+$ and $THY1^+CD34^+CD55^-FAP^+$ FLS ($p=0.0093$), while PsA displayed enrichment in $THY1^+CD34^-CD55^+FAP^+$ ($p=0.02$) and $THY1^-CD34^-CD55^+FAP^+$ FLS ($p=0.0013$). HLADR and Cad11 were significantly higher in RA subpopulations. $THY1^+FAP^+$FLS demonstrated higher expression of angiogenic mediators VEGF-A, VEGF-C, and Flt1 compared to $THY1^-FAP^-$FLS. ScRNAseq receptor-ligand-interactions demonstrated that T-cell-derived TGF-β and macrophage-derived IL-1β synergistically drive the transcriptional profile of RA $THY1^+FAP^+$FLS. At a functional level IL-1β/TGF-β synergistically promoted IL-6, IL-8, MCP-1, ICAM-1, VEGF and MMP3 secretion from RA-FLS ($p<0.05$). Furthermore, IL-1β/TGF-β synergistically induced a glycolytic phenotype in RA-FLS, with synergistic induction of basal glycolysis ($p<0.05$), proton efflux-rate ($p<0.05$), % PER-glycolysis ($p<0.05$) and compensatory-glycolysis ($p<0.001$). This was paralleled by significant increases in GLUT-1, HIF1a and PKM2 (all $p<0.05$) and ER-stress genes XBP1S, BIP and ATF6. Reduced mitochondrial size ($p<0.05$), with an increase in mitochondrial fission protein DRP-1 ($p<0.05$) was also demonstrated.
Conclusion: Distinct FLS populations with unique functional properties and regulators were identified in RA and PsA. Deeper understanding of FLS subsets and blockade of specific immune-stromal cell-interactions may offer new therapeutic intervention in RA and PsA.

Investigating the impact of PPARβ/δ on Mesenchymal Stromal Cell immunometabolism

Evelina Volkova[1], Courteney Tunstead[1], Hazel Dunbar[1], Ian Hawthorne[1], Claudia C. dos Santos[2], John G. Laffey[3], Karen English[1]
[1]Maynooth University, Maynooth, Ireland; *[2]St. Michaels Hospital, Toronto, Canada*; *[3]University of Galway, Galway, Ireland*

Purpose: The immunomodulatory potential and regenerative properties of mesenchymal stromal cells (MSCs) have been utilised in cell-based therapies for immune-mediated disorders. However, clinical trials using MSCs for the treatment of acute respiratory distress syndrome (ARDS) have been disappointing and only effective in around 40% of patients. Differences in inflammatory microenvironments in ARDS patients are thought to play a factor in MSC efficacy. Interestingly, ligands of peroxisome proliferator-activated receptor-delta (PPARβ/δ) are highly expressed in the ARDS patient environment. Recent evidence suggests that PPARβ/δ modulation alters MSC function and metabolic profile. In this study we evaluated the implications of PPARβ/δ on MSC metabolism and immunosuppressive ability *in vitro*.
Methods: Human bone marrow derived MSCs were seeded at a density of $1.2x10^5$, stimulated with PPARβ/δ agonist (GW0742) or antagonist (GSK3787) followed by pro-inflammatory cytokines TNFα and IFNγ. Gene and protein expression profiles were investigated by RNA Sequencing (RNA-Seq), qPCR and flow cytometry. The immuno-metabolic profile of hBM-MSCs pre-treated with PPARβ/δ agonist or antagonist was established using SCENITH assay.
Results: RNA-Seq data showed that MSCs stimulated with pro-inflammatory cytokines in the presence of a PPARβ/δ agonist or antagonist leads to differential changes in key metabolic pathways associated with MSC immunosuppression. Altered gene expression of *slc2a1* and *hk2* following pro-inflammatory cytokine stimulation suggests upregulation of glycolysis. PPARβ/δ activation leads to increased mitochondrial dependence and expression of *cpt1a*, the rate-limiting enzyme required for fatty acid oxidation. Conversely, PPARβ/δ antagonism is associated with an increase in glycolytic genes and *ptgs2* expression following stimulation with TNFα, both associated with MSC immunosuppressive ability. Functionally, PPARβ/δ antagonism correlates enhanced suppression of human monocyte derived macrophages by MSCs *in vitro.*
Conclusion: Differences in the metabolism of MSCs in the presence of PPARβ/δ agonist or antagonist and stimulation with pro-inflammatory cytokines dictate their immunomodulatory potential. Inhibition of PPARβ/δ to enhance MSC function and metabolic capacity has the potential to improve clinical outcomes for the treatment ARDS.

Characterization of PRIME cells identified in circulation of Individuals-At-Risk and patients with rheumatoid arthritis

Brianne Barker[1;2], Órla Tynan[1;2], Dumitru Anton[1;2], Aoife O'Rourke[1], Carl Orr[2], Douglas Veale[2], Mary Canavan[1], Ursula Fearon[1;2]
[1]Trinity College Dublin, Dublin, Ireland; *[2]ERC, St. Vincent's University Hospital, Dublin, Ireland*

Purpose: A recent study has identified CD45-CD31-PDPN+ 'pre-inflammatory mesenchymal' (PRIME) cells in the circulation as predictive of flare in patients with Rheumatoid Arthritis (RA). However, little is known about the functional capacity of 'PRIME' cells. We aim to identify and phenotype PRIME cells in the circulation and site of inflammation (joint) in healthy controls (HC), RA, and in 'individuals-at-risk' (IAR) of developing RA.
Methods: Multiparametric flow-cytometry analysis (23-color panel) was performed on peripheral blood mononuclear cells (PBMC) from HC, IAR, and RA patients. RA patients were further stratified between ACPA+ vs ACPA-. PRIME cells were identified as CD45-CD31-PDPN+ and subsequent analysis of phenotypic markers were quantified by flow-cytometry. Frequency and characteristics of PRIME-cells from circulation were compared to synovial-tissue cells by flow-cytometry.
Results: Increased frequency of PRIME cells was observed in RA PBMCs compared to HC with a significant increase seen in IAR. RA PRIME cells had trending increase of frequency/expression of proliferation (Ki67) and activation (FAP) markers compared to HC. Frequency/expression of adhesion and immunoregulatory markers CD34 ($p=0.08$),-CD44,-ICAM-1,-HLA-DR and CD200R1 were increased RA PRIME cells compared to HC. A stepwise increase in frequency of markers FAP,-CD200R1 and CD34 was shown from HC>IAR>RA. Stratification of RA patients demonstrated increased PRIME frequency ($p<0.01$) and expression of CD44,CD34, and CD200R1 in ACPA+ compared to ACPA-. These phenotypic changes were mirrored by a shift in the metabolic-profile of 'PRIME' cells where a stepwise increase in the expression of the key metabolic sensor mTOR was demonstrated from HC>IAR>RA. CD55 (lining-layer FLS-marker) was not expressed on PRIME cells across disease status, however, CD90 (sub-lining FLS-marker) was observed. Synovial-tissue had significantly higher frequency of PDPN+ cells compared to PBMC ($p<0.01$). Frequency of CD55,-CD90,-pAKT,-YAP, and CD34 were significantly higher in IAR and RA synovial-tissue compared to circulatory PDPN+ cells (all $p<0.05$). In contrast, Cadherin11,-ICAM-1, and CD200R1 were significantly higher on circulating PDPN+ cells compared to synovial-tissue (all $p<0.05$).
Conclusions: PRIME cells could function as a potential biomarker in IAR and an indicator of disease severity in RA. Understanding their functional role in RA pathogenesis could provide additional therapeutic targets.

The inflamed joint microenvironment affects endothelial cell function through soluble mediators and cell-cell interactions

Aenea Brugman[1;2], Órla Tynan[1;2], Dumitru Anton[1;2], Carl Orr[2], Viviana Marzaioli[1;2], Douglas Veale[2], Ursula Fearon[1;2]
[1]Trinity College Dublin, Dublin, Ireland; [2]EULAR Centre for Arthritis and Rheumatic Diseases, Dublin, Ireland

Purpose: While common pathogenic mechanisms exist between PsA and RA, distinct vascular morphology has been observed, with PsA displaying a tortuous, dilated, irregular shaped morphology compared to a straight regular branching pattern observed in RA. The aim of this study is to examine the effect of the PsA and RA joint microenvironment on endothelial cell function.
Methods: PsA and RA patients underwent key-hole joint arthroscopy and synovial biopsies were obtained. PsA and RA synovial fibroblasts (FLS) were isolated and grown to passage 1-5. PsA and RA FLS supernatants were harvested and referred to as conditioned media (CM). Endothelial cells (EC) were co-cultured with PsA/RA FLS or CM, and pro-inflammatory mediators were quantified by real-time PCR and flow cytometry.
Results: Gene expression of IL-6 and ICAM-1 in EC was increased in response to both PsA/RA FLS and CM. Both PsA CM and RA CM induced MCP-1 and MMP-2 expression in EC, with no effect observed in response to RA/PsA FLS. VCAM-1 expression was decreased in EC in response to both PsA CM and RA CM, however, was increased in RA FLS-EC co-culture. Key angiogenic growth factors VEGF and Ang-2 were increased by either RA/PsA CM and FLS, in addition to the matrix degrading enzyme MMP3. Either co-culture of PsA/RA FLS or PsA/RA CM with EC induced the frequency of key chemokine receptors CXCR3 and CXCR4 on EC, an effect that was more pronounced for CM vs FLS co-culture, particularly for PsA CM. Both RA FLS and RA CM decreased the frequency of CXCR5. Only co-culture with PsA and RA FLS induced the expression of ICAM-1, with no effect observed for PsA or RA CM. Both PsA/RA FLS and CM decreased VCAM-1 expression on EC, similar to that observed at the gene expression level.
Conclusion: PsA and RA FLS/CM induce angiogenic, chemokine, adhesion molecule and matrix degrading enzymes on EC, with differential effects for some mediators observed in response to PsA vs RA joint microenvironments. Furthermore, differences were observed between EC-FLS vs EC-FLS CM co-cultures, suggesting cell-cell contact and soluble mediators both influence the EC pathogenic phenotype.

Defining the effects of trained innate immunity and metabolic reprogramming on the immune functions of airway epithelial and fibroblast cells

Sarah Connolly[1], Dearbhla Murphy[1], Grainne Jameson[1], Isabella Batten[1], Donal Cox[1], Joseph Keane[1], Jean Fletcher[2], Sharee Basdeo[1]
[1]Trinity Translational Medicine Institute, Trinity College Dublin, St James's Hospital, Dublin 8, Ireland; *[2]Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland*

Background: Exposure to an infection or a vaccine can induce heterologous effects mediated by myeloid cells termed 'trained immunity' resulting in enhanced innate immune responses to subsequent infections. The interconnected effects of trained innate immunity on structural cells in the lungs is unknown. Given the critical role for cellular metabolism in the function of innate cells, targeting metabolism through aerosolised delivery of immunomodulatory drugs during infection may be clinically beneficial for difficult to treat respiratory infectious disease such as Tuberculosis. However, a significant knowledge gap remains around metabolic manipulation on the innate-structural cell axis in the lung which amplifies inflammation leading to the clearance of infection, but can also cause collateral damage to the delicate lung tissue.
Aims and Methods: Human lung epithelial (A549) and fibroblast cells (MRC-5) were exposed to conditioned medium from trained monocytes which were restimulated with *Mycobacterium tuberculosis* or untrained controls. To examine if cellular metabolism is associated with the immune functions, A549 and MRC-5 cells were treated with inhibitors of metabolic pathways prior to being stimulated with conditioned medium or innate immune cytokines. The production of IL-6 and IL-8 were quantified by ELISA. The expression of ICAM and HLA-DR were determined by flow cytometry.
Results and Discussion: Conditioned medium from trained monocytes increased IL-6, IL-8 and ICAM expression from A549 and MRC-5 cells. Additionally, IL-1β and TNF, produced by trained monocytes, act synergistically to promote IL-6 and IL-8 by A549 and MRC-5 cells. This synergistic effect is mediated in part, by glycolysis as inhibiting glycolysis with 2DG significantly attenuated the synergistic effects of IL-1β and TNF. Moreover, inhibiting fatty acid metabolism using etomoxir significantly increased IL-6 production induced by the synergistic IL-1β and TNF suggesting that fatty acid oxidation may indirectly limit an excessive inflammatory loop between myeloid and structural cells in the lung.
Conclusion: Trained innate immunity propagates an inflammatory phenotype in surrounding structural cells in the lung microenvironment and immunometabolism is a key regulatory point in the innate-structural network in the lung. This is an important finding as metabolic pathways are a tractable target to develop inhalable host-directed therapies to promote respiratory health.

Human thymus epithelial stem cells - the pillars of T cell development

Ildikó Bódi[1], Sabrina Adorisio[2], Domenico Delfino[2], Ivan Mamic[3], Lucija Bozicevic[4], Zsolt Prodan[5], Delfa RadicKristo[6], Ivana Vinkovic Vrcek[4], Danka Grčević[6], Mariastefania Antica[4;7]

Purpose: T lymphocyte development relies on the functional thymus epithelial cells. We continue our study based on the previous results showing the existence of epithelial cell precursors within the postnatal human thymus as it has been described in the mouse model. We investigate the regenerative capacity of the epithelial cell precursors and continue our study on their characterization. However, some of the markers that were used for stem cell enrichment in the mice as Plet-1 have not been described in the human thymus.
Methods: Therefore, we previously described a technique for stem cell enrichment and *in vitro* 3D culture conditions, to assess the number of stem cells obtained as it has been shown for the neuronal cells. The spheroid forming cells are putative epithelial cell precursors that have to be tested for their functional capacity to promote T lymphocyte development from hematopoietic stem cells either *in vitro* by means of re-aggregation cultures or *in vivo* by transplantation into an animal model system.
Results: Since we previously showed that spheroid bodies express genes typical for mature thymic epithelial cells - KRT5, KRT8, AIRE, CD205, FoxN1 and EpCAM, but also genes HOXA3, PAX1, PAX9, and EYA1 active during early development, in the present work we tested the expression of these antigens *in situ* on thymus sections of children of different ages. Since we found in our previous work a certain proportion of cells expressing also PDGFRbeta, we further analyzed thymus resident progenitor cells being of epithelial or mesenchymal origin.
Conclusion: Our research uncovers some previously unknown characteristics of the elusive progenitor populations and their position and frequency in the intact human thymus.

Chan School of Public Health, Boston, United States*

Gut microbiota protects the gastrointestinal system's homeostasis by producing antimicrobial substances, vitamins, and metabolites, which aid in strengthening the gut epithelial barrier, inhibiting opportunistic pathogen colonisation and regulating the immune system. In addition, same bacterial products may have prominent roles in skin barrier homeostasis. With this perspective, we identify a gut microbiome metabolite (compound X) that improves gut epithelial barrier development speed and integrity as demonstrated in gut-on-a-chip Caco-2 3D cultures. The surface application of 0.25, 1- and 4-mM doses of compound X significantly increase the gut epithelial barrier integrity compared to control ($P<0.0001$) by almost 2 times (Transepithelial Electrical Resistance-TEER), during the gut development phase of the barrier. Transcriptomic analysis shows an upregulation of gene expression associated with xenobiotic metabolism, ion, water, glucose, and amino acid transport pathways. It increases the gene expression of the tight junction protein, claudin-1 and displays anti-inflammatory activity, as demonstrated by decreased chemokines (CXCL5, 10 and 11, CCL20, 23 and 25, CSF-1 and MCP-1) and IL-1 α levels detected by proximity extension assay in media. Untargeted proteomics analysis reveals that compound X upregulates glycolysis, tricarboxylic acid cycle and oxidative phosphorylation and downregulates lipid metabolism pathways-related proteins. A 6-day pretreatment with compound X successfully prevents proinflammatory cytokine (TNF-α, IFN-γ and IL-1β) driven gut epithelial barrier impairment. Next, we assess its effects on skin epithelial barrier integrity with an *ex vivo* skin tissue model. Treatment of systemic circulation-relevant doses of compound X (0.25,1 and 4 μM) rescues surfactant (cocoyl methyl glucamide; CMG)-induced skin epithelial barrier damage within 24 hours. In addition, it reverses the inflammation caused by CMG, as demonstrated by decreased IL-18, CSF-1, PRDX-3 and PD-L1 protein levels. In conclusion, our data highlights compound X, as a promising agent for preventing, rescuing, and treating gut and skin epithelial barrier impairment. Studies are going on to confirm the associated pathways mechanistically by using CRISPR/Cas9 in human intestinal organoids and to check the mitigation effect of compound X on surfactant-treated skin of mice *in vivo*.

The fetal liver stromal compartments and hematopoiesis

Yanping Zhou[1], Francisca Soares-da-Silva[2], Mesquita-peixoto Marcia[2], Marie-pierre Mailhe[2], Ana Cumano[1]
[1]*Institut Pasteur, Université Paris Cité, INSERM U1223, Paris, France*; [2]*Institute Pasteur, Paris, France*

Purpose: During fetal development, multiple waves of hematopoietic cells emerge in the yolk sac generating erythro-myeloid progenitors, and in the intraembryonic vasculature giving rise to multipotent progenitors (MPPs). The MPPs differentiate, expand and establish the adult hematopoietic stem cell (HSC) pool in the fetal liver (FL), supported by a specialized stromal compartment, before they migrate to the bone marrow. Different stromal cells have been shown to interact with HSCs/MPPs. A better characterization of the fetal liver microenvironment during the development would provide better understanding of fetal hematopoiesis, new insights into hematologic disorders that originate in the fetus and expansion of HSC for transplantation.
Methods: we isolated different stromal cell components and optimized a 3D culture system such that they maintain the expression of structural proteins and cytokines/chemokines. We used this system to analyze individual or combinations of stromal populations for their capacity to maintain and/or expand hematopoietic stem and progenitor cells (HSPCs).
Results: Erythroid, myeloid and lymphoid cells were observed when stromal cells co-cultured with $CD45^+$ FL cells in the 3D culture system, an expansion of up to 4-fold of HSPCs was also observed, while HPSCs decreased when co-cultured $CD45^+$ FL cells in 2D culture system and co-cultured with LSK cells alone in 3D culture system.
Conclusion: The 3D culture system that we developed supports differentiation of erythroid, myeloid and lymphoid cells and HPSCs expansion from $CD45^+$ FL cells. Co-culture of LSK with other hematopoietic cells improve LSK expansion.

Clinical features and outcome in two paediatric patients with anti-MDA5 and anti-Ro52 antibodies after viral infection

Laura Miguel Berenguel[1], Daniela Aguilar[1], Ricardo Cuesta Martin de la Camara[1], Carmen Cámara Hijón[1], Ana Martínez Feito[1], Pilar Nozal Aranda[1;2]
[1]Department of Immunology, Hospital Universitario La Paz, Madrid, Spain; *[2]Centre for Biomedical Network Research on Rare Diseases (CIBERER U754), Hospital La Paz Institute for Health Research IdiPAZ, Madrid, Spain*

Background: Dermatomyositis (DM) is a rare autoimmune connective tissue disease included within the idiopathic inflammatory myopathies that is characterized by the presence of specific skin lesions and myositis. However, these lesions have been evidenced in patients without muscle disease, thus giving rise to another subgroup called amyopathic dermatomyositis. This entity is strongly linked to the presence of antibodies to melanoma differentiation-associated gene 5 (MDA5), which is associated with a poor prognosis due to rapidly progressive interstitial lung disease (RP-ILD).
Methods: We analyze two paediatric patients under follow-up at Hospital Universitario La Paz between 2020 and 2024 with positive anti-MDA5 antibodies and amyopathic dermatomyositis. Clinical presentation, immunological findings, treatments and clinical outcome are reviewed.
Results: The patients were two girls who presented at 11 and 10 years old with skin lesions compatible with dermatomyositis and fever in the context of tonsillitis and EBV infection, respectively. Interstitial lung disease appeared less than three months after this episodes. Presence of anti-MDA5 and anti-Ro52 antibodies as well as elevated inflammatory mediators were detected. They initiated corticosteroid therapy. After poor response, different immunosuppressants were added sequentially. The use of plasmapheresis did not improve the outcome. In addition, both patients suffered different nosocomial infections. The first patient died 6 months after debut due to multi-organ failure in the context of septic shock whereas the second one developed a macrophage activation syndrome and has recently started extracorporeal membrane oxygenation therapy (ECMO) as a bridge to recovery.
Conclusion: Anti-MDA5 antibodies are extremely rare, especially in paediatric population. It is essential to actively search for ILD if they are found, since it frequently appears in the first months after diagnosis and is the main risk factor in these patients. Viral infection could act as a trigger that leads to increased levels of MDA5 and loss of tolerance. Furthermore, positive anti-Ro52 antibodies are associated with worse prognosis. Evidence suggests the use of combined immunosuppressive therapy and plasmapheresis in unresponsive cases, although in our patients the decrease in antibody titre did not correlate with clinical recovery. An improved knowledge of the pathogenesis is still needed to develop more effective targeted therapies.

Increased phosphorylation indicates continuous antigen-mediated autoreactive B-cell activation in rheumatoid arthritis

Sanne Kroos[1], Nienke J. Blomberg[1], Joanneke C. Kwekkeboom[1], Rudi Hendriks[2], Odilia Corneth[2], René E.M. Toes[1], Hans U. Scherer[1]
[1]*Leiden University Medical Center, Leiden, Netherlands*; [2]*Erasmus Medical Center, Rotterdam, Netherlands*

Purpose: Many human autoimmune diseases (AIDs) are hallmarked by persistent autoreactive B cells. Unlike B cells against recall antigens, autoreactive B cells may continuously encounter their antigen. Currently, it is unknown whether this maintains continuous activation. As such, rheumatoid arthritis (RA) is hallmarked by B cells targeting post-translationally modified proteins, for instance anti-citrullinated protein antibody (ACPA)-expressing B cells. Here, we sought to develop an antigen-specific flow cytometry staining approach to assess intracellular signaling pathways in ACPA-expressing B cells, isolated directly *ex-vivo* from patients with the prototypic human AID RA.
Methods: Immortalized human B-cell lines specific for tetanus toxoid (TT) or ACPA were used for protocol development. PBMCs of 10 RA patients were subsequently analyzed using spectral flow cytometry and various B-cell differentiation markers, antigen-biotin-streptavidin tetramers, and intracellular (phosphoflow) markers. TT-specific B cells served as antigen-specific comparators.
Results: Antigen-specific staining of B-cell lines induced protein phosphorylation, even when cells were kept strictly on ice. This was prevented by adding a fixation step prior to antigen-specific staining. Using this approach, ACPA-expressing memory B cells (MBCs) from RA patients displayed enhanced expression of Ki-67 and increased SYK-, BTK-, AKT- and S6-phosphorylation compared to TT-specific MBCs.
Conclusion: Our approach allows simultaneous detection of antigen-specificity and protein phosphorylation on the single cell level. The data reveal that autoreactive B cells in RA, in contrast to B cells against recall antigens, display enhanced phosphorylation of signaling molecules downstream of the BCR, pointing towards continuous antigen-mediated activation of autoreactive B cells in RA.

Purpose: Complement system is a major player in innate immunity and an effector arm of the humoral immune system so inadequately controlled complement activation may underlie the pathogenesis of several immunomodulated processes. Rheumatoid arthritis (RA) is the most common chronic form of inflammatory arthritis, resulting from complex interactions between genes and environment, leading to a breakdown of immune tolerance and to synovial inflammation in a characteristic symmetric pattern. The implication of complement in the etiopathogenesis of RA has been proposed but the role of both functionally and individual complement components levels has not been fully characterized. This study aims to comprehensively evaluate the relationships between the functional levels of the three complement cascades and specific elements within these pathways with the characteristics of RA, such as disease activity and the presence of rheumatoid factor or anti-citrullinated protein autoantibodies.
Methods: A cross-sectional study was conducted, including 430 patients with RA who met the 2010 ACR/EULAR classification criteria. A detailed assessment of various components of the complement system belonging to all three cascades, including enzymatically generated fragments and serum regulators, was performed using functional complement assays and individual elements assessments through multiplex detection.
Results: C-reactive protein, complement system products and functional complement assays were found to be positively correlated**.** The analysis revealed that disease activity had a positive correlation with the functional test of the classical pathway specially with the products of the terminal complement pathway. However, the presence of rheumatoid factor and anti-citrullinated protein antibodies was linked to lower levels of specific complement components of the classical pathway and C3a and C4b.
Conclusions: The study findings highlight the complex relationship between disease activity and the complement system in RA. Higher or moderate disease activity indicate upregulation of the complement system components whereas the presence of rheumatoid factor and/or anti-citrullinated protein antibodies is associated with complement consumption. This relationship suggest the potential utility of targeting the complement system in new therapeutic approaches for RA. Future research is warranted to explore the clinical implications and therapeutic opportunities of modulating the complement system in RA management.

Loss of thymic interferon signature in autoimmune regulator-deficient mice

Adrianna Jebrzycka[1], Lars Breivik[1;2], Anagha Joshi[1;3], Eystein S. Husebye[1;2], Anette S.B Wolff[1;2], David Dolan[3], Bergithe E. Oftedal[1;2]

Autoimmune regulator (AIRE) plays a crucial role in the establishment of immune tolerance. AIRE orchestrates the display of tissue restricted antigens to T cells developing in the thymus, mediating elimination of self-reactive thymocytes. The devastating consequences of dysfunctional AIRE are seen in patients with autoimmune polyendocrine syndrome type 1, who develop multi-organ autoimmunity and harbour a range of tissue-specific and cytokine autoantibodies. AIRE's contribution to self-antigen presentation in the thymus has been thoroughly studied, but a comprehensive picture of how loss of AIRE affects development, maturation and function of T cells, and other immune cell populations in the thymus is still largely lacking. Furthermore, how tolerance to cytokines is lost and to what degree the thymus and AIRE are involved in this process, remains an open question.
To address these aspects, we performed an exploratory analysis using single-cell RNA sequencing of transcriptomes and adaptive immune receptors of immune cells isolated from the thymi of six-week-old AIRE-deficient and wild-type (WT) mice, with two male and two female mice in each group.
Our comprehensive dataset encompassing a total of 93,118 thymic immune cells, shows similar distribution of the immune cell subsets in AIRE-deficient and WT mice. Careful annotation of thymocytes using recognized markers expressed at different maturation stages, allowed us to track their thymic developement. Subsequent differential gene expression analysis revealed a strong downregulation of interferon-stimulated genes (ISGs) within the mature single-positive CD4 and CD8 cells, regulatory T cells and NKT cells in AIRE-deficient mice, in line with previous studies suggesting an involvement of AIRE on constitutive type I interferon (IFN) production in the thymus, and the influence of type I IFNs on thymocyte maturation. Diminished expression of ISGs was also observed in hematopoietic thymic antigen presenting cells (APCs), along with downregulation of gene sets related to antigen processing and presentation, suggesting that thymic IFNs might influence antigen-presenting capabilities of thymic APCs.
Our study supports the previously reported role of AIRE on constitutive thymic IFN production and the influence of IFN signalling on the maturation of thymocytes

The role of bacterial lipopolysaccharides and gut microbiota dysbiosis in type 1 diabetes

Satu Silojärvi[1], Linda Leino[1], Sakari Pöysti[1], Arno Hänninen[1;2]
[1]*University of Turku, Turku, Finland*; [2]*Turku University Hospital, Turku, Finland*

Type 1 diabetes (T1D) is an autoimmune disease characterized by T-cell mediated destruction of insulin producing β-cells. Possible environmental factors predisposing to T1D include gut dysbiosis. Earlier studies have reported higher abundance of *Bacteroides* species in Finland compared to Karelia (Russia), and it was shown that *Bacteroides* species synthetize a lipopolysaccharide (LPS) structurally distinct from that of *Escherichia coli*, a species more abundant in infants in Karelia with lower T1D incidence. Functional differences were also reported, as *Bacteroides* LPS failed to induce endotoxin tolerance. We recently reported that dysbiosis induces the expression of a chemokine CXCL10 in islets via elevated levels of circulating LPS, attracting activated leukocytes into islets. Elevated levels of CXCL10 in T1D have been observed both in clinical studies and in animal models.
Here we studied the effects of a single exposure of NOD mice to LPS, whereas endotoxin tolerance was modelled with multiple exposures. TNFα production by peritoneal macrophages was determined with ELISA, and T-cell and dendritic cell populations were analyzed with flow cytometry. Moreover, the expression of CXCL10 in pancreatic islets was determined with immunofluorescence staining.
Escherichia coli LPS was more efficient in stimulating macrophage TNFα production and dendritic cell activation compared to *Bacteroides vulgatus* LPS. Similar trend was observed in T-cells and their activation markers. Islet CXCL10 expression was higher in *E. coli* LPS treated NOD mice. In endotoxin tolerance experiments, unlike in macrophages from *B. vulgatus* treated mice, *E. coli* LPS exposure resulted in lower TNFα production compared to controls. Furthermore, *E. coli* LPS resulted in lower levels of CD8+ T-cells recognizing islet specific antigen compared to *B. vulgatus* LPS and control. Similarly, *E. coli* LPS induced tolerization of dendritic cells. Statistically significant differences were also observed in CXCL10 expression after two doses of *E. coli* LPS.
This study provides evidence for the role of endotoxins from two common intestinal bacterial species, *E. coli* and *B. vulgatus*, in T1D related autoimmunity. The two endotoxins differ in terms of immunogenicity— in contrast to *B. vulgatus* LPS, *E. coli* LPS is a potent activator of the immune system and induces the development of endotoxin tolerance.

The propensity of B cells to infiltrate the multiple sclerosis brain: impact of genetic variation and environment.

Laurens Bogers[1], Jasper Rip[1], Kirsten Kuiper[1], Florian Ingelfinger[2], Jamie van Langelaar[1], Liza Rijvers[1], Steven Koetzier[1], Marie-Jose Melief[1], Annet Wierenga-Wolf[1], Cato Corsten[1], Ursula Boschert[3], Lisa Gerdes[4;5], Burkhard Becher[2], Joost Smolders[1;6], Marvin van Luijn[1]
[1]MS Center ErasMS, Erasmus Medical Center, Rotterdam, Netherlands; *[2]Institute of Experimental Immunology, Zürich, Switzerland*; *[3]Ares Trading SA, Eysins, Switzerland*; *[4]Institute of Clinical Neuroimmunology, Munich, Germany*; *[5]Munich Cluster of Systems Neurology (SyNergy), Munich, Germany*; *[6]Netherlands Institute of Neuroscience, Amsterdam, Netherlands*

Purpose: The interplay between Epstein-Barr virus (EBV) and specific genetic risk variants is assumed to alter the B-cell functional program in patients with multiple sclerosis (MS). Recently, our group revealed that CXCR3$^+$ B cells are preferentially recruited to the central nervous system (CNS), correspond with local antibody production and are promising targets for next-generation Bruton's tyrosine kinase (BTK) inhibitors such as evobrutinib (EVO) in MS. Here, we explored the contribution of environmental and genetic risk factors to the inducibility of brain-homing CXCR3$^+$ B cells in MS and examined whether this could be targeted by EVO.
Methods: B-cell subsets were analyzed in blood of monozygotic twin pairs discordant for MS using mass cytometry to study the impact of environmental factors. In addition, human B-cell lines and primary B cells were selected based on the presence of an MS risk SNP in *IFNGR2* (rs9808753) to examine the IFN-γ signaling pathway using flow cytometry, phosphoflow and immunoblotting. *In vitro*-stimulated blood B cells were compared between MS patients and controls and treated with or without EVO.
Results: Amongst all B-cell subsets analyzed, frequencies of CXCR3$^+$ class-switched memory B cells were reduced in genetically identical twins with MS vs unaffected co-twins. In B-cell lines carrying the *IFNGR2* risk SNP, STAT1 phosphorylation was more pronounced after addition of IFN-γ, the main trigger of CXCR3$^+$ B cells. The IFN-γ pathway was constitutively activated in EBV-infected B cells, showing upregulation of IFNGR1, IFNGR2 and phosphorylated STAT1. In primary B cells, CD40 ligand-induced surface expression of IFNGR2 and not IFNGR1 was attenuated by EVO. In B cells from MS patients, specifically for risk SNP carriers, STAT1 phosphorylation was highest in the transitional subset (CD38^{high}CD27$^-$) and T-bet transcription was more induced by IFN-γ.
Conclusion: The twin data show that circulating CXCR3$^+$ B cells are influenced by environmental factors in patients with MS. The work also provides further evidence that EBV interacts with genetic risk variants to induce these types of B cells to enter the CNS, a process that may be prevented by BTK inhibition in MS.

Funding: Financial support was provided by Stichting MS Research and Nationaal MS Fonds.

Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with complex organ and system involvement. Although the hallmark of the disease is the presence of antinuclear antibodies, other serological markers and clinical symptoms may vary between patients, making the manifestation of SLE heterogeneous in nature. Although genetic predisposition is necessary for SLE to appear, epigenetic factors also played central role in this process. Particular methyl-rich micronutrients, such as methionine, betaine, choline, folic acid and vitamin D, take part in the mechanisms of DNA methylation. We have previously reported that the administration of high amounts of those methyl-rich components in the diet of lupus-prone MRL/*lpr* mice resulted in decreased anti-dsDNA antibody and proteinuria levels and in protected renal structures. In the present study we report that the methyl-supplemented diet also ameliorates the development of SLE and in NSG/Rag2-γc- mice humanized with lupus patients' PBMCs which defines this diet as novel possible therapeutic agent with immunomodulating potential.
Two groups of female NSG/Rag2-γc- mice were engrafted with PBMCs from SLE patients. The first group was put on a normal rodent diet, the other – on methyl-supplemented diet. Two groups of control non-humanized mice were also put on either of the diets. The experimental animals were monitored for 8 weeks with blood and urine samples being collected once a week. At the end of the dietary course the mice were sacrificed, and kidneys were examined for glomerular pathology.
The results showed a decrease in anti-dsDNA antibody and proteinuria levels in the mice put on the supplemented diet, compared to the mice put on normal diet. In addition, histopathological changes in the structure of the glomeruli were observed in the kidney of mice fed with the normal diet but not the supplemented group.
The observed beneficial effect of the methyl-rich diet may be related to the potential modulation of DNA methylation levels and subsequent changes in gene expression. These results point to the importance of DNA methylation as one of the major epigenetic factors responsible for the progression of SLE as well as to its implication as a powerful immunomodulating tool.

Exploring the reduced cytokine production capacity of lymph node T cells observed during the earliest phases of rheumatoid arthritis

Aoife O'Byrne[1;2;3], Johanna F Semmelink[1;2;3], Janne W Bolt[1;2;3], Mario Maas[4;5], Marleen G.H. van de Sande[1;2;3], Lisa G.M. van Baarsen[1;2;3]
[1]Amsterdam Rheumatology and Immunology Center (ARC), Amsterdam, Netherlands; *[2]Amsterdam UMC, Department of Rheumatology and Clinical Immunology, Movement Science Institute, Amsterdam, Netherlands*; *[3]Amsterdam UMC, Laboratory of Experimental Immunology, Amsterdam Institute for Immunology and Infectious Diseases, Amsterdam, Netherlands*; *[4]Amsterdam UMC Location University of Amsterdam, Department of Radiology, Amsterdam Movement Sciences, Amsterdam, Netherlands*; *[5]Amsterdam Movement Sciences, Tissue Function and Regeneration, Amsterdam, Netherlands*

Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease with an unknown aetiology. Autoantibody positive RA-risk individuals with no clinical inflammation provide a model to study the earliest phases of autoimmunity. We hypothesize that already before RA development, due to loss of tolerance and prolonged antigen exposure, T cells become dysfunctional. Previous work from our group highlights a decreased ability of LN T cells to produce cytokines during the earliest phases of RA even without clinically apparent disease. To determine possible mechanisms responsible for this reduced cytokine production capacity we aimed to further characterise and compare the phenotype and transcriptomic profile of LN CD4 T cells from RA, RA-risk and healthy controls (HC).
Methods: Lymph node biopsies were collected through ultrasound guided inguinal LN needle biopsy after which lymphocytes were isolated and stored in liquid nitrogen. Upon thawing, CD4+ T cells were sorted from 12 donors (4 RA patients, 4 RA-risk and 4 healthy volunteers) and gene expression profiles were analysed using a NanoString nCounter gene panel focussed on exhaustion. For detailed cellular phenotyping a fifteen colour flow cytometry panel was performed on fresh LN cell suspensions (10 RA patients, 5 RA-risk and 3 PsA patients) and analysed in a supervised (FlowJo) and unsupervised manner (FlowSOM, R).
Results: Flow cytometry analysis revealed a trend towards a skewing from effector to naïve CD4 T cells in RA and PsA compared to RA-risk. Preliminary analysis uncovered a loss in Eomes+Tbet+ naïve CD4+ T cell frequency, in RA compared to RA-risk. NanoString nCounter analysis uncovered an increased interferon gene signature in LN CD4 T cells of RA-risk compared to HCs with a similar trend for RA. We also observed a trend towards an increase in co-inhibitory receptors including TIGIT, LAG3 and CTLA4 for RA CD4 T cells compared to HCs.
Conclusions: This interferon signature combined with increased co-inhibitory receptor expression and skewing of memory populations within the LN may contribute to the reduced capacity of CD4 T cells to produce cytokines. Future studies are needed to elucidate the original trigger of this interferon signature, which may be the result of chronic antigen exposure.

Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease with multisystem involvement ranging from mild mucocutaneous manifestations to multi-organ involvement, including severe central nervous system complications. Sjögren's syndrome is a chronic autoimmune disease characterized by lymphocytic infiltration of the exocrine glands, resulting in dryness of the mouth and eyes due to salivary and lacrimal gland involvement. The aim of this study is to investigate the protein levels of soluble immune checkpoint proteins in serum samples from SLE and Sjörgen's syndrome patients to elucidate the potential of immune checkpoint blockade for the treatment of the aforementioned diseases.
Methods: This study was approved by the local ethics committee of Yeditepe University Hospitals (Approval number: 1631). The patient group consisted of patients diagnosed according to the 2019 EULAR/ACR diagnostic criteria for SLE patients and the 2016 ACR-EULAR diagnostic criteria for SS patients. Patients were informed verbally before peripheral blood samples were collected, and patients signed an informed consent form. The control group consisted of adult subjects without autoimmune diseases. For evaluation of soluble immune checkpoint proteins, serum samples were collected and stored at -80˚C in a freezer. Protein expression levels of the soluble immune checkpoints CD25, 4-1BB, B7.2(CD86), TGF-B1, CTLA-4, PD-L1, PD-1, TIM-3, LAG-3, and Galectin-9 were evaluated with the BioLegend LEGENDplex HU Immune Checkpoint Panel 1 (10 plex) using a Beckman Coulter DxFLEX flow cytometry system.
Results: Our results revealed a statistically significant difference in the expression levels of Galectin-9, LAG-3 and TIM-3 between the SLE group and the control group. Moreover, a strong correlation between PD-1/PD-L1 and TIM3/Galectin-9 levels was observed in SLE patients. No statistically significant difference was detected between the Sjögren's group and the control group in terms of the expression levels of the proteins investigated.
Conclusion: Even though further studies involving larger patient groups are needed, our results suggest that therapeutic options targeting PD-1/PD-L1 and TIM3/Galectin-9 axes may provide benefit in the treatment of SLE.

How does SARS-CoV-2 affect the immune system of lupus nephritis patients? – a two-year perspective

Anna Wardowska[1], Michał Komorniczak[1], Barbara Bułło-Piontecka[1], Katarzyna A. Lisowska[1]
[1]*Medical University of Gdańsk, Gdańsk, Poland*

Purpose: Lupus nephritis (LN), a renal manifestation of systemic lupus erythematosus, is an autoimmune disease characterized by altered activity of the immune system and kidney dysfunction. The correlation between infections, primarily viral ones, and the incidence of lupus and the disease symptoms aggravation has been widely discussed in the literature. During the COVID-19 pandemic, many LN patients were at higher risk of severe outcomes of SARS-CoV-2 infection. The lack of data regarding this virus's long-term impact on the patient's immune systems caused many concerns. Our purpose was to evaluate whether COVID-19 infection could significantly affect the immune system of LN patients, thus influencing the course of the disease.
Methods: We performed an extensive flow cytometry analysis of circulating immune cells, including T cells, B cells, and dendritic cells (DC), from LN patients. Patients were divided into groups based on the time that passed from their COVID-19 infection, either 6 or 24 months post-SARS-CoV-2 exposition. All the data were compared to LN with no COVID-19 infection in the history.
Results: LN CoV-2(+) patients were characterized with significant alterations in the T-cell memory compartment, as they had higher levels of effector memory T cells (TEM) and central memory T cells (TCM) compared to patients without the COVID-19 infection. Moreover, the percentages of TEM were lower in LN CoV-2(+)6m compared to LN CoV-2(+)24m. The latter group presented a decrease in the percentage of TEMRA and Treg cells. Little differences were observed in the B cell memory compartment, except for the decrease in non-switched memory B cells. This subpopulation was reduced in the general LN CoV-2(+) group, with a pronounced decrease in LN CoV-2(+)6m compared to LN CoV-2(+)24m. Regarding DCs, the changes related to post-infection time were detected in the cDC2 subpopulation, showing the reduction of these cells in LN CoV-2(+)24m patients.
Conclusions: Several interesting alterations were spotted between LN CoV-2(-) and LN CoV-2(+) patients and between LN patients at different post-COVID-19-infection time points. These data suggest that COVID-19 may affect the immune system of lupus patients in a longer perspective.

Transfer of IgG of Long-COVID patients induces subgroup-specific symptoms in mice

Hung-Jen Chen[1], Brent Appelman[1], W. Ashwin Mak[1], Hanneke Willemen[2], Judith Prado[2], Chiara Geyer[1], Amélie Bos[1], Sabine Versteeg[2], Patricia Silva Santos Ribeiro[2], Braeden Charlton[3], Eline L. Schüchner[1], Fanny Boisnard[2], W. Joost Wiersinga[1], Michèle van Vugt[4], Marit J. van Gils[5], Rob C.I. Wüst[3], Niels Eijkelkamp[2], Jeroen den Dunnen[1]
[1]Center for Experimental and Molecular Medicine, Amsterdam UMC, Amsterdam, Netherlands; *[2]Center for Translational Immunology, University Medical Center Utrecht, Utrecht, Netherlands*; *[3]Department of Human Movement Sciences, Vrije Universiteit Amsterdam, Amsterdam, Netherlands*; *[4]Department of Medicine, Amsterdam UMC, Amsterdam, Netherlands*; *[5]Department of Medical Microbiology and Infection Prevention, Amsterdam UMC, Amsterdam, Netherlands*

Introduction: Over 10% of individuals develop chronic symptoms after SARS-CoV-2 infection, termed Long-COVID. Currently, the disease's pathophysiology is unknown and there are no effective therapies or objective diagnostic tests available. Autoimmunity is one of the proposed mechanisms of Long-COVID, but it is unclear whether autoimmunity is causal in the disease's progression and whether autoantibodies can be used as Long-COVID biomarkers. In this study, we aimed to investigate the causal link between autoimmunity and Long-COVID. Second, we aimed to determine whether specific autoantibodies can be used as a diagnostic biomarker for Long-COVID.
Methods: Long-COVID patients, identified by WHO criteria, were assessed at least 6 months post non-hospitalized COVID-19. Long-COVID and healthy control plasma were subjected to cytokine and neurodegenerative marker quantitative analysis, proteomic analysis, alongside purification of IgG for comprehensive 'autoantibodyome' analysis for over 21,000 autoantigens. Total IgG was purified from patient and control serum, pooled (by group), and intraperitoneally injected into mice, which were then subjected to behavioral tests.
Results: Based on interferon and neurodegenerative markers, three Long-COVID subgroups were identified, each showing proteome signatures enriched in distinct pathways. Strikingly, intraperitoneal injection of pooled IgG of the three Long-COVID groups induced pronounced subgroup-specific behavioral symptoms in mice when compared to mice injected with IgG from healthy controls. IgG from patients with higher muscle protein levels reduced the locomotor activity of mice. IgG from patients with elevated leukocyte activation proteins strongly induced rapid pain sensory hypersensitivity in mice, and IgG from patients with higher neuronal damage marker levels induced delayed sensory hypersensitivity behavior. Autoantibodyome analysis revealed approximately 50 autoantigens highly specific for Long-COVID patients that also associated with main Long-COVID symptoms.
Conclusions: These findings provide compelling evidence for a causal role of IgG autoantibodies in Long-COVID. Furthermore, it provides proof-of-concept for an *in vivo* model for Long-COVID that could be used for treatment testing. Finally, the identified autoantibodies comprise a promising biomarker for Long-COVID, which we are currently incorporating into a multiplex assay to develop an objective diagnostic test for Long-COVID.

Immune parameters of patients with systemic lupus erythematosus after COVID-19 infection

Katarzyna A. Lisowska[1], Michał Komorniczak[1], Barbara Bułło-Piontecka[1], Anna Wardowska[1]
[1]*Medical University of Gdańsk, Gdańsk, Poland*

Purpose: Systemic lupus erythematosus (SLE) patients constitute a group of individuals with an increased risk of infections and infection-related mortality. Therefore, during the global SARS-Cov-2 pandemic, SLE patients were particularly vulnerable to SARS-CoV-2 infections. Moreover, several studies have shown that, compared to other patients, SLE patients seem to develop more severe manifestations of COVID-19 infection, with higher rates of hospitalization, invasive ventilation requirements, or death. Although there are many articles in the scientific literature about the impact of SARS-CoV-2 infection on immunological parameters, they largely concern previously relatively healthy people. We know little about how SAR-CoV-2 affects SLE immunology. Therefore, this study aimed to evaluate the immune parameters after SARS-CoV-2 infection in SLE patients.
Methods: We analyzed subpopulations of peripheral blood cells collected from patients with the renal manifestation (lupus nephrititis, LN) of SLE. LN patients were divided into two subgroups: those unexposed to SARS-CoV-2 and those who had COVID-19 6 months earlier. We analyzed basic subpopulations of T cells, B cells, monocytes, dendritic cells (DCs), and serum cytokines using flow cytometry.
Results: LN patients were characterized by a decreased percentage of CD3+CD4+ cells and an increased percentage of CD3+CD8+ cells. Both groups had a higher percentage of T cells with HLA-DR expression. LN CoV-2(+) patients had a higher percentage of plasmablasts (PB) and a lower percentage of non-switched memory (NSM) B cells compared to LN CoV-2(−) patients or HC. LN patients had a higher percentage of total monocytes compared with HC. LN CoV-2(+) had a higher percentage of classical monocytes than LN CoV-2(−) patients and HC. They also had a higher percentage of intermediate monocytes than HC. No difference was observed in the percentage of non-classical monocytes and DC subpopulations. LN CoV-2(−) patients had higher serum IL-10 than HC.
Conclusions: LN patients are characterized by disturbances in the basic immunological parameters of the blood. However, patients who have had COVID-19 present some abnormalities in B-cell and monocyte compartments.

Childhood Systemic Lupus Erythematosus

Farva Jalil[1], Tahir Aziz Ahmed[1]
[1]*Shifa International Hospital, Islamabad, Pakistan*

Background: Systemic lupus Erythematosus is a chronic, multisystem autoimmune disease having variable clinico pathological features. According to published data, childhood onset SLE has more severe organ system manifestations in the form of nephritis, cytopenias and neuro psychiatric disease compared to adult variant.
Aim: The objective of this case series is to review and summarize clinico pathological features, laboratory findings and treatment outcomes of childhood onset systemic lupus erythematosus in children presenting to a tertiary healthcare facility in Pakistan. We also aim to compare our study with other published data on cSLE.
Materials and methods: Patients <18 years presenting to Shifa International hospital paediatrics' department diagnosed with childhood systemic lupus erythematosus according to EULAR/ACR 2019 criteria for SLE were evaluated. Clinical data with laboratory findings and treatment outcome was collected according to a structured proforma by interviewing patients/guardians and by reviewing patients' medical record.
Results: All participants were female with median age of 11 years (age range 4.5-15 years). The most prominent clinical presentation was fever followed by rash. Lupus nephritis was diagnosed in 50% patients, proteinuria being the most prominent presenting feature in them. Low haemoglobin level, low serum C4 levels and positive Anti-nuclear antibody were most common laboratory finding present in all patients followed by positive anti-nucleosome and anti-double stranded DNA antibodies.
Conclusion: Childhood onset systemic lupus erythematosus has variable clinical and laboratory presentation with a female preponderance. Fever, rash and lupus nephritis was the most frequent clinical presentation. Anemia, positive ANA followed by positive anti nucleosome and ds DNA antibodies were the most common laboratory abnormality.

Detection of autoantibodies anti-RNP70 in the differential diagnosis and classification of connective tissue diseases

Azahara Díaz-Lozano[1], Angela Lucas Blanco[1], Luz Cheilly Mosquea Jiménez[1], María Inmaculada Alcalá Peña[1], María Luisa Vargas Pérez[1]
[1]*Hospital Universitario de Badajoz, Badajoz, Spain*

Purpose: The clinical relevance of anti-U1-snRNP antibodies detection for the diagnosis of Mixed Connective Tissue Disease (MCTD) is known and is part of its diagnostic criteria, but, to date, the involvement of its 3 main antigens (RNP70, RNP-A and RNP-C) has not been established. Moreover, anti-U1-snRNP antibodies frequently appear in other connective tissue diseases such as Systemic Lupus Erythomatosus (SLE), Undifferentiated Connective Tissue Disease (UCTD), Overlap Syndrome (OS), Scleroderma (SC) and Dermatomyositis (DM). The aim of this study is knowing the clinical significance of the autoantibody anti-RNP70 in the diagnostic and classification of these connective tissue diseases and them clinical symptoms.
Methods: A retrospective study (2008-2023) in 146 patients with autoantibody anti-U1-snRNP with or without anti-RNP70 (determined by Line-Blot and confirmed by Fluoro-Enzyme Immunoassay (FEIA)) was conducted. Based on the clinical history 7 groups were classified: MCTD (24), SLE (51), UCTD (13), OS (9), SC (2), DM (2) and Unconfirmed Diagnosis and/or lack of follow-up (NA) (45). The clinical symptoms studies were: Raynaud's disease, hand edema, Pulmonary Hypertension (PHT) or Diffuse Interstitial Lung Disease (DILD), synovitis, myositis and kidney or central nervous system involvement.
Results: Anti-RNP70 antibodies were detected in 64 patients (43.8%). Their frequency distribution for each diagnostic groups showed statistically significant differences (p=0.00037): 19/24 MCTD (79.2%), 17/51 SLE (33.3%), 5/13 UCTD (38.5%), 7/9 OS (77.8%), 0/2 SC (0%), 1/2 DM (50%) and 15/45 NA (15%). Most of OS group with anti-RNP70 (6/7, 85.7%) had MCTD pathology along with SLE (3/6, 50%) or SC (3/6, 50%). Furthermore, in the symptom analysis, patients with MCTD pathology with positive anti-RNP70 presented PHT/DILD (40%) and/or hand edema (44%), while for those with MCTD pathology but with negative anti-RNP70 these symptoms were absent, thus implying statistically significant differences with p=0.032 and p=0.022 respectively.
Conclusion: In our population, the increase in the appearance frequency of anti-RNP70 antibodies could be used as a differential diagnostic marker of MCTD compared to other connective tissue diseases studied. Furthermore, the presence of these autoantibodies could be associated with a worse prognosis of the disease due to the greater frequency of appearance of PHT/DILD symptoms and hand edema.

Clinical relevance of duodenal lymphogram as a diagnostic tool for celiac disease in adults

Angela Villegas Mendiola[1], Laura García Bravo[1], Kauzar Mohamed Mohamed[1], Maria Palacios Ortega[1], Alejandro Pereiro Rodriguez[1], Teresa Guerra Galan[1], Maria Dolores Mansilla Ruiz[1], Marc Perez-Guzman[1], Juliana Ochoa Grullon[1], Miguel Fernandez Arquero[1], María Guzmán Fulgencio[1], Silvia Sanchez-Ramon[1]
[1]*Hospital Clínico San Carlos, Madrid, Spain*

Introduction: Celiac disease (CD) is an autoimmune pathology characterized by lesions in the duodenal mucosa triggered by gluten ingestion. Duodenal lymphogram analyzes the subpopulations of intraepithelial lymphocytes (IELs), including total IELs (tIELs), TCR-γδ+ IELs, and CD3- IELs, and has been proposed as a complementary test for the differential diagnosis of CD in adults.
Objective: To compare the duodenal lymphogram of celiac patients on a gluten-containing diet (GCD), celiac patients on a gluten-free diet (GFD), and non-celiac individuals (digestive pathology different from CD).
METHODOLOGY: 120 patients were recruited and divided into: I) celiac patients on GCD (n=16), II) celiac patients on GFD (n=27), and III) non-celiac individuals (n=77). Duodenal lymphogram study was conducted on duodenal biopsy samples using flow cytometry. Cut-off points were set as follows: tIELs ≥15%; TCR-γδ+≥15%; and CD3-≤6%. Statistical analysis was performed using non-parametric Kruskal-Wallis tests. Values were expressed as mean±standard deviation ($p \leq 0.05$).
Results: When comparing duodenal lymphogram subpopulations among the three groups, celiac patients on GCD showed significantly higher tIELs values compared to those observed in celiac patients on GFD (18.18±6.35 versus 13.48±6.31, p=0.05), and non-celiac patients (11.81±9.28, p=0.001). Comparing TCR-γδ+ values, the mean values obtained in celiac patients on GCD (31.93±12.72) and celiac patients on GFD (24.59±9.08) were significantly higher than in non-celiac patients (9.55±7.51) ($p<0.0001$). Conversely, CD3- values were significantly lower in celiac patients on GCD (2.93±4.43) and celiac patients on GFD (7.70±9.71) compared to those obtained in non-celiac patients (17.10±13.49) ($p<0.0001$).
Conclusion: The results emphasize the utility of duodenal lymphogram in the differential diagnosis of CD with other digestive pathologies. Diet is a crucial parameter to consider as some lymphocytic subpopulations are not altered by it (TCR-γδ+ and CD3-), while others are (tIELs).

Exploring the Impact of EBV Infection on T-bet Expression in B Cells and Its Influence on T Cell Activation and Migration

Ioannis Piteros[1], Fabienne Läderach[1], Sandra Schmid[1], Christian Münz[1]
[1]*Experimental Immunology, Zurich, Switzerland*

Epidemiological evidence suggests that EBV infection in susceptible individuals triggers enhanced EBV-specific immune responses and asymptomatic CNS damage preceding multiple sclerosis (MS). However, the extent of cross-reactive immune responses and the mechanism by which EBV infection leads to CNS damage remain unclear. Studies on lymphocyte infiltrates in post-mortem MS brain tissue indicate that a subset of B cells expressing the T-box transcription factor (T-bet) may significantly influence CNS autoimmunity. Depending on genetic MS predisposition, EBV could potentially induce pathogenic T-bet^{+} B cells, making them a plausible contributor to this disorder. Therefore, our aim is to further elucidate the role of T-bet^{+} B cells that arise during EBV infection and their potential contribution to the pathogenesis of MS.
To investigate the impact that EBV infection has on T-bet expression in B cells, we mimic de novo infection in primary B cells *in-vitro* and monitor longitudinal changes of T-bet expression during the infection. To assess the functional capacity of EBV transformed T-bet^{+} B cells, T-bet^{high} and T-bet^{low} cells were separated from EBV transformed lymphoblastoid cell lines (LCL) and functional assays were performed.
We could show that EBV infection induces upregulation of T-bet expression in infected B cells during the early stages of infection *in-vitro*. With T-bet positivity reaching 30% percent in certain donors. Based on CXCR3 expression cells from the same donor could be sorted into a T-bet^{high} and T-bet^{low} fraction. Migration assay demonstrated that exposure to supernatant from LCL expressing high T-bet results in increased migration of total T cell numbers with preferentially activated T cells migrating compared to exposure to supernatant from low T-bet expressing LCLs.
These results indicate that EBV infection may initiate the formation of a T-bet^{+} B cell subset. This subset has the capacity to recruit activated T cells, and potentially act as antigen presenting cells promoting the development of cross-reactive and MS autoantigen-specific T cells in predisposed individuals, thereby contributing to MS pathology.

Zbtb20 as a regulator in the development and activation of the immune system in wild type and heterozygous animals.

Iliyan Manoylov[1], Lidiya Kechidzhieva[1], Katerina Ilieva[1], Nikolina Mihaylova[1], Andrey Tchorbanov[1]
[1]*Laboratory of Experimental Immunology, Department of Immunology, „The Stephan Angeloff" Institute of Microbiology, Bulgarian Academy of Sciences, Sofia, Bulgaria*

Zbtb20 is part of the Zbtb gene family. It plays a significant role in the individual development, as high genetic activity can be found during the late stages of astrocytes and chondrocytes genesis, during the formation of the thyroid gland, the liver regeneration and in the regulation of the circadian rhythms. Recent studies have shown the effect of the gene on the generation and differentiation of different lymphocyte populations. A Cre-lox recombinant mouse model was developed as the Zbtb20 gene was removed and some of the animals were complete knock-outs (homozygous, -/-). Animals with partially retained Zbtb20 activity (heterozygous animals, +/-) do not show visible changes and defects in the major systems and organs.
Heterozygous animals (+/-) were crossed in order to obtain 3 genetic types (+/+, +/- and -/-). Animals from the different genotypes were analyzed for a change in the quantity of the immune cells, their activating capacity and the histological structure of their primary and secondary lymphoid tissues. The purpose was to determine the function of the Zbtb20 gene in the development of the immune system and to define the effect of the zygosity on the immunological parameters.
Animals of different age and genotype were selected for the study. Sera were isolated and ELISA screening for IgA, IgG and IgM antibodies was performed. Flow cytometry of spleen and bone marrow was assayed for the CD19+, CD3+, CD4+, CD8+, Sca-1 and c-KIT surface markers. Cell proliferation analysis was made as well as cytological and histological evaluation of the immune organs.
Our results show different profile of the immune system in homo- (+/+) and hetero- (+/-) zigous animals. A difference in the Sca-1 and c-KIT cells populations was observed. Similar results were found regarding the proliferating capacity of the cells.
Based on the data we can speculate that different expression of the ZBTb20 gene may induce an abnormal response in conditions like autoimmunity and cancer.

This study was supported by the КП-06Н-61/5 grant by the NSF of Bulgaria.

Real-life implementation of multiple autoantibody detection for Connective Tissue Disease in a single referral center in Northern Spain

Mónica Renuncio García[1;2], Paolo Miraglia[3], Juan José Fernández Cabero[2], Juan Irure Ventura[1;2], Marcos Lopez Hoyos[1;2]
[1]Immunology Deparment. Marqués de Valdecilla University Hospital, Santander, Spain; *[2]Immunopathology Group, Marqués de Valdecilla University Hospital-IDIVAL, Santander, Spain*; *[3]Department of Clinical and Biological Sciences, University of Turin, Turin, Italy*

Purpose: Connective tissue diseases (CTD) are driven by autoimmune processes that affect connective tissue, causing skin and organ damage. Most rheumatic diseases have a variable course, including from mild to severe affections. Therefore, the detection of multiple autoantibodies involved in CTD could help to appropriately stratify patients and disease management. The aim is to evaluate the activity of a fully automated digital system utilizing particle-based multi-analyte technology (PMAT) in the detection of autoantibodies.
Methods: During the first year of PMAT implementation, 3,985 tests were executed on 2,983 different patients, with a mean age ± 2 SD of 54.53 ± 35.29 years and a ratio female/male of 3.5/1. From the total of patients, 2,114 of them were tested only once and 779 were tested more than one time. All patients had previously an anti-nuclear test positive with an indirect immunofluorescence test using HEp-2 cells. Levels greater than 40 IU/mL for ds-DNA and 5 FLU for all extractable nuclear antigens (ENA) were considered as positive, as indicated by manufacturer. In addition, medical records of 83 patients with at least 4 different ENA specificities, and 86 patients with more than 20 FLU of anti-DSF70 (control group) were collected.
Results: Out of 2,983 patients, 1,896 (63.5%) tested negative for all the specificities, 239 (8%) were positive for anti-dsDNA, 859 for anti-DFS70 (28.8%) and 1017 (34.1%) patients were positive for ENA screening. The highest prevalence in ENA screening was anti-Ro60 (18.8%), followed by anti-Ro52 (11.4%), anti-RNP (10.8%), anti-La (7.9%), anti-Scl70 (6.7%), anti-CENP (5%), anti-RiboP (1.8%), anti-Jo-1 (0.5%) and anti-Sm (0.7%). The most frequent diagnoses in the group with multiple ENA specificities were systemic lupus erythematosus (50.6%) and Sjogren's syndrome (34.9%) whereas in the control group, 90.7% of patients did not have a CTD diagnosis. In both groups, the most frequent clinical manifestations involve the joints, skin and cytopenia.
Conclusions: CTD multiparametric test gives multiple information compared to single antigen assay which is important in the growing world of CTD that comprehends a wide range of diseases. Different specificities show different clinical subsets that will help to obtain a correct risk stratification and different clinical approaches.

The role of sclerodermatosis/myositis-related autoantibodies detected by immunoblot in the diagnosis of systemic autoimmune rheumatoid arthritis diseases in 410 patients from a single referral center

Mónica Renuncio García[1;2], Carmen Secada Gómez[2;3], Diana Prieto Peña[2;3], Ricardo Blanco[2;3], Juan Irure Ventura[1;2], Marcos Lopez Hoyos[1;2]
[1]Immunology Deparment. Marqués de Valdecilla University Hospital, Santander, Spain; *[2]Immunopathology Group, Marqués de Valdecilla University Hospital-IDIVAL, Santander, Spain*; *[3]Rheumatology Department. Marqués de Valdecilla University Hospital, Santander, Spain*

Purpose: In clinical practice, immunoblot assays are being used more frequently as a diagnostic tool for systemic autoimmune rheumatic diseases (SARDs). The objective is to assess the contribution of extended analysis of autoantibodies (aAbs) related to scleroderma/myositis disorders found by immunoblot to the diagnosis of patients with SARDs.
Methods: From November 2017 to November 2023, we examined all medical and analytical records of patients at our center who had positive immunoblot results related to scleroderma or myositis. The high suspicion of SARDs in patients with nonspecific symptoms led to the request of these assays.
Results: 410 patients (127 men/283 women; mean age 58.21 ± 16.29 years) were positive for at least 1 aAb, 69 of them were positive for 2 aAbs. Main clinical features at the time of immunoblot requests were: arthralgia/arthritis (n=192), Raynaud's phenomenon (n=165), rash (n=64), myopathy (n=56) and sicca syndrome (n=50). During follow-up, 82 patients were diagnosed with overlap myositis, 75 with scleroderma, 52 with other inflammatory diseases, 41 with interstitial pneumonia with autoimmune features (IPAF), 36 with undifferentiated connective tissue disease (UCTD), 20 with Sjögren's syndrome, 18 with dermatomyositis, 17 with systemic lupus erythematosus and finally 1 with necrotizing myositis. In 68 patients the diagnosis of SARD was finally ruled out. Interstitial lung disease (ILD) was present in 133 patients, being particularly frequent in those with anti-PL12 (p=0.017) in comparison to the rest of the specificities. Cancer was detected in 35 (8.53%) patients, 20 of them were anti-Ro52+ (p=0.01). Furthermore, it was found that high creatine kinase (CK) levels correlated with the probability of being affected by myopathy (p=0.013).
Conclusion: For patients with a high clinical suspicion of SARDs, immunoblot assays are very helpful in the diagnosis process. While some aAbs, such as anti-Mi2 and anti-Th/To, remain to be nonspecific, other Abs including anti-PL12 and anti-Ro52 are particularly helpful in detecting SARDs patients with associated ILD and cancer, respectively.

The peripheral MAIT cell TCRα/β repertoires alter with age of psoriasis vulgaris patients.

Stana Tokić[1], Maja Jirouš Drulak[2], Vera Pluzaric[1;3], Marija Sola[3], Martina Mihalj[3;4], Mario Stefanic[5]
[1]Dept. of Laboratory Medicine and Pharmacy, Faculty of Medicine, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia; *[2]Dept. of Medical Chemistry, Biochemistry and Clinical Chemistry, Faculty of Medicine, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia*; *[3]Dept. of Dermatology and Venerology, University Hospital Osijek, Osijek, Croatia*; *[4]Dept. of Physiology and Immunology, Faculty of Medicine, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia*; *[5]Dept. of Nuclear Medicine and Oncology, Faculty of Medicine, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia*

Purpose: Psoriasis vulgaris (PV) is a chronic autoinflammatory skin disease characterised by dysregulated T-cell activation. Adaptive αβT cells are regularly involved, but a role for innate-like, mucosal-associated invariant T (MAIT) cells has also been proposed. These unconventional cellular players act against non-peptide antigens in MR1-restricted manner, using semi-invariant TCRVα7.2 T cell receptor (TCR). Typically, a limited number of TRAV (TRAV1-2) and TRAJ (TRAJ33, TRAJ12 or TRAJ22) genes is used, together with a more diverse panel of TRBV/D/J segments. Novel evidence, however, supports a greater MAIT TCR diversity both in terms of alternative TRAV/J gene usage and higher TRBV clonality, but the relevance of these findings for PV remains to be established.
Methods: To this end, we used cell sorting (FACSAria) and bulk-RNASeq (Archer Immunoverse™HS TCR assay, NextSeq Illumina platform) with MiXCR, VDJTools and Immunarch pipelines to decipher TCRα/β repertoires of flow-sorted MAIT cells (MR1-5-OP-RU-tetramer$^+$ TCRVα7.2$^+$) from 26 PV patients and 12 healthy controls.
Results: In total, 12219 unique TRA and 60478 TRB clonotypes were observed in PV patients and controls, with similar and predominant expression of TRAV1-2-TRAJ33/20/12 and TRBV20-1/TRBV6-4/TRBV6-1/TRBV6-2/TRBV4-2 variants. The TCRβ chain was highly polyclonal and private, contrasting oligoclonal and frequently shared TCRα repertoires. No significant differences in diversity, V/(D)/J gene usage, and clonotype distribution were observed in case-control comparisons. Age, however, emerged as a negative predictor of TRA and TRB repertoire size in PV (TRA:Spearman's rho=-0.466, p=0.017; TRB:rho=-0.530, p=0.005), but not healthy subjects. A decline of the low-frequent clonotypic variants in PV (Efron-Thisted; TRB:rho=-0.55, p=0.003, TRA:rho=-0.47, p=0.015) underlined the age-related reduction of TRA/TRB variability. The diminished TRB diversity was further accentuated by an increased proportion of hyperexpanded clonotypes (rho=0.76, p=5.64E-06), occupying >5% of the total repertoire. Hyperexpanded TRB clonotypes in PV did not overlap between individual repertoires and displayed diverse CDR3 properties, supporting influence of individually unique epitopes in MAIT repertoire arrangement.
Conclusion: Our results support substantial diversity of MAIT TCRβ repertoire and highlight the influence of age in shaping the diversity of TCRα and TCRβ repertoires in psoriasis. The earlier onset of reduced MAIT TCR repertoire diversity in PV may signify complex underlying mechanisms, warranting further investigations.

Diagnostic efficacy of anti-SSB versus anti-SSA antibodies in Sjögren's Syndrome and other connective tissue diseases

Azahara Díaz-Lozano[1], Angela Lucas Blanco[1], Ramon Garcia Alaejos[1], Marta Aguilar Criado[1], María Luisa Vargas Pérez[1]
[1]*Hospital Universitario de Badajoz, Badajoz, Spain*

Purpose: In healthcare practice, anti-SSA is frequently found without clear clinical suspicion. The aim of this study is to assess whether the appearance of anti-SSB in patients with anti-SSA antibodies improves the effectiveness of differential diagnosis of Sd. Sjögren's versus other connective tissue disorders.
Methods: A retrospective study (2022-2023) in 241 patients with autoantibody anti-SSA (anti-Ro60 and/or anti-Ro52), of whom 62 also had anti-SSB specificity (determined by Fluoro-Enzyme Immunoassay and confirmed by Line- blot) was conducted. Based on the clinical history, patients were classified into 3 diagnostic groups: Sjögren's Syndrome (SS, n=112) (with or without other connective pathologies), Other Connective Tissue Diseases (OCs, n=61) and Absence of Connective Tissue Diseases (NCs, n=68). Within these groups, the frequency of occurrence of the different specificity combinations was studied, being: anti-Ro52 with and without anti-SSB (3 and 53, respectively), anti-Ro60 with and without anti-SSB (3 and 44, respectively) and anti-Ro60/Ro52 with and without anti-SSB (56 and 82, respectively).
Results: The frequency of appearance of anti-SSA or anti-SSA along with anti-SSB antibodies in each diagnostic group showed statistically significant differences (p=0.000023). Thus, patients with anti-SSA along with anti-SSB had SS 69.4%, OCs 21% and NCs 9.7%, while those without anti-SSB had SS 38.5%, OCs 26.8% and NCs 34.6%. When examining the distribution of anti-SSA specificity (anti-Ro52, anti-Ro60, or anti-Ro52/Ro60) along with anti-SSB in each diagnostic group, statistically significant differences were found (p=0.00015). The SS diagnosis was made in 69.6% of patients with anti-Ro52/Ro60 and anti-SSB, and in 100% of patients with anti-Ro52 and anti-SSB. Those those with anti-Ro60 and anti-SSB showed a uniform frequency of occurrence in each diagnostic group (33.3%).
Conclusion: In our population, the isolated detection of anti-Ro60 and/or anti-Ro52 antibodies is not always associated with the diagnosis of connective tissue diseases. The presence of anti-SSB along with anti-SSA antibodies has demonstrated greater relevance for the diagnosis of Sjögren's syndrome than the presence of anti-SSA alone or along with other autoantibodies. This may entail an increase in unnecessary referrals to specialist consultations, which could be avoided if requests for antinuclear antibodies were more closely aligned with the patient's clinical presentation.

The TCR repertoire of circulating γδ T lymphocytes in psoriasis vulgaris varies with age and disease severity

Maja Jirouš Drulak[1], Mario Stefanic[1], Vera Pluzaric[1;2], Marija Sola[2], Martina Mihalj[1;2], Stana Tokić[1]
[1]*Faculty of Medicine Osijek, Osijek, Croatia*; [2]*University Hospital Osijek, Osijek, Croatia*

Purpose: Psoriasis vulgaris is a recurring autoinflammatory skin disease that often manifests systemically. The underlying immune aberrations are predominantly driven by T cells, with emerging evidence suggesting a potential role for innate-like γδ T cells. Healthy peripheral γδ T cell repertoires are largely composed of Vγ9Vδ2 cells, yet alterations in the diversity and composition of the γδTCR repertoire in PV remain largely unknown.
Methods: We applied bulk TCRSeq analysis (Archer Immunoverse™-HS TCR, NextSeq Illumina coupled with MiXCR, VDJTools and immunarch pipeline) to comparatively investigate the characteristics of the TCRγ and TCRδ repertoires from flow-sorted, peripheral γδ T cells (20 PV patients and 15 healthy controls).
Results: A largely public TRG repertoire was discovered alongside a highly polyclonal and private pool of TRD transcripts, with CDR3δ length varying with TRDV1 (15-23 amino acids), TRDV2 (14-19 aa) and TRDV3 (13-23 aa) gene expression. Common TRDV2/TRDD3/TRDJ1 and TRGV9/TRGJP transcripts were predominantly expressed in both groups, while TRDV1, TRDV3 and various TRGV/J expressing clonotypes dominated the rest of the repertoire, without significant differences in case-control comparisons. The TRD/TRG repertoire diversity however, significantly declined with increasing age and PASI index in the PV group, largely due to incremental increase in hyperexpanded clonotype frequencies (comprising > 5% of the repertoire), ultimately affecting TRG/TRD clonotype richness and evenness. The variety of TRDV1 and TRDV3 clonotype compartments was significantly altered in PV, likely reflecting TRDV1 clonotype expansion (Inverse Simpson Index; median (PV vs. CTRL): 3.71 vs. 7.20, p=0.037, Mann-Whitney test) and reduced TRDV3 clonotype heterogeneity (Shannon-Wiener Index; 3.91 vs 9.85, p=0.036). Moreover, an age-related increase in CDR3δ length was notably evident in the TRDV1 compartment of severely affected PV patients (Spearman's rho= 0.828, p= 0.006), suggesting potentially important effects of age and PV on TCRδ repertoire shaping. Healthy controls, conversely, exhibited increased TRDV1 and TRDV3 diversity with age.
Conclusion: Our findings underscore a complex, multilayered influence of age and disease severity on γδ TCR repertoire diversity and CDR3 characteristics, particularly in the TRDV1 and TRDV3 compartments. This intricate interplay between ageing, disease severity, and TCR repertoire dynamics in PV emphasizes the need to further investigate the underlying mechanisms.

Clinical correlation between anti-centromere antibodies (CENP-B) and autoimmune diseases

Angela Lucas Blanco[1], Azahara Díaz Lozano[1], luz cheilly Mosquea Jiménez[1], Marta Aguilar Criado[1], María Inmaculada Alcalá Peña[1], María Luisa Vargas Pérez[1]
[1]*Inmunología, Hospital Universitario de Badajoz, Badajoz, Spain*

Purpose: Anti-centromere antibodies (ACA) are useful biomarkers in Limited cutaneous systemic sclerosis (lcSSc) and can precede its clinical diagnosis by years. They are also found in other autoimmune diseases (AID) like primary biliary cirrhosis (PBC), Sjogren's disease (SjD), lupus erythematosus, rheumatoid arthritis, isolated Raynaud phenomenon and in subjects without AID.
Our aim is to describe the clinical relationship, in our setting, between ACA (CENP-B) and the presence of AID.
Methods: In a retrospective study, 473 patients (389 female, 48 male) positive for CENP-B (CENP-B+) were reviewed (2008-2023). CENP-B was detected using indirect immunofluorescence (IFI) on HEp-2000 cells and confirmed by LineDot. The data were collected from their medical record.
Results:

- 25.6% of patients were diagnosed with lcSSc. Nine were diagnosed during the follow-up (average time: 5.4 years after the initial detection). The rest were already symptomatic when the first determination was made.
- There are two peaks in CENP-B detection, between the ages of 51-60 (18.8%) and 71-80 (20%).
- The highest proportion of lcSSc patients is found between the ages of 61-70 (32.9%). The percentages are similar across age groups from 30 to 80, ranging between 27% and 32.9%, decreasing at extreme ages.
- 13.7% of patients have another AID besides lcSSc. The most frequent are PBC (5.6%) and SjD (3.7%). 21 out of 26 patients with PBC are positive for antimitochondrial antibodies. 12 out of 16 patients with SjD are positive for SSA.
- 57.9% of patients have no AID. 42% CENPB+ patients have not been evaluated by a clinical specialist, or it is not reflected in the medical record.

Conclusion: CENP-B predominantly manifest in middle to advanced-aged individuals. While the majority of them are asymptomatic, this age group also experiences a higher prevalence of lcSSc diagnoses. In our setting, CENP-B also manifest, albeit less frequently, in other AID. ACAs have proven to be predictive of lcSSc, so perhaps asymptomatic patients should receive follow-up. A significant proportion of patients without AID have not undergone autoimmune disease screening. Considering the significant number of asymptomatic individuals, it is important to request antibody determination based on clinical suspicion.

Impact of COVID-19 on the prevalence of ANA positivity within the Indian population

Vikas Saini[1], Sangita Gupta[2], Anamika Keshri[1], Sonia Malik[1]
[1]ESIC Hospital & PGIMSR, Delhi, India; *[2]ESI Hospital, Punjab, India*

Purpose: Since the Covid 19 infection, the prevalence of Antinuclear Antibodies (ANA) positive has grown. By comparing ANA data from six different years - 2017 to March 2020(pre-Covid years), and April 2020 to March 2023 (post-Covid years) - this study examines the ANA positivity rate.
Methods: ANA Indirect Immunofluorescence Assay (IFA) data for six different years - April 2017 to March 2020, representing the pre-COVID era, and April 2020 to March 2023, representing the post-COVID era are analyzed and compared in this retrospective study based on a number of characteristics, such as age, gender, prevalence rate, positivity rate by grade, and ANA patterns.
Results: Both the overall number of suspected cases and the number of ANA-positive cases increased significantly in the post-Covid era April 2020 to March 2023, rising by almost 20%. Age-related increases in positivity rates were seen, and both years showed a preponderance of females. In both eras, nuclear speckled patterns continued to be the most prevalent.
Conclusion: Our study underscores the significant role of immune modulation in the development of autoimmunity during the post-COVID pandemic period. This modulation may occur through mechanisms such as Molecular Mimicry, the production of autoantibodies upon exposure to viral epitopes through the formation of neutrophil extracellular traps (NET), or Toll-like receptor (TLR) pathways of immune modulation.

Diagnosis of antiphospholipid syndrome based on 2023 ACR/EULAR versus 2006 Sydney criteria, in a population of patients from Cádiz, Spain

Javier Galán Picón[1], Joel Gutiérrez Serrudo[1], Lucía Pedrosa García[1], Isabel Serrano García[1], Carmen Rodríguez[1]
[1]*Hospital Universitario Puerta del Mar, Cádiz, Spain*

Purpose: Antiphospholipid Syndrome (APS) is an autoimmune thrombophilic condition with vascular and obstetric manifestations and anti-phospholipid autoantibodies (apL Ab). A descriptive cross-sectional study was conducted to compare the number and clinical features of patients who meet the criteria for APS based on the 2023 ACR/EULAR classification vs the previous 2006 Sydney classification.
Methods: The population submitted to our Hospital for analysis of apL Ab during 2022 and 2023 was included in the study. Laboratory parameters (lupus anticoagulant, anticardiolipin antibodies and anti-B2-glycoprotein I antibodies) were determined and clinical data were registered. Anticardiolipin and anti-B2-glycoprotein I immunoglobulin G and M (IgG and IgM) antibodies were determined by chemiluminescence. Values above 20 IU/mL was considered moderate-positive and values above 200 IU/mL were considered high-positive. According to ACR/EULAR criteria, a total score ≥ 3 in both laboratory and clinical domains is required to classify a patient as having definite APS.
Results: From 302 patients who had at least two laboratory determinations separated by at least 12 weeks, 157 (52%) did not meet the ACR/EULAR or Sydney criteria; a total of 145 (48%) patients were evaluated following the 2023 and 2006 APS criteria. 46 (31.7%) patients met the Sydney classification criteria -average age 51.4 years, 33 (71.7%) females and 13 (28.3%) males-. However, only 26 (17.9%) patients met the ACR/EULAR classification criteria -average age 47.8 years, 19 (73%) females and 7 (27%) males-.
Conclusion: According to the new ACR/EULAR APS criteria, 20 patients (43.5 % of our cohort) previously diagnosed with APS following the Sydney classification did not meet the required score to be classified as APS.
This result depended mainly on the lack of real value of IgM apL Ab for APS diagnosis according to the 2023 criteria, because these 20 patients were found to have moderate and high titres of IgM apL Ab, but not IgG apL Ab.
In summary, a detailed analysis should be performed in order to not misdiagnose primary or secondary APS according to 2023 ACR/EULAR classification criteria.

Establishing the optimal cut-off value to detect clinically relevant figures of anti-citrullinated protein antibodies for the diagnosis of rheumatoid arthritis

Alberto Gallardo García[1], Jorge Mannelli[1], Jesús Gálvez Remón[2], Carmen Rodríguez[1]
[1]*Servicio de Inmunología. UGC Hematología e Inmunología. Hospital Universitario Puerta del Mar, Cádiz, Spain*;
[2]*UGC laboratorios clínicos. Hospital de la Línea de la Concepción, La Línea de la Concepción, Spain*

Introduction: Anti-citrullinated protein antibodies (ACPA) present a good sensitivity/specificity balance for the diagnosis of rheumatoid arthritis (RA). Its determination was included in the 2010 ACR/EULAR diagnostic criteria. These criteria assign 2 points to those 'low-positive' ACPA values -higher than the upper limit of normal (ULN)- while 3 points are assigned to 'high-positive' ACPA values -higher than 3 times the ULN-.
Purpose: To determine the optimal cut-off value for ACPA that allows us to detect clinically significant high-positive values more accurately in a cohort of ACPA-positive patients.
Patients and methods: A cohort of 168 patients from the Hospital U Puerta del Mar, Cádiz, Spain with positive ACPA results by chemiluminescence (reference values: 0.0-5.3 U/ml) were included in the study. Rheumatoid factor (RF) was determined by immunoturbidimetry. Clinical features were registered. Through ROC curve analysis, the optimal cut-off value was determined. Objective values, likelihood ratio and Cohen's κ coefficient with RF were calculated and compared with those obtained with the theoretical cut-off value outlined in the 2010 ACR/EULAR criteria, who recommends 3 times the manufacturer's recommended ULN.
Results: An optimal cut-off value for ACPA of 38.3 U/ml was obtained, showing a specificity (S) and positive predictive value (PPV) of 91% and 95% respectively. Additionally, this value presents a positive likelihood ratio (+LR) of 8.56 and a Cohen's κ coefficient of 0.4, indicating substantial agreement between ACPA and RF determinations. These values were higher than those obtained using the theoretical cut-off value of 3 times the ULN (16.0 U/ml) which showed a lower S (61%), PPV (82%), +LR (2.26) and Cohen's κ coefficient (0.3).
Conclusion: Our results indicate that a cut-off value 7.2 times the ULN has a high specificity and positive likelihood ratio for detecting ACPA-positive values of clinical significance for the diagnosis of RA.
In summary, our results highlight the importance of determining in each laboratory optimal cut-off and +LR values to improve diagnostic accuracy.

A RARE CASE OF RHEUMATOID ARTHRITIS AND SARCOIDOSIS CO-OCCURRENCE

Nurgul Naurzvai[1]
[1]*Acibadem Atakent University Hospital, Istanbul*

Introduction: Rheumatoid arthritis (RA) and sarcoidosis are autoimmune diseases that can affect multiple organ systems, including the lungs. While pulmonary involvement is common in both conditions, the coexistence of RA and sarcoidosis is rare. This case introduces a patient with RA who developed symptoms of sarcoidosis following treatment with anti-TNF medication.
Case presentation: A 42-year-old male with a 22-year history of RA initially received conventional disease-modifying antirheumatic drugs. Years back while being treated with methotrexate, hydroxychloroquine, and mycophenolate, RA progressed systemically, leading to a initiation of anti-TNF therapy. Subsequently, he developed enlarged mediastinal lymph nodes and nodular lung infiltrates. Sarcoidosis was diagnosed based on non-caseating granulomas in transbronchial lung biopsy specimens. Possible diagnosis of anti-TNF related sarcoid like reaction, anti-TNF treatment was stopped and he continued RA medications with short term low dose steroids. During the current presentation, the patient reported he has discontinued his RA medications and claimed to have been in remission for several years. He admitted to our clinic with a severe cough, sputum and shortness of breath. With mediastinal enlarged multiple lymph nodes, bilateral lung infiltrates and with previously diagnosed biopsy proven sarcoidosis, he started methylprednisolone 1mg/kg. His symptoms were revealed consequently after the steroid treatment.
Discussion: The co-occurrence of RA and sarcoidosis is rare, making this case noteworthy. The unique aspect of this case is the onset of sarcoidosis symptoms following treatment with anti-TNF medication. Unlike typical anti-TNF-related sarcoid-like reactions, the patient's lung involvement persisted even after discontinuation of anti-TNF therapy. This case underscores the importance of recognizing the rare coexistence of RA and sarcoidosis. Increased awareness of this rare association can aid in timely diagnosis and appropriate management of affected individuals.

Characterization of a model of vitiligo skin depigmentation in C57BL6/J mouse tail via immunisation with tyrosinase-related protein 2 (TRP2)

Laura Casals[1], Lluís Boix[1], Charlie Bridgewood[1], Joan Mañé[1], José Luis Montero[1], Özge Uluçkan[1], Amadeu Gavaldà[1]
[1]*Almirall, S.A., Barcelona, Spain*

Vitiligo is an autoimmune skin disorder which affects 0.5-1% of the general population. Vitiligo and the associated depigmentation is mediated by CD8+ T-cell immunogenicity against melanocytes. Based on this mechanism, various mouse models have been developed. We characterized an existing vitiligo model, induced by immunisation with melanocyte tyrosinase related protein 2 peptide 180-188 (TRP2), LPS and CpG oligodeoxynucleotides.
C57BL6/J mice received 4 immunisations with all the above, once a week. Tail skin depigmentation was evaluated by visual scoring. As JAK inhibitors (JAKi) are efficacious in vitiligo, mice were treated with oral baricitinib from wk 9 after the last immunisation, when at least 20% of tail skin was depigmented. Abundance of total CD8+ and T resident memory cells (TRMs) was monitored in the skin by spectral flow cytometry, at different time-points after immunisation (wks 1, 5, 9 and 17). Gene expression analysis was performed on tail skin homogenates on wk 17, by real-time qPCR.
TRP2-induced mice developed skin depigmentation on the tail from wk 5, which progressed to a 20%-30% average depigmentation on wks 7 to 9. Increased CD8 T-cell infiltration was seen in vitiligo mice from wk1 compared to control mice (26% *vs* 2% of total CD45+), and was still evident at wk17 (8% *vs* 1%). The % of CD8+TRM was also constantly higher than in control mice. Murine skin which was actively depigmenting (adjacent to white areas) showed a similar gene expression profile to human vitiligo skin. This included higher expression of mediators with a documented importance in human vitiligo such as CD8a, Cxcl10, IFNg, Gzmb and TNF. The JAKi, baricitinib partially decreased depigmentation (25% reduction) and resulted in lower inflammatory gene expression, however, no reduction in infiltrating CD8+ T-cells was seen. In conclusion, our results show that this model recapitulates several features of human vitiligo and responds to a JAKi, making it suitable for evaluating novel drugs for vitiligo.

The impact of peripheral T follicular cells in the diagnosis of ANCA associated glomerulonephritis

Michalis Christodoulou[1], Eleni Moysidou[1], Stamatia Stai[1], Vasiliki Nikolaidou[2], Konstantinos Badis[1], Pantelis Sarafidis[1], Asimina Fylaktou[2], Maria Stangou[1]
[1]1st Department of Nephrology, School of Medicine, Aristotle University of Thessaloniki, Hippokration General Hospital, Thessaloniki, Greece; *[2]Department of Immunology, National Histocompatibility Center, Hippokration, Thessaloniki, Greece*

Purpose: T cells play crucial role in the pathogenesis of autoimmune diseases such as ANCA associated vasculitis-glomerulonephritis (AAV/GN) by secreting immune mediators and helping B cell-mediated long-lived humoral immunity development. Specific T and B cells subsets can be used as biomarkers of patients with AAV/GN. We aimed to prospectively compare the predictive ability of such subpopulations in patients with active AAV/GN.
Methods: Flow cytometry was applied in the peripheral blood of 29 subjects. 15 AAV/GN patients (M/F 6/9), Age:62.1(28-82)years, MPO/PR3/Negative ANCA: 10/4/1) and 14 healthy controls (HC), to estimate T-cells subsets: CD4, T-folicular cells (Tfol), T-regulatory cells (Tregs), Tfh, Tfh1, Tfh2, Tfh17, and T-folicular regulatory cells(Tfr) and B-cells subsets: CD19, IgD(+)CD127(-), IgD(+)CD127(+), IgD(-)CD127(+) and IgD(-)CD127(-).
Results: Compared to HC, AAV/GN patients had reduced CD4 (698.8 vs 368.8, p=0.04) but increased proportion of Tfol, and both Tfh1 and Tfh2 cells (7% vs 12%, p=0.05, 8.4 vs 11.2, p=0.03, 13.3 vs. 45.9, p=0.09, respectively). Both Tfr (p=0.048) and Tfh (p=0.023) were also significantly higher in AAV/GN, compared to HC.
CD19 levels were lower in AAV/GN compared to HC, with reduced all subpopulation, though of not-statistical significance.
Conclusion: Specific T-cells subsets can be measured in AAV/GN patients' peripheral blood. Subpopulations such as Tfh and Tfr can be used as biomarkers to diagnose patients with active disease and their role in the pathogenesis of AAV/GN must be studied in detail to determine if they can become targets for new therapies in the future.

Genetic landscape of ulcerative colitis: possible novel genetic variants in MST1 in two familial clinical cases

Maria del Carmen Barrera Aguilera[1], Mónica Bernal[1], Ana Marin[1], Miguel Ángel López-Nevot[1;2]
[1]*Hospital Universitario Virgen de las Nieves, Granada, Spain*; [2]*Universidad de Granada, Granada, Spain*

Ulcerative colitis (UC) is a chronic inflammatory disorder of the intestinal tract secondary to immune dysregulation. In some cases, the pathology is associated with autoimmune liver diseases, such as primary sclerosing cholangitis (PSC), autoimmune hepatitis (AIH) or their combination.
In the present study, two fourth-degree related individuals (cousins) with UC associated with AIH were used as a starting point. The family history included multiple autoimmune diseases in the common kinship line (vitiligo, psoriasis, rheumatoid arthritis, AIH and systemic lupus erythematosus).
The objective was to identify possible common gene variants in both individuals predisposing to the common clinical picture. For this purpose, a massive next-generation sequencing study was carried out with a panel of genes involved in diseases related to the immune system, as well as HLA typing to identify associated alleles.
This study revealed ten common SNP variants located in the *MST1* gene (chromosome 3, NC_000003.12), all of them in heterozygosis. Of all the variants observed with possible clinical relevance, only one was previously described and reported as a variant of uncertain significance (*MST1*:c.767A>C). Of the remaining variants, two of them were *missense* variants (*MST1*:c.55C>T; *MST1*:c.3781G>C), and the remaining one was a +3 variant of a splicing donor site (*MST1*:c.94+3A>G). Non-shared variants in the *CARD9* gene, associated with UC and PSC, were also observed in both patients.
Regarding the HLA allele study, it revealed that both patients shared a haplotype. In addition, both had inherited risk alleles of the *DRB1* locus for UC (*DRB1*07:01* and *DRB1*13:01*) from the non-common line of descent.
These preliminary results point to the possibility of the existence of as yet undescribed variants in *MST1* with very low population frequency that, together with other genetic risk factors, have defined the clinical picture in a familial series with clustering of autoimmune diseases. The next steps lead to the sequencing of the progenitors of the studied individuals of the common kinship line, as well as the determination of the serum levels of the gene product to determine if there may be an impact in the MSP-RON pathway.

Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease. Although their prognosis has improved over the last decades, the mortality rate in these patients is 4.5 times higher than in the general population, so it is important to know the molecular, cellular, and immunological mechanisms involved in the development of the disease. CD4 and CD8 T cells play a relevant role in SLE; they present greater hyperreactivity and secretion of proinflammatory cytokines, contributing to tissue damage and exacerbation of the disease. The activation of CD4 T cells promotes their differentiation into cell populations such as Th1, Th2, Th17, producers of IFNγ, IL-4 and IL-17 respectively. While CD8 mainly secrete IFNγ, granzyme B (GZMB), perforins and granulysin. Deregulation of the secretion of these cytokines in SLE has been explored in patients and animal models. However, studying their prevalence together and in relation to disease activity may result in the differentiation of pathological subpopulations of T cells, such as exhausted T cells.
Methods: Peripheral blood samples were collected from patients with active and inactive SLE. For serum determination of cytokine concentration, the commercial LEGENDplex™ Human CD8/NK Panel (13-plex) kit was used. Cellular events were acquired using the MACSQuant Analyzer 10 cytometer (Miltenyi Biotec, Germany), and the results obtained were analyzed with LEGENDplex software. As a control group, samples were obtained from healthy individuals matched by age and sex with respect to the SLE group.
Results: In this study we investigated the concentration of 13 cytokines (IL-17A, IL-2, IL-4, IL-10, IL-6, TNF-α, Fas, FasL, IFN-γ, Granzyme A, Granzyme B, Perforin, Granulysin) related to the immune response of patients with SLE. We studied the behavior of cytokines in patients with active and inactive SLE and identified a subset of SLE patients with increased levels of granzymes, perforin and granulysin compared to healthy subjects.
Conclusion: Chronic inflammation in SLE promotes exposure to autoantigens that can maintain the constant activation of autoreactive clones of T cells. The study of the cytokines addressed here could be important for monitoring the possible cell populations involved in the production of these, as well as for patient monitoring.

Stratification of inflammatory arthritis using immunophenotyping

Abel Mekonnen Tesfaye[1], Erlend Holm-Nordli[2], Guro Løvik Goll[2], Hilde Berner Hammer[2], Andreas Lossius[1], Silje Watterdal Syversen[2], Asbjørn Christophersen[1]
[1]Institute of Basic Medical Sciences, University of Oslo, Oslo, Norway; *[2]Center for treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Diakonhjemmet Hospital, Oslo, Norway*

This project aims to enhance early diagnosis of inflammatory arthritis (IA) subtypes, such as rheumatoid arthritis, psoriatic arthritis, osteoarthritis and spondyloarthritis. IA subtypes may be difficult to differentiate early in the diagnostic workup with current diagnostic parameters, while delayed targeted treatment can lead to rapid joint destruction. This project aims to utilize immune-cell phenotyping of synovial tissues from inflamed joints to stratify IA subtypes.
We are collecting peripheral blood, synovial fluid and biopsies from patients referred to a large outpatient clinic that receives the majority of undiagnosed IA patients in Oslo (Diakonhjemmet Hospital). Our study will include a minimum of 10 patients from each IA subtype and will leverage a novel multi-parametric spectral analyzer and a >35-parametric self-designed panel that includes T-cell, B-cell, and myeloid cell markers for deep immunoprofiling.
By correlating the immunological profiles with clinical diagnoses and disease severity, we hope to identify unique immunophenotypic patterns specific to each IA subtype. The comparison of immune composition across synovial fluid, synovial biopsy, and blood will not only provide a more comprehensive picture but also provide information on which sample type provides the best diagnostic yield. To develop a clinically relevant diagnostic test, we will assess whether a smaller flow-cytometric panel, based on key markers from the initial findings, can be used to stratify the IA subtypes.
In conclusion, our ultimate goals are to use these immunopathological signatures to stratify IA subtypes, with a particular focus on the underutilized synovial fluid samples, and to improve personalized treatment approaches in IA.

Explorative study on the role of EBV-mimicry autoantibodies in Myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) and post-COVID syndrome

Friederike Hoheisel[1], Franziska Sotzny[1], Kerstin Rubarth[2;3], Sandra Bauer[1], Frank Konietschke[2], Claudia Kedor[1], Annika Elisa Stein[1], Kirsten Wittke[1], Martina Seifert[1], Carmen Scheibenbogen[1]
[1]Institute for Medical Immunology (IMI), Charité – Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin, Humboldt-Universität zu Berlin, Berlin, Germany; *[2]Institute of Biometry and Clinical Epidemiology, Charité – Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin, Humboldt-Universität zu Berlin, Berlin, Germany*; *[3]Institute of Medical Informatics, Charité – Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin, Humboldt-Universität zu Berlin, Berlin, Germany*

Purpose: Myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) is a debilitating multi-systemic chronic disease. Patients suffer from worsening symptoms after mild to moderate exertion named post-exertional malaise (PEM). Key symptoms are fatigue, pain, cognitive, autonomic, and flu-like symptoms. ME/CFS is triggered by various infections, e.g. EBV or SARS-CoV-2. There is evidence for autoimmunity in a subset of patients. The role of autoantibodies (AAB) including regulatory G protein-coupled receptor AABs was shown in previous studies, and underpinned by first clinical studies of AAB depletion. In the BMBF-founded research network (IMMME), we aim to investigate the role of AABs in ME/CFS and post-COVID syndrome (PCS).
Methods: To investigate the serum IgG response against EBV and potential human mimicry epitopes, we developed a novel cytometric bead array (peptide-CBA). Thereby peptide-coated beads allow a multiplex high throughput cytometric analysis of up to 15 peptide-specific IgG responses in one measurement. In the screening cohort, 44 PCS patients with 25 of them fulfilling the diagnostic criteria for ME/CFS, 34 post-infectious ME/CFS patients, and 31 healthy control subjects (HC) diagnosed at the Charité Fatigue Center were analyzed.
Results: PCS and ME/CFS patients showed more frequent serum IgG responses against several EBV peptides and the corresponding mimicry peptide sequences of human autoantigens compared to HCs. Furthermore, the level of serum IgG against mimicry epitopes correlates with disability severity assessed by Bell score, the restriction in physical functioning measured by SF-36, and the severity of the disease and several key symptoms, pointing towards a functional role of these antibodies.
Conclusion: The correlation shown between the level of peptide-specific IgG response in PCS and ME/CFS patients with disease severity provides first evidence for the role of EBV mimicry and that these AABs may contribute to pathological processes in ME/CFS and PCS, which needs to be investigated in further studies. Moreover, the diagnostic potential of mimicry peptide-specific IgG patterns has to be studied in larger cohorts.

Using genetic risk and EBV infection status to decipher the disease-inducing B cell in Multiple Sclerosis

Ana Marques[1], Sanne Reijm[1], Laurens Bogers[1], Jamie van Langelaar[1], Cato Corsten[2], Marie-Jose Melief[1], Annet Wierenga-Wolf[1], André Uitterlinden[3], Jeroen van Rooij[3], Beatrijs Wokke[2], Joost Smolders[1;2;4], Marvin van Luijn[1]
[1]Department of Immunology, MS Center ErasMS, Erasmus MC, Rotterdam, Netherlands; *[2]Department of Neurology, MS Center ErasMS, Erasmus MC, Rotterdam, Netherlands*; *[3]Department of Internal Medicine, Erasmus MC, Rotterdam, Netherlands*; *[4]Neuroimmunology research group, Netherlands Institute for Neuroscience, Amsterdam, Netherlands*

Purpose: Although the cause of multiple sclerosis (MS) remains unknown, several single nucleotide polymorphisms (SNPs) linked to disease susceptibility could affect B cell homeostasis in MS. This may be shaped by the B cell-lymphotropic Epstein-Barr virus (EBV). Besides for EBV-infected T-bet$^+$ B cells, a novel subset of B cells expressing cytotoxic molecule granzyme B (GzmB) and transcription factor Runx3 has been recently implicated in MS. Notably, the coding SNP *Runx3* is associated with MS. The goal of this work is to elucidate the interaction between EBV and genetic variants and how this influences T-bet$^+$ B cells to identify pathogenic signatures for MS.
Methods: We analysed anti-EBV (EBNA1, VCA, EA) IgG levels in 706 serum samples from MS patients and 107 controls. Genotyping was performed on 432 MS patients, followed by imputation and weighted genetic risk scores (wGRS), including several P-value thresholds with the discovery GWAS study (IMSGC, 2019), resulting in 175 SNPs. We performed functional analysis of Runx3 and GzmB in *ex vivo* human B cells using spectral cytometry and BCR- and T helper cell-dependent *in vitro* cultures.
Results: We found an association between the risk SNP *Runx3* and the anti-EBNA1 IgG levels in patient serum (p=0.02). Furthermore, we found an upregulation of GzmB in approximately 50% of naïve B cells after 2 days, especially under BCR-stimulating conditions. This was a transient effect, which coincided with both Runx3 and T-bet expression. To assess the overall impact of genetic variants on B cells, we performed wGRS and we can stratify the MS patients based on EBV infection and genetic risk profiles.
Conclusion: These findings suggest that GzmB expression is transiently induced when naïve B cells first encounter an antigen. Our current working model consists of a primary EBV infection potentiates this effect by triggering Runx3 and T-bet expression, which may increase their survival and further maturation into pathogenic subsets before MS onset. Integration of these data with RUNX3 genotype, wGRS and EBV infection status may further characterize the impact of the genetic variants on GzmB expression in T-bet+ B cells.

Identification of Epstein-Barr Virus microRNAs in blood in multiple sclerosis

Victoria Hyslop Hvalkof[1], Malene Bredahl Hansen[1], Anna Olsson[1], Stefan Gustavsen[1], Annette Bang Oturai[1], Finn Sellebjerg[1], Helle Bach Søndergaard[1]
[1]*Danish Multiple Sclerosis Center, Copenhagen University Hospital – Rigshospitalet, Glostrup, Denmark*

Purpose: Multiple sclerosis (MS) is an immune-mediated disease. Epidemiological studies indicate that Epstein-Barr Virus (EBV) infection is necessary for development of MS, but other factors are also involved. The EBV genome encodes 44 microRNAs (miRNA), which are molecules of ~20 nucleotides that regulate mRNA with hundreds of targets. MiRNAs are found in immune cells and their secreted exosomes, enabling systemic distribution. The role of ebv-miRNAs in MS is currently unknown, we therefore investigated ebv-miRNAs in MS patients with high and low disease activity, their correlation with biomarkers of inflammation, and the effect of MS treatments on ebv-miRNA.
Methods: Total RNA was extracted from whole blood (WB) and plasma exosomes (PE) from 50 treatment-naïve relapsing-remitting MS (RRMS) patients at baseline and one-year follow-up. Forty-three ebv-miRNAs were measured by qPCR using custom TaqMan Array Cards. Granzymes and cytokines were measured in WB by qPCR using TaqMan Assays. Serum IL-6 and neurofilament light (NfL) was measured by SIMOA. Age-adjusted NfL levels and presence of active magnetic resonance imaging brain lesions classified high and low disease activity. FDR-adjusted q-value<0.1 for correlations and p-value<0.05 for group comparisons was accepted.
Results: In the low compared to high disease activity groups, significantly higher levels of ebv-miR-BART20-5p and ebv-miR-BART11-3p in WB, and ebv-miR-BART5-3p in PE were observed, while opposite for ebv-miR-BART12 in PE.
In WB, positive correlations were observed between granzyme A (*GZMA*) and ebv-miR-BART19-3p; granzyme H (*GZMH*) and ebv-miR-BART20-5p; interleukin-10 (*IL-10*) and ebv-miR-BART20-5p; IL-6 and ebv-miR-BART3-5p; interferon- γ (*IFN-γ*) and ebv-miR-BART19-3p, while a negative correlation was found between *IL-10* and ebv-miR-BART12. In PE, positive correlations were found between *GZMA* and ebv-miR-BHRF1-3p; *GZMH* and ebv-miR-BART8-3p; *IL-1β* and ebv-miR-BART10-3p, and negative correlations were observed between *GZMH* and ebv-miR-BART13-5p; and ebv-miR-BART14-3p; IL-6 and ebv-miR-BART11-5p; *IFN-γ* and ebv-miR-BART13-5p. Furthermore, Teriflunomide significantly lowered ebv-miR-BART8-3p (n=13).
Conclusion: The profiling of ebv-miRNAs in exosomes and WB indicate a role in MS pathogenesis. Correlations with granzymes and inflammatory cytokines suggest ebv-miRNAs involvement in the activity of cytotoxic T and NK cells. The results also indicate anti-viral effects of Teriflunomide affects the levels of ebv-miRNA, and the presence of exosomal ebv-miRNAs shows a high regulatory potential.

Anti-Ro52 positivity is associated with poorer lung function at diagnosis in connective tissue disease and idiopathic inflammatory myopathy associated interstitial lung disease

Robert Harrington[1], Patricia Harkins[1], Richard Conway[1], Ruairi Fahy[2]
[1]St. James's Hospital Rheumatology Department, Dublin, Ireland; [2]St. James's Hospital Respiratory Department, Dublin, Ireland

Purpose: Recent cohort studies suggest an association with anti-Ro52 antibodies and more progressive ILD in CTD-ILD and IIM-ILD. This study investigates the significance of anti-Ro52 positivity in an Irish cohort of these patients.
Methods: This is a monocentric 7-year retrospective cohort study of CTD-ILD and IIM-ILD patients. 781 extended myositis panel results were screened from 2016 to 2022 to identify a suitable cohort. PFT data was analysed to explore the significance of anti-Ro52 positivity.
Results: 41 CTD-ILD and IIM-ILD patients (19 male, 22 female) were included. The mean age was 66.7 (std +/- 13.2) and a mean disease duration was 4.4 years (std +/- 2.6). 14/41 patients were anti-Ro52+. The anti-Ro52+ cohort had a significantly lower baseline DLCO at diagnosis; 41.70% vs. 55.41% (p = 0.009). Baseline FVC predicted was numerically lower in the anti-Ro52+ cohort but did not reach statistical significance; 75.78% vs. 92.83% (p = 0.083). After standard of care treatment, the anti-Ro52+ cohort had poorer FVCs; 72.16% vs. 97.06% (p = 0.028). There was no difference in all-cause mortality with 3 deaths among the anti-Ro52+ cohort and 4 among the anti-Ro52- cohort (p = 0.673). No associations between anti-Ro52 status and smoking, malignancy or ILD pattern on CT were found. Patients under 65 presented with lower baseline FVC compared with those over 65 irrespective of anti-Ro52 status; 75.45% vs. 95.6% (p = 0.026).
Conclusion: Anti-Ro52 antibodies are associated with a lower baseline DLCO in CTD-ILD and IIM-ILD patients. Patients under 65 also presented with a more markedly reduced FVC than more elderly patients, perhaps reflecting the fulminant nature of disease onset in this demographic.

Investigating biological age and ELOVL2 expression in ANCA-associated vasculitis

Jordy Smith[1], Isabella Batten[1], Matt McElheron[1], Mark Little[1], Nollaig Bourke[1]
[1]*Trinity College Dublin, Dublin, Ireland*

ANCA-associated vasculitis (AAV) is an autoimmune disease that effects the small blood vessels resulting in systemic inflammation and pathologies of the kidney, lung, and skin. AAV tends to effect people later in life than other autoimmune conditions, and occurs more often in people assigned male at birth. Within an aging immune system, genetics and lifetime environmental exposure drive the process of Inflamageing, where a key feature of this process is epigenetic changes. These epigenetic changes can be used to predict "biological age", a measure of how cellular processes associated with aging change as this process takes place. The links between these phenomena and autoimmune disease have not been fully explored, and specifically the role biological age plays in relation to the pathogenesis of AAV has not yet been described. Furthermore, determining whether this process is a sex-specific or sex-determined factor will be essential for improving our understanding of the factors driving AAV disease pathogenesis, relapse, and remission. In as-yet unpublished work within the Bourke lab, the biological age of AAV patients has been quantified with an ELOVL2 DNAm model, and demonstrated to be accelerated when compared to healthy controls, with treatment modulating this acceleration. Additionally, the expression of ELOVL2 as measured with qPCR has been demonstrated to be downregulated in active AAV patients when compared to healthy controls. Herein, we demonstrate that this difference is specific to disease state, where active AAV patients demonstrate significantly lower ELOVL2 expression compared to their remission counterparts, as well as to healthy controls. Additionally, we demonstrate that there is no significant sex difference in ELOVL2 expression in active nor remission AAV patients. This work suggests that biological age may be contributing to the pathogenesis of AAV, and consequently ELOVL2 expression changes may be specific to AAV disease state. More research is required to tease out the potential mechanisms by which biological age may be contributing to AAV pathogenesis, how the effect of treatment relates to both biological aging and AAV pathogenesis, and to investigate whether this phenonomen is AAV specific.

This work was funded by Vasculitis UK.

The presence of myositis specific and myositis associated antibodies does not alter prognosis in idiopathic pulmonary fibrosis

Robert Harrington[1], Patricia Harkins[1], Richard Conway[1], Ruairi Fahy[2]
[1]St. James's Hospital Rheumatology Department, Dublin, Ireland; [2]St. James's Hospital Respiratory Department, Dublin, Ireland

Purpose: Myositis specific antibodies (MSA) and myositis associated antibodies (MAA) can be detected in pulmonary involvement in systemic autoimmune rheumatic diseases. The prognostic effect of these antibodies in idiopathic pulmonary fibrosis (IPF) however remains unclear.
Methods: This is a monocentric 7-year retrospective cohort study of IPF patients from 2016 to 2022. IPF patients with MSA/MAA antibodies were age and sex matched 1:1 to IPF patients without antibodies. The 2 groups were analysed by PFTs, all-cause mortality, and presence of malignancy.
Results: 17/109 (15.6%) IPF patients (12 male, 5 female) with MSA/MAA antibodies were identified. Anti-Mi2-β was detected in 6/17 (35.3%). The mean age at diagnosis was 71.9 (std +/- 8.6) and the mean disease duration was 3.79 (std +/- 2.81) years. There were no differences between groups in disease duration, smoking history, or prior malignancy. There was no difference in baseline FVC between the MSA/MAA group and the antibody negative group; 90.68% vs. 89.86% ($p = 0.911$). The baseline DLCO was also the same; 60.20% vs. 58.49% ($p = 0.810$). There was no difference in the decline in FVC predicted per year between the MSA/MAA group and the antibody negative group; -2.09% vs. -2.24% ($p = 0.965$). There was also no difference in the decline in DLCO per year either; -5.65% vs. -6.24% ($p = 0.866$). There was no difference in all-cause mortality with 5 deaths in the MSA/MAA group and 7 in the antibody negative group ($p = 0.720$).
Conclusion: MSA/MAA antibodies do not alter disease trajectory in terms of lung function or all-cause mortality in IPF. Larger longitudinal studies are needed to determine if MSA/MAA antibodies in IPF are prognostically important or merely epiphenomena.

Assessment of myositis specific/associated autoantibodies during the COVID-19 pandemic and post pandemic period. The experience of a tertiary care hospital

Anastasia Bletsa[1], Stella Pomoni[1], Kleio Ampelakiotou[1], Elisavet Kontou[1], Nikolaos Athanasiou[1], Antonios Georgountzos[1], Konstantinos Soufleros[1], Konstantinos Kotsifas[1], Georgios Katsikas[1], Alexandra Tsirogianni[1]
[1]*Evangelismos General Hospital, Athens, Greece*

Background and aims: Inflammatory myopathies are an important complication associated withSARS-CoV-2 infection or vaccination. Recognition of this phenomenon led to an increase in the rate at which testing for Myositis-specific/associated autoantibodies (MSAs/MAAs) was requested by clinicians during the pandemic, with simultaneous rise in positivity against specific antigenic targets. The aim of this study is the registration, analysis and assessment of therequested tests for MSAs/MAAs, in a cohort of patients with suspected myopathy, during the pandemic period until nowadays (2020-2023), compared to the pre-COVID period (2018-2019).
Methods: 432 serum samples (group I, period 2018-2019) and 1068 serum samples (group II, period 2020-2023) were analyzed for MSAs/MAAs during the diagnostic work-up for Idiopathic Inflammatory Myopathy (IIM). The Immunoblotting Assay (IB-Euroimmun panel) was used to determine the MSAs/MAAs specificity (anti-PL-7, PL12, EJ, OJ, Mi-2, SRP, PM/Scl, Ku, TIF1g, MDA5, NXP2, SAE1, Ro52).
Results: A gradual increase in requested parameters was observedin the 3-year period following the pandemic compared to the pre-pandemic group, while the highest number of requested specific antibodies was recorded within the last year. Positive samples were recorded at a rate of 3.6% and 2.8% for the years 2018 and 2019, respectively, while the positivity for the years 2020, 2021, 2022 was recorded at 5.5%, 8.8%, and 9.2%, respectively. Especially for the post COVID year (2023) both, samples for investigation and their positivity (8.9%), have been kept steadily increased. Anti-Jo1 and anti-Ro52 were the most predominantly detected antibodies, while significant diversity was observed in terms of antibody specificity against the other various antigenic targets.
Conclusions: Our study demonstrated a gradually increasing frequency of requests for MSAs/MAAs testing during the pandemic and post-pandemic period, as well as a substantial rise in their positivity rates. This might be related to increased clinician vigilance towards the importance of detecting these autoantibodies. In any case, further investigation into the possible interlink between COVID-19 infection or vaccination and the development of IIM, is warranted.

STAT3 haploinsufficiency induces an increase in IgE+ B cell development

Virginia Andreani[1], Nils Ott[1], Bodo Grimbacher[1]
[1]*Institute for Immunodeficiency, Center for Chronic Immunodeficiencies, University Hospital Freiburg, Freiburg, Germany*

Autosomal dominant hyper IgE syndrome (AD-HIES) is a primary immunodeficiency caused by heterozygous mutations in the signal transducer and activator of transcription 3 (STAT3). Patients with AD-HIES are characterized by recurrent bacterial and fungal infections and high levels of IgE in serum, however the cause of increased IgE serum levels is not known. We created a mouse model of *Stat3* heterozygosity ($Stat3^{+/-}$) to study the humoral immune response and plasma cell development, considering that some mutations in STAT3 could have a haploinsufficient effect and not a dominant negative as it has been described for most of the STAT3 mutations.
The STAT3 protein analysis in $Stat3^{+/-}$ mice showed 50% reduction compared to WT animals, confirming the heterozygosity expected on this mouse model. Flow cytometry analysis showed that the $Stat3^{+/-}$ mice have a normal lymphocyte and myeloid development. The analysis of the serum immunoglobulin levels showed no differences in IgM, IgG1, IgG2b, IgG2c, IgG3 and IgA between WT and $Stat3^{+/-}$ mice. Interestingly, IgE levels were significantly enhanced in $Stat3^{+/-}$ mice compared to their WT counterparts, resembling the phenotype of AD-HIES patients.
To evaluate the role of STAT3 haploinsufficiency in the humoral immune response, we immunized mice with the T cell-dependent antigen NP-KLH, and 7 days later we detected an increase in the NP-specific IgE serum levels of $Stat3^{+/-}$ mice, while there was a reduction in the NP-specific IgM and IgG1 serum levels of $Stat3^{+/-}$ compared to $Stat3^{WT}$ mice. Moreover, Germinal Center IgE+ cells were significantly increased in $Stat3^{+/-}$ mice compared to their WT counterparts. Similar results were observed when the animals were immunized with the T cell-independent antigen NP-LPS.
Finally, naive B cells from $Stat3^{+/-}$ mice cultured with anti-CD40 and IL-4, in the absence of IL-21, showed a significant differentiation towards IgE+ plasma cells, in comparison to $Stat3^{WT}$ cells, with enhanced IgE levels in the supernatant of $Stat3^{+/-}$ cultures, supporting the role of IL-21 as a negative regulator of IgE+ plasma cells.
Together, these data highlights the relevance of STAT3 haploinsufficiency in humoral immunity and open new insights in understanding the role of STAT3 in IgE plasma cell differentiation.

Sex Differences Influence Circadian and Circannual Variation in Circulating Alpha-1 Antitrypsin

Emma Leacy[1], Daniel Fraughen[1;2], Mark Murphy[1], Michelle Casey[1;2], Ronan C Heeney[3], Tomás Carroll[1;3], Annie M Curtis[1], Noel G McElvaney[1;2]
[1]Royal College of Surgeons in Ireland, Dublin, Ireland; *[2]Beaumont Hospital, Dublin, Ireland*; *[3]Alpha-1 Foundation Ireland, Dublin, Ireland*

Purpose: Alpha-1 antitrypsin (AAT) is an acute phase protein with a broad range of anti-inflammatory and anti-protease functions. AAT deficiency (AATD) is a genetic condition which causes emphysema and liver complications. Daily (circadian) and seasonal (circannual) differences, and sexual dimorphism in circulating AAT levels have been reported in healthy populations. The aim of this project was to investigate circannual and sex differences in circulating AAT in an Irish cohort with AATD and healthy controls.
Methods: The national Targeted Detection Programme (TDP) is the diagnostic and screening body for AATD in Ireland. We analysed 20 years of TDP data, measuring AAT levels and diagnosing AATD by phenotype (or genotype). Data were segregated by date of test, and also by sex and age. Statistical analysis was carried out using GraphPad Prism.
Results: 19,437 complete, anonymised data entries were exported from the TDP. Of these, 11,655 were healthy (MM), 4,364 had a moderate deficiency (MZ), and 350 had a severe AAT deficiency (ZZ). Healthy MM individuals showed seasonal variations in AAT levels, with a nadir in autumn. This pattern persisted in moderately deficient MZ patients between March and September, but was lost in severe AATD (ZZ). This pattern of seasonal and circadian variation was only evident in MM males (n=5,800), with MM females (n=5,855) consistently maintaining significantly higher AAT levels year-round (median 1.46g/L vs 1.42g/L, $p<0.0001$). We also noted a discordant pattern of AAT variation between the sexes, which broadly mapped to the onset of puberty (ages 10-15) before converging upon menopause (ages 45-50), suggesting that variation in circulating AAT may correlate with oestrogen.
Conclusion: Despite consistently higher AAT levels in healthy females throughout life, healthy males showed greater circadian and circannual variation in circulating AAT levels. How these variations are linked to sex hormones and inflammatory cytokines is currently under investigation.

Mild phenotype of PSTPIP1-associated myeloid-related proteinaemia inflammatory (PAMI) syndrome: case report. A challenging diagnosis

Marina Fernandez-Gonzalez[1], Carlos Sánchez Rodríguez[1], Rosana Gonzalez-Lopez[1], Maria Jose Alegria-Marcos[1], Ana Menasalvas[1], Gema Salgado Cecilia[1], Manuel Muro Amador[1], Ana Galera[1], Olga Montes-Ares[1]
[1]*Clinical University Hospital Virgen de la Arrixaca, Murcia, Spain*

Case presentation: A two-year-old girl was referred to the immunology department for immunodeficiency suspicion due to persistent neutropenia, anaemia, growth failure, lymphocytosis and recurrent cervical abscesses. Several tests had been previously carried out without any pathological results (oxidative burst assay, MPO expression, leuko-lymphocytic inmunophenotype, anti-neutrophil antibodies). Further humoral and cellular immunity studies did not show any relevant alterations, apart from the already detected neutropenia. Next-generation sequencing was performed using a panel comprising 549 immune system disease-causing genes. The genetic analysis revealed a heterozygous autosomal dominant pathogenic variant (c.748G>A, p.Glu250Lys) in exon 11 of *PSTPIP1* (NM_003978.4, NP_003969.2), previously described in individuals with PAMI syndrome. Eventually, serum zinc and calprotectin concentrations were quantified and both were highly increased, as well as the inflammatory markers LDH and CRP, data consistent with the diagnosis of PAMI syndrome.
PAMI syndrome is a rare autoinflammatory disorder caused by specific mutations (E250K or E275K) in *PSTPIP1* gene, which is involved in T-cell and phagocyte activation, cell migration, and pro-inflammatory cytokine production, among other biological functions. Clinically, the disease is mainly characterised by the presence of anaemia, neutropenia, cutaneous and osteoarticular manifestations, hepatosplenomegaly, failure to thrive, lymphadenopathy and chronic systemic inflammation. However, the phenotype can vary from mild presentations to severe cases. Our patient has not manifested any osteoarticular symptoms, skin lesions or hepatosplenomegaly so far. Regarding laboratory parameters, high serum levels of zinc and calprotectin (MRP8/14 or S100A8/A9) are the distinctive traits to differentiate PAMI syndrome from other *PSTPIP1*-**associated inflammatory diseases (PAID).**
Conclusion: This case provides an example of the difficulties that clinicians have to face when diagnosing PAMI syndrome, given its rarity and wide spectrum of clinical phenotypes. It also highlights the importance of considering this disorder in patients with undefined systemic inflammation and neutropenia, as well as emphasises the role of genetic screening and zinc and calprotectin serum concentrations. Segregation study is currently being carried out.

Clues for diagnosis of hidden primary immunodeficiencies in B-cell lymproprolipherative diseases: a logistic regression approach

Maria Palacios Ortega[1], Adolfo Jimenez Huete[2], Teresa Guerra Galan[1], Alejandro Peixoto-Rodriguez[1], Alejandro Pereiro-Rodriguez[1], Maria Dolores Mansilla Ruiz[1], Angela Villegas Mendiola[1], Kauzar Mohamed Mohamed[1], Marc Perez-Guzman[1], Victor Sánchez Ciprian[1], Alejandra Carrero García[1], María Guzmán Fulgencio[1], Juliana Ochoa Grullon[1], Miguel Fernandez Arquero[1], Silvia Sanchez Ramon[1]
[1]*Hospital Clínico San Carlos, Madrid, Spain*; [2]*Clínica Universidad de Navarra, Madrid, Spain*

Purpose: The distinction between primary (PID) and secondary (SID) immunodeficiencies, particularly in the setting of late-onset PIDs and their relationship to hematological B-cell lymphoproliferative disorders (B-CLPD), is increasing blurred. In this work, we aimed to analyze and define the clinical and laboratory variables of SID to B-CLPD patients, identifying overlaps with late onset PIDs, which could potentially improve diagnostic precision and prognostic assessment.
Methods: We studied 40 clinical and laboratory variables in 151 SID to B-CLPD patients. These were classified as "possible PID" when the sum of serum free light chain (sFLC) kappa and lambda concentration was below 20mg/L. Bivariant statistical analysis and *rpart* method were performed to obtain a tree decision model containing the most discriminative variables.
Results: Significant statistical differences were found in 17 out of 40 variables analyzed, including 5 clinical and 12 laboratory biomarkers. Suspected PID patients showed higher frequencies of childhood recurrent and severe infections, as well as recurrent respiratory infections preceding B-CLPD diagnosis, a family history of B-CLPD and better remission rates than non-suspected PIDs. Laboratory findings showed significantly lower sFLC, immunoglobulin concentrations, as well as lower total leukocyte, B-cell and NK-cell counts at baseline. The *rpart* model developed a decision tree with 3 major variables (childhood infections, recurrent respiratory infections prior to B-CLPD diagnosis, and sFLC sum), creating a possible diagnostic route that could allow clinicians to classify B-CLPD patients into suspected SIDs or PIDs, with high sensitivity (98%) (95%CI (0.9348, 1.0000)), specificity (87%) (95%CI (0.6571, 0.9783)) and accuracy (95%) (95% CI (0.8874, 0.9868). Surprisingly, this tree-decision model classified as possible PID 75% of the 151 B-CLPD patients.
Conclusion: Significant clinical and immunological variables could aid in the difficult task of identifying late-onset PIDs among SID to B-CLPD, emphasizing the clinical utility of a comprehensive immunological history and work-up. While "possible PID" seem to have a higher grade of hematological remission, yet suffer more frequent and severe infections, and different tumor behavior, raising the importance of early, tailored diagnostic and treatment strategies for personalized patient management and follow up.

Inhibiting autoreactive CD8+ T-cells in Type 1 Diabetes using blocking anti-CD8β antibody to inhibit pancreatic β-cell islet destruction

Hamzah Aldali[1;2], Amy Ward[1], David J Morgan[1], Ian Cadby[3], Lindsay Nicholson[2], James Pearson[3], Linda Wooldridge[3]
[1]Bristol University, Bristol, United Kingdom; *[2]School of Cellular Molecular Medicine, University of Bristol, Bristol, United Kingdom*; *[3]Bristol veterinary School, University of Bristol, Bristol, United Kingdom*

Purpose: Type 1 diabetes (T1D) is an autoimmune disease, which induces selective pancreatic β-cell destruction in the pancreas. Insulin injections are provided to patients to control blood sugar levels. However, the underlying immune mediated damage remains untreated. We aim to develop an approach to block autoreactive CD8 dependant T-cells, using the YTS 156.7.7 monoclonal anti-murine CD8β antibody to inhibit β-cell destruction.
Methods: Initially, we generated F(ab)2 fragments to remove the depletion effect *in vivo*. The F(ab)2 fragments were tested using both an *in vitro* and *in vivo* proliferation assay, to measure the impact on NY8.3 autoimmune T-cell proliferation. In addition, Balb/c mice were injected with either whole YTS156.7.7 antibody or F(ab)2 fragments of YTS156.7.7 to examine the level of CD8 depletion mediated *in vivo*. The biological half-life of F(ab)2 fragments was measured using blood samples taken over 48 hours.
Results: Whole YTS156.7.7 was shown to deplete the CD8 population *in vivo*, whereas F(ab)2 fragments did not mediate depletion. We also demonstrated the ability of F(ab)2 fragments to block autoreactive CD8 T-cell proliferation both *in vitro* and *in vivo*, and measured the serum half-life of the F(ab)2 fragment (30.1 hours) in Balb/c mice. In addition, we have showed that there is no significant difference between the blockade mediated by the whole YTS156.7.7 antibody compared to the F(ab)2 fragments in inhibiting IFNγ release in an ELISA assay. The blockade of T-cell activation of primed CL4, high affinity, and primed NY8.3, autoreactive T-cells, was only observed at lower pulsed P815 concentration, 10ng to 1pg. However, unprimed NY8.3 T-cells were blocked at the highest peptide concentration.
Conclusion: The use of blocking anti-CD8β F(ab)2 fragments eliminated the *in vivo* depletion of CD8 T-cells mediated by the whole antibody. Also, it was found that the use anti-CD8β YTS156.7.7 F(ab)2 fragments is a promising approach to inhibit the release of IFNγ by diabetogenic NY8.3 T-cell and to inhibit their proliferation *in vivo* within polyclonal NOD mice.

Defects in T cell distribution and function in WHIM Syndrome patients

Clémentine Moulin[1], Pierre-Edouard Debureaux[1], Jean Donadieu[2], Marion Espéli[1], Karl Balabanian[1]
[1]*Université Paris-Cité, INSERM U1160, Institut de Recherche Saint-Louis, Paris, France*; [2]*Centre de référence des neutropénies chroniques, Registre des neutropénies chroniques, APHP, Hôpital Trousseau, Paris, France*

Introduction: The WHIM Syndrome (WS) is a rare inherited immunodeficiency caused by a gain-of-function mutation in the *CXCR4* gene. The patients suffer from human papillomavirus-induced warts, hypogammaglobulinemia, recurrent infections, myelokathexis, and severe B and T cell lymphopenia. Due to the rarity of the disease, the immune responses remain poorly characterized in WS patients. However, some studies were suggestive of inefficient adaptive immune responses and these patients have a heightened risk of developing cancer.
Objective: To understand how CXCR4 gain of function may impact immune responses we aimed to assess both the distribution and function of T cells in French WS patients.
Methods: Immune populations were analysed using a 40-color spectral flow cytometry panel from frozen peripheral blood mononuclear cells (PBMCs) of four WS patients and healthy donors (HD). One patient was studied before and after one year of treatment with a CXCR4 antagonist. CellTrace Yellow staining of PBMCs was performed to determine the proliferation after 3 days of stimulation with anti-CD3/anti-CD28 antibodies. PBMCs were stimulated *in vitro* with PMA/Ionomycin for 6 hours to evaluate TNFα, INF-γ and IL-2 release by intracellular staining.
Results: Our results reveal abnormal T-cell distribution in WS patients with an increased CD4/CD8 ratio, a decrease in naive T cells and $CD31^+$ recent thymic emigrants mirrored by an increase in effector memory cells. These defects were normalized upon treatment with a CXCR4 antagonist. Furthermore, we report an increased expression of the activation marker CD25 on CD4 T cells and the exhaustion markers CD95 and KLRG-1 on CD4 and CD8 T cells. At the functional level, WS T cells exhibited a decreased proliferation and an enhanced capacity to secrete IFN-γ, TNF-α and IL-2 upon stimulation. This increased cytokine release seems to be normalized after one year of treatment with a CXCR4 antagonist.
Conclusion: Both phenotypic and functional T cell defects were observed in WS patients, potentially contributing to the inefficiency of immune responses to infections and vaccines.

The different faces of inborn errors of immunity with case examples

Nesrin Gulez[1], Ferah Genel[1], Figen Celebi Celik[1], Ozgen Soyoz[2], Berna Uzunoglu[1], Necmi Can Yuksel[1], Emre Firat[1]
[1]Health Science of University Dr. Behcet Uz Children Education and Research Hospital Pediatric Immunology and Allergy, Izmir, Turkey; *[2]Izmir Bakırcay University Cigli Education and Research Hospital, Izmir, Turkey*

Purpose: Inborne errors of immunity (IEIs) are generally considered rare monogenic disorders of the immune system. Immune dysregulation (autoimmunity, autoinflammation, lymphoproliferation, and malignancy) and immunodeficiency (susceptibility to infection) represent two sides of the same coin and are not mutually exclusive. Based on this information, we aimed to present the different faces of IEIs with case examples.
Case 1: A 12-year-old boy presented with complaints of recurrent otitis media, neutropenia, and lymphopenia when he was 2 years old. Severe neutropenia, CD4+ T cell, CD19+ B cell lymphopenia and hypogammaglobulinemia were determined. Whole exome sequencing (WES) was performed and a missense mutation was identified in the MSN gene on the X chromosome.
Case 2: A 7-year-old girl presented with fever, dehydration and vaginal ulcers at the age of 13 months. He was diagnosed with T-B+NK+ combined immunodeficiency, severe inflammatory bowel disease (IBD), and arthritis. Homozygous mutation in CORO1A and NLRP6 genes and heterozygous mutation in NLRP 3 gene were determined by WES.
Case 3: A 16-year-old male patient, who had been followed up with the diagnosis of chronic ITP since the age of 2.5, was admitted due to recurrent fever, diarrhea and recurrent aphthous stomatitis when he 7 years old. Chronic thrombocytopenia, autoimmune thyroiditis, B cell lymphopenia, autoinflammation and hypoglobulinemia were determined. WDR1 homozygous mutation was detected by WES.
Case 4: A 16-month-old male patient was admitted on the 14th postnatal day. During the examination, widespread eczematous lesions on the skin, mucositis in the mouth, and flatness at the root of the nose were observed. Thrombocytopenia, eosinophilia, sepsis, cow's milk protein allergy, D. Coombs positivity, proportionally low CD3 and CD4 T cells were determined. ARPC1B mutation was detected in molecular testing.
Conclusion: In this article, we wanted to show the different faces of IEIs that occur with different clinical and laboratory results, such as bone marrow failure, autoinflammation, inflammatory bowel disease and autoimmunity. On this occasion, we would like to emphasize that the path to the diagnosis of IEI is primarily through awareness and looking at the patient from a holistic perspective.

LOGISTIC REGRESSION FOR THE STUDY OF COMMON VARIABLE IMMUNODEFICIENCY BIOMARKERS

Teresa Guerra Galan[1], Maria Palacios Ortega[1], Adolfo Jimenez Huete[2], Kissy Guevara-Hoyer[1], Angela Villegas Mendiola[1], Maria Dolores Mansilla Ruiz[1], Nabil Subhi-Issa[1], Antonia Rodríguez de la Peña[1], María Guzmán-Fulgencio[1], Miguel Fernandez Arquero[1], Rebeca Perez de Diego[3], Silvia Sanchez Ramon[1]
[1]Hospital Clínico San Carlos, Madrid, Spain; *[2]Clínica Universitaria de Navarra, Madrid, Spain*; *[3]Instituto de Investigación Hospital Universitario La Paz (IdiPAZ), Madrid, Spain*

Purpose: Early diagnosis of common variable immunodeficiency (CVID) remains challenging despite advancements in genetic and functional studies. Laboratory findings play a critical role but can sometimes contribute to diagnostic inaccuracies, without any markers that are pathognomonic of the disease. The aim of this study was to overcome the complexities associated with the diagnosis by evaluating the individual and combined performances of various biomarkers in accurately identifying CVID using logistic regression models.
Methods: We evaluated retrospectively 88 patients from Immunology Service of Hospital Clínico San Carlos (Madrid): 27 CVID patients, 23 selective IgA deficiency (SIgAD) patients, and 20 patients with secondary immunodeficiency (SID) due to active haematological malignancy (chronic lymphocytic leukemia (CLL) or multiple myeloma (MM)). We also studied 18 healthy controls. Routine clinical and analytical data (immunoglobulin levels, B-cell and T-cell levels and B-cell subpopulations, and specific antibody responses) were collected. We evaluated soluble BCMA (sBCMA) levels and serum free light chains (sFLC, κ and λ) in our patients' cohort. We also performed different statistics analysis including a series of logistic regression models.
Results: At first, we found that sBCMA levels and the sum κ+λ were significantly lower in CVID patients, which validates previous studies. Indeed, these biomarkers showed high sensitivity (Se) and specificity in our cohort (Se 88.89% Sp 86.96%; Se 88.00% Sp 100% respectively). We also evaluated associations between the different CVID-related biomarkers (switched-memory B cells (smB), sFLCs, sBCMA and VISUAL score). We found that the sum κ+λ was positively correlated with sBCMA levels but not with other biomarkers such as smB. As a final step, we confronted all the studied biomarkers in our patients' cohort to develop the best-fit algorithm for CVID diagnosis. The decision tree model was the most consistent and robust, with specific antibody responses and the sum κ+λ being the best diagnostic biomarkers.
Conclusion: Our exploratory study suggests that combining the measurement of specific antibody responses with the sum κ+λ may improve the early diagnosis of CVID and consequently lead to a decrease in disease morbidity and mortality.

Biomarkers in patients with haematological malignancy in response to polyclonal gammaglobulin replacement therapy

Alejandro Peixoto Rodríguez[1;2], Elsa Mayol Hornero[1], Juliana Ochoa Grullon[1], Angela Villegas Mendiola[1], Maria Palacios Ortega[1], Maria Dolores Mansilla Ruiz[1], Carlos Jimènez García[1], Miguel Fernandez Arquero[1], Silvia Sanchez Ramon[1]
[1]Hospital Clínico San Carlos, Madrd, Spain; *[2]CEU San Pablo University, Madrid, Spain*

Patients affected with B-proliferative syndromes (BPS), specifically multiple myeloma (MM) and chronic lymphocytic leukaemia (CLL), typically have a deficit in antibody production that makes them susceptible to recurrent or severe infections, and immunoglobulin replacement therapy (IGRT) is indicated.
To date, there are no studies on the use of GnRTIs on the progression of BPS or biomarkers for monitoring secondary immunodeficiency (SID).
It has been shown that TRIg is able to reprogram macrophages towards a more pro-inflammatory state, which could slow down infectious and recurrent processes. We currently have a total of 16 patients, separated into three groups, four patients with CLL, eleven patients with non-Hodking's lymphoma (NHL) and one patient with monoclonal gammopathy of uncertain significance (MGUS). The experimental development will consist of four analytical processes for each patient, first at the start of treatment, then after seven days, then after six months and finally after one year.
Preliminary results in 16 patients showed a significant increase in the population of M-MDSCs after TRIg infusion at six hours (13.37±13.17 vs. 26.62±16.52; p= 0.008). Moreover, in 3 of them this increase was maintained at 7 days. A significant increase in classical monocytes (82.38±15.04 vs 86.03±18.81; p=0.049) and a significant decrease in intermediate monocytes (13.60±10.63 vs 8.07±14.08; p=0.008 and non-classical monocytes (4.53±2.46 vs 1.79±2.72; p=0.001) was also observed.

Flow cytometry-based protocols for the assessment of B lymphocyte activation after CpG stimulation: a diagnostic approach for primary immunodeficiencies

Andreja Natasa Kopitar[1], Larisa Janzic[1], Lucija Levstek[1], Ana Kern[1], Alojz Ihan[1]
[1]*Institute of Microbiology and Immunology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia*

More than half of primary immunodeficiencies are associated with impaired antibody production, although the disease mechanisms are still largely unknown. The first signs usually appear in childhood and early diagnosis is important to initiate appropriate treatment and prevent severe infections. Functional activation tests of B cells are important to assess the function of the humoral immune system in patients with primary immunodeficiency. Based on in vitro functional tests to determine proliferation potential, differentiation to plasmablasts and immunoglobulin secretion after stimulation of B cells with CpG, we can reliably assess the activation capacity of B cells. CpG activates the B lymphocytes in a T cell-independent pathway. Proliferation is determined by measuring the incorporation of fluorescently labeled EdU into the DNA of the dividing cells. The study included two distinct groups: 25 healthy volunteers and 6 adult patients diagnosed with common variable immunodeficiency (CVID). We have shown that the B cells of healthy individuals proliferate after stimulation, differentiate into plasmablasts and secrete immunoglobulins. However, in patients diagnosed with primary immunodeficiency, B cell proliferation, plasmablast differentiation and immunoglobulin secretion are reduced or absent. To introduce the in vitro functional test into routine practice, we determined the optimal conditions for stimulating B cells with CpG. We also determined the normal values for the proliferation of B cells, naive and memory B cells and plasmablasts in healthy individuals for adults and children.

Chediak-Higashi syndrome with associated hemophagocytic lymphohistiocytosis in 3-month-old male patient

Raquel Montaña[1], Iván Menéndez[1], Carmen Luz Avendaño[1], Gema Ramírez[1], Primitivo Buendía[1], Macarena Castillo[2], Tamara Arias[2], Ariana Fonseca[2], Soledad González[2], Rebeca Alonso[1]
[1]Central University Hospital of Asturias, immunology department, Oviedo, Spain; *[2]Central University Hospital of Asturias, hematology department, Oviedo, Spain*

Hemophagocytic lymphohistiocytosis (HLH) is a severe hyperinflammatory condition caused by a permanent proliferation and activation of lymphocytes and macrophages, resulting in the characteristic clinical symptoms of inflammation. In recent years, genetic defects affecting lymphocyte cytotoxicity have been identified as the main cause of primary HLH. One of these primary forms of HLH is Chediak-Higashi syndrome (CHS). This is a rare and severe immunodeficiency characterised by partial oculocutaneous albinism (OCA), recurrent infections, mild hemorrhage, neurological dysfunction and lymphoproliferative disorder. CHS is caused by mutations in the *LYST* gene, which codes for a lysosomal trafficking regulatory protein, leading to decreased cytotoxic activity and degranulation of NK lymphocytes. Within CHS, a more severe early-onset form (first months of life) and a late-onset attenuated form have been described.
We present a 3-month-old male patient admitted to the pediatric ICU of our hospital for persistent fever over 40ºC, splenomegaly and mild respiratory symptoms. Phenotypically, the patient had partial OCA. In laboratory tests, the patient presented pancytopenia (with severe neutropenia), hyperferritinemia, hypofibrinogenemia and hypergammaglobulinemia. In the peripheral blood smear, vacuolated neutrophils with large azurophilic granules were observed and in the bone marrow smear, purplish inclusions were observed in the lymphoid series, as well as evidence of hemophagocytosis. Functional studies showed an increase in activated CD8+ T cells and a decrease in cytotoxic activity of NK cells. These data were sufficient to diagnose HLH (according to the criteria of the HLH-2004 protocol), and taking into account the patient's OCA, the main diagnostic suspicion was Chediak-Higashi syndrome with associated HLH. Finally, the genetic study was performed, finding two pathogenic variants in the *LYST* gene. After confirming the diagnosis of CHS, the patient began the search for a hematopoietic progenitor donor, as transplantation is the only curative option for this disease.

Synovial histopathological stratification reveals a relationship between pathotypes and clinical presentation in osteoarthritis.

Nicolas Gaigeard[1], Anaïs Cardon[1], Claire Vinatier[1], Frédéric Blanchard[1], Denis Waast[1;2], Benoit Le Goff[1;3], Jerome Guicheux[1], Marie-Astrid Boutet[1;4]
[1]INSERM U1229 Regenerative Medicine and Skeleton, Nantes, France; *[2]Department of Orthopaedics, CHU Nantes, Nantes, France*; *[3]Department of Rheumatology, CHU Nantes, Nantes, France*; *[4]Centre for Experimental Medicine & Rheumatology, William Harvey Research Institute and Barts and The London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom*

Osteoarthritis (OA) is the most common joint disease worldwide, mostly affecting people aged 65 and more. It is characterized by cartilage degradation, formation of osteophytes and synovitis, causing pain and disability. There is currently no curative treatment available, and only symptomatic treatments exists. The mechanisms underlying OA development remain poorly understood, but synovitis has been shown to play a major role in the initiation and progression of the disease. The current gold standard Krenn scoring of synovial inflammation, based on intimal thickness, stromal cell density and lymphocyte infiltration do not reveal relevant association between synovitis score and clinical data. We recently identified three histological pathotypes based on the nature and distribution of synovial immune cells infiltration, namely pauci-immune (PI), diffuse-myeloid (DM), and lympho-myeloid (LM). Here, we aim to study how pathotypes relate to clinical and radiographic changes in OA, and reveal their specific transcriptomic signature.
Synovial tissue, tibial plateau cartilage and infrapatellar Hoffa's tissue (fat pad) from 94 OA patients (8 PI, 43 DM and 43 LM) were collected at the time of joint replacement together with clinical data, and a subset of 15 (3 PI, 6 DM and 6 LM) synovial tissues were analysed by bulk RNA-sequencing. Synovial pathotypes were determined by immunohistochemistry, fat pad inflammation was characterized using a relevant score set up by our group following H&E staining, and cartilage degradation was assessed using the OARSI score. Our results confirmed the non-redundancy between pathotypes categorization and the gold standard Krenn score. Moreover, 78% of the patients with LM pathotype presented important radiographic joint damage (Kellgren Lawrence score = 4), compared to only 60% of the DM and 57% of the PI synovium. In addition, synovial pathotypes differently associated with fat pad inflammation. However, at this stage of the disease, cartilages were highly degraded and OARSI scores did not correlate with synovial inflammation. Importantly, preliminary RNA-sequencing analysis revealed pathotype-specific transcriptomic signatures, paving the way for the development of personalized therapeutic strategies. Altogether, our results confirm the relevance of OA patient's stratification based on synovial pathotypes.

Discovering the T-Cell Receptor Repertoire in APECED Patients

Alexandra Elsakova[1], Jaanika Kärner[1], Kai Kisand[1]
[1]*University of Tartu, Tartu, Estonia*

Adaptive immune receptor repertoire sequencing has become a powerful tool in studying immune responses and their correlation with various health conditions. This study explores the T-cell receptor (TCR) repertoire within individuals diagnosed with polyendocrinopathy-candidiasis-ectodermal dystrophy (APECED) to investigate potential links with melanocytes and melanoma antigens. APECED patients seem to be protected against cancer, except for squamous cell carcinoma of the oral cavity and oesophagus, often linked to chronic candidiasis on mucosal surfaces. This protective mechanism is considered to arise from a diverse TCR repertoire targeting autoantigens.
The primary objective of this research is to evaluate the prevalence of melanocytes/melanoma-specific TCRs within the circulating T-cell populations of APECED patients. We aim to identify unique facets of the immune response specific to this autoimmune disorder by comparing these results with data from healthy individuals. Additionally, we seek to classify each melanocyte/melanoma-specific TCR according to T-cell functional subtypes to gain deeper insights into the roles of distinct T-cell populations in developing autoimmune processes.
To achieve these goals, eight T-cell subpopulations were isolated from each individual (ten patients and ten age-matched controls), and TCR beta-CDR3 deep sequencing was conducted, followed by the analysis of T-cell subpopulations for each melanocyte/melanoma-specific TCR. Since autoantigen-specific T-cells are scarce, we stimulated peripheral blood mononuclear cell (PBMCs) samples to increase the autoreactive population. Then, single cells were sorted and amplified for TCR alpha and beta sequencing, and repertoire overlap analysis was conducted among patients and various cell types, along with distributions of V or J genes, including clustering and PCA, etc.
This study aims to investigate potential therapeutic implications in the interplay between immune responses, autoimmune disorders, and melanoma. By deciphering the mechanisms underlying self-tolerance and immune surveillance against cancer, we aspire to identify novel targets for therapeutic intervention. Ultimately, the insights gained from this study could be used to develop personalised treatments for autoimmune diseases and melanoma, which could revolutionise current treatment approaches.

Immune Dysregulation, Hypopigmentation and Silvery Hair Syndromes, Single Centre Experience

Neslihan Karaca[1], Ilke Bas[1], Guzide Aksu[1], Necil Kutukculer[1]
[1]*Ege University Faculty of Medicine, Dept of Pediatrics, Izmir, Turkey*

Purpose: Chediak-Higashi syndrome (CHS) is a rare autosomal recessive disorder characterized by immune dysregulation, neurological dysfunction, hypopigmentation of the skin and hair, and a bleeding tendency. Other diseases with partial albinism and immunodeficiency are Griscelli syndrome (GS), Elejalde syndrome, and Hermansky-Pudlak syndrome (HPS). Associated immunological and neurological defects and a predilection for hemophagocytic lymphohistiocytosis (HLH) make them a distinctive entity in pediatric practice. Haematopoietic stem cell transplantation (HSCT), which is the treatment of the diseases, is known to improve clinical and hematological symptoms, but does not prevent progressive neurological deterioration or oculocutaneous albinism.
Methods: The follow-up files of six patients with CHS and GS who were admitted to Ege University Department of Paediatric Immunology between 2009 and 2023 were retrospectively analyzed.
Results: Two of the six patients were diagnosed with GS and four with CHS. The mean age at diagnosis was 34 months (2 months–167 months). One patient was presented with HLH, the presenting symptoms of the others were fever, rash, recurrent pulmonary infections, hair findings and gait disturbance. All patients had pigmentation disorder in the form of grey hair colour change. Three of the patients had retarded neuromotor development (NMG) stages. Four of them developed HLH during the follow-up. Four patients underwent HSCT. One patient died before HSCT and one after HSCT. One is in process of HSCT.
Conclusion: Early diagnosis and treatment of HLH, which is a remarkable cause of mortality in the disease, and HSCT from HLA-matched donors improve the prognosis in patients with Chediak-Higashi and Griscelli syndromes.

Will sarcoidosis help us understand granulomatous disease in Common Variable Immunodeficiency (CVID) patients?

Jessica Ceccato[1;2], Giulia Gualtiero[1;2], Maria Piazza[1;2], Samuela Carraro[1;2], Helena Buso[1;3], Sabrina Manni[1;2], Francesco Piazza[1;2], Gianpietro Carlo Semenzato[2], Livio Trentin[1], Marcello Rattazzi[1;3], Carlo Agostini[1;3], Riccardo Scarpa[1;3], Fabrizio Vianello[1;2], Francesco Cinetto[1;3]
[1]Univeristy of Padua, Department of Medicine, Padua, Italy; *[2]Veneto Institute of Molecular Medicine (VIMM), Padua, Italy*; *[3]Rare Diseases Referral Center, Internal Medicine 1, Ca' Foncello Hospital, Treviso, Italy*

Purpose: Granulomatous Lymphocytic Interstitial Lung Disease (GLILD) occurs in about 20% of CVID patients, with a negative prognostic impact. Disease induction and maintenance mechanisms are still unclear. GLILD shares histological and some clinical features with sarcoidosis, another rare multisystemic inflammatory disease of unknown etiology. Recent studies demonstrated the relevance of innate immunity in granulomas formation in sarcoidosis. Macrophages, in particular, were identified as microenvironmental influencers, with the mTOR pathway playing a key role in their polarization and activity. Little is known about the role of macrophages in GLILD, and *in-vitro* models are lacking. Thus, we sought to investigate similarities and differences between GLILD and sarcoidosis, starting from multinucleated giant cells (MGC) formation and mTOR activation and aiming to develop a 3D *in-vitro* model.
Methods: Monocytes from THP-1 cell line and from peripheral blood of sarcoidosis, CVID without GLILD, GLILD patients and healthy donors were stimulated 7 days with GM-CSF and 7 days with IL-4 to obtain MGC. Cells underwent immunofluorescence staining and images were analysed to evaluate the fusion index, MGC% and area. By Western Blot we evaluated P-S6/S6total as marker of mTOR pathway activation while CD301 due its involvement in IL-4-induced MGC formation. A 3D model was developed by human bone fragments decellularization and recellularization with macrophages. 3D digital reconstructions were performed by confocal microscopy.
Results: We obtained MGC from THP-1 and from primary macrophages of all sources. We found a statistically higher MGC% and fusion index in GLILD and sarcoidosis compared to the non-granulomatous controls; sarcoidosis MGC presented the smallest cell area. Healthy MGC showed a statistically higher CD301 expression and S6 phosphorylation compared to the non-treated macrophages. Experiments are ongoing with patients' macrophages. THP-1 and primary macrophages were also able to adhere on the bone-based 3D scaffold, paving the way for MGC studies in a 3D setting.
Conclusion: Macrophages from GLILD and sarcoidosis patients show a similar in vitro behavior, compared to heathy donors and CVID patients without GLILD. *In-vitro* models might help to unravel GLILD etiopathogenesis, being the 3D model a potential platform to design patient tailored therapies in such a rare disease.

Human IL12RB1 deficiency reveals essential roles of IL-12 and IL-23 in innate and adaptive immune responses

Alessio Mazzoni[1], Roberto Semeraro[1], Anna Vanni[1], Marta Baragli[1], Lorenzo Salvati[1], Boaz Palterer[2], Manuela Capone[1], Giulia Lamacchia[1], Benedetta Peruzzi[3], Sara Bencini[3], Roberto Caporale[3], Lucia Bartoli[1], Francesca Matani[1], Stefania Francalanci[1], Francesco Liotta[1], Lorenzo Cosmi[1], Paola Parronchi[1], Laura Maggi[1], Alberto Magi[1], Francesco Annunziato[1]
[1]University of Florence, Florence, Italy; *[2]Harvard Medical School, Boston, United States*; *[3]Careggi University Hospital, Florence, Italy*

Purpose: *IL12RB1* deficiency is the most frequent cause of Mendelian Susceptibility to Mycobacterial Diseases. We recently described the case of an adult patient with disseminated *M. xenopi* infection diagnosed with *IL12RB1* deficiency. Since IL-12Rβ1 is shared between IL-12 and IL-23 receptors, its deficiency impairs leukocytes' response to both cytokines. *IL12RB1* deficiency has already been studied at cellular level, however there is still paucity of data showing how it affects leukocytes' development and functionality at molecular level.
Methods: PBMNC from an *IL12RB1* deficient patient were studied by flow cytometry and single-cell RNA sequencing. Genome-wide DNA methylation on $CXC3^+$ $CD4^+$ and $CD8^+$ T cells was evaluated by sequencing.
Results: Leukocytes' development in the bone marrow showed no abnormalities. In the circulation, $CD4^+$ T cells displayed reduced absolute numbers and impaired IFN-γ production and CXCR3 expression. Additionally, we demonstrated by scRNAseq that the cluster of CXCR3+ CD4+ T cells with a TEMRA phenotype was functionally impaired in the *IL12RB1*-deficient patient, with significantly reduced expression of cytotoxic genes. A similar finding was observed also for $CD8^+$ T cells, which exhibited marked contraction of the memory cell cluster characterized by expression of cytotoxic genes. Gene set enrichment analysis showed downregulation of immune system-related pathways in both $IL12RB1^{-/-}$ CD4+ and CD8+ T cells. Genome-wide DNA methylation study performed on $CXCR3^+$ $CD4^+$ and $CD8^+$ T cells further demonstrated that *IL12RB1* deficiency affects the epigenome of T cells with type I effector functions. NK cells displayed reduced circulating absolute numbers and belonged to the classical $CD56^{dim}CD16^+$ subset. However, among these cells we did not observe expansion of the memory $NKG2C^+$ cluster, characterized by a distinct transcriptional signature, that has been described upon CMV infection. Since the patient is CMV^+, this finding demonstrates that IL-12 and/or IL-23 are fundamental for the development of adaptive-like NK cells *in vivo*. B cells were also reduced in the circulation and exhibited contraction of the memory cluster. Finally, monocytes demonstrated significant downregulation of gene signatures related to IFN signaling and antigen processing capability.
Conclusion: Collectively, these data demonstrate that IL-12Rβ1 deficiency significantly impairs the functionality of both innate and adaptive branches of immunity.

Obesity leads to reduced Vaccine Responses to SARS-CoV-2 in Male C57BL/6 Mice

Nora Geissler[1], Anna Schmid[1], Maria Orola-Taus[1], Erika Garner-Spitzer[1], Pia Gattinger[2], Rudolf Valenta[2], Irma Schabussova[1], Aleksandra Inic-Kanada[1], Ursula Wiedermann[1]
[1]Institute of Specific Prophylaxis and Tropical Medicine, Medical University of Vienna, Vienna, Austria; *[2]Institute of Pathophysiology and Allergy Research, Medical University of Vienna, Vienna, Austria*

Background: Obesity poses an increasing health problem worldwide. Obesity predisposes to a wide-range of diseases and is connected to immunological disorders. Previous studies indicate that obesity influences the immune response to certain vaccines and impairs their efficacy or longevity of protection. During the COVID-19 pandemic, obese individuals belonged to the high-risk group for severe diseases; the impact of the COVID-19 vaccination was less well investigated.
Methods: C57BL/6 mice were fed a high-fat or standard diet for 18 weeks. After ten weeks, mice were immunized intramuscularly: 1) twice with different doses of COVID-19 origin mRNA vaccine, 2) three times with 0,25µg against OMICRON XBB.1.5 in three-week intervals. After the last vaccination, spike-specific antibodies in sera and mucosae (bronchoalveolar lavage (BAL)), and the spike-stimulated cytokine response from spleen cells were measured. The distribution of the spike-specific lymphocytes in the spleen was investigated by flow cytometry.
Results: In the 0,25µg vaccination group against the original strain, we measured a significantly decreased level of spike-specific IgG in sera of obese compared to lean animals. Due to the fast mutation rate of the virus, further experiments were performed using mRNA vaccine against the Omicron XBB1.5. After three vaccinations, a downregulation of spike-specific antibody levels in sera and a significant reduction in the BAL was noted in obese compared to lean mice. Despite higher B cell levels, the percentage of spike-specific memory B cells in obese mice was reduced compared to lean animals. Splenocyte stimulation showed induced IL-2 levels in obese mice only. Additionally, obese vaccinated mice exhibited significantly higher levels of Tregs in the spleen.
Conclusion: In obese mice, three times vaccination of mRNA vaccine was necessary to induce a spike-specific antibody response comparable to lean mice. The spike-specific antibodies were significantly lower at the mucosal site, suggesting a higher vulnerability against infection in obese mice. Also, spike-specific memory B cells were reduced, showing that long-term protection might be impaired in obese animals. Finally, the finding that IL-2 in the obese mice was induced and that the Tregs population was increased compared to lean mice suggests a mechanism of immune impairment.

Clinical impact of a non-canonical splicing variant in NFKB1 gene

Alicia Jurado Orozco[1], Carmen Morales Garcia[1], Alba Exposito Bey[1], Jose Manuel Lucena Soto[1]
[1]*Hospital Universitario Virgen del Rocio, Sevilla, Spain*

Purpose: We report the case of a 25 years-old patient with common variable immunodeficiency (CVID) presenting recurring infections (influenza A and invasive neumucocical pneumonie) since last year with sinusitis, abscess, molluscum contagiosum, asthma splenomegaly, and severe periodontitis. The patient refered infectious episodes such as acute media otitis and suspicion of allergic reactions in childhood.
Methods: His blood tests had revealed agammaglobulinemia IgG2 <2 mg/dL (242-700), undetectable IgA and IgM < 10 mg/dL. The patient was qualified for immunoglobulin replacement therapy. There was no vaccine response, and the immunophenotype revealed lymphopenia T, B, and NK. The genetic analysis revealed an intron variant (c.2125-9 G>A) next to the splice region of *NFKB1* gene, outside the canonical splicing region. The genetic variant is in heterozygosis, not present in healthy controls and not described in association with NFKB1 haploinsufficiency. It has been classified as uncertain significance but Alamut algorithm indicates that it is very likely to alter splicing, giving rise to a new acceptor site in the intron 18 that that would affect the processing of exon 19.
Results: After analyzing the patient's mRNA to test for splicing alterations, a new splicing site produced an mRNA with the insertion of 7 nucleotides, resulting in a frameshift and a premature stop codon G709I*4.
It was performed mutational analysis of this variant in their progenitors and the brother; it was found also in the father who refered pharyngitis, oral aphthosis and candidiasis in childhood. As an adult, he suffers from recurrent pyorrhea. He showed decreased serum IgG1 298 mg/dL (382 -929) with <8% of switched memory B cells (CD27+IgD-) .
Conclusion: We identified an intron variant outside the canonical splicing region in the *NFKB1* gene leading to a new splicing site and a premature stop codon classified finally as pathogenic: the phenotype of both patients (father and son) showed the coexistence of both humoral immunodeficiency and recurrent infections.
Loss-of-function NFKB1 variants are the most common monogenic cause of CVID, a primary immunodeficiency, characterized by primary hypogammaglobulinemia and increased infections susceptibility.

Common variable immunodeficiency not associating recurrent infections

Vivian Lizeth Stewart DelCid[1], Ernesto Roldan Santiago[1], Eulalia Rodríguez Martín[1], Rafael Rodriguez Ramos[1], José Luis Veiga González[1], Ivan Garcia De La Torre[1], Daniel Albert Mendoza Bravo[1], Paula Batres Faba[1], Celia Ferrez Hernández[1], Elena Manterola Navarro[1], Rebeca Perez de Diego[2], Ana De Andres Martin[1]
[1]Hospital Universitario Ramon y Cajal, Madrid, Spain; *[2]Hospital Universitario La Paz, Madrid, Spain*

Introduction: Common variable immunodeficiency is the most common symptomatic primary immunodeficiency. It is a heterogeneous group of clinical manifestations due to dysregulation of the immune system, generating an increased risk of recurrent infections, autoimmunity and lymphoproliferative syndromes.
Results: We report the case of a 50-year-old patient with a history of recurrent sinusitis. He presented Hodgkin's lymphoma with nodular sclerosis at the age of 28 and diffuse large B cell non-Hodgkin lymphoma associated with Epstein Barr virus at the age of 46, treated with chemotherapy and local radiotherapy, achieving complete remission in both cases. Subsequently, he developed a relapse of diffuse large B-cell lymphoma at the age of 49, treated with chemotherapy and autologous transplantation. During first lymphoma diagnosis, the patient presented sustained IgG, IgA and IgM hypogammaglobulinemia, decreased immunoglobulin production in vitro, absence of response to vaccines and decreased memory B lymphocytes. In view of these data, common variable immunodeficiency was suspected and substitutive treatment with intravenous immunoglobulins was started. In addition, CD4/CD8 ratio was inverted with CD4+ T cell lymphocytopenia, requiring prophylactic antibiotics. CD132 (common gamma chain) expression of CD4-CD8 T lymphocytes, NK and B lymphocytes without alterations. Autoimmune thrombocytopenia was associated. The genetic study detected a heterozygous variant in TNFRSF13B gene (exon 4, c.542C>A), with pathogenicity prediction, associated with common variable immunodeficiency type 2, and a hemizygosis variant in IL2RG gene (exon 7, c.918C>A) of uncertain significance.
Conclusion: Common variable immunodeficiency associates greater risk of developing lymphoproliferative syndromes, probably being the clinical debut of the disease. Treatments for hematological diseases can mask an underlying primary immunodeficiency. In a young patient with a history of lymphoproliferative syndrome, it is important to perform a complete immunological study and follow up to distinguish a primary immunodeficiency from a secondary one. Acquiring special relevance the asymptomatic patients, the lack of typical symptoms as recurrent infections can lead to late diagnosis of the immunodeficiency.

Activated phosphoinositide 3-kinase delta syndrome type I in a patient with significant neurodevelopmental delay

Jorge Mannelli[1], Daniel García-Cuesta[1], María Sánchez-Códez[1], Estrella Peromingo-Matute[1], Francisco Mora-López[1], Raquel De la Varga-Martínez[1]
[1]*Hospital Universitario Puerta del Mar, Cádiz, Spain*

Purpose: The purpose of this abstract is to share an unexpected result that we encountered from an 8-year-old female patient while performing a Next Generation Sequencing (NGS) analysis, targeting genes associated with intellectual disability and hypotonia. The patient presented with proximal hypotonia of the shoulder girdle, recurrent febrile & afebrile seizures, intellectual disability and dysphagia. She first presented with failure to thrive, but ultimately achieved adequate weight and height. At 7 months old she was admitted for bronchiolitis, and later for splenomegaly due to an EBV infection. Since then, she has suffered recurrent respiratory infections that occasionally require antibiotics.
Methods: Blood analysis revealed leukocytosis (22,000/mcL, [normal values (NV): 4,800-12,000]) with a predominance of neutrophils (16,000/mcL, [NV: 1,700-8,000]) and a slight elevation of GGT (40U/L, [NV: 5-36]). A slight elevation of IgM (285 mg/dL, [NV: 47-240]) was detected, with IgG (1,128 mg/dL, [NV: 552-1,631]) and IgA (132 mg/dL, [NV: 21-282]) levels within normality. The autoimmunity study was negative and vaccine response was adequate. High-resolution chest CT of the lungs detected cylindrical and saccular bronchiectasis in the right lower lobe.
Exome targeting genes related to hypotonia and intellectual disability was requested.
Results: One heterozygous Single Nucleotide Variant was identified in the PIK3CD gene (NM_005026.5): c.3061G>A (p.Glu1021Lys), which was classified as pathogenic.
Conclusion: The PIK3CD gene encodes for the catalytic subunit p110δ of the phosphoinositide 3-kinase delta (PI3Kδ) enzyme. This protein is mostly present in leukocytes and participates in the metabolism, cellular growth, survival and apoptosis inhibition of T and B cells. Pathogenic gain-of-function mutations in PIK3CD result in the overactivation of PI3Kδ and are associated with Activated phosphoinositide 3-kinase delta syndrome (APDS) type I. APDS is a rare Inborn Error of Immunity (IEI), first described in 2013, with a variable clinical phenotype that is primarily characterized by increased susceptibility to recurring viral & bacterial infections (mainly sinopulmonary), as well as lymphoproliferation and autoimmunity. Our patient was presenting very striking neurological manifestations that drew the clinical suspicion away from IEI. As a result of the NGS, the mutation p.Glu1021Lys was found, allowing for the diagnosis of APDS type I.

Patients with common variable immunodeficiency should be vaccinated against viral infections - insight into cellular and antibody responses

Jitka Smetanova[1;2], Michal Rataj[3], Tomas Milota[3]
[1]Motol University Hospital, Prague; *[2]Second Faculty of Medicine, Prague, Czech Republic*; *[3]Motol University Hospital, Prague, Czech Republic*

Purpose: Patients with common variable immunodeficiency (CVID) have a defect in the B cells development leading to decreased production of IgA/IgG antibodies. This reduced/absent concentration is therefore associated with a wide range of clinical manifestations, such as infections and non-infectious complications. Infectious manifestations are effectively managed by immunoglobulin substitution. Although patients with CVID are further characterized by failure to produce specific antibodies after vaccination to protein and/or polysaccharide antigens, vaccination still represents a great benefit for them, such as the formation of memory T cells. Until 2020, mRNA vaccines were only used for research purposes and their immunogenicity was not known in patients with immune disorders who were not included in clinical trials monitoring the effectiveness and safety of vaccines against SARS-CoV-2. We focused on the persistence of antibody and cellular response after vaccination with mRNA (BNT162b - Pfizer, BioNTech) against SARS-CoV-2 and inactivated vaccine (Vaxigrip Tetra 2022/2023 – Sanofi Pasteur) and compared their effectiveness and safety.
Methods: Serum and full blood from 21 CVID patients and 23 age matched healthy controls (HC) was collected at 1, 3, and 6 months after the vaccine administration and used for the detection of SARS-CoV-2/H1N1 IgG antibodies by immunoblot/ELISA methods. The cellular response was detected by cytokine production after stimulation by specific peptides.
Results: 52.4% (n=11/21) of vaccinated patients developed IgG against S –protein (S-RBD) of SARS-CoV-2 and 46% (n=11/21) T cells immune response one month after vaccination. The S-RBD IgG concentration continuously decreased in patients compared to HC and finally, at month 6 after vaccination, only 33% (n = 5/15) of patients had a positive titer compared to 100% of HC. In addition, significantly fewer virus-neutralizing antibodies were detected in CVID patients. The cellular response of patients was comparable to HC. H1N1 IgG concentration and cellular response values in CVID patients will be presented at the congress.
Conclusion: The mRNA vaccine induced the formation of specific antibodies in a large percentage of patients. However, the concentrations of these antibodies declined more rapidly compared to HC.

The project has been supported by the grant number NU22-05-00402.

Clinical, immunological, and genetic features in patients with NF-κB1 and NF-κB2 defects

Nazanin Fathi[1], Matineh Nirouei[2], Zahra Salimian Rizi[3], Saba Fekrvand[3], Hassan Abolhassani[3,4], Fereshte Salami[3], Arsh Haj Mohamad Ebrahim Ketabforoush[5], Gholamreza Azizi[6], Amene Saghazadeh[3], Marzie Esmaeili[3], Amir Almasi-Hashiani[7], Nima Rezaei[3]
[1]Research Center for Immunodeficiencies, Pediatrics Center of Excellence, Children's Medical Center, Tehran University of Medical Sciences, Tehran, Iran; *[2]Alborz University of Medical Sciences, Karaj, Iran*; *[3]Tehran University of Medical Sciences, Tehran, Iran*; *[4]Department of Biosciences and Nutrition, Karolinska Institute, Stockholm, Iran*; *[5]Iran University of Medical Sciences, Tehran, Iran*; *[6]Department of Neurology, Thomas Jefferson University, Philadelphia, United States*; *[7]Department of Epidemiology, School of Health, Arak University of Medical Sciences, Arak, Iran*

Purpose: Inborn errors of immunity (IEIs) encompass various diseases with diverse clinical and immunological symptoms. Precisely characterizing each IEI entity is challenging, as manifestations can be heterogeneous even among patients with the same mutated gene. In this study, we conducted a systematic review of patients documented with NF-κB1 and NF-κB2 defects, two of the most prevalent monogenic IEIs worldwide.
Methods: The search for relevant literature was conducted in databases including Web of Science, PubMed, and Scopus. From these reports, demographic, clinical, immunological, and genetic data were extracted from cases with mutations in *NFKB1* and *NFKB2*.
Results: A total of 430 patients were included in the study, 290 had *NFKB1* mutations, and 140 had *NFKB2* mutations. NF-κB1 and NF-κB2 defects predominant cases (82.7% and 62.5% respectively) initially presented with a CVID-like phenotype. NF-κB1 defect patients often experienced hematologic autoimmune disorders, whereas NF-κB2 patients were more prone to other autoimmune diseases. Viral infections were significantly higher in NF-κB2 defect cases compared to NF-κB1 (P-value < 0.001). NF-κB2 defect patients exhibited a greater prevalence of ectodermal dysplasia and pituitary gland involvement than NF-κB1 patients. Most NF-κB1 and NFκB2 defect cases showed low CD19+ B cells, with NF-κB2 having more cases of this type and low memory B cells being more common in NF-κB1 patients. The identified mutations included H67R and N291Mfs*141 in NFKB1 and R853*, and A867V in NF-κB2, with missense mutations being predominant in NFKB1, and NFKB2 having more cases with nonsense mutations.
Conclusion: Patients with NF-κB2 mutations, particularly p52LOF/IκBδGOF, are at a higher risk of viral infections, pituitary gland involvement, and ectodermal dysplasia compared to those with NF-κB1 mutations. Genetic tests are essential for resolving the initial complexity and confusion surrounding the clinical and immunological features. Emphasizing the significance of functional assays in determining the probability of correlation between mutation and immunological and clinical characteristics of patients is crucial.

NAD+ as a potential biomarker for chronic lymphocytic leukemia and monoclonal gammopathy of undetermined significance patients with secondary immunodeficiency

Elsa Mayol Hornero[1], Kauzar Mohamed Mohamed[1], Maria Palacios Ortega[1], Angela Villegas Mendiola[1], Maria Dolores Mansilla Ruiz[1], Won Cheol Choi[2], Silvia Sanchez Ramon[1], Jaekyung Cecilia Song[2]
[1]*Hospital Clínico San Carlos, Madrid, Spain*; [2]*Luterion R&D Institute, Seoul, South Korea*

Purpose: Primary immunodeficiencies (PIDs) are genetic disorders affecting immune function, leading to heightened susceptibility to infections and diseases. Secondary immunodeficiencies (SIDs) arise from external factors, such as infections or hematological malignancies such as chronic lymphocytic leukemia (CLL) and multiple myeloma, an advanced stage of monoclonal gammopathy of undetermined significance (MGUS).
We hypothesize that the diminished responsiveness of immune cells to infections and tumors in individuals with immunodeficiencies (ID) could be associated with disruptions in mitochondrial function. Specifically, we postulate that alterations in the levels of the coenzyme nicotinamide adenine dinucleotide (NAD+), which is essential for mitochondrial health, might underlie the compromised state of the immune system. The aim of this study is to assess the NAD+ levels in PBMCs from patients with ID, including CVID, MGUS and CLL, in comparison to those from healthy controls (HC).
Methods: Blood samples were collected from 14 PID patients with CVID; 17 SID patients, including 12 CLL and 5 MGUS patients; and from 19 HC. PBMCs were isolated and NAD+ levels were quantified using a colorimetric assay. Additionally, mitochondrial respiration was studied by measuring the oxygen consumption rate in PBMCs from 3 CLL patients and compared with 3 HC.
Results: Interestingly, NAD+ levels in PBMCs from CVID patients were not significantly different from those in HC (mean values, 7.5 pmole/10^6 cells ±5.38 vs 6.98 pmole/10^6 cells ±2.42; p=0.5773), despite noticeable variability among the CVID patients. Conversely, patients with SID, specifically those diagnosed with CLL and MGUS, exhibited significantly reduced NAD+ levels than HC. CLL patients presented a mean NAD+ level of 3.35 pmole/10^6 cells ±1.46 (p=0.0001), and MGUS patients had a mean of 2.88 pmole/10^6 cells ±2.39 vs 6.98 pmole/10^6 cells ±2.42; (p=0.0028). Furthermore, the PBMCs from the three CLL patients examined displayed an altered mitochondrial bioenergetic profile compared to those from HC.
Conclusion: These data suggest that NAD+ levels could serve as a prognostic and mitochondrial function-related biomarker for diseases such as CLL and MGUS. Our preliminary findings advocate the need to increase our sample size and conduct further research, not only to establish this biomarker, but also to explore novel therapeutic agents.

Exploring SEC61A1 deficiency: a rare genetic cause of common variable immunodeficiency

Carmen Morales Garcia[1], Alba Exposito Bey[1], Alicia Jurado Orozco[1], Jose Manuel Lucena Soto[1]
[1]*Hospital Universitario Virgen del Rocío, Sevilla, Spain*

Background and Purpose: 53-year-old female patient with no history of consanguinity or recurrent infections during childhood. The patient presents to the emergency department with generalized pruritus and exacerbation of chronic urticaria, with no analytical data suggestive of allergy. In the past year, she had experienced SARS-CoV-2 infection followed by pneumonia, *H. pylori* gastritis, acute conjunctivitis lasting two months, and a new episode of bronchopneumonia, in addition to the urticarial lesions.
The immunological study revealed leukopenia, with slightly decreased levels of NK cells and normal levels of T and B cells, albeit with a moderate reversal of the CD4:CD8 ratio. B cell subpopulations showed markedly reduced levels of non-switched memory B cells and elevated levels of CD21low B cells. Additionally, severe hypogammaglobulinemia and absence of response to polysaccharide vaccines were observed. Abdominal ultrasound revealed mild splenomegaly.
Methods: Exome sequencing with targeted analysis of 464 genes associated with Inborn Errors of the Immune System was performed using the Twist CE2_v2 Kit with the NextSeq 500 sequencing system platform (Illumina). The SOPHiA DDM platform was used for bioinformatics analysis.
Results: One genetic variant present in heterozygosity in the SEC61A1 gene not previously described was identified: a deletion of 2 nucleotides (c.1294_1295del). The genetic variant is considered `Likely Pathogenic´ as it results a premature nonsense codon (p.Ser432Glyfs*4).
Conclusion: SEC61A1 Deficiency is an autosomal dominant (AD) disorder related to Common Variable Immunodeficiency (CVID) primarily characterized by plasmablast alteration. Pathogenic genetic variants within SEC61A1 are extremely rare and have been correlated with distinct pathologies. Initially, also under AD inheritance, it was linked to Tubulointerstitial Kidney Disease, subsequently extending to CVID. Moreover, it has also been associated with severe congenital neutropenia and with pustular psoriasis accompanied by hypogammaglobulinemia. The presence in our patient of recurrent infections, hypogammaglobulinemia, B cell abnormalities and the identification of the genetic variant in heterozygosis in the SEC61A1 gene not previously described lead us to the diagnostic of CVID caused by SEC61A1 Deficiency.

Neutrophil functions in patients with a rare disease: pulmonary alveolar proteinosis

Nurgul Naurzvai[1;2], Aysenur Kokoglu[1], Ferhad Kohansal Koshksaray[1], Ayshan Mammadova[3], Cagri Ulukan[1], Nurdan Kokturk[3], Nilgun Yilmaz Demirci[3], Caglar Cuhadaroglu[4], Haluk Turktas[5], Gunnur Deniz[1], Esin Cetin Aktas[1]
[1]Istanbul University Aziz Sancar Experimental Medicine Research Institute, Istanbul, Turkey; *[2]Acibadem Atakent University Hospital, Istanbul, Turkey*; *[3]Gazi University, Ankara, Turkey*; *[4]Acibadem Hospital Group, Istanbul*; *[5]Losante Hospital, Ankara, Turkey*

Purpose: Pulmonary alveolar proteinosis (PAP) represents a rare interstitial lung disease, occurring at a rate of 2-6 per 1.000,000 individuals. The increased mortality associated with infection in PAP patients is closely linked to the presence of autoantibodies against Granulocyte Macrophage-Colony Stimulating Factor (GM-CSF). Whole lung lavage (washing lung with 10-15 litre fluid), stands as the definitive treatment for this severe condition. GM-CSF treatment has shown beneficial for a subset of PAP patients. This study aims to analyse the immunophenotyping and functional analysis of neutrophils in individuals diagnosed with PAP.
Methods: Nine patients with PAP, and ten age- and gender-matched healthy control subjects were included in this study. Isolated neutrophils were stimulated with *Escherichia coli* for phagocytic activity, phorbol myristate acetate for oxidative burst and formyl methionyl-leucyl-phenylalanine for chemotactic activity and analysed by flow cytometry. Given the susceptibility to infections in PAP patients, the ratio of CD3+ T, CD3+CD4+ helper T, CD3+CD8+ cytotoxic T, CD3-CD19+ B and CD3-CD16+CD56+ NK cell ratios were determined using flow cytometry. Additionally, demographic data, biochemical parameters, and complete blood counts were examined.
Results: PAP patients exhibited no significant impairment in vital organ systems. The ratio of lymphocytes to neutrophils, and neutrophil levels did not significantly differ between PAP patients and healthy controls. Furthermore, neutrophil functions, including phagocytic activity, oxidative burst, and chemotactic activity, remained comparable between PAP patients and healthy subjects. These findings suggest that the fundamental functional capacity of neutrophils to combat pathogens and inflammation remains intact in PAP. Notably, percentages of cytotoxic and helper T cells, B cells, and NK cells did not differ significantly between the groups.
Conclusion: Contrary to existing literature indicating impaired anti-microbial functions of neutrophils in PAP patients, our study showed that neutrophil functions in PAP patients were within normal limits. In our study six symptomatic PAP patients had a history of GM-CSF treatment, while the remaining three of them had a non-symptomatic disease. This could have affected the neutrophil functions and might be the underlying reason for the indifference between groups.

The in vitro functional memory B cell response is intact in most patients with Common Variable Immunodeficiency Disorder

Sophie Steiner[1], Kirsten Wittke[1], Carmen Scheibenbogen[1;2], Leif Hanitsch[1;2]
[1]*Institute for Medical Immunology, Charité–Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt Universität zu Berlin, Berlin, Germany, Berlin, Germany*; [2]*Berlin Institute of Health at Charité - Universitätsmedizin Berlin, BIH Center for Regenerative Therapies (BCRT), Berlin, Germany, Berlin, Germany*

Purpose: Common Variable Immunodeficiency Disorder (CVID) is the most prevalent primary immunodeficiency characterized by defects in B cell maturation or differentiation. Patients suffer from decreased levels of class-switched (CS) memory B cells (MBC) and CS plasmablasts (PB) resulting in hypogammaglobulinemia, poor vaccine responses and inability to produce pathogen-specific antibodies. Therefore, patients are prone to more frequent and severe infections and need life-long Immunoglobulin replacement therapy. The underlying pathogenesis of impaired antibody secreting cell (ASC) differentiation is still poorly understood. Here, we aimed to characterize functional defects of MBC differentiation and to restore ASC generation *in vitro* in CVID patients.
Methods: We examined *in vitro* generation of IgG, IgA and IgM ASC from CVID patients (n=15) and healthy controls (HC, n=10) by stimulating PBMCs for 7 days with a T cell depended (TD) and T cell independent (TI) protocol. Functional MBC response was investigated using ELISpot technique in combination with flow cytometry B cell phenotyping. Quantity and quality of secreted antibodies were assessed by ELISA.
Results: Using our stimulation protocols we were able to drive differentiation of MBCs into class-switched (CS) PB as main source of ASC in all CVID patients, albeit with lower frequencies compared to HC. ELISpot analysis revealed IgG responses in 14/15 CVID patients upon TD stimulation comparable to HC, whereas significantly less patients (n=8) exhibited IgG responses following TI stimulation (p=0.0013). In terms of IgA secretion, both stimulation protocols elicited significantly less IgA secretion in 8/15 patients compared to HC (TI p=0.0286; TD: p=0.0002). All patients had the capability to generate IgM from IgM-only PB induced by TD stimulation and 12/15 from TI stimulation. *In vitro* generated CS PB of CVID patients were shown to secrete protective IgG antibodies against different antigens, including *Streptococcus pneumonia*. Autoantibodies targeting double-stranded DNA were not induced.
Conclusions: Our data indicate almost normal functionality of MBC and IgG/IgM ASC in the majority of patients examined, when subjected to adequate TD stimulatory signals. This opens up future opportunities for potential clinical translation of targeted and adoptive cell therapy in CVID.

The role of LFA-1 and regulatory T cells in skin inflammation

Maike Hartmann[1], Tanja Klaus[1], Alicia Wilson[2], Matthias Bros[1], Tobias Bopp[2], Stephan Grabbe[1]
[1]Department of Dermatology, University Medical Center, Mainz, Germany; *[2]Research Center for Immunotherapy and Institute of Immunology, University Medical Center, Mainz, Germany*

Purpose: Leukocyte-specifically expressed β2-integrins that are composed of a variable alpha (CD11a-d) and a constant beta (CD18) subunit are essential for cell-cell communication, the extravasation of leukocytes from blood into inflamed tissues, and cell signaling. Humans with reduced or defective β2-integrin expression develop Leukocyte Adhesion Deficiency Syndrome Type-1 (LAD-1). The most prominent clinical symptoms of LAD-1 are profound leukocytosis, high susceptibility to infections and the development of autoimmune diseases. Leukocyte function-associated antigen 1 (LFA-1) is the only β2-integrin family member expressed on T cells. We generated mice specifically lacking LFA-1 on regulatory T cells (Treg) ($CD18^{Foxp3}$) to investigate the cell-specific role of LFA-1 on Treg.
Methods: $CD18^{Foxp3}$ mice were sensitized and challenged topically with oxazolone to induce contact dermatitis responses. Ear and skin-draining lymph node single-cell suspensions were subjected to flow cytometry to assess their immunological phenotype. Enzyme-linked immunosorbent assay was performed to evaluate IgE, IgG1 and IgG2a levels in serum. Single-cell RNA sequencing of splenic Treg and gene enrichment analysis was performed to delineate the role of LFA-1 for the immunophenotype of Treg.
Results: We observed profound systemic T_H2 pathway-based autoinflammation in $CD18^{Foxp3}$ mice that correlated with age showing also massively elevated IgE, IgG1, IL4, eosinophilia and lung tissue damage in the steady state. Furthermore, $CD18^{Foxp3}$ mice developed aggregated T_H2-driven immune responses in a model of allergic contact hypersensitivity associated with an expansion of T_H2-promoting $IRF4^+$ $PDL2^+$ cDC2. Gene expression profiles of LFA-1-deficient Treg revealed elevated expression of T_H2-related receptors and transcriptionfactors (e.g. Gpr15, Klrg1, IL18R, IL33 and Gata3) associated with atopy and characteristic for tissue repair Treg.
Conclusion: Our results suggest that the dysregulated expression of genes associated with suppressive activity in β2-integrin-deficient Treg may cause systemic T_H2-polarization. This in turn may drive the manifestation of the T_H2-dominated phenotype of $CD18^{Foxp3}$ mice. We conclude that LFA-1 deficient Treg are not able to induce a tolerogenic state in DC and to counteract T_H2-driven allergic responses. Altogether, our study demonstrates an indispensable role of LFA-1 on Treg for maintaining immune homeostasis.

Expanding the clinical phenotype of TRAF3 haploinsufficiency syndrome

Blanca Angelica Urban Vargas[1], Laura Battle Masó[1], Marina García Prat[1], Alba Parra Martínez[1], Aina Aguiló Cucurull[1], Janire Perurena Prieto[1], Mónica Martínez Gallo[1], Laith Moushib[1], Maria Antolin Mate[1], Jacques G. Rivière[1], Pere Soler Palacin[1], Romina Dieli Crimi[1], Clara Franco Jarava[2], Roger Colobran[1]
[1]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [2]Hospital Universitario Joan XXIII, Tarragona, Spain

TRAF3 (TNF receptor-associated factor 3 protein) is one of the most diverse adaptor proteins of the TRAF family, with roles in various signaling pathways. Autosomal dominant TRAF3 deficiency had been associated to herpes simplex virus-1 encephalitis, and a recent study reported the TRAF3 haploinsufficiency (TRAF3Hl) as a condition including recurrent bacterial infections, autoimmunity, systemic inflammation, and hypergammaglobulinemia.
The purpose of this study was to conduct a genetic re-analysis of our cohort of patients with inborn errors of immunity (IEI), in whom Next-Generation Sequencing (NGS) was previously performed, to identify cases of TRAF3Hl and describe its impact on human immunity through the characterization of clinical and molecular features.
We performed a TRAF3 targeted re-analysis of NGS data from 800 patients with IEI from Hospital Vall d'Hebron (Catalonia, Spain). This involved comprehensive clinical and genetic characterization of identified patients, including familial studies to elucidate inheritance patterns and phenotype-genotype correlations. Additionally, western blot and flow cytometry immunophenotyping were performed to enhance the characterizations.
Three patients (P1, P2 and P3) from two different families with TRAF3Hl were identified in our cohort. Genetic analysis revealed stop-gain heterozygous TRAF3 variants that were de novo in one patient (P3) and inherited (P1) from her symptomatic mother (P2). All patients exhibited recurrent sinopulmonary infections, lymphoproliferation, various types of gastrointestinal complications, and had previously been diagnosed of common variable immunodeficiency (CVID). However, P2 also had clinical manifestations consistent with T-cell dysfunction. Immunological studies showed that all three patients had low absolute CD4+ counts with a low CD4+/CD8+ ratio, impaired B cell maturation, and a profound reduction of naive subpopulations in both, CD4+ and CD8+ T cells. P2 and P3 showed altered lymphoproliferative function, with P2 showing more severe impairment.
Our research highlights the significance of periodically reanalyzing genetic data, especially in response to novel phenotype descriptions. While our patients initially resembled CVID cases, we observed a wider spectrum of phenotypes, including combined immunodeficiency and immune dysregulation. These differences may reflect the phenotypic variability in TRAF3Hl. Our findings broaden the clinical phenotype associated with TRAF3Hl, potentially aiding in the identification of similar cases among patients previously diagnosed with CVID.

AD-HIES patients with impaired STAT3 signalling contain pre-Th17-cells that are activated by opportunistic pathogens to produce IL-10

Giorgia Moschetti[1], Chiara Vasco[1], Francesca Clemente[1], Sara Maioli[1], Elena Carelli[1], Lucia Baselli[2], Rosy Dellepiane[2], Maria Carrabba[2], Giovanna Fabio[2], Jens Geginat[1;3]
[1]INGM, Milan, Italy; *[2]Policlinico Ca Grande, Milan, Italy*; *[3]Università degli studi, DISCCO, Milan, Italy*

Background: STAT3 is critical for T-cell differentiation, and dominant-negative STAT3 mutations cause Autosomal Dominant-Hyper-IgE Syndrome (AD-HIES). AD-HIES patients lack IL-17-producing CCR6^{+}T-cells and present consequently recurrent infections with opportunistic bacteria and fungi.
Objective: We previously identified a population of IL-10 producing CCR6^{+}T-helper cells, and asked if they were STAT3-dependent and pre-committed to a Th17 fate (pre-Th17).
Methods: CCR6^{+}T-cell subsets from the blood of healthy donors and AD-HIES patients were analysed by multi-dimensional flow cytometry for phenotype, cytokine production, differentiation potential and responsiveness to pathogens.
Results: CCR6^{+}T-helper cells that lacked other differentiation markers (CCR6$^{\text{single-positive(SP)}}$), were central memory T-cells (T_{CM}) that expressed some RORγt, but produced only low levels of Th17 effector cytokines. Non-polarized CCR6^{SP}T-cells efficiently acquired IL-17 and IL-22 producing capacities upon TCR stimulation in the absence of polarizing cytokines. IL-12 induced in addition IFN-g and thus Th1/17 differentiation. CCR6^{SP}T-cells produced IL-10 upon TCR stimulation that activated STAT3 and promoted Th17 differentiation in an autocrine manner. In AD-HIES, CCR6^{+}T-cells were strongly and selectively reduced, but CCR6$^{SP}T_{CM}$ and Th1/17-cells were nevertheless present. Residual CCR6^{+}T-cells in AD-HIES were activated *in vivo* and produced increased amounts of IL-10. Moreover, they were activated by antigens derived from opportunistic pathogens to produce IL-10, but not IL-17. Upon stimulation with bacteria they produced also high levels of IL-2 and IFN-g.
Conclusions: Th17 differentiation in AD-HIES patients with impaired STAT3 signalling in response to pathogens is not completely blocked, but arrested at an intermediate stage of pre-Th17-cells, which produce IL-10 and could directly differentiate to Th1/17-cells.

Heterozygous SERPINA1 defects and their impact on clinical manifestations of patients with predominantly antibody deficiencies

Styliani Sarrou[1], Ioanna Voulgaridi[2], Athanasia Fousika[1], Katerina Dadouli[2], Olympia Margaritopoulou[1], Ioannis Kakkas[3], Christos Hadjichristodoulou[2], Fani Kalala[1], Matthaios Speletas[1]
[1]Department of Immunology & Histocompatibility, Faculty of Medicine, University of Thessaly, Larissa, Greece; *[2]Laboratory of Hygiene and Epidemiology, Faculty of Medicine, University of Thessaly, Larissa, Greece*; *[3]Department of Immunology and Histocompatibility Department, "Evaggelismos" General Hospital, Athens, Greece*

Introduction: Patients with predominantly antibody deficiencies (PAD) display hypogammaglobulinemia and pulmonary and hepatic manifestations irrelevant to autoimmunity. Therefore, additional genetic polymorphisms, may affect their clinical and laboratory phenotype. Alpha-1 antitrypsin (AAT) encoded by *SERPINA1* gene has antiprotease activity along with the ability to modulate both inflammation and apoptosis leading to lung and liver dysfunction and might contribute to PID phenotype.
Purpose: The study was conducted to investigate the possible contribution of *SERPINA1* defects in the clinical phenotype of patients with PAD.
Methods: A total of 80 PAD patients enrolled in the study, including 70 with common variable immunodeficiency (CVID), a patient with combined IgA and IgG subclass deficiencies with a CVID-like clinical phenotype, two patients with pathogenic *CTLA4* mutations and seven patients with unclassified hypogammaglobulinemia (displaying mild to moderate) with recurrent infections and a negative work-up for secondary immunodeficiencies. Genomic DNA was extracted from peripheral blood and a PCR amplification of all five exons (including exon–intron boundaries) of the *SERPINA1* gene was performed. Thereafter, PCR products were purified and sequenced.
Results: *SERPINA1* genetic analysis revealed both pathogenic and non-pathogenic defects in 67 out of 80 participants (84.0%). Among them, 10 patients (12.5%) exhibited pathogenic defects, all in heterozygous state; interestingly, all these patients suffered from CVID. The pathogenic defects include PI*Z variant, PI*S variant, rs61761869, rs1379209512 and rs77598233. The presence of the Z allele (rs28929474) was found in three patients and was significantly associated with liver disease (Odds Ratio: 29.57, p=0.006). Additionally, hepatic complications were observed in two more patients carrying the p.Leu23Gln (rs1379209512) and the p.Phe76del (rs775982338) alleles, respectively. Conversely, no correlation of *SERPINA1* defective variants was observed with respiratory complications, although patients with pathogenic variants exhibit a reduced probability of developing autoimmune diseases compared to those without pathogenic defects (Odds Ratio: 0.17, p-value=0.03).
Conclusion: The present study clearly demonstrates that CVID patients and defective *SERPINA1* variants may display a higher probability of developing hepatic complications. We recommend *SERPINA1* genetic analysis in PAD, in order to identify patients with a higher risk for liver disease.

Common variable immunodeficiency (CVID) is marked by deficient immunoglobulin concentrations and causes recurrent airway and gut infections and several complications.
This study aims to classify CVID patients using the Freiburg and the EUROclass classification, which combines the Freiburg and Paris classifications, by measuring B cell subsets of switched memory (sm) and $CD21^{+low}$ in peripheral blood samples and assessing the correlation between the specific CVID classes and changes in T cell populations. Additionally, we checked Ig titers, C3 and C4 concentrations in each sample, and Anti-Nuclear Autoantibodies (ANA) to identify correlations with CVID patient categories.
We analysed B and T cell subsets by flow cytometry, both as frequency and absolute count, in 25 CVID adult patients treated with Ig replacement therapy.
Results often display a normal B-cell frequency but a significant alteration in the frequency and absolute count of B-cell subsets, compared to the reference ranges, in all the patients. In almost all CVID samples, both follicular-like and regulatory T cells had very low frequency and absolute counts. According to the Freiburg or EUROclass classifications, the ANA positive test is often associated with groups "2 or 1b" and "$smB+21^{norm}$", respectively. Additionally, IgA titres were higher in groups "2" and "smB+21norm". The Freiburg group 1b displays a sm frequency <0,4% and a $CD21^{+low}$ frequency <20%, while group 2 display a sm frequency >0,4%. The EUROclass $smB+21^{norm}$ group displays a sm>2% frequency and a $CD21^{+low}$ frequency < 10%.
In conclusion, improving patient classification could provide helpful insight into the follow-up of CVID patients.

Immunological and genetical characterization of novel homozygous DIAPH1 variants

Ebtehal Al sheikh[1;2], Tracy Briggs[2], Glenda Beaman[2], Tracy Hussell[1], Peter Arkwright[1;3]
[1]Lydia Becker Institute of Immunology & Inflammation, University of Manchester, Manchester, UK;, Manchester, United Kingdom; *[2]2Manchester Centre for Genomic Medicine, St Mary's Hospital, Manchester, UK, Manchester, United Kingdom*; *[3]3Department of Paediatric Allergy & Immunology, Royal Manchester, Children's Hospital, Manchester, UK, Manchester, United Kingdom*

Purpose: Diaphanous-related Formin 1 (DIAPH1) deficiency is associated with microcephaly, developmental delay, early infancy epilepsy, vision loss and recently with combined immunodeficiency. The observed immunological defects marked DIAPH1 biallelic loss of function as an Inborn Error of Immunity (IEI). This study aims to investigate and expand the genetical, clinical and immunology data of multiple patients with DIAPH1 deficiency.
Methods: Clinical, laboratory information, genetic analysis and comprehensive immunophenotyping via a Multi-color flow cytometry panel was used to investigate T-cell lymphopenia and B-cell maturation deficits in DIAPH1 deficient patients.
Results: DIAPH1 Biallelic loss of function mutational spectrum included intronic variants. The immunological clinical phenotype is that of a combined immunodeficiency, with recurrent bacterial sinopulmonary, viral and fungal infections. Although basic B-cell, T-cell numbers and serum immunoglobulins may be low or normal, there is a distinct lack of naïve CD4 and CD8 T cells. Markers of senescence on T-cells, such as CD57 and exhaustion TIGIT are typically raised, as is PD-1.
Conclusions: The mutational catalog of DIAPH1 is diverse and diagnosis might be missed in intronic cases. Although the typical clinical features of DIAPH1 are neurological with microcephaly, epilepsy, severe developmental delay and blindness, more subtle immune abnormalities are also a feature, partially in terms of lack naïve T-cells and increased senescence of mature T-cells. The presented abnormalities may promote frequent infections with viruses, fungal and particularly bacterial sinopulmonary infections. Highlighting that indeed DIAPH1 is IEI affecting the adaptive immune response in T cells.

Keywords IEI, DIAPH1, immunodeficiency, T-cell lymphopenia, microcephaly

Associations between prenatal per- and polyfluoroalkyl substances (PFAS) exposure and antibody response to childhood vaccines in Norwegian children

Berit Brunstad Granum[1], Gro Tunheim[1], Johanna Bodin[1], Cathrine Thomsen[1], Marta Baranowska-Hustad[1], Azemira Sabaredzovic[1], Thea Kristine Rogne Møller[1], Line Småstuen Haug[1], Merete Åse Eggesbø[1], Nina Iszatt[1]
[1]*Norwegian Institute of Public Health, Oslo, Norway*

Purpose: Per- and polyfluoroalkyl substances (PFAS) are immunotoxicants, and there is a need to study their effects in populations with different exposures. We assessed prenatal PFAS exposure and vaccine antibody response in Norwegian school-aged children.
Methods: We combined two sub populations of the Norwegian Mother, Father and Child Cohort Study (MoBa, 2002-2009): HELIX (n=268, aged 7-10 years) and the Norwegian Environmental Biobank II (n=642, 7-14 years). PFAS were measured in maternal 2nd trimester and childhood samples (five different PFAS in HELIX and up to 12 in NEB II). 10 persistent organic pollutants (POPs) were also measured. Antibody responses (IgG) to tetanus, diphtheria and rubella were measured in childhood samples using in-house multiplex immunoassays. We assessed single-pollutant associations between PFAS and IgG, adjusted for covariates, and stratified analyses by sex and age (<12 yrs/ ≥12 years). Analyses were restricted to those with the recommended vaccine doses (DTP 4 doses, MMR 2 doses).
Results: In children under 12 years, per interquartile range (IQR) increase in exposure, prenatal perfluorononanoic acid (PFNA) was associated with higher diphtheria antibodies in boys (β=0.19, 95% CI: 0.02–0.36). In children 12 years and over, perfluorooctanoic acid (PFOA) levels were associated with lower diphtheria antibodies, particularly in girls (β=-0.39, 95% CI: -0.75– -0.02), while perfluorooctane sulfonic acid (PFOS) was associated with lower levels only in boys (β=-0.42, 95% CI: -0.84– -0.01). Additional adjustment for POPs did not affect results. Similar trends were found for tetanus and rubella antibodies.
Conclusion: Prenatal PFAS exposure may have differing effects on the immune response based on child's age and sex, possibly due to puberty. We will further investigate mixture effects and current exposure.

Heterozygous LIG4 gene variant in a patient diagnosed with common variable immunodeficiency: a case study

Joel Gutierrez-Serrudo[1], Daniel García-Cuesta[1], Jorge Mannelli[1], Javier Galán Picón[1], Raquel De la Varga-Martínez[1], José Miguel Aparicio[2], Antonio Nieto[1]
[1]Servicio Inmunología. Hospital Puerta del Mar, Cadiz, Spain; *[2]Servicio Medicina Interna. Hospital San Carlos, San Fernando. Cadiz, Spain*

Introduction: Common Variable Immunodeficiency (CVID) represents a set of deficiencies in antibodies with a complex, heterogeneous and polygenic nature that cause hypogammaglobulinemia and a defect in the production of specific antibodies. Patient's phenotypes are highly heterogenous due to a high variety of related complications, such as autoimmune manifestations, lymphoproliferation, enteropathy, and lymphoid malignancies, suggesting that CVID could be a common outcome of diverse immune system failures. Exome sequencing is a cost effective approach to identify disease-causing mutations in CVID patients with severe phenotypes. Recently, monoallelic LIG4 missense mutations have been reported as a novel cause of immune disregulation in patients with hypogammaglobulinemia, lymproliferation and autoimmunity.
Objectives: To describe a case of a patient meeting CVID criteria with significant pulmonary and hepatic involvement that presents a novel missense mutation in LIG4.
Case report: A 67-year-old female patient was referred to the Immunology department due to severe hypogammaglobulinemia and longstanding splenomegaly. She experienced recurrent respiratory infections, with some requiring hospitalizations. Additionally, she was monitored for liver cirrhosis and portal hypertension. The patient also had autoimmune hypothyroidism. The analysis showed intense panhypogammaglobulinemia, absence of isohemagglutinins, and low levels of antibodies, including a poor response to vaccination. An inversion in the CD4/CD8 ratio was observed due to TCD4+ lymphopenia. Switched memory B cells were diminished. The leukocyte count was within the normal range, while the platelet count was reduced. Chest CT revealed subcarinal lymphadenopathies, bronchiectasis, and findings suggestive of lymphoid granulomatous disease. Biopsy results showed non-caseating granulomas and lymphoid hyperplasia, raising suspicion of sarcoidosis, although it was not confirmed. Additionally, lymphoproliferative syndrome was ruled out. Recently, the patient has also been diagnosed with cholangiocarcinoma.
Exome sequencing analysis was performed and a novel missense mutation (Leu903Ser) was identified in the LIG4 gene, classified as a variant of uncertain significance (VUS). This mutation lies within the BRCT 2 domain of the protein.
Conclusions: The disease phenotype closely resembles that recently described for the first time as being secondary to heterozygous LIG4 mutations resulting in haploinsufficiency. This suggests that the variant found in LIG4 may play an important role in the observed immunological dysregulation in the patient.

Purpose: During HIV disease, several biomarkers of inflammation and immune activation increase and remain elevated despite antiretroviral therapy (ART). Chronic inflammation and immune activation are key features of HIV disease and have been shown to impact both disease progression and various immune responses. The present study aimed to investigate inflammation and immune activation in HIV+ women in Cameroon and their HIV-exposed uninfected children.
Methods: Blood samples from 106 pregnant, HIV+ women receiving ART and 103 pregnant, HIV- women were collected during the 3rd trimester. Additionally, cord blood and peripheral blood samples were collected from the children at birth and at 3 months of age. Soluble biomarkers of inflammation measured in plasma included markers for microbial translocation (IFABP, sCD14) and 21 cytokines or chemokines covering angiogenesis, innate cytokines, Th1, Th2 and Treg cytokines. Frequencies of activated, exhausted and senescent T-cell subsets were measured in PBMCs. In addition, CMV and RSV antibodies were measured in plasma.
Results: While sCD14, IFABP and MCP-1 plasma levels were elevated in HIV+ compared to HIV- pregnant women in Cameroon, no difference was observed for other soluble markers in plasma or for T-cell subsets. Assessment of CMV seropositivity revealed a 90-100% CMV prevalence in the Cameroon cohort, compared to 50% prevalence in Germany. Irrespective of HIV status, participants from Cameroon had significantly higher levels of various plasma cytokines compared to participants from Germany, denoting unusually high grade of inflammation in the HIV-negative women from Cameroon. Moreover, several inflammation measures were positively correlated to each other across participants from Cameroon, denoting distinct profiles within the cohort. This observation was also made in the cord blood of HIV-exposed and -unexposed children. Intriguingly, various pro-inflammatory markers (e.g. IL-1b, IL-6) in cord blood plasma negatively correlated with anti-RSV antibodies in the cord blood. Lastly, HIV-exposed children showed significantly lower RSV seroconversion rate at three months of age compared to HIV-unexposed children.
Conclusion: Our study suggests a link between high levels of inflammation in pregnant mothers in Cameroon, which, irrespective of HIV, may limit the transfer of maternal antibodies and have consequences for long-term immunity in newborns.

Evidence of exhausted lymphocytes after the third anti-SARS-CoV-2 vaccine dose in cancer patients

Kauzar Mohamed Mohamed[1], Javier David Benitez Fuentes[2], Carlos Jimenez Garcia[1], Kissy Guevara Hoyer[1], Miguel Fernandez Arquero[1], Silvia Sanchez Ramon[1], Pedro Perez Segura[1]
[1]Department of Immunology, IML and IdISSC, Hospital Clínico San Carlos, Madrid, Spain; *[2]Department of Medical Oncology, Hospital Clinico San Carlos, IdISSC, Madrid, Spain*

Introduction: Evidence is scant regarding the long-term humoral and cellular responses Q7 triggered by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) mRNA vaccines in cancer patients after repeated booster doses. The possibility of T-cell exhaustion following these booster doses in this population has not yet been fully studied and remains uncertain.
Methods: In this single-center prospective observational study, we explored the specific humoral and cellular response to S1 antigen in 36 patients with solid malignancies at baseline, and after the second and third doses of the mRNA-1273 vaccine.
Results: A dual behavior was observed: 24 (66.7%) patients showed partial specific IFN-γ response after the second dose that was further enhanced after the third dose; and 11 (30.5%) already showed an optimal response after the second dose and experienced a marked fall-off of specific IFN-γ production after the third (4 patients negativization), which might suggest T cell exhaustion due to repetitive priming to the same antigen. One (2.8%) patient had persistently negative responses after all three doses. Seroconversion occurred in all patients after the second dose. We then studied circulating exhausted CD8+ T-cells in 4 patients from each of the two response patterns, those with increase and those with decrease in cellular response after the third booster. The patients with decreased cellular response after the booster had a higher expression of $PD1^+CD8^+$ and $CD57^+PD1^+CD8^+$ exhausted T cells compared with those with an increased cellular response both *in vivo* and *in vitro*. The proportion of $PD1^+CD8^+$ and $CD57^+PD1^+CD8^+$ exhausted T cells inversely correlated with IFN-γ production.
Discussion: Our preliminary data show that the two-dose SARS-CoV-2 vaccine regimen was beneficial in all cancer patients of our study. An additional booster seems to be beneficial in suboptimal vaccine seroconverters, in contrast to maximal responders that might develop exhaustion. Our data should be interpreted with caution given the small sample size and highlight the urgent need to validate our results in other independent and larger cohorts. Altogether, our data support the relevance of immunological functional studies to personalize preventive and treatment decisions in cancer patients.

Effect of Pfizer-BioNTech COVID-19 vaccine booster doses: implications for vaccination strategies in healthcare workers

Ester Irene Reina Alfonso[1], Pablo Álvarez Heredia[1], Mónica Espinar García[1], Isabel María Vallejo Bermúdez[1], Carmen María Gutiérrez González[1], Alexander Batista Duharte[1], Fakhri Hassouneh[1], Juan Eduardo Molina Alcaide[1;2], Rafael Solana Lara[1;3], Alejandra Pera Rojas[1;3]
[1]Immunology and Allergy, Maimonides Biomedical Research Institute of Cordoba (IMIBIC), Córdoba; *[2]Immunology and Allergy Service. Reina Sofía University Hospital, Córdoba*; *[3]Department of Cell Biology, Physiology, and Immunology. University of Córdoba, Córdoba*

Introduction: The booster vaccine against SARS-CoV-2 is indicated in at-risk groups, including those aged 60 and older, chronic illnesses or immunocompromised individuals, and healthcare workers. Recent scientific attention has turned towards dose tolerance and immunological exhaustion, particularly in response to mRNA-based vaccines, which show a notable increase in IgG4 levels with repeated administrations compared to adenovirus-based vaccines. Preclinical trials have indicated a potential decrease in T cell response and an increase in exhaustion markers following repeated antigen exposure. However, there is a scarcity of studies on the effects of COVID-19 booster doses.
Methods: Thus, we aim to investigate both humoral and cellular responses to the fourth dose (second booster dose) of the Pfizer vaccine in 37 healthy individuals with no declared history of COVID-19 symptoms, stratified by age (Young, N=13; Middle-aged, N=14; Old, N=10), 10-12 months after the first booster dose (third dose) of Pfizer vaccine (T1) and 3-5 weeks after the second booster dose (T2). We measured spike protein IgG antibody serum levels and evaluated PBMC cytokine production in response to SARS-CoV-2 spike protein stimulation using multiparametric flow cytometry.
Results: Older individuals showed lower antibody levels initially but experienced a significant increase after the booster dose ($p<0.01$), suggesting they benefit most from additional vaccination. Individuals with lower initial antibody levels exhibited greater fold changes in response to the booster dose. We identified two groups based on their response: vaccine responders (VR) and non-responders (VnR). As expected, VR individuals showed increased antibody levels post-booster ($p<0.0001$). Surprisingly, VnR individuals, predominantly young and middle-aged (87%), exhibited decreased levels. The functionality assay showed similar T cell responses in both groups.
Conclusion: The high levels of IgG spike antibodies presented in some individuals could be blocking the antigen of the vaccine, affecting the humoral response. Despite no signs of immune exhaustion in our cohort, repeated antigen exposure could potentially induce this state, as seen in preclinical trials. These findings suggest that the vaccination schedule for healthcare workers in these age groups should be reconsidered, as the current annual booster strategy could lead to a poorer response to future SARS-CoV-2 infections.

Characterizing tumor microenvironment-mediated exhaustion in CD8 T Cells: Insights from a hepatocarcinoma model

Hacene Dreidi[1], Marie Le Moine[1], Sébastien Denanglaire[1], Solange Dejolier[1], Abdulkader Azouz[1], Stanislas Goriely[1], Fabienne Andris[1]
[1]*ULB, Brussels, Belgium*

Purpose: CD8 T cells play a pivotal role in tumor immunity; however, within the tumor microenvironment (TME), they often become functionally hyporesponsive (exhausted), hindering anti-tumor responses. Recent studies have identified distinct exhaustion profiles in T lymphocytes, depending on the type of chronic antigenic stimulation they encounter. Despite considerable progress in T cell-reinvigorating immunotherapy using checkpoint inhibitors, only a subset of cancers responds to these treatments. This highlights the need for a deeper understanding of the role played by the tumor microenvironment (TME) in contributing to T cell exhaustion. This project aims to unravel genetic and epigenetic programs guided by the TME during CD8 T cell differentiation toward dysfunctional states.
Methods: We developed a murine hepatocarcinoma model using oncogene-expressing plasmids via hydrodynamic transfection. Plasmids also expressed ovalbumin (OVA), serving as a surrogate tumor-specific antigen, enabling tracking antigen-specific T cell fate. Hydrodynamic injection of ovalbumin-expressing plasmid in the absence of oncogenes drove the expression of OVA in non-transformed (healthy) hepatocytes. Transfer of OVA-specific lymphocytes in these mice allowed us to follow antigen-specific T cell fate in response to the same antigen in the context of healthy or advanced hepatocarcinoma liver environment.
Results: Antigen-specific T cells exhibited exhaustion features (PD1, TOX, etc…) in all mice, but tumor-bearing mice expressed more advanced T cell exhaustion with impaired functionality (reduced IFNg and TNFa production). RNAseq and ATACseq analyses revealed consistent transcriptional and epigenetic signatures of exhausted CD8 T cells, when subjected to tumor or healthy liver chronic antigenic stimulation. Single-cell transcriptomic studies provided further insights into the heterogeneity within exhausted T cells, facilitating the identification of candidate genes for subsequent in vivo and in vitro testing.
Conclusion: Distinct exhaustion profiles associated with advanced hepatocarcinoma highlight a potential for targeted interventions and personalized immunotherapies to alleviate CD8 T cell exhaustion.

Exclusive expression of PD-1/TIGIT versus TIM3 differentially associates with metabolic plasticity and polarization of HIV-specific CD8+ T cells

Ilya Tsukalov[1;2], Marta Calvet-Mirabent[1;2], Ildefonso Sánchez-Cerrillo[1;2;3], Alba Roca[1;4], Aránzazu Rosado-Díez[5], Olga Popova[1;2], Lucio García-Fraile[2;3], Ana Quintas[5], Arantzazu Alfranca[1;2], Ana Dopazo[5], María José Calzada[1;2], Eduardo Balsa[1;4], Ignacio de Los Santos[2;3], Francisco Sánchez-Madrid[1;2;5], Enrique Martín-Gayo[1;2;3]
[1]Universidad Autónoma de Madrid, Madrid, Spain; *[2]Hospital Universitario de La Princesa, Madrid, Spain*; *[3]Infectious Diseases CIBER (CIBERINFECC), Madrid, Spain*; *[4]Centro de Biología Molecular Severo Ochoa, Madrid, Spain*; *[5]Centro Nacional de Investigaciones Cardiovascualres, Madrid, Spain*

Purpose: Response of HIV-specific CD8+ T cell from people with HIV (PWH) to dendritic cell (DC) depends on the co-expression of PD-1, TIGIT and TIM3. However, mechanisms underlying these associations remain unclear and could be crucial to improve immunotherapies against HIV-1. In this study, we characterized CD8+ T lymphocytes defined by the expression of these receptors at the transcriptional, metabolic and functional levels.
Materials and methods: PD-1/TIGITDP (PD-1+TIGIT+TIM3-), TIM3SP (PD-1-TIGIT-TIM3+) and TN (PD-1-TIGIT-TIM3-) central memory CD8+ T cells (n=4 healthy donors) induced after 5 days in culture with allogeneic DCs activated with STING and TLR3 agonists were used for transcriptional studies by RNA-seq. Computational analysis of differentially expressed genes (DEG) of each population compared to TN cells was performed using Ingenuity Pathways Analysis. Validation of selected DEG, mitochondrial mass and ROS (MitroTracker and MitoSOX) and polarization in response to Gag peptides (IFNg, IL-13, CD107a) of CD8+T cells was performed using n=25 PWH.
Results: DEG identified in TIM3SP cells (1671) were differentially associated with upregulation of modulators of oxidative phosphorylation, TCA cycle, amino acid and lipid metabolism expression in contrast to PD-1/TIGITDP lymphocytes (866), which preferentially transcribed genes associated with immune exhaustion and mitochondrial dysfunction. Consistently, higher ratios of cells with TCF1hi vs ToxLow positive cells were detected in TIM3SP but not in PD-1/TIGITDP CD8+ T cells from PWH (p=0.0059). Also, PD-1/TIGITDP cells exhibited significantly higher (p=0.002) mitochondrial stress levels defined by ROS accumulation than TIM3SP from PWH. In addition, FACS analysis validated upregulated expression of ARG2 (p=0.0012) and MGST2 (p=0.0674) in TIM3SP from PWH, involved in amino acid and lipid metabolism, respectively. These metabolic patterns associated with higher transcription of genes related to degranulation and Tc1 in TIM3SP, and with higher polarization to Tc2 in PD-1/TIGITDP CD8+ T cells that demonstrated high IL-13 secretion (p=0.002) in response to gag peptide stimulation.
Conclusion: TIM3SP cells represent a less exhausted, metabolically plastic population with cytotoxic profiles compared to exhausted PD-1/TIGITDP cells, predisposed to induce Tc2 responses against HIV-1. Thus, our data may be relevant to improve immunotherapies against HIV.

Atf7ip-deletion results in attenuated T cell exhaustion and reduced tumor growth

Sujit Kashyap[1], Jun Sin[1], Michael Waterfield[1]
[1]*University of California San Francisco, San Francisco, United States*

ATF7ip is an epigenetic regulator, involved in the formation of the H3K9me3 histone mark and is highly expressed in immune cells. Previously, we have shown increased memory and effector responses in mice with *Atf7ip*-deletion after acute infection with LCMV Armstrong. This enhanced effector and memory response was due to the difference in H3K9me3 deposition at key immune gene loci. Here we interrogate *Atf7ip*-deletion in T cells with chronic infections and cancer.
CD4-Cre/*Atf7ip*$^{fl/fl}$ mice infected with LCMV clone13 showed increased GP33 tetramer positive CD8 T cells compared to *CD4*-Cre/*Atf7ip*$^{+/fl}$ mice. Transfer experiments with congenially distinct P14+/*Atf7ip*$^{+/fl}$ or P14+/*Atf7ip*$^{fl/fl}$ CD8+ T cells in a host mice infected with LCMV clone 13 resulted in significantly higher Tcf1+ *Atf7ip*$^{fl/fl}$ CD8+ T cells and higher cytokine secretion (TNFα and IFNγ) in *Atf7ip*$^{fl/fl}$ CD8+ T cells. Using B16GP33 tumor cells, we found that *CD4*-Cre/*Atf7ip*$^{fl/fl}$ mice had enhanced tumor immune response and survival. Expression profiling with tumor infiltrating lymphocytes (TIL's) revealed higher GZMK positive cells and increased expression of genes responsible for a T cell exhaustion signature in the *CD4*-Cre/*Atf7ip*$^{+/fl}$ mice. Single cell RNAseq using TIL's from *CD4*-Cre/*Atf7ip*$^{fl/fl}$ mice and *CD4*-Cre/*Atf7ip*$^{+/fl}$ mice showed higher CD4+ T cells present in the tumor of *CD4*-Cre/*Atf7ip*$^{fl/fl}$ mice along with enhanced expression of *Il7r*. Flow experiments with these mice confirmed downregulated expression of *Tox* in TIL's from CD4-Cre/ *Atf7ip*$^{fl/fl}$ mice. To understand the intrinsic CD8+ response, we carried out a second single cell RNAseq experiment using a transfer model with P14+/*Atf7ip*$^{+/fl}$ or P14+/*Atf7ip*$^{fl/fl}$ CD8+ T cells co-injected with B16gp33 tumor cells in C57BL/6 mice. We found that the exhaustion cluster was highly depleted in P14+/*Atf7ip*$^{fl/fl}$ CD8+ T cells along with downregulated expression of *Tim3* and an enhanced memory signature.
Based on our findings, deletion of *Atf7ip* may result in increased progenitor population under chronic conditions that results in the anti-tumor response of *Atf7ip*$^{fl/fl}$ CD8+ T cells. These results demonstrate the therapeutic potential of *Atf7ip*-deletion in T cells that can help in improved tumor control and effective T cell-based therapy.

NLRP3 activation of macrophages regulates intratumoral T cell dysfunction in a pancreatic cancer model - dual mechanism of NLRP3-mediated cytokine secretion and PD-L1 expression

Vanessa Zimmer[1], Benedikt Slusny[1], Bettina Geisel[1], Katrin Roth[2], Malte Buchholz[1], Thomas M. Gress[1], Christian Bauer[1]
[1]Clinic for Gastroenterology, Endocrinology, Infectiology, and Metabolism, University Hospital Marburg, Philipps-Universität Marburg, Marburg, Germany; *[2]Core Facility Cellular Imaging, Center for Tumor Biology and Immunology, Philipps University Marburg, Marburg, Germany*

Purpose: Intratumoral cytotoxic $CD8^+$ T lymphocytes (CTLs) enter a dysfunctional state called T cell exhaustion, described by the loss of effector function and specific changes in the transcriptional profile. One prominent mechanism that results in T cell exhaustion is mediated by T cellular IL-18 receptor (IL-18R) signaling. IL-18 is activated and secreted by the NLRP3 inflammasome, commonly expressed in macrophages. However, macrophage and T cell interaction mechanisms regarding IL-18R-mediated T cell exhaustion remain unknown. This work will investigate the role of myeloid NLRP3-derived IL-18 on T cell plasticity and motility.
Methods: A 2D coculture system of bone marrow-derived macrophages (BMDMs) with OT-1 $CD8^+$ T cells was used to investigate the role of myeloid NLRP3-derived IL-18 on T cell plasticity in the context of T cell exhaustion. Additionally, to analyze T cell motility using a 3D TruLive light-sheet microscope, we established a murine pancreatic spheroid model of PancOVA cells with BMDMs and OT-1 CTLs. Furthermore, a murine pancreatic cancer model was utilized to characterize the TME of wildtype and *Nlrp3*$^{-/-}$ mice.
Results: *In vitro* activation of the NLRP3 inflammasome by LPS and Nigericin treatment resulted in the secretion of IL-1β and IL-18 in wild-type macrophages but also caused increased levels of PD-L1, rendering those macrophages more immunosuppressant. In a murine pancreatic tumor model, NLRP3-deficient TAMs had low PD-L1 levels compared to wild-type TAMs. Supplementation of IL-1β in cell culture experiments indicated that lack of myeloid-derived IL-1β results in decreased expression of PD-L1 *in vivo* and, thus, a less immunosuppressive phenotype of these TAMs. Additionally, a less prominent subset of exhausted intratumoral $CD8^+$ T cells in the tumors of NLRP3-deficient mice was found.
Conclusion: Our results highlight the NLRP3 inflammasome and NLRP3-derived cytokines as potential regulators of an immunosuppressive tumor milieu. In a pancreatic tumor model, a dual mechanism of NLRP3-mediated cytokines IL-18 and IL-1β and the PD-1:PD-L1 axis was demonstrated to promote intratumoral T cell dysfunction.

Dysregulated inflammatory response and poor fracture healing in polytrauma

Augustine Saiz[1], Maryam Rahmati[1], Robert Gresham[1], Tony Baldini[1], Jane Burgan[1], Mark Lee[1], Benjamin Osipov[1], Blaine Christiansen[1], Thaqif EL Khassawna[2;3], Florian Wieland[4], Andre Lopes[4], Clement Blanchet[5], Kent Leach[1]
[1]Department of Orthopaedic Surgery, UC Davis Health, Sacramento, United States; *[2]Experimental Trauma Surgery, Justus-Liebig University Giessen, Giessen, Germany*; *[3]Faculty of Health Sciences, University of Applied Sciences, Giessen, Germany*; *[4]Institute of Metallic Biomaterials, Helmholtz Zentrum Hereon, Geestacht, Germany*; *[5]European Molecular Biology Laboratory EMBL, Hamburg Site, c/o DESY Notkestrasse 85, 22603, Hamburg, Germany*

Purpose: Bone healing is primarily concerned with treating isolated fractures in orthopedic patients. However, fractures in over 30% of polytrauma patients with multiple injuries exhibit impaired healing. There are significant gaps in our understanding of how fractures heal in this polytrauma environment. We aimed to characterize the temporal local and systemic immune responses to polytraumatic injuries in a polytrauma murine model using four experimental groups including healthy, chest trauma, isolated fracture and polytrauma groups.
Methods: To study the local and systemic immune responses and cytokine expression after injury, we collected serum, bone marrow from uninjured limb, femur, and lungs at 0 h, 6 h, 12 h, 24 h, 72 h & 3W following injury. Immune cell distribution from isolated bone marrow, femur, or lung tissue were assessed with a BD Fortessa 18-color flow cytometer. Femur tissues were collected after 3 weeks to study fracture healing using micro computed tomography, histological staining, immunohistochemistry, torsion test and small angle X-ray scattering.
Results: Our flow cytometry results indicated significantly higher expression of innate immune cells in the polytrauma group compared to other groups locally and systemically. In contrast, the expression of B and T cells was dramatically suppressed in the polytrauma group at 6h following injury and remained low throughout the 3 weeks' timeline of the study. The decreased expression of B and T cells demonstrated an exhaustion of the adaptive immune system response that could be a contributor to fracture nonunion.
Conclusion: Our data confirms the early, dysregulated inflammatory state in polytrauma correlated with impaired fracture healing and the formation of a poor and dysregulated callus in this polytrauma group. Taken together, this study elucidates the role of persistent immune and inflammatory dysregulation that leads to poor fracture healing.

A pseudo-temporal framework analysis of exhausted CD8 T cells (Tex) across PD-1 therapy revealed limited "reinvigorability" of exhausted progenitor cells and underlying regulatory pathways

Jean-Christophe Beltra[1;2], Sasikanth Manne[3], Morgan Le Gall[1], Hélène Mereau[1], John Wherry[2;3]
[1]Department of Biomedicine - University of Basel, Basel, Switzerland; *[2]Parker Institute for Cancer Immunotherapy, San Fransisco, United States*; *[3]University of Pennsylvania, Philadelphia, United States*

Exhaustion of CD8 T cells limits immunotherapy outcomes. Targeting the immune checkpoint PD-1 temporally relieve some functional constraints on exhausted CD8 T cells (T_{EX}) but most patients do not experience long-term benefits. As acquired resistance mechanisms to checkpoint therapy begin to be elucidated, whether cell-intrinsic regulatory mechanisms also restrict durability of T_{EX} cell responses to PD-1 blockade remains poorly explored. To identify such mechanisms, we took advantage of the murine LCMV model and performed an unprecedented pseudo-temporal framework analysis of T_{EX} cell responses to PD-1 therapy, capturing the precise cellular, functional, and transcriptional changes occurring in T_{EX} subsets across the whole duration of the therapy. This time-course analysis revealed that T_{EX} cell responses to PD-1 blockade decline in three temporally regulated phases including a transient regain of cytotoxic potential followed by a single proliferative wave initiated at the T_{EX} progenitor (T_{EX}^{prog}) stage that perpetrates in downstream subsets, resulting in a temporal numerical burst of "effector-like" T_{EX} intermediate (T_{EX}^{int}) cells. Importantly, we uncovered an acquired cell-intrinsic inability of T_{EX}^{prog} cells at sustaining this proliferative response that restricts the durability of T_{EX} responses to PD-1 therapy. Using longitudinal scRNAseq profiling of T_{EX} cells isolated across the duration PD-1 therapy, we uncovered the transcriptional changes underlying T_{EX}^{prog} cell acquired proliferative impairment. This analysis pointed-out dynamic activities of various pathways and transcription factors in T_{EX}^{prog} cells across PD-1 therapy with potential incidence on the biology of this key T_{EX} subset. Together, this work uncovers a direct incidence of PD-1 therapy on T_{EX}^{prog} cell biology and identifies potential causative pathways for the arrested reinvigoration of these cells that might represent intersting therapeutic targets.

Type 1 interferons and Foxo1 down-regulation play a key role in age-related T-cell exhaustion in mice

Aurélie Durand[1], Nelly Bonilla[1], Level Théo[1], Zoé Ginestet[1], Amélie Lombès[1], Morgane Le Gall[1], Bruno Martin[1], Cédric Auffray[1], Bruno Lucas[1]
[1]*Institut Cochin INSERM U1016 CNRS UMR8104 Université Paris Cité, Paris, France*

Purpose: Aging of an organism is progressive and cumulative, leading to alterations in the functions of multiple cells, tissues and organs, including the immune system. Indeed, age-related alterations in the immune system make older adults more susceptible to infectious diseases and tumors, resulting in increased morbidity and mortality. In addition, the efficacy of vaccination is considerably reduced in the elderly population, limiting preventive prophylaxis. Foxo family transcription factors are critically involved in multiple processes, such as metabolism, quiescence, cell survival and cell differentiation. Although continuous, high activity of Foxo transcription factors extends the lifespan of some species, the involvement of Foxo proteins in mammalian aging remains to be determined. The aim of this project is to study Foxo1 involvement in T-cell aging.
Methods: Flow cytometry – transcriptomic analysis – adoptive transfer – cell culture.
Results: We observed that Foxo1 expression is down-regulated with age in mouse T cells leading to a rewiring of their transcriptional signature. Indeed, transcriptome analysis shows a significant overlap between the transcriptional signatures of naive CD4 T cells from young adult mice deficient for Foxo1 expression in T cells and old wild-type mice. Foxo1 down-regulation in T cells may contribute to several defects of the T-cell compartment with age including disruption of naive T-cell homeostasis leading to increased numbers of memory T cells and increased exhaustion of aged T cells characterized by PD1, TIGIT and TOX overexpression. Using adoptive transfer experiments, we show that the age-dependent down-regulation of Foxo1 in T cells is mediated by T-cell-extrinsic cues. In particular, we showed that type 1 interferons induce Foxo1 down-regulation *in vitro* and that this involves the PI3K/AKT signaling pathway. We confirmed these results *in vivo* as the T-cell compartment of old mice deficient for the expression of the type 1 interferon receptor appears to be less affected by aging than that of old wild-type mice.
Conclusion: Taken together, our data suggest that type 1 interferon-induced Foxo1 down-regulation is likely to contribute significantly to T-cell dysfunction in aged mice.

Purpose: In the case of chronic inflammation such as cancer, prolonged inflammatory signals and over expression of growth factors stimulate the bone marrow to meet the increased demand for myeloid cells. This results in an emergency myelopoiesis in which the immature myeloid cells fail to differentiate into mature cells before their egress from the bone marrow. In recent years, it has become evident that the abnormal accumulation and function of the immature myeloid cells are important facets of the cancer. MDSC are composed of immature myeloid cells at different stages of myelopoiesis and are identified with certain myeloid lineage markers. As common properties of MDSC, they have low-density (<1.077 g/mL) and display HLA-DR$^{low/-}$ immunophenotype. MDSC are further categorized into two major groups as monocytic MDSC (M-MDSC) and granulocytic/polymorphonuclear MDSCs (PMN-MDSC). This study aims to analyze the suppressive effects of PMN-MDSC on PD-1$^+$ and PD-1$^-$ effector memory CD4$^+$ T cells in the presence of PD-1 blockade.
Methods: Peripheral blood samples of 8 colorectal cancer, 2 melanoma patients, and 6 healthy donors were collected. Peripheral blood samples were layered over 1.077 g/mL Histopaque solution and PBMC were collected. Cells were labelled with anti-human -CD45, -CD11b, -CD33, -CD14, -CD66b, -PD-L1, -HLA-DR, -CD3, -CD4, -CD8, -PD-1, -CCR7, -CD45RA, and -CD45RO monoclonal antibodies.
Results: The frequency of total and PD-L1-expressing PMN-MDSCs was increased in the patients. Amongst the central memory (T_{CM}), effector memory (T_{EM}), terminally-differentiated effector memory (T_{EMRA}), and naïve (T_{Naive}) CD4$^+$ T cell populations, T_{EM} was the most prominent subtype in which PD-1 expression (median 35%, min 4.4% - max 54.4%) was detected. Next, CD4$^+$CD45RO$^+$CCR7$^-$PD-1$^-$ and CD4$^+$CD45RO$^+$CCR7$^-$PD-1$^+$ T cells were purified by FACS. CD11b$^+$CD33^{dim}HLA-DR$^{-/low}$CD66b$^+$ PMN-MDSC were purified with MACS followed by FACS. CFSE-labelled autologous T cells were stimulated with CD3/CD28 beads and co-cultured with PMN-MDSCs in the presence or the absence of anti-PD-1 mAb. After 72 hours of incubation, PMN-MDSC suppressed proliferation of both PD-1$^+$ and PD-1$^-$ T_{EM} CD4$^+$ T cells.
Conclusion: Although PD-1$^+$ T_{EM} CD4$^+$ T cells were more prone to immune suppression by PMN-MDSC, PD-1 blockade recovered T cell proliferation in both groups to certain extent.

The impact of metformin on circulating natural killer and natural killer T cell activation in prediabetes

Adelle Ankadu[1], Vuyolwethu Mxinwa[1], Bongani B. Nkambule[1]
[1]*University of Kwa-Zulu Natal, Durban, South Africa*

Introduction & aim of the study: The function of natural killer and natural killer T cells is altered in people living with obesity and prediabetes. The role of these immune cells in the development of impaired glucose tolerance is not yet fully understood, especially in individuals who are living with prediabetes and are on glucose lowering therapy. This study aimed at investigating the frequency and activation status of circulating natural killer and natural killer T cells as well as assessing the effect of high-fat diet feeding and metformin monotherapy on NK and NKT cells using a murine model of diet-induced obesity.
Methods: Whole blood samples were drawn from the lateral tail vein of male C57BL/6 mice (n=24). The animals were randomised into three groups (n=8/group), these included an LFD group (n=8), HFD group (n=8) and HFD+Met group (n=8). All mice underwent an oral glucose tolerance test (OGTT) following the eight-week diet phase, to detect the onset of prediabetes. The animal body weights, lipid profiles and haematological parameters were measured at experimental weeks, 8 and 13. The levels of circulating NK and NKT cells were determined using flow cytometry.
Results: NK and NKT cell levels were significantly elevated in both the HFD and HFD+Met groups in comparison to the LFD group ($p<0.05$). The expression of CD49b was significantly increased in the HFD group 10.96[7.51-46.08] and HFD+Met 10.70[7.43-12.69] when compared to the control group 0.59[0.02-1.50], ($p=0.0004$). Similarly, the levels of NKp46 positive cells were increased in the HFD group (28.79 ± 6.23) and HFD+Met group (25.85 ± 5.87) in comparison to the control group (8.59 ± 8.41), ($p=0.0002$). Interestingly, the levels of NK1.1 positive cells, were significantly increased following HFD-feeding 11.28[8.72-15.36] and remained persistently elevated after short-term treatment with metformin 12.15[10.94-14.25] in comparison to the control group 2.43[0.29-6.10], $p=0.0032$. Furthermore, NK1.1 levels correlated with fasting plasma glucose concentrations ($r=-0.7233$; $p=0.0426$).
Conclusionù: We observed significant alterations in circulating NK and NKT cell levels following HFD-feeding, suggesting an association between immune dysregulation and metabolic dysfunction. Furthermore, metformin treatment demonstrated promising immunoregulatory effects by its ability to mitigate NK and NKT cell activation.

Tbet+CD11c+ B cells: Professional antigen-presenting cells in untreated rheumatoid arthritis

Sarah McGrath[1], Kristoffer Nilsson Grimstad[1;2], Katrin Thorarinsdottir[1], Kristina Forslind[3;4], Daniel Glinatsi[5], Monica Leu Agelii[1], Alaitz Aranburu[1], Timothy Sundell[1], Charlotte Jonsson[1], Alessandro Camponeschi[1], Anna-Karin Hultgård Ekwall[1;6], Andreas Tilevik[2], Inger Gjertsson[1], Lill Mårtensson[1]
[1]Department of Rheumatology and Inflammation Research, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; *[2]School of Bioscience, University of Skövde, Skövde, Sweden*; *[3]Section of Rheumatology, Department of Clinical Sciences, Lund University, Lund, Sweden*; *[4]Stenshult Research and Development Centre, Halmstad, Sweden*; *[5]Department of Rheumatology, Skaraborg Hospital, Skövde, Sweden*; *[6]Department of Rheumatology, Sahlgrenska University Hospital, Gothenburg, Sweden*

Purpose: Among mature B cells, subsets of $CD21^{-/low}$ memory B cells (MBCs), including $CD27^{-}IgD^{-}$ (double negative) and $Tbet^{+}CD11c^{+}$ cells, are expanded in a range of chronic inflammatory diseases. In rheumatoid arthritis (RA), $CD21^{-/low}$ MBCs correlate with joint destruction, however whether these cells are $Tbet^{+}CD11c^{+}$, and their function in RA, is unknown. Here, we investigate $CD21^{-/low}$ $Tbet^{+}CD11c^{+}$ MBCs and their association with disease in untreated RA (uRA) patients.
Methods: We (i) combine clinical observations with extensive flow cytometry and in-depth single-cell (sc) RNA and V(D)J sequencing (seq) of peripheral blood MBCs from uRA patients; (ii) compare the transcriptome of peripheral blood Tbet+CD11c+ MBCs to that of synovial B cells; (iii) co-culture $Tbet^{+}CD11c^{+}$ B cells with T cells in vitro.
Results: We find $CD21^{-/low}$ $Tbet^{+}CD11c^{+}$ MBCs are significantly increased in peripheral blood and correlate with joint destruction in uRA. These $Tbet^{+}CD11c^{+}$ MBCs show evidence of clonal expansion and express somatically mutated V-genes. From differential gene expression and functional enrichment analyses, we identify over 150 significantly upregulated genes associated with antigen presentation functions, signatures that are mirrored in $Tbet^{+}CD11c^{+}$ B cells from the inflamed synovium of established RA. In vitro co-culture of $Tbet^{+}CD11c^{+}$ B cells with T cells, polarize $CD4^{+}$ T cells to RORgT-expressing Th17 cells.
Conclusion: Our findings demonstrate that peripheral blood $Tbet^{+}CD11c^{+}$ MBCs correlate with joint destruction in uRA, that they are poised for antigen presentation in the RA synovium and drive polarization to Th17 cells, thereby potentially contributing to ectopic lympho-neogenesis and bone destruction in RA.

Diversity and Survival of Circulating and Bone Marrow-resident Memory T Cells

Emilia Schneider Revueltas[1], Lukas Heiberger[1], Marta Ferreira-Gomes[1], Pawel Durek[1], Gabriela M. Guerra[1], jun dong[1], Koji Tokoyoda[1;2], Frederik Heinrich[1], Mir-Farzin Mashreghi[1], Hyun-Dong Chang[1;3], Andreas Radbruch[1;4]
[1]Deutsches Rheuma-Forschungszentrum Berlin, Berlin, Germany; *[2]Tottori University, Tottori, Japan*; *[3]Technische Universität Berlin, Berlin, Germany*; *[4]Charité University Medicine, Berlin, Germany*

Memory T cells circulating in the blood and those residing in tissues, can be detected for decades after apparent clearance of their cognate antigen. We have shown earlier that memory T cells residing in the bone marrow are essential to maintain long-term memory to systemic antigens. Obviously, circulating memory T cells (T_{CIRCM}) and bone marrow-resident memory T cells (T_{BM}) have different lifestyles. Here we define their gene expression profiles and survival mechanisms.
We have analyzed the single cell transcriptomes of T_{CIRCM} and T_{BM} and their antigen receptor repertoires, from three human donors. Their different repertoires define T_{CIRCM} and T_{BM} as separate compartments, including CD69 negative T_{BM} as truly resident cells. Gene expression profiles, not unexpectedly, indicate T_{CIRCM} as mobile cells, while T_{BM} are expressing genes of quiescent cells, encoding mRNA-binding proteins that prevent the translation of bound mRNAs, in particular those with ARE-motifs, e.g. TNF-family genes.
In addition, for murine T_{BM} we show, by blocking the integrin-mediated binding of T_{BM} to the stromal cells, or the resulting activation of the PI3K-signaling pathway, that maintenance of CD69+ T_{BM} is dependent on their contact to stromal cells, similar to the maintenance of bone-marrow-resident memory plasma cells. In contrast, survival of human T_{CIRCM} (*ex vivo*) is dependent on a distinct serum component, other than interleukin-7 or -15, activating a particular G-protein coupled receptor and transducing signals apparently through AKT, bypassing PI3K, but addressing the same downstream signaling pathway.
Dependency on a fluctuating serum component versus a stable stromal cell connection may thus contribute to the differences in persistence of T_{CIRCM} and T_{BM} over time. Beyond that, persistence may also depend on the individual competence of the memory T cell, i.e. its gene expression profile. In summary, our analysis confirms the compartmentalization of T cell memory, and defines different survival mechanisms for T_{CIRCM} and T_{BM}.

Specificity in encoding and phenotype of innate immune memory

Aoife O'Farrell[1], Zijian Niu[1], Jingxin Li[1], Laura Van Eyndhoven[1], Arjun Raj[1]
[1]*University of Pennsylvania, Philadelphia, United States*

Purpose: Innate immune cells build memory of prior experiences in a process termed "trained immunity," where "trained" cells respond stronger and faster to restimulation compared to non-experienced cells.[1] But which aspects of this prior experience are remembered, and which are forgotten? Here, we interrogate **specificity in the encoding of cellular memory** in macrophages across three key axes: the single cell, the individual donor, and the inducing stimulus.
Methods: Monocyte-derived macrophages were obtained from the apheresis product of healthy donors. Inflammatory stimulus was added to culture for 24 hours, followed by 5 days of rest. Memory of this prior exposure in the epigenome was evaluated by bulk ATAC sequencing. The functional effects of this memory were evaluated over time at single cell resolution with RNA fluorescence in-situ hybridization (smFISH)[2] of *TNF, IL6, IL1β,* and *CXCL10*, and pH-rodo labelled *E. Coli* was used to assess phagocytosis.
Results:

- ***Any single cell can build memory:*** Within hMDMs, there does not appear to exist a privileged subpopulation of cells that build memory, suggesting a lack of single-cell specificity in memory encoding.
- ***Memory retention is dependent on initial state:*** We can predict whether an individual donor's macrophages will show training based on the untrained (baseline) state of the population – cells with a low baseline inflammatory response are best able to be trained ex vivo.
- ***Different stimuli build distinct memories*****:** hMDMs trained with different inflammatory stimuli differ in functional capabilities, chromatin accessibility, and gene expression patterns across time, suggesting that cells specifically remember what was previously experienced and retain that information over several days.

Conclusions: We propose that cellular memory (such as that displayed by trained macrophages) allows for context-adjusted and time-adjusted responses to stimulation, as cells 'learn' appropriate responses based on prior experiences. As we continue efforts to profile cellular heterogeneity, map cell fate and function, and engineer cells to perform specific tasks, we require a stronger understanding of how cells remember their history.

Investigating the impact of Staphylococcus aureus exposure on innate immune memory

Seán Cahill[1], Cliodhna Daly[1], Rachel McLoughlin[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Purpose: Although once considered to be an exclusive feature of the adaptive arm of the immune system, evidence suggests that innate immune cells develop immunologic memory-like features in response to specific stimuli in a process known as "trained immunity". Given its duality as a commensal and a pathogen, *Staphylococcus aureus* antibodies are found almost ubiquitously in the general population. It's possible this exposure stimulates innate immune training which could greatly contribute to host defence against subsequent insult and have wide-reaching potential in disease treatment.
Methods: To investigate the impact of *S. aureus* exposure on innate training we established a novel model of long-term persistent colonisation whereby germ-free mice were mono-colonised with *S. aureus*. Bone marrow-derived macrophages (BMDMs) were generated and challenged in vitro with LPS, *S. aureus*, or *Klebsiella pneumoniae*. In a second model, conventional mice received recurrent intraperitoneal *S. aureus* injections on Day 0, 7 and 14. On Day 35 mice were sacrificed and the immune response was investigated.
Results: BMDMs from mono-colonised mice released elevated levels of IL-6 and IL-10 in comparison to germ-free controls. Additionally, bone marrow extracellular fluid (ECF) gathered from mono-colonised mice expressed more IL-1β than germ-free mice when measured via ELISA.
BMDMs from previously-infected *S. aureus* mice exhibited elevated IL-6 and IL-10 levels compared to naïve counterparts. Furthermore, ECF IL-1β levels were higher in previously-infected *S. aureus* mice when compared to their naïve controls.
Flow cytometric analysis on bone marrow progenitor cells of mono-colonised and previously-infected mice revealed increases in the levels of long-term haematopoietic stem cells and multipotent progenitor 3 cells compared to germ-free and naïve mice respectively.
Conclusion: Overall, both commensal or pathogenic *S. aureus* exposure impacts myelopoiesis and induces innate immune training which is protective against *S. aureus* or heterologous insults such as LPS or *K. pneumoniae*. The development of future efficacious vaccines and therapeutics against *S. aureus* are contingent on our understanding of this *S. aureus*-induced innate immune training.

Examining B cell maturation and antibody diversity in HIV-1 vaccine response: A multimerization and high-throughput sequencing study in the rhesus macaque model

Shawn Herring[1;2], Andrew Raappana[2], Nicholas Dambrauskas[2], Madeline Glad[2], Vladimir Vigdorovich[2], Noah Sather[1;2]
[1]*University of Washington, Seattle, United States*; [2]*Seattle Children's Research Institute, Seattle, United States*

Purpose: Human Immunodeficiency Virus 1 (HIV-1) continues to be a significant global health challenge, affecting approximately 39 million people worldwide. Despite advances in treatment, an effective HIV-1 vaccine remains elusive. This gap highlights the need for in-depth understanding of immune mechanisms, particularly B-cell maturation, which is crucial for generating effective immune responses. Our study addresses this gap by examining the impact of antigen multimerization on vaccine-elicited B cell maturation in *rhesus macaques* (RM). Focusing on key immunological processes such as the IgM to IgG class switch, clonality, and somatic hypermutation (SHM), we aim to uncover insights that could guide the development of more efficacious HIV-1 vaccines.
Methods: We employ two distinct yet complementary high-throughput sequencing approaches. Firstly, we leverage the 10X Genomics platform (10X) to sequence tetramer-sorted Envelope (Env)-specific B cells. High throughput processes enable the expression and characterization of paired heavy (H) and light (L) chains as recombinant antibodies, linking B cell receptor (BCR) sequence features to antibody functionality. Secondly, we utilize Next-Generation Sequencing (NGS) to analyze the immunoglobulin H (IgH) locus, capturing the broad spectrum of BCR diversification and evolution. This involves isolating B cells from peripheral blood mononuclear cells of immunized RMs, followed by culture stimulation to induce IgH/L locus transcription. Post-stimulation, the IgH locus is amplified using 5'RACE PCR and prepared for in-depth Illumina sequencing, which allows for detailed insights into the BCR repertoire.
Results: Preliminary analysis indicates differences in BCR clonality and SHM correlated with the level of antigen multimerization. The application of 10X has enabled detailed characterization of Env-specific B cell maturation processes. Concurrently, NGS has facilitated a broad analysis of the BCR repertoire evolution. This dual approach allows for an in-depth examination of the effects of antigen presentation on B cell responses following HIV-1 vaccination.
Conclusion: Our research advances understanding of B cell responses to HIV-1 vaccine modalities in RM, focusing on antigen multimerization effects. Utilizing 10X and NGS, we dissect key B cell maturation aspects crucial for HIV-1 vaccine development. This study informs future vaccine design, enhancing our ability to tackle HIV-1 and other pathogenic challenges.

Training for disaster: Macrophages, obesity, and the potential of mesenchymal stromal cells

Laura Bitterlich[1], Andrew Hogan[1], Karen English[1]
[1]*Maynooth University, Maynooth, Ireland*

Purpose: In recent years, innate training has drawn increasing attention as both a potential beneficial and detrimental influence in health and disease. Training stimuli associated with obesity, like saturated free fatty acids (FFAs), have been associated with increased disease severity and higher mortality in pre-clinical models due to elevated expression of pro-inflammatory cytokines by trained macrophages. Mesenchymal stromal cells (MSCs) are known for their anti-inflammatory properties. In our study, we aimed to determine if palmitate trains macrophages, if this training is associated with epigenetic and metabolic changes, if MSCs are able to block the training by the saturated FFA palmitate, the mechanism by which this is accomplished, and if MSCs are able to suppress *in vivo*-trained macrophages to the same degree as untrained macrophages.
Methods: For the training experiments murine haematopoietic stem and progenitor cells and human peripheral blood monocytes were exposed to 0.3 mM palmitate for 24 hr, washed and differentiated into macrophages over 7 days. After this rest period, the macrophages were stimulated with 100 ng/mL LPS for 24 hr, supernatants were collected and analysed for concentrations of TNFα and IL-6. For epigenetic changes, the methyltransferase inhibitor methylthioadenosine was added 30 minutes before palmitate and remained in the well for the training period. Metabolic changes were observed by adding 2-DG in low glucose medium, oligomycin, CB839, or etomoxir during stimulation with LPS. To investigate if MSCs are able to block palmitate-mediated training and further elucidate potential associated pathways, MSCs were added in a transwell during the training period, either untreated, pre-treated with the COX-2 inhibitor NS-398, or in the presence of an IL-1RN neutralising antibody. Finally, to investigate *in vivo*-trained macrophages, blood from human patients with obesity (PWO) and healthy controls was collected.
Results: Palmitate-trained macrophages from both mouse and human sources responded to secondary LPS stimulation with increased TNFα and IL-6 expression. Inhibition of methyltransferases and co-incubation with MSCs in transwells inhibited training. Blocking of the COX-2 pathway in MSCs restored macrophage training for TNFα, while neutralisation of IL-1RN restored macrophage IL-6 training, implying different training pathways. Interestingly, MSCs also affected the training-associated changes in macrophage metabolism.

Dietary supplementation with b-glucan induces trained immunity, correcting immune-metabolic perturbations and enhancing anti-tumour function in dietary induced obesity

Anna Ledwith[1], Hannah Prendeville[1], Cian Horneck Johnston[1], John McGrath[1], Stephen Cunnningham[1], Frederick Sheedy[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Background: Innate immune cells can exhibit memory-like features when exposed to stimuli such as yeast β-glucans. This phenomenon is termed "trained immunity", defined by bone marrow myelopoiesis and enhanced production of cytokines following secondary stimulation. Recently, it has been shown that induction of trained immunity by IP administered β-glucans supports anti-tumor function. Little is known about the immuno-metabolic consequences of **dietary** β-glucans (WGP). High fat diets (HFDs) drive myelopoiesis and enhance inflammatory functions of myeloid cells. This inflammatory phenotype, induced by HFD, is pathogenic and promotes the development of metabolic disease. We hypothesized that dietary WGP could reverse the metabolic defects caused by HFD by inducing beneficial trained immunity.
Results/Methods: Dietary supplementation with WGP increases myelopoiesis, as evidenced by increased MPP3 population in bone marrow. In BMDMs, WGP enhances TNF production in response to LPS stimulation and heightens phagocytic ability. BMDMs also show altered epigenetic profiles, with heightened global H3K27 acetylation, and altered metabolic function, with heightened OXPHOS and glycolysis. Given the heightened metabolism and increased cytokine production, we hypothesized that WGP may protect against the accelerated tumor growth often seen in mouse models of HFD. In MC38 tumor model, tumor growth was inhibited in WGP fed mice. This effect is likely due to heightened mitochondrial ROS (mitoROS) production and heightened TNF and IFNg production in tumor macrophages and NK cells. Feeding HFD and supplementing a HFD with WGP (HFD+WGP) both show expansion of myeloid progenitor precursors. HFD+WGP feeding attenuated the rates of glycolysis and OXPHOS in unstimulated BMDMs. In MC38 tumor model, HFD mice show accelerated tumor growth, potentially due to decreased NK and CD8 T cell function. Mice fed HFD+WGP show increased tumor clearance, with heightened TNF and IFNg production, which are important for anti-tumor immunity. In HFD tumors, macrophages have lowered mitoROS production, HFD+WGP tumor macrophages and NK cells rescue mitoROS levels with a return to SFD mitoROS levels.
Conclusions: Feeding WGP induces trained immunity features, altering hematopoiesis and immune function. Dietary WGP is a simple, cost-effective means to reverse the immunometabolic defects of obesity. This may have implications for treatment of metabolic diseases such as cancer.

Inflammatory skin diseases like psoriasis, atopic dermatitis (AD) and allergic contact dermatitis (ACD) are characterized by persistent site-specific recurring lesions. Tissue-resident memory T (T_{RM}) cells remain sessile in those skin lesions and have been linked to the recurring chronic pathology. Epstein-Barr Virus-induced gene 2 (EBI2 or GPR183) mediates chemotaxis towards its ligand 7α,25-dihydroxychlesterol (7α,25-OHC). CH25H and CYP7B1 are the enzymes that synthesize 7α,25-OHC. A number of inflammatory disease pathologies are associated with the EBI2-oxysterol-axis, such as of rheumatoid arthritis, MS, COPD and IBD. EBI2 has not been described in the context of T_{RM} cells as of today.
Using an experimental murine ACD model, contact hypersensitivity (CHS), and a public human transcriptome bulk-RNAseq dataset, we compared mRNA expression of EBI2-oxysterol-axis-genes in lesional vs. non-lesional skin. Utilizing high-parameter flow cytometry and clustering algorithms, we analyzed EBI2 expression of T_{RM} cells in lesional vs. non-lesional skin of biopsies from murine CHS ears and psoriasis patients. We also screened different T_{RM} cells of different human organs like the lung and the colon for EBI2 expression.
Gene expression of the EBI2-oxysterol-axis-genes was upregulated in murine (CHS) and in human (psoriasis and AD) lesional skin, compared to non-lesional skin. While only up to 40% of circulating $CD8^+$ T cells express EBI2, a striking 80 (human) to 95% (mouse) of skin $CD8^+$ T_{RM} cells are $EBI2^+$. Murine $CD8^+$ T_{RM} cells upregulate EBI2 expression during differentiation from effector cells. Lung and colon T_{RM} cells also express EBI2, similar to skin T_{RM} cells.
T_{RM} cells are known to reside in ex-lesional skin and mediate chronic flare ups. We find those cells expressing EBI2 in mouse and human skin. The upregulation of EBI2 expression of skin $CD8^+$ T_{RM} cells, compared to circulating $CD8^+$ T cells, in conjunction with the upregulation of the expression of EBI2-oxysterol-axis-genes in lesional murine and human skin, is a strong indicator that the EBI2-oxysterol-axis is involved in the pathology of inflammatory skin diseases and implicates a functional role for EBI2 on T_{RM} cells that is yet to be uncovered. High EBI2 expression by lung and colon T_{RM} cells suggests a similar role in those organs.

Exploring MAL signalling as a mechanistic mediator of IFNγ-induced trained immunity

Isabella Batten[1], Dearbhla Murphy[1], Sarah Connolly[1], Grainne Jameson[1], Sharee Basdeo[1]
[1]*Trinity Translational Medicine Institute, St. James's Hospital, Trinity College Dublin, Dublin, Ireland*

Background: Interferon gamma (IFNg) has been shown to play an important role in the induction of innate immune training, a memory-like state in innate immune cells involving metabolic and epigenetic reprogramming that results in heightened responses to infection. The mechanisms that drive this phenotype remains unclear. *TIRAP* is a gene that codes for MAL, an adaptor protein involved in multiple inflammatory signalling pathways. The S180L single nucleotide polymorphism (SNP), within *TIRAP* decreases the affinity of MAL for its receptors, thereby decreasing cellular signalling. This common SNP is reported to affect susceptibility and response to multiple infections including tuberculosis and sepsis. MAL facilitates signalling through the IFNg receptor. We therefore hypothesise that IFNg-induced innate immune training is affected by the presence/absence of the S180L SNP in *TIRAP*.
Methods: DNA was extracted from saliva samples collected from healthy donors (n=103) and genotyped for the presence of the S180L SNP using PCR allelic discrimination. Innate immune training assays were carried out on a small cohort of donors with either the presence of the SNP on both alleles (LL; n=3) a single allele (SL; n=7) or those who lack the presence of the SNP (SS; n=7). Blood samples were collected, and monocytes enriched from PBMCs, trained with IFNg for 24hrs, washed and allowed to return to homeostasis and rest. On day 6, monocyte-derived macrophages (MDMs) were challenged with irradiated *M.tb* for a further 24hrs. Activation and co-stimulatory marker expression was analysed using flow cytometry while cytokine production was measured by ELISA.
Results: Human MDMs show significantly increased TNFa, IL-1b, IL-6 and IL-10 production and CD40, CD14 and HLA-DR expression in response to *M.tb* challenge post IFNg training compared to untrained cells. SL and LL individuals produce significantly lower TNF*a* following IFNg training compared to SS individuals and similar trends are noted with regards to IL-1b and IL-10 production. However, no changes in IL-6 production or CD40, CD14 and HLA-DR expression were noted between genotypes post IFNg training.
Conclusion: Although MAL has a role in inflammatory cytokine production post IFNg training, MAL signalling is likely not the primary mechanism involved in IFNg-induced trained immunity.

Effect of immunosuppressive regimen on cellular and humoral immune response to SARS-CoV-2 vaccination in anti-CD20 treated hematological patients and in solid organ transplant recipients

Laura Maggi[1], Anna Vanni[1], Manuela Capone[1], Lorenzo Salvati[1], Alessio Mazzoni[1], Giulia Lamacchia[1], Seble Tekle Kiros[1], Lorenzo Cosmi[1], Benedetta Puccini[2], Vito Terlizzi[3], Paola Romagnani[1], Gian Maria Rossolini[1], Alessandro Bartoloni[1], Francesco Liotta[1], Francesco Annunziato[1]
[1]University of Florence, Florence, Italy; *[2]Hematology Unit, Careggi University Hospital, Florence, Italy*; *[3]Meyer Children's University Hospital, Florence, Italy*

Purpose: Immunocompromised patients are a fragile category of subjects, particularly exposed to infections and characterized by an impaired ability to respond to vaccination. An extensive knowledge on the immune response status of these subjects in terms of specific antibodies production and T cells activation is fundamental to improve the immunization strategy.
Methods: We monitored humoral (IgG serum levels) and cellular (antigen-specific T cells by multiparametric flow cytometry) memory responses after mRNA SARS-CoV-2 vaccination in lung transplanted cystic fibrosis patients (CFT) or not transplanted (CF), in kidney transplant recipients (KT) and in hematological patients in course of biologic therapy with anti-CD20 monoclonal antibodies or 3-24 months after the end of the treatment.
Results: Immunocompromised transplanted patients displayed a weak cellular and humoral memory immune response to SARS-CoV-2 mRNA vaccination and in particular the therapy regimen including antimetabolites, mainly affecting the humoral compartment, induced a lower humoral and cellular response also after booster dose. As expected, SARS-CoV-2 specific humoral immune response is absent in hematological patients under anti-CD20 treatment, whereas is evident in hematological patients vaccinated after therapy termination. In particular patients treated also with bendamustine, an antimetabolite, showed lower levels of SARS-CoV-2 specific Ig. Both cohorts of hematological patients, vaccinated during of after the anti-CD20 treatment, showed a robust SARS-CoV-2 specific T cells response, not particularly influenced by bendamustine treatment.
Conclusion: These results suggested that immunocompromised patients, in particular in case of antimetabolite treatment, need adequate interventions to improve humoral and cellular immune response to mRNA SARS-CoV-2 vaccine such as additional jab or modulation of immunosuppressive therapy. Of note, these findings could open the way to further investigation on induction and/or maintenance of memory immune response in immunocompromised patients in response also other vaccination different from SARS-CoV-2 to improve immunization strategy.

Killing IgE+ plasma cells: The role of IgE B cell receptor in human IgE+ plasma cell survival

Faruk Ramadani[1;2], Tooki Chu[2], Helena Tolarova[2], Pavel Tolar[2]
[1]King's College London, London, United Kingdom; *[2]Institute of Immunity and Transplantation, Division of Infection and Immunity, University College London, London, United Kingdom*

Allergen-specific IgE antibodies, secreted by plasma cells (PCs), play a fundamental role in the severity of allergic disease, including asthma. Analysis of IgE^+ B cell differentiation into PCs indicate that class switching is followed by a dynamic up-regulation of surface expression of IgE B cell receptor (mIgE). Although mouse IgE^+ PCs express surface mIg 4-fold higher than $IgG1^+$ PCs, the crosslinking of the BCR on mouse PCs leads to their preferential killing in a Syk, BLNK and PLCγ2 dependent manner. However, the human mIgE exhibits unique characteristics, differing not only from those of other antibody classes but also from those of mouse mIgE. Namely, humans express a short and a long form of membrane IgE: $mIgE_S$ and $mIgE_L$, which differ in their capacity to signal and in their expression during PC differentiation; $mIgE_S$, a homologue of the mouse mIgE, is upregulated, whereas $mIgE_L$ is downregulated in IgE^+PCs.
To investigate the functional significance of this differential expression we generated IgE^+ cells from human tonsil B cells. We then evaluated the killing capacity of anti-IgE antibodies that target different regions of mIgE, and characterised the molecular mechanisms involved by combining CRISPR/Cas9 gene targeting with inhibitors against various BCR signalling components.
We observed that IgE^+PCs were highly apoptotic when either $mIgE_L$ or both $mIgE_S$ and $mIgE_L$ where crosslinked. Also, IgE^+ PCs were killed at a higher rate than $IgG1^+$PCs after BCR crosslinking with anti-**λ** and anti-**κ**. Inhibition of Syk and intracellular Ca^{2+} signalling rescued the killing of both IgE^+ and $IgG1^+$PCs, whereas the inhibition of PI3K p110δ enhanced the apoptosis of IgE^+PCs by modulating the expression of BIM, a pro-apoptotic factor. Most importantly, we discovered that IgE^+ PCs, compared to $IgG1^+$ PCs, express significantly higher levels of PTEN, a phosphatase that negatively regulates PI3K signaling. CRISPER/Cas9 knockout of PTEN, as well as that of BIM, was able to rescue the killing of IgE^+PC but not that of $IgG1^+$PCs.
Overall, here we show that Syk and intracellular Ca^{2+} are required for the BCR killing of both IgE^+ and $IgG1^+$PCs, whereas modulation of PI3K signalling plays an important role in the survival of IgE^+PCs only.

Stiffness regulates dendritic cell and macrophage subtype development and increased stiffness induces a tumor associated macrophage phenotype in cancer co-cultures

Carla Guenther[1]
[1]*Immunology Frontier Research Center, Osaka University, Osaka, Japan*

The mechanical properties of tissues including stiffness change throughout our lives, during both healthy development as well as accompanying chronic diseases like cancer. The impact of changes to stiffness during cancer progression specifically on leukocytes remains unknown. To address this, I analyzed myeloid phenotypes resulting from mono- and cancer co-cultures of primary murine and human myeloid cells on two- and three-dimensional hydrogels with varying stiffnesses. On soft hydrogels, conventional DCs (cDCs) developed, whereas on stiff hydrogels plasmacytoid DCs (pDCs) developed. Cell populations expressing macrophage markers CD14, Ly6C, and CD16 also increased on stiff hydrogels. In cancer co-cultures, CD86+ populations decreased at higher stiffnesses across six different cancer models. High stiffness also led to increased VEGFA, MMP, and CD206 expression; 'M2' markers expressed by tumour-associated macrophages (TAMs). Indeed, the majority of CD11c+ cells expressed CD206 across human cancer models with high stiffness. Targeting the PI3K-Akt pathway led to a decrease in CD206+ cells in murine cultures only, while human CD86+ cells increased. An increased stiffness in cancer could thus lead to the dysregulation of infiltrating myeloid cells and shift their phenotypes towards a M2-like TAM phenotype actively enabling tumor progression. Additionally, stiffness-dependent signaling appears species-dependent, which might contribute to the high failure rate of clinical trials.

RNAseq analyses uncover the transcriptional signature of NK cells and reveal S1P5 and CXCR4 as new targets to modulate tumor cell killing

Marta Puig Gamez[1], Martijn Van Attekum[2], John E Park[1]
[1]*Boehringer Ingelheim Pharma GmbH & Co. KG, Department Cancer Immunology and Immune Modulation, Biberach an der Riss, Germany*; [2]*Boehringer Ingelheim Pharma GmbH & Co. KG, Department Global Computational Biology and Data Sciences, Biberach an der Riss, Germany*

Natural Killer (NK) cells are innate lymphocytes that can kill stressed cells without antigen-restriction. Malignant tumor cells often down-regulate MHC-I molecules to escape killing by conventional CD8+ T cells. NK cell activity is thus critical in such instances to build a robust anti-tumoral immune response. Circulating NK cells are highly heterogeneous and present different profiles in cytokine response, cytotoxicity and tumor infiltration. Here, we set out to identify new intrinsic modulators of NK cell activation. We challenged cytokine-treated and untreated human primary blood-borne NK cells with the HCT116 human colon cancer cell line and used detection of LAMP1 (CD107a) in the plasma membrane as a marker of rapid NK cell degranulation and thus, engagement. RNA sequencing of these cells produced a transcriptomic profile restricted to LAMP1^{hi} NK cells which we refer to as "Early-bird signature". *CXCR4* and *S1PR5* stood out as top down-regulated genes in the rapid NK cell responders. Using compounds which modulate activity of CXCR4 and S1P5, we confirmed that both proteins play a role not only in NK cell, but also in CD8+ T cell cytotoxicity. Along with S1P5, other members of the Shingosine-1-Phosophate (S1P) signaling pathway are demonstrated to be involved in NK and CD8+ T cell activity. Interestingly, ligands of both CXCR4 and S1P5 are enriched in the TME of some tumors and act as chemoattractants to facilitate lymphocyte infiltration. The co-regulation of CXCR4 and S1P5 will be examined. Together, these data suggest that specifically targeting CXCR4 and S1P5 activity in the TME could be a good strategy to unleash full cytotoxic potential of cytotoxic effector cells in the tumor.

KIR2DL5 in bladder cancer susceptibility and treatment response

Inmaculada Ruiz Lorente[1], Lourdes Gimeno Arias[2], Alicia López Abad[3], Maria Victoria Martínez Sánchez[1], Diana Ceballos Francisco[1], Pedro López Cubillana[3], Alfredo Minguela Puras[1]
[1]IMIB-Arrixaca (Immunologie Service), Murcia, Spain; *[2]University of Murcia-IMIB-Arrixaca, Murcia*; *[3]University Hospital Virgen de la Arrixaca (Urology Service), Murcia, Spain*

Purpose/Introduction: KIR2DL5 is an inhibitory human killer-cell immunoglobulin-like receptor (KIR) that has gain interest recently as a cancer immunotherapy target since poliovirus receptor (PVR, CD155) has been described as its ligand. The biology and therapeutic potential of the KIR2DL5/PVR interaction are largely unknown. It has been shown that KIR2DL5/PVR interaction inhibits synapse formation and its blockade robustly augmented the NK cytotoxicity against PVR+ human tumors. Data from our groups involved KIR2DL5 with bladder cancer susceptibility and cancer progression.
Methods: This work explores the frequency of KIR2DL5 in three independent series of patients with bladder cancer, one retrospective (n=79) and two prospective series 2013-15 (n=59) and 2019-22 (n=191) as well as in other solid (n=196) and hematologic (n=323) cancers and healthy donors (n=615). The impact that the presence of KIR2DL5 has on the response to BCG (non-infiltrating cancers) or chemotherapy (infiltrating cancers) treatments is analyzed.
Results: The frequency of KIR2DL5 was increased in the 3 bladder cancer series (68.4%, 65.9%, and 63.9%, $p<0.001$) compared to other solid (56.6%) and hematological (51.1%) cancers or healthy donors (51.5%). A total of 152 patients were treated with BCG (46.2%). KIR2DL5 was associated with better overall survival (OS) in patients with non-infiltrating tumors treated with BCG (mean OS of 7.7±0.4 vs. 6.3±0.55 years, $p<0.05$), but not in patients with infiltrating tumors treated with chemotherapy (mean OS of 56.4±0.35 vs. 58.5±0.54 years). KIR2DL5 did not significantly impacted OS of patients with other solid or hematological cancer.
Conclusion: KIR2DL5 was significantly associated with higher susceptibility to bladder cancer. Unexpectedly, KIR2DL5 was associated with better survival in patients treated with BCG. Our data suggest that it would be advisable to investigate whether intraurethral stimulation with BCG favors more potent antitumor NK cell responses, and therefore if the use of immunotherapies against KIR2DL5/PVR interaction could be useful.

Modulation of ILC3 metabolism as a potential therapeutic target for colitis-dependent colorectal cancer

Raquel Castillo-González[1;2], Lucía Sancho[1;2], Lúa Blanco-Axpe[1], Irene Torres-Pulido[1], Alba Seguí-Pérez[1], Cristina Villa-Gómez[1], Aranzazu Cruz-Adalia[1;2]
[1]Departament of Inmunology, Ophthalmology and ENT, Faculty of Medicine, Complutense University of Madrid, Madrid; *[2]Health Research Institute Hospital 12 de Octubre (imas12), Madrid, Spain*

Colorectal cancer (CRC) is a leading cause of death. Patients with inflammatory bowel disease (IBD) are more likely to develop CRC, although the factors that mediate the IBD-CRC transition remain unclear. Innate type 3 lymphocytes (ILC3s) are tightly involved in IBD pathogenesis and may be related to the transition from IBD to CRC. Moreover, the hypoxia-inducible transcription factor (HIF-1α) favors tumor growth in hypoxic environments and regulates ILC3 function.
To elucidate the function of HIF-1α in ILC3s during the transition from IBD to CRC, mice with HIF-1α deletion in RORγt^{+} cells (HIF-1α$^{\Delta Rorc}$; CRE) were analysed. Additionally, RAG-1KO HIF-1α$^{\Delta Rorc}$ mice (CRE), which produce no mature B or T cells, were used to ascertain HIF-1α's specific role in ILC3s. Both models were subjected to chemical treatments with 3% DSS that induced colitis or with the carcinogen AOM followed by 2.5% DSS as a CRC model.
In both colitis and CRC models, CRE mice exhibited more severe tissue damage and significantly lower survival than their controls, throughout the treatment. Furthermore, in the colitis model, CRE mice presented a greater number of ILC3 NCR^{+} lymphocytes.
Results reveal the protective role of the endogenous factor HIF-1α in ILC3 cells during the development of the colitis-associated CRC. Additionally, the higher number of ILC3 NCR^{+} lymphocytes in CRE mice suggests enhanced cell proliferation in the absence of the HIF-1α factor. However, further research is needed to delve into the mechanism through which ILC3s, without HIF-1α, affect CRC development and susceptibility.

Multiparametric lymphocyte characterization in ovarian cancer: Identifying possible targets for immunotherapy.

Veronika Lutz[1], Hartmann Raifer[1], Magdalena Huber[1]
[1]*Philipps University Marburg, Marburg, Germany*

Purpose: Ovarian cancer (OC) is the deadliest gynecological malignancy, characterized by accumulation of fluid termed ascites at an advanced stage. Considering that OC-ascites comprises tumor cells, tumor cell spheroids, innate and adaptive immune cells, and its accessibility, ascites provides an excellent source to investigate the impact of tumor microenvironment on anti-tumor immune response. It is known that OC-ascites influences the differentiation and activation state of several lymphatic subpopulations. Published data suggest alterations in innate and adaptive lymphocyte populations, which contribute to tumor progression. The limitations of these studies is the focus on only one lymphatic subpopulation. The goal of this comprehensive study is to identify alterations in composition of the innate and adaptive lymphocyte populations by comparing OC-ascites to patient peripheral blood (PB) and PB from healthy donors (HD).
Methods: To identify alterations in the lymphocyte composition caused by OC, PB from OC patients and healthy donors are compared. Further, alterations in the lymphocyte composition caused by OC-ascites were analyzed by comparing PB and ascites samples from the same OC patients. For this, PBMCs from healthy donors, PBMCs, and ascites from patients with short and long survival in late stages of OC are analyzed. To identify possible targets within lymphocyte subpopulations in PB and ascites from OC patients for immunotherapy spectral flow cytometric analysis of PBMC and ascites lymphocytes was used. Two 37 marker panel to identify several subpopulations, including several CD4, CD8 and NK subpopulations, but also their differentiation, activation and cytokine profile were used.
Results: Comparing lymphocyte clusters from HD, OC blood and ascites samples revealed distinct expression patterns and differences between the three groups. Samples from ascites showed increased CD8 and NK cell cluster and decreased CD4 cluster, whereas PB from HD and OC patients differed in the abundance of CD8 and CD4 Treg cluster. Further, each group showed clear distinct patterns in their differentiation and activation state.
Conclusion: We believe that the obtained knowledge will give hints for the development of new therapy strategies employing specific drugs to reverse the OC-caused alterations in the lymphocyte clusters, their activation, differentiation, exhaustion, or functional state.

SH2D2A is an indicator of favourable prognosis in bladder cancer and is enriched in activated Treg cells

Brian Christopher Gilmour[1], Johan Georg Visser[1], Alvaro Kohn-Luque[2;3], Andreas Lossius[1], Anne Spurkland[1]
[1]Department of Molecular Medicine, Institute of Basic Medical Sciences, University of Oslo, Oslo, Norway; *[2]Oslo Centre for Biostatistics and Epidemiology, Institute of Basic Medical Sciences, University of Oslo, Oslo, Norway*; *[3]Oslo Centre for Biostatistics and Epidemiology, Research Support Services, Oslo University Hospital, Oslo, Norway*

The growing importance of RNA sequencing (RNA-seq) technologies has brought about an expansion in the quality and accessibility of the method and its data output. The conventional approach that has defined much of life sciences begins with measurable phenomena, natural or otherwise, and proceeds, by identification of the mutations or aberrations that produce it, to a gene's function. While this approach has produced a great body of scientific progress, its Achille's heel is its reliance on measurable phenomena. With the expanding availability of RNA-seq and other such high dimensional data it is now possible to consider a complementary approach working in the opposite direction *i.e.*, from transcriptomics up towards protein function. This approach may prove fruitful in producing information on the function of cytosolic-bound proteins such as adaptor proteins.
To test the validity of this method, we made use of several public datasets to interrogate the cancer-specific role of the adaptor protein SH2D2A: a protein enriched in T and NK cells, and a known interactor of the kinase LCK, whose function remains uncertain. We found that SH2D2A is a favourable marker for prognosis in urothelial bladder cancer (BLCA). Digging further, we identified a population of $SH2D2A^{+}$ $FOXP3^{+}$ $IL2RA^{hi}$ activated Tregs as the main expressors of SH2D2A in BLCA. This suggests that the expression of SH2D2A in these Tregs contributes to a beneficial prognostic effect. Further comprehension of SH2D2A's function in these cells holds the potential for advancing treatment in BLCA.

Tumour exosomes induce changes in immune system cells, promoting a state of tolerance that facilitates tumour progression. In neutrophils, exosomes from different tumours induce the release of extracellular traps (NETs), which contribute to pre-metastatic niche formation and tumour dissemination. However, little is known about the adhesion molecules and receptors that mediate the binding and uptake of these exosomes and the pathways and type of NETosis they induce. Our group has described, among others, that the tetraspanin CD9 is involved in the uptake of colocarcinoma exosomes by mesothelial cells by modulating the activity of several adhesion molecules and metalloproteases. In this work, we investigate the ability of exosomes from the colocarcinoma cell line Colo320 to induce NETosis in neutrophils from the promyelocytic line HL-60 and the role of tetraspanin CD9 in tumour exosome-neutrophil interaction.
Exosomes were isolated from the Colo320 or the CD9-overexpressing Colo320 colocarcinoma cell lines using tangential flow filtration and size exclusion chromatography. Exosomes were incubated with neutrophils derived from the retinoic acid treated human promyelocytic HL-60 cell line. As controls, neutrophilic HL60 cells were exposed to LPS or PMA for NET induction. NET production was analysed by fluorescence microscopy and flow cytometry using DAPI, MPO and citrullinated H3 as NETosis markers.
Our results indicate that tumour exosomes derived from colocarcinoma cells have the ability to induce NETosis in neutrophilic HL60 cells by inducing H3 citrullination and the release of DNA and MPO at early time points. In addition, CD9 expression on tumour exosomes greatly increased NET formation, shortened the time required to detect NETosis and increased the number of cells undergoing NETosis.
Expression of the tetraspanin CD9 in tumour-derived exosomes promotes the binding/uptake of these microvesicles by neutrophils, resulting in an increase in the formation of NETs that are detected at early time points.

Mitochondria transfer, a potential mechanism of CD4+ T cell exhaustion in oral cancer

Bárbara Antilef[1], Solange Cisterna[1], Romina Quiroga[1], Sergio Sanhueza[1], Camilo Cabrera[1], Camila Muñoz[1], Felipe Zúñiga[1], Luciano Ferrada[2], Wilfredo González[3], Patricia Luz[3], Andrés Caicedo[4], Andy Perez[5], Mauricio Hernandez[6], Estefania Nova-Lamperti[1]
[1]Molecular and Translational Immunology Laboratory, Clinical Biochemistry and Immunology Department, Pharmacy Faculty, Universidad de Concepcion, Concepcion, Chile; *[2]CMA BIO BIO, Faculty of Biological Sciences, Universidad de Concepción, Concepción, Chile*; *[3]Universidad de los Andes, Santiago, Chile*; *[4]Universidad San Francisco de Quito USFQ, Quito, Ecuador*; *[5]Departamento de Análisis Instrumental, Facultad de Farmacia, Universidad de Concepción, Concepción, Chile*; *[6]Melisa Institute, San Pedro de la Paz, Chile*

Purpose: Oral squamous cell carcinoma (OSCC) is the most frequent type of oral cancer, and its tumor microenvironment (TME) induces an exhausted phenotype and metabolic reprogramming in CD4+T- lymphocytes. The mitochondria are the main metabolic organelle and in recent years it has been shown that several cells have the capacity to transfer mitochondria, including cancer cells. Moreover, we identified several mitochondrial proteins in secretomes from biopsies of patients with OSCC. However, it has not been evaluated whether mitochondria transfer from OSCC cells into CD4+T-lymphocytes promotes an exhausted phenotype in the T cells. The aim of this work was to analyze the exhausted phenotype with metabolic changes in CD4+T-lymphocytes after artificial transfer of mitochondria obtained from the oral cancer cell line HSC-3.
Methods:
MitoTracker-labeled mitochondria from oral cancer tumor cells were Mitocepted into CD4+T- lymphocytes. Then, surface molecule expression, proliferation and cytokine secretion mediated by tumor mitochondrial transfer were analyzed by flow cytometry. In addition, Mitocepted CD4+T- lymphocytes were evaluated by proteomic and metabolomic analysis, determination of superoxide production, glucose uptake and lactate production.
Results:
TCD4+ lymphocytes that acquired malignant mitochondria had increased expression of TIGIT, CTLA4, PD-1, PLD-1 and LAG3, compared to the control group. In addition, the mitocepted lymphocytes exhibited a significant decrease in proliferation compared to the control. For cytokine analysis, a significant decrease was observed in the mitocepted group for IFN-gamma, TNF-alpha, IL-10, and IL-4 secretion, compared to control. Metabolomic and proteomic analysis showed a reduction in the pyruvate dehydrogenase cofactor called Vitamin B1 and an increase in hypoxia, glycolysis, and mitochondrial superoxide production in the mitocepted group versus the control. In fact, mitocepted lymphocytes with malignant mitochondria uptake more glucose, produce more reactive oxygen species and lactate than non-mitocepted cells and cells mitocepted with autologous mitochondria from the same T-cells.
Conclusion: The acquisition of isolated mitochondria from HSC-3 cancer cells by CD4+T-lymphocyte induces mitochondrial oxidative stress in the recipient cell and a possible reduction of the Krebs cycle, mediated by low thiamine. This effect promotes a salvage glycolytic metabolism, an exhausted phenotype and a dysfunctional $CD4^{+}$T-cell, affecting the anti-tumor response.

Differential regulation of the chemokine CCL21 in the antitumor immune response in non-small cell lung cancer.

Maria Riutort-Garvi[1], Pablo Delgado-Wicke[2], Carlos Cuesta–Mateos[2], Arantzazu Alfranca[2]
[1]Immunology Service, La Princesa University Hospital, Madrid, Spain; *[2]Department of Immunology, Biomedical Research Institute La Princesa Hospital (IIS-IP), Madrid, Spain*

Lung cancer is one of the leading causes of death worldwide. The use of therapies aimed at enhancing the antitumor immune response, such as anti-PD-1 antibodies, has been a milestone in the treatment of this pathology. However, the effectiveness of this therapy is still limited. Therefore, the study of the mechanisms that mediate the antitumor effect of these treatments is of great relevance. Previous studies from our group demonstrate that anti-PD-1 antibodies induce an increase in CCL21 production in the tumor microenvironment of non-small cell lung cancer (NSCLC), as well as the formation of tertiary lymphoid structures (TLS) within the tumor, which correlate with the response to treatment.
Using a murine model of NSCLC, we have analyzed the possible source of tumor CCL21 by immunohistochemistry techniques in tumor samples, and by PCR in different cell types *in vitro*. Likewise, we have studied serum CCL21 levels in these mice using ELISA, to determine if they can be useful in monitoring tumor evolution and response to immunotherapy.
We have found two patterns of CCL21 production in the tumor, one associated with TLS and another associated with the tumor stroma. Likewise, we have determined that tumor cells, reticular fibroblastic cells, and endothelial cells are capable of expressing CCL21 mRNA in response to proinflammatory cytokines *in vitro*. Finally, we have observed an increase in serum CCL21 concentration in parallel with tumor progression, although it is not related to the size of the tumor and its progression is independent of treatment with anti-PD-1 antibodies.
The data obtained reflect that tumor CCL21 can originate locally in various cellular compartments, and point to a differential regulation of CCL21 detected systemically. The detailed characterization of the regulatory mechanisms of CCL21 will provide relevant information about the antitumor immune response and the response to immunotherapy in NSCLC.

Exploiting the cGAS/STING pathway to revert the immunosuppressive environment of multiple myeloma and boost Natural Killer cell-mediated immunosurveillance

Chiara Cassone[1], Eleonora Gnocchini[1], Elena Sproviero[1], Francesca Fazio[2], Maria Teresa Petrucci[2], Cristina Cerboni[1], Alessandra Soriani[1], Marco Cippitelli[1], Alessandra Zingoni[1]

Purpose: Multiple myeloma (MM), a bone marrow-resident hematological malignancy of plasma cells, is characterized by an immunosuppressive microenvironment, which causes a progressive dysfunction of immune cell populations, such as NK cells, implicated in MM surveillance. The main subject of this study is to reverse the tumor-mediated immune paralysis potentiating NK cell-mediated functions against MM cells. The GAS/STING pathway that leads to type I IFNs production is currently being explored as potential immunotherapeutic target in cancer. Since IFNs prime strong effector activity in NK cells, the GAS-STING pathway is an attractive candidate to our aim. We propose to improve this pathway directly in cancer cells by using the synthetic STING agonist diABZI.
Results and Methods: Reduced survival rate of MM patients is significantly correlated to a low STING expression in MM cells and we also found through Real Time PCR that STING levels were negatively regulated by bone marrow plasmas of MM patients, thus it is crucial to find strategies to reinforce the cGAS/STING pathway. Our results showed that diABZI induced the production of IFNs, IFN λ among all, and the activation of *interferon-stimulated genes* (ISGs) in MM cells. Notably, treating MM cells with recombinant IFN λ led to a strong inhibition of their proliferation. Since combinatorial therapy is the best approach for MM treatment, diABZI was used in combination with the chemotherapeutic agent bortezomib and the monoclonal antibody Daratumumab, which targets the ISG CD38. The combined use of diABZI and bortezomib remarkably induced MM cellular senescence performing β-galactosidase assay and an immunostimulatory Senescence-Associated-Secretory-Phenotype (SASP). Moreover, we observed through Real time PCR and flow cytometry that diABZI significantly upregulated CD38 expression in MM cells and that increased NK cell mediated-*ADCC* triggered by Daratumumab.
Conclusion: In sum, these results provide the rationale for the combined use of STING agonist, monoclonal antibodies and chemotherapeutic agents as new strategy to potentiate MM immunosurveillance and overcome tumor immune evasion.

RNA Polymerase I Inhibition and activation of Nucleolar Stress Response in the anticancer activity of Natural Killer cells against Multiple Myeloma

Elena Sproviero[1], Tommaso Cipollone[1], Eleonora Gnocchini[1], Sara Petillo[2], Chiara Cassone[1], Alessandra Zingoni[1], Alessandra Soriani[1], Cristina Cerboni[1], Maria Teresa Petrucci[3], Francesca Fazio[3], Marco Cippitelli[1]
[1]Department of Molecular Medicine, Sapienza University of Rome, Rome, Italy; *[2]National Eye Institute (NEI), NIH, Bethesda, United States*; *[3]Hematology, Department of Translational and Precision Medicine, Sapienza University of Rome, Rome, Italy*

Purpose: RNA polymerase I (Pol-I)-mediated transcription of the ribosomal RNA (rRNA) genes (rDNA) is rate-limiting for ribosome biogenesis, a process that is significantly elevated in rapidly dividing tumor cells. Perturbation of rDNA transcription is known to elicit Nucleolar Stress Response (NSR), which is heightened in cancer cells and offers novel opportunities for therapeutic targeting of human malignancies. To date little information has been provided about the role of the NSR and regulation of anticancer immune response.
We investigated the regulation of NSR in the tumor model Multiple Myeloma (MM) and its role in the Natural Killer (NK) cell response against this tumor.
Methods: Induction of NSR was triggered in MM cells using two "first in class" Pol-I inhibitors (Pol-Ii), CX-5461 and BMH-21 (nanomolar range). SKO-007(J3) and RPMI-8226 MM human cell lines have been treated with Pol-I inhibitors (at different concentrations/time) to evaluate by flow-cytometry and qReal-Time PCR, the expression levels of ligands for NK cell-activating and inhibitory receptors (MICA/B, ULBPs, PVR/CD155, Nectin-2, NCR-ligands), HLA-ABC, HLA-E, and CD38 (the molecular target of the therapeutic mAb Daratumumab). To investigate the functional consequences of Pol-Ii regulated changes of NK cell-activating ligands, HLA and CD38 expression, we analyzed by flow cytometry the upregulation of the lysosomal marker CD107a on NK cells of PBMCs from healthy donors, upon interaction with SKO-007(J3) cells (degranulation assay).
Results: We observed that the two drugs differently regulated the expression of NK cell activating ligands, HLA and CD38 in MM cells. Interestingly, while BMH-21 increased degranulation activity of NK cells against MM cells and IFN-γ/TNF-α levels, CX-5461 did not elicit the same effect. This correlated with a higher upregulation of DNA Damage Response (DDR) and senescence by CX-5461 as compared to BMH-21. RNA-seq analysis showed a significant enrichment of genes related to MHC presentation only in CX-5461 treated cells, and we confirmed higher levels of HLA-ABC and HLA-E by FACS analysis. Interestingly, inhibition of the ATR kinase reduced upregulation of HLA-E and increased degranulation activity when used in combination with Pol-Ii.
Conclusions: Inhibition of Pol-I and induction of NSR in MM, enhances NK cell-mediated response against this tumor.

Dendritic cell reprogramming through the tumor secretome affects anti-tumor immunity in PDAC

Tharrun Daniel Paul[1], Benedikt Stegemann[1], Caroline Lewe[1], Michael Hertl[1], Matthias Lauth[2], Elke Pogge von Strandmann[2], Prof. Johannes U Mayer[3]
[1]Department of Dermatology and Allergology, Marburg, Germany; *[2]Center for Tumor Biology and Immunology, Marburg, Germany*; *[3]Department of Dermatology and Research Center for Immunotherapy (FZI), University Medical Center Mainz, Germany*

Purpose: Antigen presenting cells, such as dendritic cells (DC) are crucial to initiate antigen-specific adaptive immune responses making them highly relevant in the context of anti-tumor immunity. DCs differentiate from hematopoietic stem cells and belong to the myeloid lineage. However, their ability to present antigens is reduced in many cancers, leading to ineffective anti-tumor immunity. Based on these observations we hypothesized that cold tumors, such as aggressive solid cancers like pancreatic ductal adenocarcinoma (PDAC) and ovarian cancer might be particularly affected by this response contributing to the ineffective priming of adaptive immune cells.
Methods: To develop a robust mid-throughput screening platform to assess the activation status of primary DC from murine and human stem cells, we have optimized murine classical DC culture systems and phenotyped the resulting immature DC by flow cytometry using a detailed myeloid cell surface marker panel to differentiate between various DC lineages and activation states. Immature DC were exposed to tumor cell line conditioned media from aggressive and remissive PDAC tumors to assess cellular activation/suppression. In parallel, we analyzed DC activation *in vivo* focusing on the expression of DC activation and inactivation markers.
Results: We observed DC inactivation profiles in both *in vitro* and *in vivo* settings, suggesting that tumor secreted molecules directly contribute to DC suppression. We now aim to identify the molecular mechanisms that result in DC suppression and profile a number of different tumor types to identify common and specific mechanisms of DC suppression/exhaustion.
Conclusion: Our preliminary data suggest that immune suppressive effects within the tumor microenvironment affect DC suppression and exhaustion and might represent suitable targets for solid tumor immunotherapy.

Investigating the expression of soluble immunomodulatory mediators in risk-stratified pancreatic cystic fluid and its effect on immune cell migration and T cell function.

Rebecca Lyons[1;2], Laura Kane[2], Gregory Mellotte[3], Aoife Kilgallon[1], Barbara Ryan[3], Stephen Maher[2], Joanne Lysaght[1]
[1]Cancer Immunology and Immunotherapy Group, Department of Surgery, School of Medicine, Trinity St. James's Cancer Institute, Trinity College Dublin, Dublin, Ireland; *[2]Cancer Chemoradiation Research Group, Department of Surgery, School of Medicine, Trinity St. James's Cancer Institute, Trinity College Dublin, Dublin, Ireland*; *[3]Department of Gastroenterology, Tallaght University Hospital, Dublin, Ireland*

Pancreatic cystic lesions (PCLs) are fluid-filled structures found within or on the surface of the pancreas. While many PCLs are benign, others such as intraductal papillary mucinous neoplasms can undergo malignant transformation and are regarded as precursor lesions of pancreatic cancer (PC). Current guidelines used to stratify PCLs as low- or high-risk of PC progression remain highly contended. Chemokines guide the migration of immune cells into tissues. However, the desmoplastic microenvironment in PC alters the dense extracellular matrix and adhesive capacity causing exclusion of anti-tumour effector immune cells. Furthermore, dysregulated chemokine release contributes to poor immunotherapy responses in immune-excluded pancreatic tumours. The influence of PCL-secreted chemokines and growth factors on PC initiation, promotion and progression remains unstudied.
Custom flow-based multiplex ELISAs were employed to screen pancreatic cystic fluid (PCF) and patient-matched sera for a range of relevant chemokines and growth factors that are associated with the promotion and progression of cancer. We assessed this panel of analytes in PCF from 18 patients. Pseudocysts, largely pancreatitis-derived non-neoplastic lesions with no risk of malignant transformation, were used as controls. Experimental findings were correlated with standard recorded clinical parameters. Functional chemotaxis assays were performed to elucidate key chemokine pathways that drive immune cell migration within the soluble microenvironments of PCLs and surrounding tissues. Flow cytometric analysis was carried out to investigate the capacity of risk-stratified PCF to impair T cell activation, anti-tumour functions and to assess if risk-stratified PCF induces a phenotypic switch in T cells towards a pro-tumour phenotype.
Twenty-five soluble immunomodulatory mediators were detected across all samples at varying concentrations, dependent upon sample type and risk status. Immune cell migration was assessed using Boyden chamber chemotaxis assays. Our results indicate that the migration of effector immune cells towards high-risk PCF is dysregulated compared to low-risk PCF.
Our preliminary data identifies immune targets within PCF and sera that may contribute to PC development and elucidates potential immune pathways that could be targeted to enhance immune cell infiltration into tumour tissue. These immune parameters could potentially be incorporated into stratification guidelines to more accurately identify high-risk patients for earlier diagnosis and treatment.

Characterizing the Impact of Lymphocyte-Derived Extracellular Vesicles on T Cell Function in Hematologic Malignancies

Lucija Levstek[1], Larisa Janzic[1], Alojz Ihan[1], Andreja Natasa Kopitar[1]
[1]*Institute for Microbiology and Immunology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia*

Purpose: Extracellular vesicles (EVs) are small, membrane-derived particles that have been identified as key players in cell-to-cell communication and were shown to influence immune responses, blood clotting, and the spread of cancer. In hematologic malignancies, tumor-derived EVs can significantly inhibit immune functions, impacting the effectiveness of immunotherapies, including advanced T cell-based treatments like CAR T cell therapies. The aim of this study is to optimize isolation and characterization processes of lymphocyte EVs from patients with hematologic malignancies and to determine the potential inhibitory properties of the isolated EVs on T cell function, which is critical for understanding and enhancing the efficacy of T cell immunotherapeutic products.
Methods: EVs were isolated from blood of healthy donors and patients with hematologic malignancies using high-speed centrifugation followed by purification with tangential flow filtration. The isolated vesicles were stained with a variety of reagents and fluorescently labeled antibodies, including carboxyfluorescein succinimidyl ester (CFSE), CellMask Deep Red^{TM}, CD9, CD63, and CD83 antibodies to assess their efficiency in staining lymphocyte vesicles. Preliminary measurements were obtained using a BD FACS Canto I cytometer, and the origin and subsets of the vesicles were determined by measuring parent cell markers for lymphocyte subpopulations (CD19, CD3, CD4, CD8). Our further research will focus on determining the exhaustion and activation signals of EVs on immune cell effector function, with an emphasis on identifying potential markers of exhaustion and activation.
Results: The staining techniques using CFSE and CellMask Deep Red^{TM} were shown to effectively stain the majority of the isolated lymphocyte vesicles, staining 98 % and 72 % of isolated lymphocyte vesicles, respectively. These methods proved to be significantly more effective than staining with CD9, CD63, and CD83 antibodies, which only labeled 46 % of the vesicles. The preliminary results suggest a significant role of EVs in modulating immune responses, highlighting their potential in predicting and monitoring the inhibitory effects on immune cells.
Conclusion: EVs show promising potential for predicting and monitoring immunotherapy progression. However, the standardization of EV handling procedures and the identification of precise vesicle biomarkers are crucial for better understanding their involvement in hematologic malignancies and immune system responses.

An organoid-based model to study innate lymphoid cells in colorectal cancer.

Lorenzo Lucantonio[1], Andrea Kosta[1], Giuseppe Pietropaolo[1], Francesca Sozio[1], Silvia Ruggeri[1], Mattia Laffranchi[1], Laura Beltrame[1], Helena Stabile[1], Rosa Molfetta[1], Giuseppe Sciumè[1], Giovanni Bernardini[1], Silvano Sozzani[1;2], Angela Gismondi[1], Angela Santoni[1;2], Cinzia Fionda[1]
[1]*Sapienza University of Rome, Rome, Italy*; [2]*Istituto Mediterraneo di Neuroscienze Neuromed, Pozzilli, Italy*

Purpose: Innate lymphoid cells (ILCs) emerged as central innate immune mediators during gastrointestinal homeostasis, inflammation, and tumorigenesis. The role of ILCs in cancer is still controversial since they have been associated with either pro- and antitumor activities. The aim of this study was to perform a comprehensive evaluation of phenotype and functions of natural killer cells (NK) and ILC subsets in the context of colorectal cancer (CRC) focusing on the direct impact of tumor on these lymphocytes.
Methods: We developed an 3D intestinal organoid model to use in *in vivo* and *in vitro* approaches. We set out a mouse model of CRC based on orthotopic transplantation of tumour organoids in an immunocompetent setting and to provide an in-depth characterization of tumor infiltrating ILCs we employed an 18-color flow cytometry panel. Moreover, to study tumor-ILC interaction, we performed RNAseq analysis to profile gene expression and flow-cytometric analysis of evaluate the degranulation ability and cytokine production of NK/ILC upon co-culture with tumor organoids.
Results: In the mouse model of CRC, we observed that healthy intestinal lamina propria was populated by ILC1, ILC2 and ILC3 while innate lymphocytes infiltrating colon tumours consisted mainly of NK and ILC1-like cells, indicating a key role for these subsets in controlling cancer progression. In parallel, *in vitro* tumor organoid-NK cell coculture system showed that cancer-derived soluble factors can inhibit target cell-induced degranulation and IFN-γ production by NK cells. These functional consequences are associated with changes of NK cell gene expression program. Indeed, RNAseq analysis demonstrated that tumor intestinal organoids can affect gene pathways controlling leukocyte proliferation, metabolism, and cell-cell-adhesion in NK cells.
Conclusion: Taken together, these results suggest a major role of NK and ILC1-like cells in innate immune response against CRC as well as the direct effects of inhibitory molecules produced by cancer cells on NK cells possibly leading to tumor escape.

A prototype of biocompatible solid lipid nanoparticles targeting CD19 antigen

Raquel Bernardo[1;2], Ana Navas[1;2], Juan Eduardo Molina Alcaide[1;2], Carmen Gutiérrez[1], Lide Arana[3], Aurora Jurado Roger[1;2]
[1]Immunology and Allergy Research Unit, Maimonides Biomedical Research Institute of Córdoba (IMIBIC)/ University of Córdoba/ Reina Sofía University Hospital, Córdoba, Spain; *[2]Department of Immunology and Allergy, Reina Sofía University Hospital, Córdoba, Spain*; *[3]Department of Applied Chemistry, Vasque Country University, Donosti, Spain*

Purpose: The aim of this investigation was to generate a preclinical model of biocompatible solid lipid nanoparticles (SLNs) targeted with an antibody against CD19, with the perspective of immunomodulate the immune system.
Methods: SLNs were developed through microemulsion, functionalized with variable proportions of anti-CD19 using avidin-streptavidin (Av:Ab) and dialysis systems and conjugated with FITC. Parameters including Z-average size (nm), polydispersity index, and Z-potential (mV) were assessed. Once generated, SLNs were co-cultivated for 1 up-to 24 hours with $CD19^-$ Jurkat cell line, $CD19^+$ NALM-6, as well as total blood and peripheral mononuclear cells to determine optimal nanoparticle concentration, dynamics and specificity of capture/internalization. Trypan-blue was used to quench extracellular signal and differentiate between capture and internalization processes. Additionally, SLNs were covered with PEG to improve capture/internalization specificity. Experiments fixing the cellular membrane and blocking CD19 were also performed. All the analyses were conducted using Flow cytometry (Facs CantoII) and analysed based on median intensity fluorescence (MFI).
Results: Proportions of Av:Ab at 1:50 and 1:150 demonstrated the most promising results with stable z-average size, polydispersity index and z-potential. Concentrations above 2 mg/mL of SLNs were toxic, whereas concentrations below 0.1 mg/mL were not enough to be captured/internalized. Capture/internalization was directly proportional to the concentration of nanoparticles but inversely proportional to the amount of anti-CD19 loaded. Almost all nanoparticles were internalized after 10 minutes of incubation. When fixing cellular membrane, capture/internalization was even higher. Optimal specificity was not achieved as SLNs were captured and internalized by both $CD19^+$ and $CD19^-$ cells even when they were covered with PEG. However, it seemed that B lymphocytes exhibited higher MFI values. This PEG neither achieved capture/internalization of SLNs in total blood samples. Finally, when blocking CD19 target, a slight decrease in the MFI was observed in NALM6 but not in Jurkat cells.
Conclusion: Hydrophobic nature of SLNs could be the underlying cause of not achieving a specific capture/internalization by $CD19^+$ cells. The inclusion of PEG did not improve that specificity. Further experiments involving the charge and the size of SLNs, the type of transport or alternative covering materials are needed to succeed in the specificity.

Repeated antigenic stimulation induces expression of surface 'Tumor necrosis factor Related Apoptosis Ligand' on human invariant Natural Killer T cells.

Zeynep Ayyildiz[1], Gerhard Wingender[1]
[1]*İzmir Biomedicine and Genome Center, İzmir, Turkey*

Purpose: Invariant Natural Killer T (*i*NKT) cells are unique innate-like T cells that recognize lipid antigens, like α-galactosylceramide (αGalCer), presented on CD1d. Following antigenic stimulation, *i*NKT cells rapidly display effector functions, like the production of various cytokines and cytotoxicity. The 'Tumor necrosis factor Related Apoptosis Inducing Ligand' (TRAIL), via its binding to the death receptors (DRs) 4 and 5, preferentially induced apoptosis in cancerous or unhealthy cells. Although it was suggested that *i*NKT cells can induce cell death in tumour cells via TRAIL, conflicting data were reported.
Methods: Peripheral blood mononuclear cells (PBMCs) of healthy donors were isolated and *i*NKT cells were expanded *in vitro* with αGalCer. TRAIL expression on *i*NKT cells (live $CD3^+$ $6B11^+$ cells) was analysed over time with or without activation by flow cytometry.
Results: Human PBMC-derived *i*NKT cells did not express TRAIL *ex vivo* and the expression on expanded *i*NKT cell lines was weak. However, restimulation of expanded *i*NKT cell lines with αGalCer gradually induced surface TRAIL expression, peaking on day 2 after the restimulation and decreasing towards baseline by day 7. Preliminary data suggest that surface TRAIL is lost by shedding.
Conclusion: Human peripheral blood *i*NKT cells express surface TRAIL only after a second antigenic stimulation. These data will help to better understand the TRAIL-mediated cytotoxicity by *i*NKT cells in the tumour microenvironment.

Effect of local X-ray radiation doses on circulating immune populations in melanoma tumour-bearing mice by flow cytometry

Ainara Barco-Tejada[1;2], Rocio López-Esteban[2], Elena Blázquez-López[2], Marjorie Pion[2], Rafael Correa-Rocha[2], Manuel Desco[1;2;3], Lorena Cussó[2;3;4]
[1]Universidad Carlos III de Madrid, Leganés; *[2]Unidad de Medicina y Cirugía Experimental. Instituto de Investigación Sanitaria Gregorio Marañón, Madrid*; *[3]Unidad de Imagen Avanzada. Centro Nacional de Investigaciones Cardiovasculares Carlos III (CNIC), Madrid*; *[4]Centro de Investigación Biomédica en Red de Salud Mental (CIBERSAM), Madrid*

Purpose: Melanoma is a disease whose incidence is rising nowadays, causing more than 7000 deaths in 2023. However, radiation theraphy alone is rarely an option to treat early-stage melanomas, although it is able to activate an antitumor immune response. **To characterise the effects of X-ray radiation on circulating immune cells in melanoma tumor bearing-mice.**
Methods: 27 male C57BL/6 of 26 grams of weight were subcutaneously inoculated with 200.000 melanoma B16/F1 cells in both hind flanks. Before tumors reached a size of 0,5 cm, the right hind tumor was irradiated with a single dose of 4 Gy (n=9), 8 Gy (n=5), 12 Gy (fraccionated in two sessions; n=5), or no radiation (controls, n=8). Periferal blood (PB) samples were collected pre-irradiation, at 2 hours and day 7 post-irradiation (p.i). Whole blood was labeled with 27 antibodies distributed across two panels and acquired in a 16-channel Flow Cytometer. Tumor growth was measured daily using calipers.
Results: Compared with controls, 4 and 8 Gy irradiated mice showed no differences in any PB immune subpopulations. However, 12 Gy irradiated animals exhibited a decrease in the total leukocytes 2 hours p.i. This reduction was observed both in the myeloid and lymphoid compartments, particularly in granulocytes, monocytes, type 1 dendritic cells, NK cells, and T and B lymphocytes. However, at 7 days only the MHC-expressing neutrophils were decreased. Tumors growth was decreased only after 12 Gy.
Conclusion: Fraccionated irradiation with 12 Gy induced a reduction in PB leukocytes and was succesful in the treatment of the irradiated melanoma tumors by limiting their growth. The decrease of total leukocytes could indicate either a migration of the immune cells to the irradiated tissue, or an immune depletion due to radiation, resulting in fewer immune cells present in the peripheral blood. However, single doses of 4 Gy and 8 Gy have no effect in tumor growth and the circulating immune populations.

Blinatumomab and Tyrosine Kinase Inhibitors in B-acute leukemia: friends, or enemies?

Adam Obr[1], Michal Plodik[1], Tereza Koranova[1], Denisa Myslivcova[1], Katerina Kuzelova[1], Barbora Frdlikova[1], Kristyna Smilauerova[1]
[1]*Institute of Hematology and Blood Transfusion, Prague, Czech Republic*

Introduction: Blinatumomab, a bi-specific T cell engager (CD3/CD19), is primarily used in the treatment of relapsed and refractory B-acute lymphoblastic leukemia (B-ALL) or as a salvage therapy before transplantation. It has been observed that relapses after blinatumomab treatment often manifest as extramedullary disease, indicating potential changes in cell adhesion specificity. Tyrosine kinase inhibitors (TKIs) are widely employed in the therapy of Ph+ leukemia, targeting the BCR-ABL oncogene and Src family kinases while also influencing leukemia cell adhesion. Recent clinical trials have successfully combined blinatumomab with TKIs for treating Ph+ B-ALL, although theoretically, the combination should not be effective due to TKIs inhibiting the essential SRC kinases involved in T cell activation.
Materials & Methods: In our study, we utilized lymphocytes from healthy controls (either freshly isolated or expanded in vitro) and B-ALL cell lines (RAJI, REH, ARH-77) as experimental models. These cells were subjected to treatment with blinatumomab and/or TKIs (dasatinib and ponatinib). Using flow cytometry, we evaluated: 1) the effectiveness of blinatumomab- and TKI-induced cytotoxicity, 2) alterations in the expression of cell adhesion molecules prompted by the treatment, and 3) the activation status of both effector T cells and target leukemia cells. Additionally, we used the Seahorse XFp device to assess changes in cellular metabolism in B-ALL cells following the treatment.
Results & Conclusion: In summary, we demonstrate that even though TKIs inhibit SRC kinases necessary for T cell activation, the lowest clinically relevant levels of TKIs do not impede the cytotoxic effect of blinatumomab. Moreover, TKIs have an impact on the levels of CD62L on the surface of B-ALL cells, indicating potential changes in cell adhesion specificity. Additionally, TKIs decreased B-ALL cell oxygen consumption, while not having a significant effect on glycolysis. Together, these findings provide valuable insights into the mechanisms underlying the effectiveness of combination therapy and emphasize the importance of further investigating the interplay between blinatumomab, TKIs, and cell adhesion molecules in the context of B-ALL treatment.

Comparative analysis of adjuvants and their synergistic effect for the activation of murine liver non-parenchymal cells

Malin Svensson[1], Yanira Zeyn[2], María-José Limeres[1], Maximiliano Cacicedo[1], Rocio Gambaro[1], Ignacio Berti[1], German Islan[1], Matthias Bros[2], Stephan Gehring[1]
[1]Children's Hospital, University Medical Center Mainz, Mainy, Germany; *[2]Department of Dermatology, University Medical Center Mainz, Mainz, Germany*

Purpose: Non-parenchymal cells (NPCs) within the liver hold a critical role in inducing liver tolerance, making the liver a challenging environment for intrahepatic immunotherapeutic approaches and limiting the potency of intrahepatic anti-tumor responses. However, these immune cells can be activated by suitable adjuvants to initiate effector T-cell responses. The aim is to identify an adjuvant and an adjuvant combination that highly activate the immune cell population in the liver, together with encapsulated mRNA- encoded antigen, to enhance the immune response in a therapeutic anti-cancer vaccine approach.
Methods: Murine liver NPCs were isolated by liver perfusion and stimulated with different adjuvants and combinations overnight to test *in vitro* activation. Expression of surface activation markers and the secretion of pro-inflammatory cytokines were measured by flow cytometry and cytometric bead array (CBA), respectively. Thymidine incorporation assay assessed T-cell proliferation in a co-culture setting. For the *in vivo* study, C57BL/6J mice were injected i.v. with *ovalbumin* mRNA encapsulated in lipid nanoparticles together with adjuvants to test *in vivo* activation of NPCs. Liver and spleen were dissected and the single-cell suspensions were analyzed by flow cytometry. Serum and culture supernatant were assessed for the secretion of pro-inflammatory cytokines by CBA.
Results: *In vitro* screening of adjuvants revealed that co-stimulation with combined adjuvants induced the highest activation response in regard to expression of activation markers and cytokine secretion compared to individual adjuvants, suggesting a synergistic effect. The *in vitro* T-cell proliferation assay showed high proliferation of $CD8^+$ T-cells with all adjuvants alone and combined, while $CD4^+$ T-cells only showed high proliferation with the adjuvant R848, alone and in combination. *In vivo* testing showed high expression of activation markers and cytokine secretion in both NPCs and splenic dendritic cells with adjuvant R848 alone and combined.
Conclusion: We could identify that R848 alone and in combination incorporated together with an mRNA-encoded antigen in a nano-carrier delivery system, highly activated the immune cell population in the liver. Conducting *in vitro* and *in vivo* testing of adjuvants is essential to identify potent activators for liver NPCs in order to overcome liver tolerance and enabling an adequate intrahepatic immune response.

B cells as a target for immunotherapy in non-alcoholic steatohepatitis and subsequently for hepatocellular carcinoma

Aysan Pousardegh Zonouzi[1], Svenja Schühle[2], Zeynep Ergun[1], Mathias Heikenwälder[2], Ari Waisman[1]
[1]University medical center of Johannes Gutenberg Mainz, Mainz, Germany; *[2]German Cancer Research Center (DKFZ), Heidelberg, Germany*

Purpose: The purpose of this study is to investigate the role of adaptive immunity, specifically B cells, in the development of non-alcoholic steatohepatitis (NASH) and and its role as a driver of hepatocellular carcinoma (HCC). Furthermore, we aim to explore the gut-liver axis by profiling liver and intestinal B cells.
Method: The researchers employed various mouse models, including $JH^{-/-}$ mice lacking B cells and μMT mice lacking mature B cells but retaining IgA^{+} B cells in the lamina propria, which were fed a choline-deficient high-fat diet (CD-HFD) to induce NASH. Additionally, wild-type mice and μMT mice were treated with αCD20 to deplete B cells. We employed high-dimensional flow cytometry and single-cell RNA sequencing to identify subpopulation and gene expression profiles.
Results: The study found mice lacking mature B cells exhibited the absence of steatosis, liver inflammation and fibrosis when fed a CDHFD, whereas μMT mice resulted in hepatic steatosis, inflamed but did not showed signs of fibrosis. In addition, depletion of B cells by αCD20 treatment in wild type and μMT under CD-HFD, showed an abrogation of steatosis, inflammation and fibrosis. Our preliminary data from single-cell RNA sequencing revealed three subpopulations of intestinal B cells: naïve, activated, and germinal center B cells. Germinal center B cells were decreased in the curse of NASH and exhibited the highest differential gene expression compared to controls.
Conclusion: The findings suggest that B cells play a significant role in the development of NASH, liver, fibrosis, and potentially hepatocellular carcinoma (HCC). Additionally, the study provides insights into the gut-liver axis, highlighting changes in intestinal B cell composition and gene expression profiles during NASH progression. This research underscores the importance of adaptive immunity, particulary B cells, in NASH and NASH-to-HCC transition. Eventually this may lead to the indentification of potential therapeutic targets for the disease.

B cell expansion during gut inflammation exacerbates colorectal cancer development

Romy Mittenzwei[1], Petra Adams-Quack[1], Thomas Wunderlich[1], Björn Clausen[1], Johannes Friedhelm Vogt[1], Nadine Hoevelmeyer[1]
[1]*Institut für Molekulare Medizin, Mainz, Germany*

Colorectal cancer (CRC) is the third most common cancer worldwide with a rapidly increasing incidence rate in individuals even under 50 years of age. Besides genetic factors, patients with long-standing intestinal inflammation have a significant higher risk to develop CRC. However, the precise mechanisms underlying tumour-promoting inflammatory processes in CRC are, so far, insufficiently characterized. Here, we provide evidence that B cells exert dual roles, either tumour promoting or supressing, depending on the degree of intestinal inflammation. B cells are the dominant cell type in the healing colon after DSS treatment, with an expansion of an IFN-induced B cell subset. In line with these data, B cell depletion accelerated recovery upon DSS driven colonic injury. We further demonstrate that B cell-deficient mice show significantly ameliorated intestinal inflammation upon DSS administration to be resistant to CRC development accompanied with less immune cell infiltrates into the colonic lamina propria as well as reduced production of pro-inflammatory cytokines. In particular, we reveal IL-10 secretion by B cells to actively contribute to tumour development in the intestine via polarization/activation of gut resident macrophages towards an M1 phenotype. Thus, targeting B cell specific mechanism in colorectal cancer might be a promising avenue to combat this still fatal disease.

Acquired resistance to trastuzumab and neratinib sensitizes HER2+ breast cancer cells to trastuzumab-dependent cell-mediated cytotoxicity

Javier Sanchez Ramirez[1], Debbie O'Reilly[1], John Crown[2], Denis M Collins[1]
[1]*Life Science Research Facility, Dublin City University, Dublin, Ireland*; [2]*Department of Medical Oncology, Saint Vincent's University Hospital, Dublin, Ireland*

Purpose: Acquired resistance to HER2-targeted therapies leads to therapeutic failure in breast cancer patients and there is limited information whether trastuzumab-dependent cell-mediated cytotoxicity (T-ADCC) can be seriously affected. This study is aimed to study the impact on T-ADCC of acquired resistance to FDA-approved HER2-targeted therapies trastuzumab and neratinib in breast cancer cells.
Methods: Two acquired HER2-targeted therapy resistant breast cancer cell lines (BCCLs) were studied: trastuzumab-resistant SKBR3 (SKBR3-Tras) and neratinib-resistant HCC1954 (HCC1954-Ner). SKBR3-Tras and HCC1954-Ner were generated after 6-month continuous exposure to 10µg/mL of trastuzumab and 150nM of neratinib, respectively. Their therapy-naive or parental (Par) counterparts were used as baseline controls. Flow cytometry assays were carried out to determine T-ADCC using healthy volunteer (HV)-derived peripheral blood mononuclear cells against BCCLs. Levels of membrane-bound proteins modulating T-ADCC in BCCLs were also checked by flow cytometry. The panel included HER2, HLA-A/B/C, HLA-G, HLA-E, E-cadherin, MIC-A/B, ULBP-2/5/6, PD-L1, ICAM-1 and CD95. Unpaired t-tests were performed to compare therapy-resistant BCCLs against Par counterparts ($p<0.05$ is significant).
Results: SKBR3-Tras and HCC1954-Ner were more sensitive to T-ADCC than their respective parental counterparts (SKBR3 [HV3: p=0.0009; HV4: p=0.0484], HCC1954 [HV3: p=0.0004; HV4: p=0.0450]). In relation to their respective parental counterparts, SKBR3-Tras increased HER2 levels (p=0.081) but HCC1954-Ner experienced a decrease (p=0.0354). For ICAM-1, SKBR3-Tras showed lower levels (p=0.0069) while HCC1954-Ner had higher levels (p=0.0010). CD95 and E-cadherin did not change in SKBR3-T however, their expression dropped in HCC1954-Ner (p=0.0215 and p=0.0070, respectively). HLA-A/B/C and ULBP-2/5/6 downregulation were detected in SKBR3-Tras (p=0.0142 and p=0.0168, respectively) and no alteration was observed in HCC1954-Ner. Unmodified levels of PD-L1, HLA-G, HLA-E and MIC-A/B were seen in both SKBR3-Tras and HCC1954-Par.
Conclusion: Resistance to HER2-targeted therapies changes the expression profile of ADCC modulators. Acquired resistance to HER2-targeted therapies may sensitise tumour cells to T-ADCC.

Microbial metabolites suppress the tumorigenic functions of IL-36 cytokines in colon cancer.

Méabh Finucane[1], Aileen Houston[1], Elizabeth Brint[1]
[1]*University College Cork, Cork, Ireland*

The Interleukin (IL)-36 cytokines are a recently described subset of the IL-1 family of cytokines, comprising of three agonists, (IL-36α, IL-36β, and IL-36γ), an antagonist (IL-36Ra) and a receptor (IL-36R). Similar to all other IL-1 family members, IL-36 cytokines have complex dual functions in cancer, exhibiting both pro- and anti-tumorigenic functions. Metabolites generated by the microbiome have also been shown to have dual functions in colon cancer. For instance, butyrate is a short chain fatty acid which has been shown to have tumour suppressive activity, while deoxycholic acid (DCA) is a secondary bile acid with potential tumour promoting functions.

The aim of this study was to investigate if microbiome-encoded metabolites alter the tumour-promoting activity of IL-36 family members in colon cancer. Cell proliferation was measured by both resazurin reduction and BrDU incorporation assay. Cell migration was assessed by wound scratch assay. Gene expression was measured by qRT-PCR and signalling was assessed by Western Blot.

Stimulation of human (HT29) and murine (CT26) colon cancer cell lines with IL-36β and IL-36γ increased cellular proliferation, migration, and inflammation in vitro. Butyrate (1mM) alone had little effect on cell proliferation and migration but significantly suppressed the ability of IL-36β and IL-36γ to induce these tumorigenic processes. Similarly, DCA alone (25μM) slightly suppressed basal level cell proliferation and migration, while co-treatment of DCA with IL-36 agonists significantly suppressed IL-36-mediated cell proliferation and migration. Western blotting for intracellular signalling pathways known to play a role in IL-36-mediated cell proliferation was preformed, with co-treatment of cells with butyrate and IL-36γ resulting in decreased phosphorylation of RPS6, potentially implicating the AKT/mTORC1 pathway. Both butyrate and DCA modified IL-36-induced cytokine and chemokine production.

These studies have shown that the pro-tumorigenic functions of IL-36 cytokines are suppressed by microbiome-derived metabolites, suggesting that bidirectional interaction with the microbiota may impact on the activity of IL-36 family members.

Serial Monitoring of the Inflammatory Response in Resectable Lung Cancer.

Laura Staunton[1], Brian Hendersen[1], Derek G. Doherty[1], Ronan Ryan[2], Gary Fitzmaurice[2], Kathy Gately[1]
[1]Trinity Translational Medicine Institute, Dublin, Ireland; *[2]St James Hospital, Dublin, Ireland*

Purpose: Profiling the immune response of patients undergoing lung cancer resection, could give valuable insights into systemic inflammation and immunosuppression, triggered by surgery. Detection of circulating tumour cells can be seen 6 weeks post-surgery, alongside post-operative immunosuppressive state, in some cases up to 6 months. Dissemination and evasion of tumour cells, impaired cellular immunity and elevated cytokines, due to surgical stress, can make way to recurrence, metastasis and negatively impact immunotherapy response. Inflammatory indexes can be used as a prognostic tool to predict clinical outcomes. Systemic Inflammatory Response Index (SIRI), Neutrophils x Monocytes / Lymphocytes, is shown to predict poor outcomes, including post-operative complications (≥1.2) and for pre-treatment chemoradiotherapy (≥2) in NSCLC. Systemic Inflammatory Index (SII), Neutrophils x Platelets / Lymphocytes, (>730) and SIRI were evaluated on peri-operative patients. Cross-linked fibrin is linked with tumour cell angiogenesis and invasion. Elevated preoperative D-dimer (>500ng/mL) is associated with tumour stage, nodal involvement and is a prognostic indicator for recurrence and metastasis.
Methods: Full Blood Count and D-Dimer were taken at baseline (n=26), 2-4 days post operatively (n=26) and 6-9 weeks (n=14) post-operatively. SIRI and SII were calculated. PBMCs were isolated and stored for serial monitoring of T and B cell subsets.
Results: 69% and 50% had an elevated SIRI and SII at baseline, of those 46% and 38% had complications. 31% and 50% did not have an elevated SIRI and SII at baseline, of those 20% and 46% had complications. The higher the SIRI and SII at baseline, the more likely to have complications. 64% and 93% continued to have an elevated SIRI and SII after 6-9 weeks. 38% had an elevated D-Dimer pre-operatively. 100% had a D-dimer of >500ng/mL after 6-9 weeks. T and B cell subsets will also be presented.
Conclusions: In this cohort of patients, baseline elevated SIRI and SII, can correlate with post-operative complications. Inflammatory indexes and D-Dimer remain elevated 6-9 weeks post-operatively, showing on-going dysregulation of immune response. This has previously been shown to impact immunotherapy response, overall and drug free survival. Further studies will characterise these cells using flow cytometry.

Cyp27a1-driven metabolic control in macrophages regulates the tumor microenvironment

Piyal Saha[1], Paul Ettel[1], Roko Sango[1], Andrea Vogel[1], Lovro Davidovski[1], Jayne Louise Wilson[1], ThomasW Weichhart[1]
[1]*Medical University of Vienna, Vienna, Austria*

Purpose: 27-hydroxycholesterol (27-HC) is the most abundant oxysterol, and it is metabolized via a cytochrome P450 oxidase, CYP27A1. Although 27-HC-mediated functional diversity of macrophages has been studied in breast cancer and atherosclerosis, how the overall macrophage metabolism is influenced by CYP27A1 is yet to be explored. In this study, we aimed to investigate the CYP27A1-mediated association between oxysterol metabolism and other metabolic pathways along with the immunometabolic crosstalk between macrophages and lymphoid cells during cancer.
Methods: We generated bone marrow-derived macrophages (BMDMs) from macrophage-specific Cyp27a1 knockout mice (Cyp27a1 fl/fl, Cx3cr1-Cre; Cyp27a1 MKO) to explore the cellular metabolism using liquid chromatography-mass spectrometry. To study the functional aspects of altered oxysterol metabolism in macrophages, we introduced two murine cancer lines (B16-F10 and MC38) in our Cyp27a1 MKO mice to investigate cancer growth by survival analysis and measuring tumour volume. Through flow cytometry, we analyzed the composition of immune cell populations in these cancer models.
Results: At basal condition, in BMDMs from Cyp27a1 MKO mice, along with bile acid metabolism, we observed a significant decrease of intracellular purine and pyrimidine molecules compared to BMDMs from littermates. Since increased purine and pyrimidine metabolism in tumour-associated macrophages was associated with an anti-tumorigenic effect, we hypothesized that Cyp27a1 MKO mice should have a better cancer prognosis. In alignment with our hypothesis, we found that in both MC38 and B16-F10 tumour models, the Cyp27a1 MKO group had a better survival rate with a significant decrease in tumour volume. To delineate the underlying mechanism, we analyzed the immune cell population in tumour tissue collected from both groups. Surprisingly, we found significantly decreased CD4+ and CD8+ T cell infiltration in tumour tissues of the Cyp27a1 MKO mice.
Conclusion: Through our study, we have highlighted the association between 27-HC metabolism with purine and pyrimidine metabolism in macrophages. On top of that, Cyp27a1 in macrophages undermines efficient anti-tumour immunity by a surprising effect in regulating the composition of the tumour microenvironment.

Effect of melanoma on circulating immune populations in a murine model by flow cytometry

Ainara Barco-Tejada[1;2], Rocio López-Esteban[2], Elena Blázquez-López[2], Rafael Correa-Rocha[2], Marjorie Pion[2], Manuel Desco[1;2;3], Lorena Cussó[2;3;4]
[1]Universidad Carlos III de Madrid, Leganés; *[2]Unidad de Medicina y Cirugía Experimental. Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain*; *[3]Centro Nacional de Investigaciones Cardiovasculares Carlos III (CNIC), Madrid, Spain*; *[4]CIBER de Salud Mental, Instituto de Salud Carlos III, Madrid, Spain*

Purpose: Melanoma is a disease whose incidence is rising nowadays, causing more than 7000 deaths in 2023. Although a dysregulation in the immune system is implicated in the emergence of tumor cells, the immune alterations are still unknown at early stages of the desease. To evaluate changes induced by subcutaneous melanoma implantation in peripheral blood (PB) immune populations by flow cytometry.
Methods: 43 male C57BL/6J mice of 26 grams of weight were used. 21 mice were subcutaneously inoculated with 200,000 melanoma B16/F1 cells in both hind flanks, while the remaining wild-type animals (WT, n=22) are controls. When tumors reached a size of 0.5 cm, 100µl of PB were collected in EDTA tubes from both groups. PB was lysed and labeled according to our 2 novel cytometry panels with 14 markers each, that enable to visualize most leukocytes subsets including different types of myeloid and lymphoid cells. PB samples were acquired in a 16 channels flow cytometer.
Results: Compared with WT, tumour-bearing animals showed a decrease in total leukocytes at 10 day. Also myeloid cells were increased, although no differences were found in the granulocytic population, except for those expressing the MHC marker, which were also increased in the tumor group. In the monocyte compartment, Type M1 and M2 monocytes were also increased. In contrast, plasmacytoid dendritic cells and conventional mature type 1 dendritic cells were decreased. Tumour-bearing animals showed a decrease in all T cell subpopulations, regarding differentiation (Th1, Th2, Treg..) and activation states (naive, effector and central memory). A decrease was also observed in NKT and plasmatic B cells.
Conclusion: Moderate growth of subcutaneous B16/F1 melanoma tumours (no more than 0.5 cm) induced alterations in the studied PB immunological populations of both lymphoid and myeloid lineages. These alterations allow us to better understand the immune status in early stages of tumour progression, even in minority subpopulations such as MCH II monocytes or dendritic cells.

RANK pathway inhibition impairs immunosuppression in macrophages enhancing the anti-tumour response

Luminal breast tumours generally exhibit low immune infiltration and are unresponsive to immunotherapy. RANK pathway inhibitors have emerged as putative therapeutic target in breast cancer, with pleiotropic effects on cancer and immune cells. In breast adenocarcinomas RANK is expressed by tumour cells and tumour-associated macrophages (TAMs). Previous results demonstrate that RANK signalling activation in tumour cells enhances stemness and immunosuppression, but whether and how RANK influences macrophage (MØ) phenotype and functionality is unknown. We hypothesize that RANK expression in TAMs may contribute to generate an immunosuppressive phenotype, promoting tumour progression and metastasis.
Here, results from the window of opportunity clinical trial D-BIOMARK (NCT03691311) demonstrate that RANK expression in the stroma, which is mainly located in TAMs, associates with highly proliferative luminal tumours. Transcriptional profiling evidences that preoperative single agent denosumab in luminal breast cancer leads to a decrease in immunosuppressive MØs and an increase in monocytes-related genes, together with enhanced activation of innate and adaptive immune pathways. Indeed, RANK expression increases during the differentiation from human and mouse monocytes to macrophages. These results indicate that denosumab interferes with MØ differentiation and their immunosuppressive role.
In preclinical mouse models of breast cancer with strong RANK expression in TAMs, we have found that RANK deletion exclusively in myeloid cells delays tumour onset and reduces lung metastasis. At single cell level, an enrichment of the transcription factors Stat1/Irf1, Ifn-driven genes and antigen presentation genes is found in RANK-null TAMs, resulting in Ifn activation in T cells and enhancing the anti-tumour immune response. Comparably, pharmacological inhibition of RANKL also leads to a proinflammatory TAM profile in line with the clinical data.
Altogether, our preclinical and clinical results demonstrate that RANK expression in myeloid cells favours breast cancer progression, and that RANKL inhibition impairs the immunosuppressive phenotype of TAMs, supporting the immunomodulatory potential of RANKL inhibitors in breast cancer.

ROR-1 defines a population of atypical B cells in peripheral blood phenotypically linked to malignant cells of chronic lymphocytic leukemia

Antonia Mikulova[1], Olga Vondálová-Blanářová[1], Hana Plešingerová[1;2], Petr Tauš[3], Jitka Stančíková[4], Jan Stuchlý[4], Jana Kotašková[2;3], Karla Plevová[2;3], Tomáš Arpáš[2], Tomáš Kalina[4], Vítězslav Bryja[1], Pavlína Janovská[1]

Chronic lymphocytic leukemia (CLL) is the most common leukemia in the Western world. It is a hematological malignancy characterized by clonal expansion of B cells in secondary lymphoid organs and their evasion to the peripheral blood (PB). It is a heterogeneous disease the origin of which is still unknown. However, there are several diagnostic markers which unify CLL cell phenotype among patients. One such marker is the receptor tyrosine kinase like orphan receptor 1 (ROR-1) which is one of key players in Wnt/planar cell polarity (PCP) signalling. In our previous study, we have shown that CLL cells exhibit increased expression of not only ROR-1 but multiple other components of the Wnt/PCP signalling (Kaucká et al., 2013). This indicates that ROR-1-mediated signalling might be contributing to malignant transformation in CLL. This hypothesis was further supported by almost complete absence of ROR-1+ B cells in PB of healthy donors (HD, 1-5% from total B cells) and their partial enrichment in individuals with condition preceding CLL, called monoclonal B lymphocytosis (MBL, 30-98% from total B cells).
Therefore, we aimed to describe ROR-1+ B cells and elucidate if a specific subpopulation of ROR-1+ B cells might give rise to CLL clone. Using spectral flow cytometry, we showed that ROR-1+ B cells of HDs are enriched mainly in the population of unswitched memory B cells but they also form clusters of cells phenotypically close to CLL clone. To inspect ROR-1+ B cell heterogeneity, we performed CyTOF experiment with 30-marker panel and we found a specific cluster of ROR-1(dim) cells lacking the expression of CD21 the absence of which has already been linked to atypical B cells with possible autoreactive potential. Furthermore, trajectory analysis of CyTOF data (performed using specialized tool, tviblindi) identified ROR-1(dim) CD21(low) population as the cluster interconnecting normal B cell development trajectory with the malignant clone. Finally, using scRNAseq combined with advanced data analysis, we elucidated that ROR-1+ population of interest displayed increased activity of multiple signalling pathways (NFκB, MAPK) and transcription factors (STAT3, JUN) supporting proliferation and survival of CLL cells.

This study was funded by the Czech Science Foundation grant 23-05561S.

Autoantibodies against AFP in liver diseases

Juan Francisco Delgado de la Poza[1], Jordi Sánchez Delgado[2], María Isabel Aparicio Calvente[1], Raquel Escribano Tembleque[1], Meritxell Casas Rodrigo[2], Cristina Solé Martí[2], Mireia Miquel Planas[2], Mercè Vergara Gómez[2]
[1]Immunology Laboratory. Clinical Laboratories Service. Consorci Corporació Sanitària Parc Taulí. Institut d'Investigació i Innovació I3PT., Sabadell, Spain; *[2]Liver Unit. Digestive System Service. Consorci Corporació Sanitària Parc Taulí. Institut d'Investigació i Innovació I3PT., Sabadell, Spain*

Purpose: Hepatocellular carcinoma (HCC) ranks as the second leading cause of cancer-related mortality and the sixth most prevalent cancer globally. Unfortunately, the majority of HCC cases are diagnosed at advanced stages, resulting in poorer survival outcomes. A surveillance program, primarily targeting at-risk individuals with cirrhosis, recommends regular abdominal ultrasound screenings every six months. The immune system plays a crucial role in cancer control, with tumor-associated antigens (TAA) emerging as essential proteins implicated in cancer transformation and progression to malignancy. Therefore, they hold significant promise as diagnostic and therapeutic targets. This study aims to investigate the presence of antibodies against the TAA human recombinant AFP (hrAFP) in HCC and other liver diseases, with the goal of assessing its potential as a biomarker for early diagnosis and monitoring of HCC patients.
Methods: We recruited diferent populations of patients to compare the levels of hrAFP and to evaluate their useful as a pilot study. We included 67 patients with HCC and cirrhosis (HCC-Cirr), 29 HCC without cirrhosis (HCC-NoCirr), 73 patients with cirrhosis without HCC (Cirr), 48 chronic hepatitis (CH), and 44 non-hepatic diseases serum blood donors. The anti-AFP antibodies were analyzed using a homemade ELISA assay employing recombinant human AFP. A group of positive sera was selected for epitope mapping to identify the epitope eliciting the highest reactivity.
Results: The presence of anti-AFP antibodies was assessed using rhAFP, with a cutoff established at 93.2% specificity compared to healthy donors. The presence of these autoantibodies was 83.6% in HCC-Cirr, and 6.9% in HCC-NoCirr, 75.3% in Cirr and 29.2% in HC. Epitope mapping was conducted with a group of positive samples, identifying a 20-amino acid peptide. The immunoassay of the identified peptide was performed using a cutoff with 92.3% specificity compared to healthy donors. The presence of autoantibodies against the peptide was 89.4% in HCC-Cirr, 0.0% in HCC-NoCirr, 87.1% in Cirr and 45.8% in HC. There were no statistically significant differences observed between the use of rhAFP and the identified peptide.
Conclusion: Anti-AFP autoantibodies are not a reliable biomarker for HCC diagnosis but can serve as a biomarker for liver cirrhosis.

Role of innate CD8 T-cells in the control of residual disease in chronic myeloid leukemia

Amandine Decroos[1;2], Sarah Meddour[1;2], Amélie Pioch[1;2], Alice Barbarin[1], André Herbelin[1], Jean-Marc Gombert[1;3], Emilie Cayssials[1;4;5]
[1]Université de Poitiers, IRMETIST INSERM U1313, Poitiers, France; *[2]Centre Hospitalier Universitaire de Poitiers, Poitiers, France*; *[3]Service d'Immunologie et Inflammation, CHU de Poitiers, Poitiers, France*; *[4]Service d'oncologie hématologique et de thérapie cellulaire, CHU de Poitiers, Poitiers, France*; *[5]INSERM CIC 1402, Université de Poitiers, Poitiers, France*

Purpose: Innate CD8 T-cells (ITC-CD8) are unconventional T-cells sharing features of both adaptative and innate immunity. Based on their NKG2A and panKIR2D and/or KIR3DL1DL2 surface expression profiles, ITC-CD8 can be divided into 4 subsets. The ITC-CD8-NKG2A+ subset exhibits production of IFN-γ in response to IL-12/IL-18 stimulation while ITC-CD8-KIR+ subsets display NK-like cytotoxicity through CD16, perforin or granzyme B expression. These characteristics suggest a potential role in protection against cancer, an hypothesis that we have been tested in a hematopoietic cancer, chronic myeloid leukemia (CML), in which a control by the immune system is supported by the appearance of CML-specific CD8 T-cells in patients in remission. Importantly, ITC-CD8, which are impacted numerically/functionally at CML diagnosis, are in part restored in patients in remission. Here, we hypothesized that ITC-CD8 subsets contribute to the control of residual disease following treatment discontinuation, leading to successful maintenance of sustained treatment-free remission (TFR). To this end, ITC-CD8 subsets were compared between patients with TFR and those who experienced disease relapse (DR).
Methods: Peripheral blood mononuclear cells (PBMC) from healthy donors (HD), CML-TFR and CML-DR patients were thawed and stained for analysis by flow cytometry *ex vivo*. Data were acquired on an Aurora spectral flow cytometer (Cytek Biosciences). Unmixing/compensations and statistical analysis were performed using SpectroFlo v3.0, and FlowJo10, GraphPad Prism 10 and OMIQ software applications, respectively.
Results: Numerical analysis highlights an imbalance in ITC-CD8 subset distribution in favour of ITC-CD8-panKIR2D+, known to include activating KIR receptors, from CML-TFR patients (*versus* HD and CML-DR patients). Transcription factor expression (Eomes/PLZF/T-bet) are impaired at diagnosis, and recovered in all ITC-CD8 subsets from both groups of patients. Functional analysis shows higher expression of CD69 in all the ITC-CD8 KIR+ subsets from CML-DR patients (*versus* HD) while perforin surface-expression frequencies of ITC-KIR+ subsets tend to increase in CML-TFR patients (*versus* CML-DR patients). In contrast, PD-1 expression is higher in all ITC-CD8-KIR+ subsets from CML-DR patients (*versus* CML-TFR patients).
Conclusion: Taken together, our results support the hypothesis that the ITC-CD8 compartment, especially its KIR+ subsets, contribute to the control of residual CML disease, and could represent a functional signature of TFR.

Immunomodulatory Effects of Repetitive Radiofrequency Ablation in Inoperable Pancreatic Adenocarcinoma

Nino Toria[1], Tinatin Chikovani[1], Malkhaz Mizandari[1], Nona Janikashvili[1], Nino Kikodze[1]
[1]*Tbilisi State Medical University, Tbilisi, Georgia*

Pancreatic ductal adenocarcinoma (PDAC) remains a formidable challenge in oncology, claiming the lives of half a million individuals annually worldwide. Despite advances in treatment, the dense tumor stroma and immune suppression characteristic of PDAC often hinder the effectiveness of therapeutic interventions. Radiofrequency ablation (RFA) has shown promise in triggering tumor-specific immune responses and disrupting the tumor microenvironment. In our study, we investigated the impact of repetitive RFA on immunological parameters in patients with inoperable PDAC. Peripheral blood samples were collected from PDAC patients subjected to three consecutive rounds of endoluminal RFA and compared to age-matched healthy controls. Our findings revealed that repetitive RFA led to a significant reduction in protumorigenic cytokines, including transforming growth factor-beta (TGF-β) and interleukin-17 (IL-17), as well as a decrease in protumorigenic CD4+CD39+ and naive CD45RA T cells. Notably, these immunomodulatory effects were observed only after repetitive RFA, highlighting the distinct impact of multiple treatments.This study represents a pioneering exploration into the immunological benefits of repetitive RFA in inoperable PDAC patients. While these findings underscore the potential of repetitive RFA in modulating the immune landscape of PDAC, it is important to note that the observed changes cannot be solely attributed to RFA due to the absence of a control group with alternative treatments. Further comprehensive investigations, involving larger cohorts, diverse treatment modalities, and intricate immune readouts, are essential to validate and enhance our understanding of the clinical advantages associated with repetitive RFA in the context of pancreatic cancer.

The Tyrosine Kinase Inhibitor Dasatinib impedes adaptive cell surveillance in peripheral lymph nodes

Daniela Claudino Carvoeiro[1], Ana Marcos-Jiménez[2], Cecilia Muñoz-Calleja[2;3], Jens Volker Stein[1]
[1]Department of Oncology, Microbiology and Immunology, University of Fribourg, Fribourg, Switzerland; *[2]Department of Immunology, Biomedical Research Institute La Princesa Hospital (IIS-IP), Madrid, Spain*; *[3]CIBER Infectious Diseases (CIBERINFECC), Instituto de Salud Carlos III, Madrid, Spain*

Dasatinib is a tyrosine kinase inhibitor approved as first-line treatment for Philadelphia chromosome-positive leukemia including chronic myeloid leukemia and is increasingly used in other clinical settings. While effective and well tolerated, patients commonly present a diverse range of side effects, reflecting a wide spectrum of dasatinib-inhibited off-targets. Examining preclinical mouse models and human patients data, we have recently published that dasatinib induces a temporary contraction of spleen stroma, which leads to an expulsion of splenocytes. This explains the drug-induced transient lymphocytosis previously associated to a better response rate in patients. Whether dasatinib also affects the function of other secondary lymphoid organs, such as peripheral lymph nodes (PLNs), has remained elusive. Here, using mouse models we report that whereas dasatinib did not induce PLN contraction, intravital imaging uncovered a strong reduction in interstitial motility of both T and B cells. As dasatinib affects in vitro B cell but not T cell migration to lymphoid chemokines, we examined an indirect activity of dasatinib leading to reduced lymphocyte motility in vivo. Lymphocyte arrest following dasatinib treatment correlated closely with a local increase in PLN hypoxia, which was accompanied by a constriction of PLN blood vessels as assessed by intravital imaging. Accordingly, dasatinib-induced hypoxia was reversed by pharmacological inhibition of the contraction-promoting factor Rho-associated protein kinase. In sum, our work provides evidence that dasatinib-induced reduction of lymphocyte motility in PLNs is a consequence of drug-induced vasoconstriction and the subsequent decline in oxygenated blood supply, affecting adaptive immune cell function in these organs.

Dysfunctional γδ T cells are associated with aggressive squamous cell carcinoma in Epidermolysis bullosa

Leonie Schöftner[1], Julia Feiser[1], Michael Lew[1;2], Anshu Sharma[1], Suraj Varkhande[1], Monika Ettinger[3], Susanne Kimeswenger[3], Christina Guttmann-Gruber[2], Giorgia Nasi[1], Iris Gratz[2;4;5]
[1]Department of Biosciences and Medical Biology, University of Salzburg, Salzburg, Austria; *[2]EB House Austria, Department of Dermatology and Allergology, University Hospital of the Paracelsus Medical University Salzburg, Salzburg, Austria*; *[3]Johannes Kepler University Linz, Department of Dermatology and Venereology, Medical Faculty, Linz, Austria*; *[4]Department of Biosciences and Medical Biology, Center for Tumor Biology and Immunology, Paris-Lodron University Salzburg, Salzburg, Austria*; *[5]Benaroya Research Institute, Seattle, United States*

Epidermolysis bullosa (EB) is an inherited skin disorder, characterized by mucocutaneous fragility and blister formation upon minimal trauma. Patients who suffer from the severe form, recessive dystrophic EB (RDEB), often develop highly aggressive cutaneous squamous cell carcinomas (SCC). SCC in RDEB patients has a higher morbidity and mortality compared to SCC in patients without RDEB, although they share similar driver mutations. The patho-mechanisms are still largely unknown and currently there is no effective therapy available. Therefore, we analyzed whether the aggressive nature of SCC in RDEB patients is associated with a dysfunction in tumor immune surveillance. Gamma Delta (γδ) T cells display anti-tumor functions and the presence of tumor infiltrating γδ T cells was the most significant favorable prognostic immune population among 39 human cancer types. We discovered that the fraction of IFN-g producing cells was reduced among circulating and tumor infiltrating gd T cells isolated from RDEB patients with SCC. Based on these results, we hypothesize that γδ T cells are dysfunctional, and that this dysfunction is mechanistically linked to the formation of SCC. Whereas γδ T cell function has been studied in various skin cancer entities, their role in regulating the growth of the uniquely aggressive SCC in RDEB patients has not been investigated. To fill this knowledge gap, we mechanistically dissect how the SCC tumor microenvironment modulates the function of γδ T cells in RDEB patients. We utilize our innovative and unique *in vitro* 3D organotypic skin and *in vivo* tumor xenografting models to elucidate the cellular communication between γδ T cells and tumor cells. This study will provide comprehensive and mechanistic insights on the anti-tumor function of γδ T cells in RDEB patients with SCC. Furthermore, our results will contribute to the development of effective immuno-therapies against the highly aggressive SCC in RDEB patients.

Role of SHP-2 and PD-1 in lymphoid and myeloid antitumor responses

Irene Buzzago[1], Pedro Ventura[1], Alessandro Zenobi[1], Hanif Javanmard Khameneh[1], Francesca Silini[1], Laurent Brossay[2], Greta Guarda[1]
[1]IRB, Bellinzona, Switzerland; *[2]Brown University, Providence, United States*

Immune cells infiltrate the tumoral mass and, due to antigenic and inflammatory stimuli, their functions can be altered. For example, T cells can reach a state of "exhaustion", characterized by expression of inhibitory receptors, such as programmed cell death protein 1 (PD-1). SH-2 domain-containing phosphatase (SHP)-2 is reported to be an important component of the inhibitory effects of PD-1 by interacting with it. Paradoxically, SHP-2 is best known as a positive regulator downstream of growth factor receptors and inhibitors targeting this phosphatase are currently under clinical evaluation to dampen cancer progression.
To date, the biological meaning of the interplay between SHP-2 and PD-1 and their downstream signalling remains an open question. Whereas their interaction is thought to be essential for T cell exhaustion, *in vivo* data from our lab indicate that Shp-2 is dispensable for PD-1 signaling in T cells and that its homologous phosphatase SHP-1 does not play a redundant function.
This brought us to:
1) generate mice lacking PD-1 in the T cells, which show an improved tumor control and of which we will further characterize the molecular mechanism;
2) evaluate whether the PD-1/SHP-2 axis might be important in other immune cells, such as macrophages, emerging mediators of the immune anticancer responses. In our hands, single deletion of these proteins in myeloid cells causes delayed tumor growth, indicating that these cells are key for establishing tumor suppression. Moreover, the lack of Shp-2 results in altered phenotype and signaling downstream of colony-stimulating factor 1 receptor.

We are currently investigating through *in vitro*, *in vivo*, and multi-omics approaches how PD-1 and Shp-2 diverge or converge into a tumor-supportive role of lymphoid and myeloid cells. Our results will help elucidate the role of PD-1 and SHP-2 in different aspects of the antitumor immune response by highlighting the potential benefits and risks for future anti-cancer therapies.

Analysis of infiltrating MC subsets in Colorectal Cancer by single-cell RNA-sequencing

Erisa Putro[1], Alessia Carnevale[1], Caterina Marangio[1], Giovanna Peruzzi[2], Cinzia Fionda[1], Helena Stabile[1], Giuseppe Pietropaolo[1], Giuseppe Sciumè[1], Angela Gismondi[1], Rosa Molfetta[1], Valerio Fulci[1], Rossella Paolini[1]
[1]Department of Molecular Medicine, Laboratory Affiliated to Istituto Pasteur Italia-Fondazione Cenci Bolognetti, Sapienza University of Rome, Rome, Italy; *[2]Center for Life Nano Science@Sapienza, Istituto Italiano di Tecnologia, Rome, Italy*

Purpose: Mast cells (MCs) are tissue resident cells that derive from bone marrow pluripotent cells and are mainly involved in IgE-mediated allergic disorders. They are frequently observed in different tumors including colorectal cancer, but their role is poorly understood. Two main subsets of MCs have been described so far in the intestine: mucosal MCs located near the epithelium and expressing the proteases Mcpt1 and Mcpt2 and connective tissue-like MCs that are present in intestinal submucosa and express Mcpt4-7. The aim of this study was to phenotypically and functionally characterize tumor-infiltrating intestinal MC subsets.
Methods: To this aim we used a conventional colitis-induced CRC mouse model (AOM/DSS). We first analyzed by flow cytometry MC frequency and cytokine production in both adenomas and adjacent tissue. To further investigate the role of tumor-infiltrating MCs we performed single cell RNA-sequencing analysis on ckit+/FceRI+ cells, isolated from intestinal adenomas.
Results: We found that MCs accumulate in tumor lesions and produce a higher amount of proinflammatory cytokines compared to MCs that reside in tumor-free adjacent tissue. Single cell analysis demonstrated that tumor infiltrating MCs form different clusters based on differentially expressed genes (DEGs). A first cluster expresses both mucosal and connective protease transcripts and is enriched in pathways related to cell adhesion, migration, and proliferation, suggesting that it represents a MC precursor population. A second cluster shows a selective mucosal phenotype and displays cell activation and cytokine production signatures. The last cluster displays a connective-tissue phenotype and shows a clear signature of MC degranulation and activation expressing the highest levels of genes involved in histamine and prostaglandin biosynthesis and in the angiogenesis pathway.
Conclusion: All together our results shed light in the functional heterogeneity of tumor-infiltrating MCs, revealing the existence of distinct subsets that may play different roles in tumor progression. However, further studies are needed to explore the transcriptional differences between them in order to better discriminate their developmental trajectories. To this purpose, we are currently repeating a single cell RNA-seq on MCs deriving from tumors as well as from adjacent tissue.

Grants: AIRC (AIRC IG-24955) and Istituto Pasteur Italia-Fondazione Cenci Bolognetti (2020-366).

Intra-tumour mature tertiary lymphoid structures (TLSs) predict better prognosis and response to immunotherapy in clear cell renal cell cancer

Jiahe Lu[1;2], Wenhao Xu[1;2], Xi Tian[1;2], Aihetaimujiang Anwaier[1;2], Shiqi Ye[1;2], Yuhao Wu[3], Wangrui Liu[4], Hailiang Zhang[1;2], Dingwei Ye[1;2]
[1]Department of Urology, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China; *[2]Shanghai Genitourinary Cancer Institute, Shanghai, China*; *[3]Institute of Photomedicine, Shanghai Skin Disease Hospital, School of Medicine, Tongji University, Shanghai, China*; *[4]Department of Interventional Oncology, Renji Hospital, Shanghai Jiao Tong University, Shanghai, China*

Purpose: Tertiary lymphoid structures (TLSs) are structured clusters of immune cells that arise in response to pathological conditions, such as chronic inflammation and tumours. TLSs normally consist of B-cell follicles with a germinal centre enclosed by T-cell zones and dendritic cells. The increasing interest in TLSs in the tumour microenvironment (TME) is owing to their prognostic significance and their potential role as mediators of anti-tumour immunity. This study comprehensively evaluated the predictive value of TLSs for prognosis and response to immunotherapy in patients with clear cell renal cell cancer (ccRCC).
Methods: We collected long-term follow-up records from 395 patients with ccRCC who received surgical excision and 230 patients who underwent combination therapy with Tyrosine Kinase Inhibitors (TKIs) and immune checkpoint inhibitors (ICIs), from multiple cohorts. The relative location to the tumour and the maturation status of TLSs were examined by H&E staining and immunohistochemistry. The immune cell composition of TLSs and infiltration into the surrounding TME was assessed using 12-marker multispectral fluorescence. The prognostic implications of TLSs were assessed using log-rank tests, Cox proportional hazards models and scoring nomograms. The molecular mechanism of TLS function was explored by analysing spatial transcriptomic data.
Results: TLSs, particularly intra-tumour TLSs and secondary follicle-like TLSs, showed a strong correlation with longer survival of ccRCC patients and better objective response to anti-PD-1/PD-L1 immunotherapy. In ccRCC samples harbouring peri-tumour TLSs and enriched in primary follicle-like TLSs, the proportion of tumour-associated macrophages and Treg infiltration in the peri-tumour regions increased significantly, indicating a suppressive TME. Spatial transcriptome annotation revealed an abundance of mature plasma cells within mature TLSs producing IgA and IgG, and stem T cells outnumbering exhausted T cells. An immunologically active zone composed of IgG^+ PCs in close proximity to $CXCL13^+$ T cells and $SPP1^+$ macrophages was also observed in ccRCC TLSs.
Conclusion: This work has provided the first insights into how the localisation and maturation heterogeneity of TLSs affect the immune status and responses of ccRCC and suggested an easy-to-use, cost-effective tool for predicting the prognosis of ccRCC patients in clinical application.

A tale of two species: Unveiling the involvement of tissue type 3 dendritic cells with intratumoral T cell behavior

Giuseppe Rocca[1], Alessia Donato[1], Giulia Protti[1], Anna Celant[1], Marco Galli[1], Giulia Stucchi[1], Stefano Cozzi[1], Ilaria Fontana[1], Laura Marongiu[1], Metello Enzo Innocenti[1], Francesca Granucci[1]

Conventional dendritic cells (cDCs) play a pivotal role in activating adaptive immune responses. They include cDC1s and cDC2s, with cDC2 represented by two major populations: DC2s and DC3s. DC3s have significant implications in chronic conditions such as lupus, psoriasis, and severe COVID-19.
We investigated the potential role of DC3s in lung cancer by analyzing publicly available sc-RNAseq datasets of non-small cell lung cancer (NSCLC). We observed an enrichment of DC3s with a potential immunosuppressive phenotype in advanced stages. This was accompanied by a reduction in the frequency of DC2 and cDC1 subsets. By conducting crossspecies sc-RNAseq analysis of human and mouse lung cells, we identified tissue murine DC3s and established a flow cytometry-based method for cDC1s, DC2s, and DC3s distinction. We confirmed DC3 enrichment in an ICB-resistant adenocarcinoma mouse model, mirroring findings in advanced human lung adenocarcinoma.
Using a multiplexing analysis, we spatially mapped immune components in mouse adenocarcinomas. This revealed that DC2s were located outside the tumor, while DC3s were positioned inside the tumor near CD4+ T cells, including Tregs. Similar proximity between cDC2s and CD4+ T cells was confirmed in human tumors. DC3s constituted the primary subpopulation among cDC2s in NSCLC. Furthermore, an analysis of whole-slide sections demonstrated remarkable heterogeneity in T cell and DC distribution within the same tumor. Some regions were enriched in DC3s and CD4+ T cells, while others in CD8+ T cells but lacked DC2s.
Our investigation is still ongoing to obtain functional insights through CITE-seq and single-cell spatial transcriptomic analyses on adenocarcinoma samples. Given that ICB therapy relies on reactivating CD8+ T cells, confirming that DC3- and CD4+ T cell infiltration is preferred in advanced stages could provide valuable insights into ICB treatment outcomes.

Neutrophil subset investigation in stage III melanoma patients undergoing anti-PD-1 immunotherapy or anti-BRAF/MEK target therapy

Marialuisa Trocchia[1], Leonardo Cristinziano[2], Luca Modestino[3], Annagioia Ventrici[1], Stefania Loffredo[1;2;4], Anne Lise Ferrara[1], Carlo Gabriele Tocchetti[1], Teresa Troiani[5], Gianni Marone[1;2;4], Maria Rosaria Galdiero[1;2;6]
[1]Department of Translational Medical Sciences (DiSMeT), University of Naples Federico II, Naples, Italy, Naples, Italy; *[2]Center for Basic and Clinical Immunology Research (CISI), University of Naples Federico II, Naples, Italy, Naples, Italy*; *[3]Department of Internal Medicine and Clinical Immunology, University Hospital of Naples "Federico II", Naples, Italy*; *[4]Institute of Experimental Endocrinology and Oncology (IEOS), National Research Council (CNR), Naples, Italy, Naples, Italy*; *[5]Medical Oncology Unit, Department of Precision Medicine, Università degli Studi della Campania "Luigi Vanvitelli", 80131 Naples, Italy, Naples, Italy*; *[6]Department of Internal Medicine and Clinical Immunology, University Hospital of Naples "Federico II", Naples, Italy*

Background: Melanoma displays a rising incidence and the mortality associated with the metastatic form remains high. Monoclonal antibodies (mAbs) that block programmed death (PD-1) and PD-Ligand 1 (PD-L1) network as well as small molecules targeting BRAF/MEK axis have revolutioned the therapeutic approaches to melanoma patients. PD-L1 is expressed on several immune cells and can be also expressed on human neutrophils. In addition to normal density neutrophils (NDNs), a population of low density neutrophils (LDNs) increases in certain cancer patients and correlates with cancer progression. The role of NDNs and LDNs in melanoma patients is largely unknown.
Methods: 59 stage III melanoma patients (MPs) candidates to anti PD-1 therapy or to anti-BRAF/MEK therapy were prospectively recruited. 28 Healthy controls (HCs), sex- and age- matched, were also recruited. NDNs and LDNs were isolated from peripheral blood, before and during the therapy, to evaluate their activation status and PD-L1 expression by flow cytometry. Plasma concentrations of cfDNA, Citrullinated Histone H3 (CitH3) and MPO-DNA complexes were measured as Neutrophils Extracellular Traps (NETs) biomarkers. Moreover, matrix metalloproteinase-9 (MMP-9) and CXCL8/IL-8 plasmatic levels were evaluated as neutrophils related mediators, by Elisa.
Results: Melanoma patient NDNs displayed an activated phenotype (increased percentages of $CD16^{+}Cd62L^{-}$ cells) and increased PD-L1 levels compared to HCs. Melanoma patients presented increased percentages of LDNs, which displayed higher levels of PDL-1 and an activated phenotype compared to HCs. NDN and LDN PD-L1 expression levels and activation status did not change during therapy. Melanoma patients displayed higher plasma concentrations of NETs compared to HCs. Kaplan Meier curves.
Conclusions: Neutrophils play important roles in immune-mediated clinical conditions such as infection, autoimmunity, and cancer. The activation status and PD-L1 expression in melanoma patients NDNs and LDNs were modified compared to HCs. In addition, both anti-PD-1 immunotherapy and anti-BRAF/MEK inhibitors did not modify these peculiar aspects. Further instigations are in progress to evaluate any prognostic/predictive significance for NDNs and LDNs in stage III melanoma patients undergoing anti-PD-1 immunotherapy or anti-BRAF/MEK target therapy.

Plasma cell hyperplasia in immune- cold triple negative breast cancer is prognostic of inferior outcome

Ellie Alberts[1;2], Victoire Boulat[1;2], Miu Shing Hung[2], Fangfang Liu[1], Thomas Hardiman[1], Mengyuan Li[1], Jelmar Quist[1], Cheryl Gillett[1], Sarah Pinder[1], Dinis Pedro Calado[2], Anita Grigoriadis[1]
[1]*King's College London, London, United Kingdom*; [2]*Francis Crick Institute, London, United Kingdom*

Triple-negative breast cancers (TNBCs) are characterised by an aggressive behaviour and limited treatment options compared to other subtypes of breast cancer. TNBCs with higher stromal tumor-infiltrating lymphocytes (sTILs) often exhibit a more favorable prognosis. This includes longer distant metastasis free survival (DMFS), particularly when accompanied by the presence of germinal center (GC) formations in the axillary lymph nodes (LNs). While immunotherapy holds promise for these TNBCs, the majority present with low sTIL infiltration and subsequently lack effective treatment options. This underscores the urgent need for innovative therapies tailored to target immune cold TNBCs and improve patient outcomes.
We analysed transcriptional data of four TNBC cohorts, totalling 618 cases, alongside sTIL scoring and immunofluorescence imaging of primary tumors, cancer-free, and involved LNs. Transcriptional data was deconvoluted using publicly available scRNAseq data of B, T lymphocyte and myeloid populations. We found that TNBC patients with the lowest DMFS were characterised by histologically low sTIL levels, elevated expression of plasmablasts/plasma cell genes and fewer GC formations in patient paired LNs. Plasmablast/plasma cell hyperplasia was confirmed in the primary tumour and involved LNs of these patients using multiplex immunostaining.
We characterised a series of orthotopic mouse models of TNBC and found that the most representative model of the human TNBC immune cold scenario also displayed plasmablasts/plasma cell hyperplasia within the tumour draining LNs at the expense of GC formations. Plasmablasts/plasma cell hyperplasia was unaffected in mice lacking SAP1/Sh2d1A, which is critical for GC B cell formation, possibly indicating an extrafollicular origin. Notably, targeted depletion of plasmablasts/plasma cells altered the phenotype of CD8 T cells leading to their increased functionality and effective impairment of tumour growth.
This study indicates that the induction of extrafollicular plasmablast/plasma cell hyperplasia within immune cold TNBC tumours disrupts tumor directed CD8 T cell immune responses. This discovery introduces a novel and unforeseen stratification of immune cold TNBC tumors, suggesting that therapeutic interventions targeting the depletion of plasmablast/plasma cells could potentially improve patient outcomes.

Hepatocellular carcinoma drives tissue-resident NK cell regulation of CD8+ T cells through the PD-L1 axis

Stephanie Kucykowicz[1], Gloryanne Aidoo-Micah[1], Daniel Brown Romero[1], George Finney[1], Anandita Mathur[1], Alberto Quaglia[2], Andrew Hall[3], Jack Leslie[4], Derek Mann[4], Laura J Pallett[1], Mala K Maini[1], Mariana Diniz[1]
[1]Institute of Immunity & Transplantation; Division of Infection and Immunity; University College London, London, United Kingdom; *[2]Department of Cellular Pathology; Royal Free London NHS Foundation Trust and UCL Cancer Institute, London, United Kingdom*; *[3]Institute for Liver and Digestive Health; Royal Free London NHS Foundation Trust, London, United Kingdom*; *[4]Newcastle Fibrosis Research Group; Faculty of Medical Sciences; Newcastle University, Newcastle, United Kingdom*

Purpose: Hepatocellular carcinoma (HCC) is the third leading cause of cancer-related deaths globally. Despite the shift to immunotherapy, sustained responses are limited, underscoring the need for novel treatment strategies. Tissue-resident lymphocytes have a critical role in tumour immunosurveillance but their interplay within the profoundly immunosuppressive tumour microenvironment (TME) in HCC is not well-characterised. We have previously identified a subset of liver-resident NK cells that can negatively regulate T cell function in the settings of chronic hepatitis B infection and in therapeutic vaccination through TRAIL, NKG2D and PD-L1. We hypothesize that intra-tumoral NK cells can similarly constrain anti-tumour T cells in HCC and that defining the pathways can identify new therapeutic targets.
Methods and results: We took advantage of our access to freshly isolated lymphocytes from human HCC surgical samples for *ex vivo* immune cell phenotyping by multiparametric flow cytometry. Within the tumour, CD8+ T cells expressed high levels of PD-1. Tissue-resident NK cells, representing 40% of the total infiltrating NK cell pool, expressed PD-L1 at higher levels than tumour-infiltrating conventional NK cells or NK cells from background liver or blood. *In situ* imaging of the TME visualised NK cells and CD8+ T cells localising in close proximity. To understand the drivers of PD-L1 upregulation on NK cells in HCC, we used *in vitro* co-cultures to test multiple features of the TME. Direct contact with HCC cell lines upregulated expression of PD-L1 on NK cells, a feature not driven by the HCC secretome. To test the functional role of this pathway *in vivo* we have established subcutaneous and orthotopic HCC mouse models and confirmed that these recapitulate the upregulation of PD-1 and PD-L1 on tissue-resident CD8+ T cells and NK cells respectively.
Conclusion: In summary, we demonstrate the upregulation of the PD-1/PD-L1 pathway on CD8+ T and NK cells in human HCC, showing that this may be driven by tumour cells within the TME. Our mouse models recapitulate our human findings and will allow us to investigate the therapeutic potential to boost anti-tumour T cell immunity by targeting tissue NK cell regulation.

Association of circulating inflammatory factors with postoperative complications after gastric cancer surgery

Neringa Dobrovolskiene[1], Agata Mlynska[1], Daniel Doval[2], Vita Pasukoniene[1]
[1]National Cancer Institute, Vilnius, Lithuania; *[2]Vilnius Gediminas Technical University, Vilnius, Lithuania*

Gastric cancer is the world's leading cancer in terms of mortality. Despite steady medical progress and a reduction in the incidence of gastric cancer over the past decades, this malignancy remains a major public health concern due to its high prevalence and the high mortality-to-morbidity ratio associated with its detection at advanced stages. Post-operative complications related to surgical removal of the tumour are known to be a common problem in the management of gastric cancer. During infection, the role of circulating CD14 and lipopolysaccharide-binding protein (LBP) molecules in the immune response is important. Together, CD14 and LBP play a key role in the initiation and amplification of the inflammatory response by facilitating the recognition and response to bacterial pathogens. The activation of these immune mechanisms is essential for the elimination of bacterial invaders and the restoration of homeostasis.

Evaluation of the circulating factors CD14 and LBP associated with post-operative complications, their pre- and post-operative levels and their correlation with post-operative complications, could help to determine the potential predictive value of these parameters in predicting post-operative complications.

Our aim was to evaluate the levels of circulating inflammatory factors CD14 and LBP in the serum of gastric cancer patients in order to investigate the potential predictive value of these parameters in predicting postoperative complications. To this end, we determined serum levels of circulating CD14 and LBP molecules by ELISA and compared them between patients with different types of postoperative complications. We also performed a fecal calprotectin test to check for inflammation in the intestines of the patients.

Serum circulating CD14 levels were significantly different between gastric cancer patients receiving chemotherapy and surgery (with a decrease after surgery), indicating that the immune response is enhanced against bacterial infections. The calprotectin test was significantly different between the baseline and surgical group (decreased after surgery), indicating a reduction in intestinal inflammation. Our results suggest that the identification of the factors CD14 and calprotectin in the prediction of early postoperative complications may help in the development of diagnostic tests for early detection and monitoring of the disease.

Tumours of different invasiveness secrete small extracellular vesicles of distinct lipid composition influencing CD1a-restricted T cell responses.

Mikolaj Klimczuk[1], Felicja Gajdowska[1], Michał Młynarczyk[2], Weronika Hewelt-Belka[2], Danuta Gutowska-Owsiak[1]
[1]*University of Gdańsk, Gdańsk, Poland*; [2]*Technical University of Gdańsk, Gdańsk, Poland*

Purpose: Exosome-enriched small extracellular vesicles (sEVs) are one of the three types of extracellular vesicles (EVs). The size of sEVs falls into a range of 40-150nm in diameter, which allows for long distance cellular communication, with potential significance in tumour progression and evasion. We have previously determined that the membrane of sEVs may serve as a source of CD1a ligands and affect T cell responses. CD1a antigens may have a permissive (stimulatory) or non-permissive (inhibitory) effect on CD1a-restricted T cells depending on headgroup size and lipid fit into the CD1a binding groove and that a pathological state can affect their content in sEVs.
The project aims to investigate the lipid composition of sEVs secreted from benign and malignant tumours with potential differential effect in the downstream T cell responses.
Methods: sEVs were isolated from RT4 and T24 bladder cancer cell lines cultured in EV-depleted complete RPMI-1640. Conditioned media were collected after 24h and sEVs were isolated by serial centrifugation. Lipidomic analysis was performed by mass spectrometry to assess lipid composition of isolated sEVs. The effect of sEV supplied lipids on CD1a-restricted T cell responses was performed with IFNγ ELISpot assay with CD1a-transfected K562 cells serving as antigen presenting cells. Prior to ELISpot assay CD1a-K562 cells were pulsed with sEVs, which were digested by phospholipase A2 (PLA2) to liberate lipids from the sEV membranes.
Results: Lipidomic mass spectrometry detected that both types of lipids could be found in the sphingomyelin (SM; nonpermissive), and phosphatidylcholine (PC; permissive) classes, with differential content of nonpermissive lipids in tumorigenic lines in contrast to non-tumorigenic. We determined that the addition of lipid antigens supplied by sEVs to the K562-CD1a/T cell coculture affected CD1a-dependent IFNγ responses in comparison to the control unpulsed cells as determined by differential IFNγ secretion.
Conclusions: The results showed that sEV lipids secreted by tumours of different invasiveness differ in lipid content which contributes to differences in activation of CD1a-restricted T cells. Secreting differentially-composed sEVs by cancer cells could potentially constitute one of tumour immune evasion strategies.

NK-LGL comprise dominant pools of adaptive NK cells that help distinguish from NK cell expansions.

Tim Holmes[1;2], Ram Pandey[2], Paollo Cirillo[1], Yenan Bryceson[1;2]
[1]University of Bergen, Bergen, Norway; [2]Karolinska University, Stockholm, Sweden

Large granular lymphocytic (LGL) leukemia is a chronic malignant disorder characterized by the expansion of cytotoxic T- or natural killer (NK)-lymphocytes, accounting for 2-5% of chronic lymphoproliferative disorders. NK-LGL is subdivided as indolent NK chronic lymphoproliferative disorder (CLPD-NK), and rare aggressive NK-LGL leukemia (ANKL). It is currently difficult to distinguish CLPD-NK from reactive expansions of NK cells arising during viral infection or autoimmunity. Phenotypic analysis of NK-LGL patients revealed dominant populations of adaptive NK cells in both ANKL and CLPD. Characterization revealed loss of the PLZF transcription factor and signaling adapters FceRg, Syk and Eat-2 that distinguish adaptive NK cells but little of the common adaptive marker NKG2C. Transcriptomic and epigenetic analyses of sort-purified NK-LGL NK cells revealed dysregulation of oncogenic factors including RUNX1 and BCL11B. Several differentially expressed genes were supported by changes in chromatin accessibility specific to NK-LGL adaptive NK cells. Amongst these genes were known tumor drivers of LGL such as STAT3 together with putative candidates RUNX1 and RHOH. These were further evaluated in both knockdown and overexpression models in primary NK cells and NK-LGL cell lines suggesting a contribution to lymphoproliferative phenotypes. Our results refine a phenotypical definition that can aid diagnostics of CLPD-NK leukemia and further reveal dysregulated pathways that may underlie pathological lymphoproliferation.

Lamps and autophagy as predictive markers in colorectal cancer - A pilot study

Tsvetomira Ivanova[1;2], Diana Molander[1], Dorian Dikov[3], Yordan Sbirkov[1;2], Maria Kazakova[1;2], Valentin Dichev[1;2], Nikolay Mehterov[1;2], Angel M . Dzhambov[2], Nikolay Belev[4], Boyko Atanasov[4], Victoria Sarafian[1;2]
[1]Medical University of Plovdiv, Plovdiv, Bulgaria; *[2]Research Institute at Medical University-Plovdiv, Plovdiv, Bulgaria*; *[3]Grand Hospital de l'Este Francilien, Jossigny, France*; *[4]University Hospital ´Eurohospital, Plovdiv, Bulgaria*

Long-term management of colorectal cancer (CRC) relies on effective chemotherapy and the prevention of metastatic disease, which ultimately is the main cause of mortality. However reliable prognostic biomarkers for better stratification and treatment of CRC patients, and thus prevention from relapse are currently missing. At present the fundamental role of autophagy in maintaining cell homeostasis is well defined with lysosomes playing a major role in it. Nevertheless, in oncogenesis, a dual role of autophagy is also indicated, either in promoting or inhibiting tumor growth. Tumor budding has been proposed as a poor prognostic factor but is not yet included in the routine diagnosis of CRC. The current study aimed to investigate and evaluate the relationship between the lysosomal proteins LAMP1 and LAMP2, tumor budding, and clinicopathological parameters, in CRC. The clinical significance of tissue expression, serum protein and gene expression levels from primary CRC and healthy patients were assessed. We found moderate to strong expression of LAMP1 and LAMP2 in the tumor stroma, parenchyma and tumor front in CRC. Moderate correlation and association between tumor budding, lymph nodes, lymphatics, and blood vessels were also detected. Specifically, intense LAMP1 and LAMP2 staining were observed in the front of tumor invasion compared with tumor parenchyma and noncancerous tissue. Upregulated LAMPS gene expression in WBC and elevated LAMP1 levels in sera from CRC patients were also noted. Here we show the concurrence of the spatial immunochemical expression of the lysosome-associated membrane proteins LAMP1 and LAMP2, and tumor budding in CRC patient samples, as well as their prognostic significance for the stratification, and treatment of CRC.

Significance of standard laboratory techniques in the monitoring of monoclonal gammopathies

Mariem Marrak[1;2], Dhouha Krir[1;2], Imen Zamali[1;2], Yosra Nasri[1], Hayet Kebaier[1], Ines Ben Sghaier[1], Ahlem Ben Hmid[1;2], Melika Ben Ahmed[1;2], Yousr Galai[1;3]
[1]Pasteur Institute of Tunis, Department of Clinical Immunology, Tunis, Tunisia; *[2]Faculty of Medicine of Tunis, University of Tunis El Manar, 1068, Tunis, Tunisia*; *[3]Faculty of Pharmacy of Monastir, University of Monastir, Monastir, Tunisia*

Plasma cell proliferative disorders often involve the synthesis and secretion of a monoclonal immunoglobulin. The clinical guidelines recommend serum protein electrophoresis, serum immunofixation and serum free light chain measurement as monoclonal gammopathy testing. This study aimed to assess the effectiveness of standard laboratory tests in monitoring monoclonal gammopathy.
We conducted a retrospective review of 404 immunofixation (IF) cases performed at the Clinical Immunology Laboratory of the Pasteur Institute of Tunis from August 2021 to July 2022 using the Sebia HYDRAGEL IF9 system. Quantitative Immunoglobulin Testing (QIg) and free light chain (FLC) assays were carried out using the Optilite automated system 5the Binding Site®).
Among the 404 samples, 50 showed a monoclonal band on IF, yet the M-protein was either barely detectable or not quantifiable on serum protein electrophoresis (SPEP). Based on the IF results, monoclonal gammopathies of the IgG type were most frequently observed (26 cases, 52%), with 22% classified as κ type and 30% as λ type. IgA type gammopathies ranked second (13 cases, 26%), while free light chain isotypes were identified in 8 cases. A FLC assay was conducted on 11 patients, revealing a pathological serum FLC kappa/lambda ratio (sFLCR) in 63% of cases. Urinary protein immunoelectrophoresis was performed on 28 patients, with 81% showing pathological results. Only 5 patients underwent QIg testing, and among them, 2 patients with an IgA monoclonal gammopathy on IF had IgA levels exceeding 3.5g/L.
Our findings suggest a concordance between the IF results and other assays, including QIg, FLC assay, and urine analysis. These diagnostic methods may provide valuable insights into disease progression, highlighting their significance in monitoring monoclonal gammopathies.

Strong YKL-40 expression in the invasive tumor front of colorectal cancer - A pilot study

Maria Kazakova[1;2], Tsvetomira Ivanova[1;2], Diana Molander[1], Dorian Dikov[3], Kiril Simitchiev[4], Yordan Sbirkov[1;2], Victoria Sarafian[1;2]
[1]Medical University of Plovdiv, Plovdiv, Bulgaria; *[2]Research Institute at Medical University-Plovdiv, Plovdiv, Bulgaria*; *[3]Grand Hospital de l'Este Francilien, Jossigny, France*; *[4]Plovdiv University Paisii Hilendarski, Plovdiv, Bulgaria*

The poor prognosis of patients initially diagnosed at an advanced stage of colorectal cancer (CRC) and the heterogeneity within the same tumor stage define the need for additional predictive biomarkers. Tumor buds are proposed as a poor prognostic factor for CRC, however, they are still not implemented into routine pathology reporting. In turn, the chitinase-3-like protein 1 (CHI3L1) also known as YKL-40, is regarded as a candidate circulating biomarker and therapeutic target in CRC. The aim of our study was to investigate tissue YKL-40 localization and tumor budding in CRC. Thirty-one CRC patients and normal colonic tissues were examined. The correlation between YKL-40 levels, tumor budding and clinocopathological parameters was evaluated by polychoric correlation analysis. The immunohistochemical assessment revealed high YKL-40 expression in CRC in contrast to normal mucosa. Specifically, intense YKL-40 staining was detected in the front of tumor invasion compared with tumor parenchyma and noncancerous tissue. We present novel data for increased YKL-40 expression in tumor buds within the front of tumor invasion. We assume that the combination of this morphological parameter with the tissue level of the pleotropic YKL-40 glycoprotein could serve as a future prognostic biomarker for CRC stratification and treatment.

Histone 3 acetylation is altered in NK cells from metastatic breast cancer patients

Ethan Collins[1], Clair Gardiner[1], Ciara O'Hanlon Brown[2]
[1]Trinity College Dublin, Dublin, Ireland; *[2]Trinity St.James's Cancer Institute, Dublin, Ireland*

Purpose: NK cells are cytotoxic lymphocytes which play a major role in eliminating cancer cells and are a key focus of emerging immunotherapies. However, previous work from our lab and others has shown that NK cells from metastatic breast cancer patients are functionally and metabolically impaired. Epigenetics and metabolism are linked through acetyl CoA, a key metabolite which also acts as a substrate for histone acetylation reactions, an epigenetic modification which generally enhances gene transcription. Therefore, we sought to identify if altered metabolism can impact global levels of acetylated histone 3 in NK cells from metastatic breast cancer patients. Furthermore, we investigated the role of the enzymes acetyl CoA synthetase 2 (ACSS2) and ATP-citrate lyase (ACLY) as they have been shown to support histone acetylation by generating nuclear acetyl CoA in other cell types. In addition, we measured the effects of TGFβ, an anti-inflammatory cytokine which plays a direct role in NK cell dysfunction in the tumour microenvironment also.
Methods: Peripheral blood mononuclear cells (PBMC) from metastatic breast cancer patients and healthy controls were activated by overnight treatment with IL-12 (30ng/ml) and IL-15 (100ng/ml) in the presence or absence of TGFβ (10ng/ml) or small molecule inhibitors of ACLY (BMS-303141) and ACSS2 (ACSS2i). Acetylated H3 levels were measured by intranuclear flow cytometry.
Results: Healthy donor NK cells were shown to substantially upregulate H3 acetylation in response to IL-12/15 stimulation. In contrast, there was no increase observed in NK cells from metastatic breast cancer patients. Interestingly, use of a small molecule ACLY inhibitor blocked IL-12/15 induced upregulation of H3 acetylation while the ACSS2i had no effect. Finally, TGFβ caused a moderate decrease in H3 acetylation.
Conclusions: NK cells from healthy donors substantially increase H3 acetylation in response to IL-12/15 stimulation with ACLY derived acetyl CoA potentially playing an important role. In contrast, NK cells from metastatic breast cancer patients have altered histone acetylation patterns. Failure to upregulate H3 acetylation in response to cytokine stimulation may contribute to NK cell dysfunction in metastatic breast cancer.

Activated human macrophages suppress growth and kill cancer cells

Jan-Morgan Dybdal[1,2], Inger Øynebråten[1,2], Alexandre Corthay[1,2,3]
[1]*Tumor Immunology Lab, Department of Pathology, Rikshospitalet, Oslo University Hospital, Oslo, Norway*
[2]*Hybrid Technology Hub - Centre of Excellence, Institute of Basic Medical Sciences, University of Oslo, Oslo, Norway*
[3]*Institute of Clinical Medicine, University of Oslo, Oslo, Norway*

Purpose: The presence of tumor-associated macrophages (TAM) is well-documented. This fact, together with macrophages' role in clearing out dead cells and damaged tissues, make macrophages a highly interesting target for cancer immunotherapy. However, there is an ongoing debate on the role of TAMs in cancer since it has been reported both positive and negative correlations between TAM densities and patients' clinical outcome. This study aims at clarifying the ability of activated human macrophages to kill cancer cells *in vitro*.
Methods: We have established a time-lapse microscopy-based assay to visualize and quantify the killing of cancer cells by human macrophages. Macrophages were differentiated *in vitro* from monocytes isolated from the blood of healthy donors. Macrophages were activated with various stimuli such as interferons and toll-like receptor agonists, and co-cultured with several human cancer cell lines expressing fluorescent protein. The killing of cancer cells by activated macrophages was monitored over time and quantified by image analysis algorithms. A fluorescent caspase 3/7 probe was used to visualize apoptosis induction in cancer cells.
Results: We found that human macrophages can be triggered to either kill cancer cells or arrest cancer cell growth. This anti-cancer activity of macrophages was only seen in activated macrophages, and was dependent on the mode of activation. We are currently working on deciphering the cellular and molecular mechanisms involved.
Conclusions: Human activated macrophages can efficiently kill cancer cells of various origin and inhibit cancer cell proliferation. These experimental data support the potential of macrophages for cancer immunotherapy in humans.

The interplay between intracellular pathogen proliferation and host cell death induction and metabolism during L. major infection

Leon-Alexander Dewitz[1], Iris Baars[1], Andreas Müller[1]
[1]*Institute for moleculare and clinical immunology, Magdeburg, Germany*

Leishmania major (L. major) is an intracellular pathogen that is located mainly in macrophages during an established infection. We have shown previously that *L. major* parasites occur as high and low proliferating subpopulations, which seem to be correlated with differential host cell death induction in vitro and in vivo.
Whether activation of host cell death pathways is causally linked with the different proliferation rates of the infecting *L. major* parasites has remained unclear. To elucidate this question, we have generated killed but metabolically active (KBMA) *L. major* parasites, which are not able to proliferate, but retain their metabolic functions and the differentiation capacity from promastigote into amastigote upon infection.
By infecting macrophages with proliferation-competent versus KBMA parasites and comparing the infected macrophages to each other, we have determined the influence of the parasite proliferation on the host cell. Using flow cytometry and live cell imaging, significant differences in host cell death and expression of the lipid transporter CD36 and the uptake of long chain fatty acids and low-density-lipoprotein could be observed dependently of the intracellular pathogen proliferation state. CD36 expression also correlated with pathogen proliferation in experiments with an in vivo reporter system. Furthermore, we observed a differential activation of Caspase-1 versus Caspase-3 upon infection with proliferation-competent pathogen in vitro and in vivo.
These results suggest a differential influence of the proliferation rate of *L. major* parasites on their host phagocytes, highlighting the proliferation as an important factor influencing the host-pathogen interaction during an infection with *L. major*.

Mitochondria in intercellular communication between stem cells and B cells

Veronika Somova[1], Natalie Fikarova[1], Daniel Vasek[1], Natalie Jaborova[1], Martin Prevorovsky[1], Zuzana Nahacka[2], Jiri Neuzil[2;3;4], Magdalena Krulova[1]
[1]Department of Cell Biology, Faculty of Science, Charles University, Prague, Czech Republic; *[2]Laboratory of Molecular Therapy, Institute of Biotechnology, Czech Academy of Sciences, Prague-West, Czech Republic*; *[3]Department of Physiology, Faculty of Science, Charles University, Prague, Czech Republic*; *[4]School of Pharmacy and Medical Science, Griffith University, Southport, Australia*

Purpose: The significance of mitochondrial transfer is increasingly acknowledged as a vital immunomodulatory process employed by mesenchymal stem cells (MSCs). Although the effects on T cells and macrophages have been studied, the effects on B cells remain an area yet to be explored. This research focuses on understanding how MSC-mediated mitochondrial transfer influences the fate of B lymphocytes.
Methods: MSCs, either labeled with MitoTracker dyes or derived from mito::mKate2 transgenic mice, were co-cultured with syngeneic or allogeneic splenocytes. Flow cytometry was used to measure the transfer of mitochondria into different immune cell populations, to evaluate levels of reactive oxygen species (ROS), apoptosis, glucose uptake and mitophagy. RNA sequencing was then performed on CD19+ cells acceptors and non-acceptors of mitochondria. Changes in gene expression following mitochondrial uptake were identified by differential gene expression analysis. Furthermore, in an acute inflammation model induced by LPS, MSCs from mito::mKate2 transgenic mice were administered, and subsequent mitochondrial transfer and phenotypic changes in B cells from various organs were assessed.
Results: MSCs were observed to transfer mitochondria to CD19+ cells, although to a lesser extent compared to other immune cell types. Mitochondrial transfer was found to be associated with levels of ROS and was further affected by the induction of mitophagy. Cells that received mitochondria exhibited increased expression of CD69 and glucose uptake, indicating enhanced glycolytic activity. We also observed a reciprocal exchange of mitochondria, with immune cells transferring dysfunctional mitochondria to MSCs and receiving functional ones in return. CD19+ cells that acquired mitochondria displayed enhanced viability, proliferation and upregulation of genes linked to cell division and the downregulation of those involved in antigen presentation. The relevance of these findings *in vivo* was underscored by the transfer of mitochondria to B cells across various organs in a model of acute inflammation induced by LPS.
Conclusion: These discoveries reveal the complex interactions between MSCs and immune cells through mitochondrial trafficking and provide valuable insights into potential therapeutic applications of MSC-mediated immune modulation.

Molecular mechanisms and therapeutic implications of T and B cell subpopulations in Common Variable Immunodeficiency with Granulomatous-Lymphocytic Interstitial Lung Disease

Alejandro Pereiro Rodríguez[1], Nabil Subhi-Issa[2], Maria Palacios Ortega[1], Teresa Guerra Galan[1], Kauzar Mohamed Mohamed[1], Maria Dolores Mansilla Ruiz[1], Angela Villegas Mendiola[1], Marc Perez-Guzman[1], María Guzmán-Fulgencio[1], Miguel Fernandez Arquero[1], Silvia Sanchez Ramon[1]
[1]Servicio de Inmunología Hospital Clínico San Carlos, Madrid, Spain; *[2]Fundación para la Investigación Biomedica Hospital Clínico San Carlos, Madrid, Spain*

Purpose: Granulomatous lymphocytic interstitial lung disease (GLILD) is one of the most serious non-infectious complications that can occur in up to 20 percent of common variable immunodeficiency (CVID) patients. An increase in follicular helper T cells type 1 (Tfh1) has been observed in these patients, which has recently been associated with an increase in Age Associated B cells (ABCs). It appears that interferon gamma (IFN-γ) may play an important role, however, the underlying molecular mechanisms are still not fully understood. This study investigates how treatment with rituximab and mycophenolate affects both subpopulations in a CVID patient with GLILD.
Methods: The patient received weekly intravenous Rituximab for 4 cycles along with daily mycophenolate. Blood was collected 1 week before treatment and 2 months after treatment. T and B cells were analyzed using 10-color and 8-color flow cytometry panels, and functional analysis was conducted with PMA and ionomycin.
Results: Clinically, the patient suddenly improves his pulmonary capacity and dyspnea. However, he relapses again 6 months later requiring a new dose of rituximab. Regarding T cells, total CD4 count and Tfh1 populations appear to be quantitatively unaffected by the treatment. Functionally, the percentage of CD4 cells synthesizing IFN-γ decreased with treatment. IFN-γ expression in Tfh1 cells couldn't be studied due to lost membrane markers with the *in vitro* conditions. Regarding B cells, before treatment, the patient exhibited elevated percentages of ABCs. After treatment, a marked reduction in CD21 high-intensity expressing cells was observed, while ABCs surprisingly persisted and increased in relative proportion.
Conclusion: Although Tfh1 cells did not show significant quantitative changes, a decrease in IFN-γ signal in CD4 cells after tretament suggested functional alterations. This would explain the immediate improvement of the patient.
On the other hand, ABCs appear to be resistant to treatment, since a relative increase in this subpopulation is observed after therapy. We speculate that the persistence of Tfh1 and ABCs causes the patient's relapse and would explain the need for chronic treatment with rituximab. However, further studies are needed to investigate the pathophysiological mechanisms Tfh1 and ABCs in GLILD. In this way, more specific treatments can be obtained.

Mast cells switch their secreted cytokine profile from pro-inflammatory to pro-tolerant upon prologued IL-33 exposure

Andrea Teufelberger[1], Carolin Költgen[1], Melanie Heßler[2;3], Magda Babina[2;3], Peter Wolf[1]
[1]Department of Dermatology, Medical University of Graz, Graz, Austria; *[2]Institute of Allergology, Charité - Universitätsmedizin Berlin, Berlin, Germany*; *[3]Fraunhofer Institute for Translational Medicine and Pharmacology ITMP, Allergology and Immunology, Berlin, Germany*

Purpose: Upon activation, mast cells can release a myriad of factors, such as histamine, heparin, proteases, lipid mediators, and cytokines with which they influence their environment. IL-33 is well known to mediate a type 2 immune response upon allergen exposure in cells that carry its receptor ST2, such as mast cells. In the skin, these cells also express the Mas-related G protein coupled receptor X2 (MRGPRX2). Wasp venom and alum, which are repeatedly injected during desensitization therapy, can trigger an IL-33 release in the skin, and mastoparan in wasp venom can activate MRGPRX2. During desensitization, the immune response towards an allergen switches from a type 2 pattern with IL-4, IL-5, and IL-13 towards a tolerance response, with TGF-β and IL-10 being the main driving cytokines. It is however not clear, how this switch is initiated.
Methods: Unexposed or IL-33 pre-exposed LAD2 cells and primary skin mast cells were stimulated with IL-33 and *Hymenoptera* venom or Compound 48/80. Additional activation with FcεRI-crosslinkage was tested in LAD2 cells. We measured cytokine release by multiplex assay and ELISA, degranulation as increase in CD63 surface expression by flow cytometry, and intracellular signaling by a human phospho-kinase array.
Results: The combination of ST2 and MRGPRX2 stimulation was necessary to cause secretion of pro-inflammatory cytokines and TGF-β. IL-33 exposure for 4 days led to a switch in the secreted cytokine profile in LAD2 cells as well as primary skin mast cells upon stimulation. In IL-33 pre-exposed and stimulated LAD2 cells, the with-no-lysine [K] 1 kinase was activated, and the cells mainly secreted TGF-β. This switch in secreted cytokine composition happened independently of FcεRI-crosslinkage.
Conclusion: This different cytokine profile of mast cells could potentially skew other immune cells towards a tolerance response to the administered allergen during desensitization therapy.

Activation of the Noncanonical Caspase-4/-5 inflammasome in Human Endothelial Cell Results in Secretion of Proinflammatory Proteins and Macrophage Activation

Katariina Nurmi[1], Martina Lorey[1], Jukka Parantainen[1], Wojciech Cypryk[2], Vesa-Petteri Kouri[1], Tuula Anneli Nyman[3], Kari K. Eklund[4]
[1]Helsinki University, Helsinki, Finland; *[2]Centre of Molecular and Macromolecular Studies Polish Academy of Sciences, Lodz, Poland*; *[3]Oslo University Hospital, Oslo, Norway*; *[4]Helsinki University Hospital, Helsinki, Finland*

The alterations in microbiome composition and heightened levels of circulating microbial components, known as metabolic endotoxemia, have been linked to the development of various chronic low grade inflammatory diseases, most notably cardiovascular diseases (CVD). Gut dysbiosis plays pivotal role in modulating the severity of metabolic endotoxemia and the nature of the ensuing inflammatory response. Nevertheless, the precise mechanism by which circulating microbial components, such as lipopolysaccharides (LPS), contribute to CVD pathogenesis remains elusive.
Cells detect microbial components via innate immune receptors, and their activation triggers intracellular communication through secretion of mediators, damage-associated molecular patterns, and extracellular vesicles (EV). We studied the activation of the noncanonical inflammasome induced by intracellular LPS in human coronary endothelial cells (HCAEC) and human umbilical vein endothelial cells (HUVEC). LPS was introduced into cells either by transfecting liposome-encapsulated LPS or by stimulating cells with bacterial outer membrane vesicles.
Intracellular LPS led to elevated expression of cell adhesion molecules, robustly increased protein secretion within the EV fraction, and induced pyroptotic cell death. This was dependent on caspase-4/5 as well as mixed lineage kinase domain-like (MLKL) but was independent of the NLRP3 inflammasome or Toll like receptor 4. Intracellular LPS induced significant secretion of EV-encapsulated proteins, without affecting the size or the quantity of the secreted EVs. Mass spectrometric analysis of EV fractions revealed over 2200 proteins, with more than 200 proteins exclusively identified following LPS transfection. The EV proteins included enzymes, kinases, peptidases, phosphatases, regulators of transcription and translation, transporter proteins, and transmembrane receptors. EVs derived from LPS-transfected HCAECs activated human primary macrophages, inducing expression of proinflammatory cytokines and interferon response.
LPS activates the noncanonical inflammasome in endothelial cells, resulting in secretion of EVs capable of macrophage activation, thus representing a potential link between dysbiosis, metabolic endotoxemia and vascular inflammation.

Signaling lymphocyte activation molecule 7 (SLAMF7) in the differentiation of human, pathogen-specific T cells

Lisette Fickenscher[1], Katrin Vogel[1], Irina Han[1], Aditya Arra[1], Holger Lingel[1], Jan-Erik Sander[1], Dirk Bretschneider[2], Monika Brunner-Weinzierl[1]

[2]*Department of Paediatrics, Hospital St Marienstift, Magdeburg, Germany*

Misdirected T cell responses can be the cause of autoimmune diseases such as systemic lupus erythematosus (SLE). Understanding T-cell differentiation and the role of costimulatory molecules in pathological processes could open new ways to develop therapeutic approaches. As we found that a major inhibitory molecule on T cells - CTLA-4 - strongly controls the signalling lymphocyte activation molecule F7 (SLAMF7), a role for SLAMF7 in T cell differentiation was hypothesised.
We investigated the role of SLAMF7 in human T helper (Th) cell differentiation. Enriched naive $CD4^+$ T cells were antigen-specifically stimulated with heat-inactivated pathogens presented on APCs. In addition to functional assays, the activated human T cells were characterised by flow cytometry using characteristic expression of differentiation-associated molecules. Using a human model of antigen-specific T cell differentiation, we found that SLAMF7 is differentially expressed depending on the inflammatory cytokine milieu. While SLAMF7 is not expressed in resting Th cells, it is upregulated in activated cells with a strong correlation to the activation-associated surface molecule CD71. In addition to correlation to activation, the frequency of SLAMF7-expressing Th cells increases after completion of the first cell cycle. Notably, SLAMF7 expression is also age-dependent. This suggests a central role for SLAMF7 in Th differentiation. Its role in immune pathologies will be discussed.

Targeting of SLAMF7 on human CD8+ T cells to enhance responsiveness against tumor-associated antigens

Jan-Erik Sander[1], Holger Lingel[1], Katrin Vogel[1], Aditya Arra[1], Irina Han[1], Lisette Fickenscher[1], Monika Brunner-Weinzierl[1]
[1]*Department of Experimental Paediatrics, University Hospital, Otto-von-Guericke University, Magdeburg, Germany*

In recent years, novel immunotherapy approaches, in particular immune-checkpoint blockade, revolutionized multiple therapy regimens against different type of cancer. Nonetheless, there are patients who don´t respond or only take little advance of it, while immune related adverse events occur frequently and often leads to limitation of the therapy. To improve anti-tumoral $CD8^+$ T-cell responses we identified the self-ligating receptor SLAMF7 as a promising target structure. SLAMF7 is expressed on various immune cells, where it´s activation leads to different immunoregulatory cues, depending on the intracellular adaptor molecule. On $CD8^+$ T cells we characterized SLAMF7 as a critical regulator during priming.
In this study, we investigated the effect of SLAMF7 activation on human $CD8^+$ T lymphocytes. Further, we examined whether activation of the SLAMF7 receptor in combination with an ICB leads to increased effectiveness of immunotherapy against tumour antigens. For this purpose we designed a method where we stimulated human $CD8^+$ T-cells, isolated from peripheral blood, via appropriate antibodies coupled on microspheres. As tumour antigen, we expose the T-cells to the cancer-testis antigen NY-ESO-1, which is re-expressed on wide range of malignant cells. The ICB is induced in APC/$CD8^+$ T-cell co-culture and is connected up- or downstream with targeting of SLAMF7. As read out we analyzed different surface and intracellular markers via FACS and functional assays (ELISpot, cytokine multiplex assay), which allow conclusions to be drawn about the activation status and effector function of the $CD8^+$ T cells.
We found that SLAMF7 is increasingly expressed on the surface of human $CD8^+$ T cells during activation. Thereby it´s expression is upregulated through proinflammatory cytokines, in particular IL-12. In addition, we demonstrated that activation of SLAMF7 via agonistic antibodies led to an increased expansion of $CD8^+$ T cells when simultaneously encountering their antigen presented on recombinant MHC molecules. This indicates a favourable effect of SLAMF7 during T cell activation. Taken together this research could provide and characterize SLAMF7 as a new target molecule for immunotherapeutic approaches to enhance anti-tumoral $CD8^+$ T-cell responses.

Supported by a PhD scholarship (Otto-von-Guericke University Magdeburg (Germany)) and by the BMBF and the Sander Foundation.

Immunity of lipid-lowering drugs – how statins and PCSK9 inhibition shape immune phenotype and function

Philipp Schatzlmaier[1], Michael Leutner[2], Sarah Hofer-Zeni[2], Alexandra Kautzky-Willer[2], Hannes Stockinger[1]
[1]Institute for Hygiene and Applied Immunology, Center for Pathophysiology, Infectiology and Immunology, Medical University of Vienna, Vienna, Austria; *[2]Division of Endocrinology and Metabolism, Department of Medicine III, Medical University of Vienna, Vienna, Austria*

High levels of pro-atherogenic low-density lipoprotein cholesterol (LDL-C) and triglycerides are significant risk factors for cardiovascular disease (CVD), the leading cause of death worldwide. Thus, lipid-lowering drugs are commonly prescribed, effectively reducing atherogenic inflammation and CVD incidence and mortality. There are currently two types of LDL-C inhibitors in use: statins and monoclonal antibodies (mAbs) targeting proprotein convertase subtilisin/kexin type 9 (PCSK9). Statins inhibit 3-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA) reductase, the rate-limiting enzyme in cellular cholesterol synthesis effective also in immune cells. In contrast, therapeutic PCSK9 mAbs inhibit the interaction of PCSK9 with the LDL receptor in hepatocytes, interfering with receptor degradation. Consequently, systemic LDL-C is cleared without stalling cell-intrinsic cholesterol synthesis.
However, cholesterol as pleiotropic molecule shapes cell membrane composition and signalling capacity throughout the body. Its metabolites are essential precursors for broadly operating molecules, including bile acids, vitamin D and steroid hormones. Thus, cholesterol and cholesterol-targeting therapies exert complex and potentially contradictory effects in a variety of (patho)physiological mechanisms, involving cell proliferation, synapse formation, antigen presentation, vaccine response, cognitive function, tumour surveillance, osteoporosis, and depression. To understand the impact of lipid-lowering therapies on immune homeostasis and function, we analyse the longitudinal effects of HMG-CoA reductase and PCSK9 inhibition alone and in combination by 40-color spectral flow cytometry. We phenotype patient leukocytes in high quality and unprecedented detail prior to and three, six and twelve months after therapeutic intervention. Further, we perform *ex vivo* stimulation and functional assays to link immune phenotypes with functional outcome, including calcium fluxing and cytokine production. Furthermore, we analyse and correlate various clinical biomarkers, including circulating hormones, hepatic fat composition, bone density and skeletal microarchitecture. By gaining new mechanistic insights into how lipid-lowering therapies shape immune homeostasis and the function of other bodily systems, we hope to inform the development of novel patient-tailored therapeutic strategies.

Role of the production of cytokines induced by excess mechanical stress in human periodontal ligament cells

Hidenobu Senpuku[1], Erika Yamashita[1], Toshiki Uematsu[1], Shinichi Negishi[1]
[1]*Nihon University School of Dentistry at Matsudo, Matsudo, Japan*

Purpose: Improper mechanical stress may induce various cytokines as side effects on the periodontal ligament cells during orthodontic treatment. If the roots and alveolar bones are extensively resorbed by cytokines such as IL-6 and RANKL following excess mechanical stress, unplanned tooth mobility and inflammation can occur. Although multiple factors are believed to contribute to the development of side effects, the cause depending of cytokines is still unknown. Sonic Hedgehog (Shh), one of the Hedgehog signals significantly associated with cell growth and cancer development, promotes osteoclast formation in the jawbone. Shh may be associated with root and bone resorptions during orthodontic treatment. In this study, we investigated the relationships among Shh, RANKL and IL-6 in human periodontal ligament (hPDL) cells exposed to improper mechanical force.
Methods: Weights were placed on hPDL cells and human gingival fibroblasts (HGFs), control to hPDL cells, for the optimal orthodontic force group (1.0 g/cm^2) and the heavy orthodontic force group (4.0 g/cm^2). A group: no orthodontic force was used as a control to force. B group: placing only glass plate was used as a control to weights. Real-time PCR, SDS-PAGE, and western blotting were performed to examine the effects of orthodontic forces on the expression of Shh, RANKL and IL-6 at 2, 4, 6, 8, 12 and 24 hours after placing glass plate and weights.
Results: The protein expression of Shh was not clearly induced by forces of 1.0 and 4.0 g/cm² compared with the controls in HGFs and hPDL cells. In contrast, RANKL and IL-6 gene and protein expression was significantly induced by weights, 1.0 and 4.0 g/cm² in hPDL cells for 6~24 hours. However, neither protein was expressed in HGFs. RANKL and IL-6 expressions in response to forces and in the controls were clearly inhibited by Shh inhibitors RU-SKI 43, cyclopamine and Gant 61.
Conclusion: Shh did not directly link to RANKL and IL-6 for root and bone resorptions by orthodontic force but associate with cell activities to be finally guided with the production of cytokines in hPDL cells.

Cytokine profiling in mouse spleen cell culture supernatants using multiplexed bead-based immunoassay: comparison of flow cytometry and xMAP technology

Raluca Chelmus[1], Irina-Elena Ionescu[1], Iuliana Caras[1], Vlad Tofan[1], Catalin Tucureanu[1], Adrian Onu[1;2], Crina Stavaru[1]
[1] "Cantacuzino" National Medical-Military Institute for Research and Development, Bucharest, Romania; *[2] "Titu Maiorescu" University, Faculty of Pharmacy, Bucharest, Romania*

Purpose: This study aimed to characterize cytokine profiles, particularly Th1 and Th2 responses, in spleen cell culture supernatants using multiplex immunodetection methods, and to compare results obtained through flow cytometry and xMAP technology.
Methods: Splenocyte supernatants were collected after 24 hours culture of splenocytes isolated from female BALB/c mice immunized with SARS CoV-2 spike-derived antigens produced in a prokaryotic system and stimulated ex vivo with a SARS-CoV-2 S1 peptide pool. The cytokines analyzed included IL-5, IL-13, IL-2, IL-6, IL-10, IFN-γ, TNF-α, and IL-4, which are secreted by Th1 and Th2 cells. Cytokine production was assessed using two commercially available immunodetection assays, which utilized flow cytometry and xMAP technology for analysis.
Results: Using both multiplexed bead-based immunoassay analyses: flow cytometry and xMAP technology, significant increases were observed in the secretion levels of both Th1 and Th2 cytokines following in vitro stimulation with the peptide pool in mice immunized with the antigen compared to the control group. More specifically, there was a significant increase in the secretion of Th1 cytokines (IFNγ, IL-2, TNFα) and Th2 cytokines (IL-4, IL-5, IL-13), alongside a reduced secretion of cytokines associated with regulatory functions (IL-10/IL-6). It is worth mentioning that these responses exhibited consistency across both assays, despite the baseline secretion levels appearing higher in the flow cytometry assessments. The strong correlation, evidenced by a Pearson coefficient ranging from 0.8 to 0.99 for all tested cytokines, underscores the coherence and reliability of the data, highlighting the consistency between both tests.
Conclusion: Our findings demonstrate distinct cytokine profiles in spleen cell culture supernatants of immunized mice, with significant increases in both Th1 and Th2 cytokines following antigen stimulation. Most importantly, there is a high degree of correlation between both multiplexed bead-based immunoassay analyses: flow cytometry and xMAP technology indicating the robustness of multiplex immunodetection methods in cytokine profiling.

The impact of growth factors and differentiation conditions on murine bone marrow-derived dendritic cells: Phenotypic and functional evaluation

Irina-Elena Ionescu[1], Catalin Tucureanu[1], Raluca Chelmus[1], Vlad Tofan[1], Adrian Onu[1;2], Crina Stavaru[1], Iuliana Caras[2]
[1] "Cantacuzino" National Medical-Military Institute for Research and Development, Bucharest, Romania; *[2] "Titu Maiorescu" University, Faculty of Pharmacy, Bucharest, Romania*

Purpose: Selecting a relevant and reproducible method for generating murine bone marrow-dendritic cells (BM-DCs) poses multiple challenges due to the plasticity of dendritic cells (DCs) and the multitude of experimental protocols. Consequently, assessing the characteristics of *in vitro* generated BM-DCs is crucial in order to tailor protocols based on particular research objectives while maintaining the functional and phenotypic traits of DCs.
Methods: We conducted a study to evaluate the phenotypic and functional characteristics of BM-DCs generated using GM-CSF with or without IL-4 and the impact of differentiation conditions on T cell responses. We analysed BM-DCs activation following LPS (lipopolysaccharide) stimulation by examining cytokine secretion and specific cell surface markers. In addition, we evaluated the ability of antigen-pulsed BM-DCs to prime naive T cells in an *in vitro* model consisting of a BM-DCs/T cells co-culture system. Also, to enhance antigen-specific responses, activated T cells were restimulated by new antigen-pulsed BM-DCs. Prime and boost stimulation were analysed using a multiplex assay in order to assess cytokines secreted by different subclasses of T helper cells.
Results: BM-DCs generated with GM-CSF alone exhibited high levels of costimulatory molecules indicative of a mature phenotype, but preserved the ability to respond to LPS maturation by cytokine production. Moreover, cytokine secretion patterns observed in the co-culture system indicate the potential of antigen-pulsed BM-DCs to prime naive T cells. In contrast, the addition of IL-4 in the developmental stages of BM-DCs led to cells with an immature phenotype, responsive to LPS-induced maturation but also promoted nonspecific T cell signalling, potentially impeding the induction of antigen-specific T cell responses.
Conclusion: These results show how different combinations of growth factors influence both the phenotypic and functional characteristics of BM-DCs. Furthermore, the study emphasises the importance of reviewing even widely used protocols for DCs differentiation and considering the impact of these protocols on experimental designs such as the evaluation of T cell responses.

Human MAIT cell profiles biased towards IL-17 or IL-10 are transient effector states directed by the cytokine milieu

Caroline Boulouis[1], Elli Mouchtaridi[1], Thomas R. Müller[1], Jeffrey Y.W. Mak[2], David P. Fairlie[2], Peter Bergman[3], Jakob Michaëlsson[1], Jonas Halfvarson[4], Jenny Mjösberg[1;5], Marcus Buggert[1], Johan K. Sandberg[1]
[1]Center for Infectious Medicine, Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden; *[2]Centre for Chemistry and Drug Discovery, Australian Research Council Centre of Excellence for Innovations in Peptide and Protein Science, Institute for Molecular Bioscience, The University of Queensland, Brisbane, Australia*; *[3]Department of Laboratory Medicine, Division of Clinical Microbiology, Karolinska Institutet, Stockholm, Sweden*; *[4]Department of Gastroenterology, Faculty of Medicine and Health, Örebro University, Örebro, Sweden*; *[5]Clinical Lung and Allergy Research Unit, Medical Unit for Lung and Allergy Diseases, Karolinska University Hospital Huddinge, Stockholm, Sweden*

Mucosal-associated invariant T (MAIT) cells are unconventional MR1-restricted T cells mediating rapid innate-like antimicrobial immunity. However, how the functional heterogeneity of human MAIT cell responses is controlled is largely unclear. Here, combining functional and transcriptomic analyses we define distinct MAIT cell effector programs directed by the cytokine milieu during antigen recognition. Activation by TCR signaling together with IL-12 or IL-23 drives c-MAF-dependent IL-10 production, with intermediate levels of IFNγ/TNF, and elevated expression of TIM-3, LAG-3, and PD-1. The MAIT-derived IL-10 mediates both autocrine and paracrine immune regulation. In active Crohn's disease, the MAIT cell IL-10 regulatory profile appears to be suppressed. In contrast to the action of IL-12, co-activation of MAIT cells with IL-18 strongly co-activates IL-17, GM-CSF, IFNγ and TNF, while counteracting IL-10 expression. Finally, TCR activation without cytokine co-activation drives primarily cytolytic arming. These activation states are transient and do not represent stable subsets. Altogether, these findings demonstrate how cytokine cues direct transient MAIT cell effector response programs.

Limited information exists regarding the impact of interferons (IFNs) on the information carried by extracellular vesicles. This study aimed at investigating whether IFNα2b, IFNβ, IFN-γ, and IFN-λ1/2 modulate the content of EVs released by primary monocyte-derived macrophages (MDM).
Small-EVs (sEVs) were purified by size exclusion chromatography from supernatants of MDM treated with IFN. To characterize the concentration and dimensions of vesicles, Nanoparticle Tracking Analysis was used. SEVs surface markers were examined by flow cytometry.
IFN treatments induced a significant down-regulation of the exosomal markers CD9, CD63, and CD81 on sEVs, and a significant modulation of some adhesion molecules, major histocompatibility complexes and pro-coagulant proteins, suggesting IFNs influence biogenesis and shape the immunological asset of sEVs. Autologous PBMCs were treated with sEVS released by IFN-stimulated MDM, showing significant modulation of lymphocyte activation and IL-17 release.
Altogether, our results show that EVs composition and activity is affected by IFN treatment of MDM.

Regulation of Natural Killer Cell Metabolism and Anti-Tumour Responses by Macrophages

Cathal Keane[1], Maxim Nosenko[1], Cristhiane Favero de Aguiar[1], Chloe Choi[1], David Finlay[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Oxidised cholesterol derivatives called oxysterols have diverse roles in many cellular processes. Their role in controlling NK cell metabolism and effector functions through inhibiting SREBP transcription factor activation is well-described. However, other SREBP-independent effects of oxysterols on NK cell responses are not well defined. For instance, oxysterols are known to alter plasma membrane structure through a number of mechanisms, which may impact many critical processes required for NK cell functions such as endocytosis, receptor signalling and degranulation.
Exposure of previously cytokine-activated NK cells to the oxysterols 25-hydroxycholesterol (25HC) and 27-hydroxycholesterol (27HC) for just 4 hours causes an impairment in cytotoxicity against K562 and RMA/S target cells despite no observed change in their expression of granzyme B, perforin or interferon-γ. The oxysterol-treated NK cells also had an accumulation of transferrin receptor at the cell surface, potentially due to oxysterol-mediated inhibition of endocytosis of the transferrin-iron complex. Furthermore, plasma membrane probes revealed alterations to membrane structure in oxysterol-treated NK cells, which may potentially impact endocytosis and degranulation.
Oxysterol-rich environments are known to arise due to pro-inflammatory macrophages in various infections. Ligation of TLR-2/6, -3 and -4 induce >10-fold increases in the expression of Ch25h (the enzyme the synthesises 25HC) in BMDMs stimulated with TLR agonists for just 6 hours. Culture of NK cells with stimulated BMDMs results in significant decreases in NK cell size, interferon-γ expression and expression of cytolytic molecules. These NK cell also showed significant impairments in their cytotoxicity. This suggests a new metabolic inhibitory pathway between macrophages and NK cells that could have implications for anti-viral and anti-tumour immunity.

Dysregulation of the TLR3/IFIH1 pathway at juvenile dermatomyositis onset may implicate viral infection as a disease trigger

Thomas Moreau[1;2;3], Vincent Bondet[2], Chloe Albert-Vega[2], Yves-Jean Zhu[1], Florian Dubois[2], Rahal Farah[2], Etienne Villain[2], Bodemer Christine[3;4], Samuel Bonhomme[1;3], Margaux Cescato[1;3], Laurye-Anne Eveillard[3;4], Marie-Louise Frémond[3;4;5], Benjamin Fournier[3;4], François Maillet[1], Pierre Quartier[3;4], Eugénie Sarda[3;4], Adrien Schvartz[4], Isabelle Melki[3;4], Cyril Gitiaux[3;4], Brigitte Bader-Meunier[4], Mathieu Rodero[1;3], Darragh Duffy[2]
[1]CNRS, Paris; *[2]Institut Pasteur, Paris, France*; *[3]Université Paris Cité, Paris*; *[4]AP-HP, Paris, France*; *[5]Institut Imagine, Paris*

Purpose: We previously reported elevated type I IFN responses, and an association with SARS-CoV-2 acute infection, in onset juvenile dermatomyositis (JDM) a rare autoimmune disease. Here we tested the hypothesis that dysregulation of specific viral nucleic acid sensor pathways may be implicated in the JDM onset.

Methods: We prospectively recruited 19 JDM patients at diagnosis and age- and sex-matched paediatric controls. Whole blood inflammatory profiles were assessed by single-cell phosphoproteomics using mass cytometry. Cellular responses of nucleic acid sensors were evaluated using standardized ex vivo whole blood stimulation assays (TruCulture) with Toll-like receptor (TLRs) agonists: R848 for TLR7/8, Poly(I:C) for TLR3/IFIH1 and ODN for TLR9. Cytokine secretion was quantified using Luminex and digital ELISA (Simoa) while transcriptomic signatures were determined by bulk RNA barcoding and sequencing (BRB-seq).

Results: We observed high heterogeneity in the phosphoproteome profile within JDM patients at diagnosis, with a sub-group of patients showing a strong over-activation as compared to controls. None of JDM patients at diagnosis had a similar phosphoproteomic profiles. Median levels of type I interferon and specific ISG proteins were 10 times higher in JDM patients at basal state compared to controls. Following TLR stimulation JDM patients showed a dysregulated response specifically to Poly(I:C) stimulation at both proteomic and transcriptomic levels. In contrast, responses to R848 and ODN stimulation were no different. Transcriptomic analysis identified an enrichment of the interferon pathway in JDM patients at basal state. IFIH1, but not TLR3, was up-regulated in JDM at diagnosis compared to controls.

Conclusion: JDM at diagnosis is characterized by a type I interferon (IFN-I) signature which was observed at both proteomic and transcriptomic levels. We identified a defective response to Poly(I:C) stimulation in JDM implicating the TLR3/IFIH1 pathway which may lead to the over-production of IFN-I. Further single cell studies will help to better understand the cellular specificities that drive the IFIH1 dysregulation and lead to JDM pathogenesis.

Development of pooled CRISPR screening method for primary human macrophages

Miaomiao Qiao[1], maximilian jordan[1], Feng Liu[1], Liye Chen[1]
[1]*Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom*

Purpose: Macrophages are important in innate immune system, responding to pathogens or tissue damage. During pathogen infection, the pro-inflammatory cytokine, interferon-γ (IFNγ) is known to work with tumor necrosis factor α (TNF-α) or Toll-like receptor signaling to trigger macrophage cell death [1,2]. For human cells, CRISPR screens have been developed for immortalized myeloid cell line (U937 and THP-1) and iPSC-derived macrophages [3-5], but not yet for primary macrophages, impeding in depth biological study of macrophage functions in complex tissue microenvironment in human diseases. This study aims to develop a CRISPR screening method for primary human macrophages though overcoming main technical barriers, including low lentiviral infection efficiency, compromised cell survival after lentiviral infection, and inefficient Cas9 delivery into macrophages.
Methods: Lentivirus was generated using HEK 293T cells which were transfected with LentiGuide-Puro, psPAX2 and pMD2.G. Primary human monocytes were isolated from PBMCs of healthy donors. Monocytes were infected with lentivirus, Vpx virus-like particles (Vpx-VLPs) and polybrene. Cas9 protein was delivered into infected macrophages though electroporation. IFNγ, lipopolysaccharide (LPS) and TNF-α were used to induce macrophage cell death. Transduction efficiency of single-guide RNA (sgRNA), target gene knockout efficiency and live macrophage number were detected though flow cytometry.
Results: Firstly, efficient sgRNA transduction (30%) mediated by lentivirus has been achieved in macrophages though Vpx-VLPs. Secondly, macrophages could maintain survival and pro-inflammatory function post infection with low amount of lentivirus. Thirdly, efficient target gene knockout (20%) was achieved in sgRNA lentivirus infected macrophage though optimized program-mediated Cas9 electroporation. IFNγ combined with LPS or TNF-α stimulation induced around 50% and 20% macrophage cell death, respectively.
Conclusion: Here, we have overcome certain technical difficulties for the performance of CRISPR screening in primary human macrophages. Next, we will perform a transcription factor (TF) pooled CRISPR screening to identify overlapped or specific TFs involved in the synergism of IFNγ with TNF-α or LPS-induced macrophage cell death pathways.

Dynamics of human T and B cells followingantigenic stimulation

Emilia Malvicini[1], Ganesh Phad[2], Serena Curti[1], Valeria Bevilacqua[1], Federica Sallusto[3;4], Ludovica Bruno[1], Antonio Lanzavecchia[1]
[1]National Institute of Molecular Genetics, Milan, Italy; *[2]Christine Kühne – Center for Allergy Research and Education (CK-CARE), Davos Wolfgang, Switzerland*; *[3]Institute for Research in Biomedicine, Università della Svizzera italiana, Bellinzona, Switzerland*; *[4]Institute of Microbiology, ETH Zürich, Zurich, Switzerland*

We are interested in dissecting immune T and B cell repertoires by integrating different datasets obtained through single-cell transcriptomics, proteomics, T cell receptor (TCR)/B cell receptor (BCR) sequencing and isolation of antigen specific T cell clones and monoclonal antibodies. This approach has led to the functional definition of different memory subsets characterized by distinct transcriptional profiles, clonal composition, and antigenic specificity, in addition to the characterization of populations of highly expanded memory B cells as well as CD4 and CD8 T cell clones with unique transcriptional profiles.
We are now focusing on the immune system's rapid response following Flu and SARS-CoV-2 infection or vaccination. To do so, we collected peripheral blood mononuclear cells (PBMCs) from different donors six days after antigen exposure and isolated both plasmablasts and recently activated T cells for ex-vivo analysis. In parallel, we in-vitro stimulated the total PBMCs and compared this immune response to a generic and strong stimulus with the antigen-specific one.
We show that, after infection or vaccination, recently activated Ki67+ cells represent family bursts of small antigen-specific clones that undergo vigorous expansion in vivo. In contrast, during steady state, recently activated T and B cells represent a random sample of the total repertoire and derive from most populations, ranging from naïve cells to terminally differentiated expanded cells. These findings are consistent with two modes of activation shared by T and B cells: i) the rapid proliferative response of specific clonal families following antigenic stimulation and ii) the homeostatic expansion of single cells driven by cytokines in an antigen-independent fashion.
Collectively our analysis performed on serial samples provides a snapshot of the dynamics of the immune response at the single-cell level.

Investigating the effect of Fibroblast growth factor-23 on neutrophil migration

Naeman Ali[1], Onn Shaun Thein[1], David Tickett[1], Aaron Scott[1], Dhruv Parekh[1]
[1]*University of Birmingham, Birmingham, United Kingdom*

Introduction: Fibroblast growth factor 23 (FGF23) is an endocrine hormone associated with vitamin D and phosphate homeostasis. We have previously shown an association with elevated FGF23 concentrations and increased mortality in critical illness. The effect of vitamin D on innate immune function is well described. However, little is known about how FGF23 interacts with innate immune cells. An array of FGF receptors (FGFRs) and binding partners (heparin, klotho), make unpicking the specific effects difficult. Neutrophils do not express klotho and are key cells in critical illness.
Methods: Neutrophils were isolated from venous blood (healthy donors) by density gradient separation. FGFR expression was assessed by flow cytometry. The effect of FGF23 pre-treatment (100ng/ml, 1 hour), on neutrophil migration towards IL-8 was assessed by Transwell migration assay and F-actin polymerisation using Phalloidin staining and confocal microscopy.
Results: Neutrophils predominantly express FGFR1 and FGFR2. FGFR3 had lower and variable levels of expression. When permeabilised only FGFR1 expression increased (28.02%, p=0.0165 n=8). FGF23 pre-treatment resulted in decreased migration through a Transwell insert to an IL-8 gradient, when compared with vehicle (veh=$5.6x10^4$, FGF23= $3.6x10^4$, p=0.0068, n=12). FGF23 pre-treatment resulted in decreased levels of F-actin accumulation, compared to vehicle, however this difference was not statistically significant (MFI: FGF23= 21.76, veh= 34.28, p=0.1457, n=5).
Discussion: FGFR1 and 2 are present on the cell surface of healthy peripheral blood neutrophils. FGFR1 expression increased after permeabilization, suggesting intracellular FGFR is present in the cytosol in homeostasis. FGF23 reduces neutrophil migration, demonstrating previously uncharacterised biological activity of FGF23 in these cells independently of klotho. We hypothesise that FGF23 reduces F-actin polymerisation and therefore prevent neutrophil migration. We have previously shown that elevated levels of FGF23 are associated with increased mortality, here we begin to show mechanism of how FGF23 may alter the neutrophil response.

Analysis of platelet monocyte complexes in patients with ST-elevation myocardial infarction

Talia Ahrazoglu[1], Jennifer Isabel Kluczny[1], Tamara Straub[2], Fabian Nienhaus[3], Jonathan Rohrer[3], Patricia Kleimann[2], Lisa-Marie Irschfeld[3;4], Maren Döring[5], Ann Katrin Bergmann[6], Florian Bönner[3], Ulrich Flögel[2;7], Norbert Gerdes[3;7], Sebastian Temme[1;7]
[1]Department of Anesthesiology, University Hospital and Faculty of Medicine, Heinrich-Heine-University, Düsseldorf, Germany; *[2]Institute of Molecular Cardiology, University Hospital and Faculty of Medicine, Heinrich-Heine-University, Düsseldorf, Germany*; *[3]Department of Cardiology, Pulmonology, and Vascular Medicine, University Hospital and Faculty of Medicine, Heinrich-Heine University, Düsseldorf, Germany*; *[4]Department of Radiation Oncology, University Hospital and Faculty of Medicine,Heinrich-Heine-University, Düsseldorf, Germany*; *[5]Institute of Translational Pharmacology, University Hospital and Faculty of Medicine, Heinrich-Heine-University, Düsseldorf, Germany*; *[6]Core Facility Electron Microscopy (CFEM), Heinrich-Heine-University, Düsseldorf, Germany*; *[7]Cardiovascular Research Institute Düsseldorf (CARID), Heinrich-Heine-University, Düsseldorf, Germany*

Purpose: Direct physical interaction of platelets with leukocytes can lead to the formation of platelet leukocyte aggregates (PLAs) and is often associated with a bidirectional activation that enhances the proinflammatory state. Elevated numbers of PLAs can be found under inflammatory conditions, but the pathophysiological relevance of is largely unclear. Here, we investigated formation and functional alterations of PLAs in the blood of human patients after ST-elevation myocardial infarction (STEMI).
Results: Flow cytometry of blood samples revealed that the relative frequency of CD41+ as well as CD62P+ monocytes (MPAs) was strongly increased in the blood of STEMI patients on day 1 post MI compared to patients with stable coronary heart disease (CHD) or healthy volunteers. However, CD41+ neutrophils or lymphocytes were only slightly increased. Of note, MPA levels were elevated in patients up to six months post STEMI despite anticoagulant treatment. Analysis of MPA formation in monocyte subtypes revealed that MPA formation was mainly increased in classical and intermediate monocytes. Immunofluorescence-, transmission- and raster-electron-microscopy revealed that CD41+ monocytes are associated with intact platelets rather than CD41+ microvesicles or exosomes. Functional analyses showed an increased uptake of perfluorocarbon nanoparticles (PFCs) in CD41+ monocytes from healthy volunteers, CHD and STEMI patients. Migration towards gradients of the chemokine monocyte chemoattractant protein (MCP)-1 was increased in CD41+ monocytes from healthy volunteers, but not from STEMI patients. Intracellular TNFα expression as well as uptake of the glucose analogue 2-NBDG was higher in MPAs from STEMI patients compared to healthy controls. Finally, correlation analyses revealed that patients with a high number of intermediate MPAs have larger infarct sizes, increased endsystolic and enddiastolic volumes and higher CRP levels in the blood.
Conclusion: Here we show that particularly heterotopic aggregates of platelets with classical and intermediate monocytes are strongly increased in STEMI patients and remain elevated for up to six months. Monocytes associate with intact platelets which can lead to functional alterations such as increased phagocytosis of nanoparticles. However, future studies must unravel the precise functional consequences and the pathophysiological relevance of MPAs for the acute inflammatory and the subsequent healing reaction post STEMI.

Tonsil organoids reveal that plasmacytoid dendritic cells modulate the humoral immune response to ChAdOx1 nCoV-19

Maria Pudjohartono[1;2], Kate Powell[3], Eleanor Barnes[1;3], Paul Klenerman[1;2;3]
[1]Translational Gastroenterology Unit, University of Oxford, Oxford, United Kingdom; *[2]Pandemic Sciences Institute, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom*; *[3]Peter Medawar Building for Pathogen Research, Nuffield Department of Clinical Medicine, University of Oxford, Oxford, United Kingdom*

Purpose: To understand how vaccines induce productive immune responses, it is critical to study the processes that occur at the site of immune priming – secondary lymphoid tissues. However, access to such tissue is limited.
Methods: To overcome this, we have refined a recently developed human tonsil organoid model to explore the processes that regulate the induction of humoral responses to the ChAdOx1 nCoV-19 vaccine.
Results: Upon exposure to ChAdOx1 nCoV-19, tonsil cultures exhibited robust innate immune activation and cytokine release within 24 hours. This innate activation subsequently led to both global and antigen-specific B cell activation, along with the secretion of spike-specific antibodies during the ensuing 14-day culture period. Notably, exposure to an unrelated ChAdOx1 GFP vector did not elicit any detectable spike-specific antibody production. Among the immune cell types, plasmacytoid dendritic cells (pDCs) exhibited the highest levels of transduction and activation. Crucially, depletion of pDCs resulted in diminished innate and humoral responses. Blocking IFN-α had a similar effect to pDC depletion, while adding IFN-α to pDC-depleted cultures rescued humoral responses. Furthermore, IL-6 played a pivotal role in enhancing humoral responses, with its production being regulated in an IFN-α-dependent manner, even in the absence of pDCs, indicating intricate cross-talk signalling interplay.
Conclusion: In summary, this model underscores the essential role of pDCs in initiating humoral responses to ChAdOx1 nCoV-19, primarily through IFN-α. IFN-α appears to exert both direct and indirect effects by inducing IL-6 secretion to amplify the humoral response. Moreover, this model holds promise for investigating other vaccine platforms.

Evaluation of HLA-G levels in human umbilical cord blood-derived mesenchymal stem cells after co-culture with PBMCs

Ayse Erol Bozkurt[1], Sule Karataş[1], Figen Abatay Sel[1], Mediha Süleymanoğlu[1], Beril Yaşa[2], Hayriye Şentürk Çiftçi[1], Fatma Savran Oğuz[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Medical Biology Department, Istanbul, Turkey; *[2]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medical Sciences, Department of Child Health and Diseases, Istanbul, Turkey*

Mesenchymal stem cells (MSCs) are multipotent stem cells capable of differentiating into various cell types such as osteoblasts, adipocytes, chondroblasts, and neurons. They can be sourced from various fetal and adult tissues. MSCs exhibit immunomodulatory properties through the expression of soluble factors including human leukocyte antigen (HLA)-G, prostaglandin-E2, and transforming growth factor beta-1. These factors enable MSCs to suppress the proliferation of NK, B, and T cells, and inhibit the differentiation of dendritic cells and B cells.
In our study, we aimed to investigate the impact of co-culturing MSCs derived from human umbilical cord blood with stimulated and unstimulated peripheral blood mononuclear cells (PBMCs) on HLA-G levels. MSCs were co-cultured at ratios of 1:5 and 1:10 with PBMCs for 24 and 72h to induce an inflammatory environment. HLA-G levels in the co-culture supernatants were measured using an ELISA assay.
Results showed that when co-cultured at a 1:5 ratio with both stimulated and unstimulated PBMCs, HLA-G levels in CB-MSCs were significantly higher in 24 h cultures compared to 72 h cultures. In WJ-MSCs, there was a significant increase compared to 24 h in 72 h in co-cultured at a 1:5 ratio with both stimulated and unstimulated PBMCs.
In 72 h CB-MSCs with PBMC co-cultures at a 1:10 ratio were significantly higher compared to those at a 1:5 ratio in both stimulated and unstimulated groups. In the unstimulated group, there was a significant increase at a 1:10 cell ratio, while in the stimulated group, there was a significant decrease. In the co-culture of WJ-MSCs and PBMCs at a 1:5 ratio, a significant increase was observed at 72 h in both the unstimulated and stimulated groups, compared to the 24h.
In conclusion, our study highlights the dynamic nature of MSC immunomodulation in response to inflammatory stimuli. The duration of co-culture and the ratio of MSCs to PBMCs were found to play crucial roles in modulating HLA-G expression. These findings emphasize the importance of optimizing co-culture conditions for therapeutic applications in immune-related disorders.

Peripheral blood lymphocyte cell subsets in subjects with silicosis due to engineered stone

Gema Jiménez-Gómez[1], Antonio Campos-Caro[1;2], Alejandro Nuñez-García[1], Antonio Molina-Hidalgo[1;3], Antonio León-Jiménez[1;3]
[1]Biomedical Research and Innovation Institute of Cadiz (INiBICA)., Cádiz, Spain; *[2]Genetics Area, Biomedicine, Biotechnology and Public Health Department, School of Marine and Environmental Sciences, University of Cádiz. Spain, Cádiz, Spain*; *[3]Pulmonology Dept, Puerta del Mar University Hospital, Cádiz, Spain*

Silicosis produced by Artificial Quartz Agglomerates or engineered stone (ES-silicosis) evolves more aggressively than the classical form of miners. This entity is emerging worldwide and a significant group of cases has been detected in the province of Cádiz (Spain) in recent years. Although the role of the cellular immune response in its pathogenesis is recognized, few studies have been reported on the lymphocyte subsets in patients with silicosis. In particular, none has been published on patients with ES-silicosis.
Purpose: to characterize lymphocyte subsets in the peripheral blood of patients diagnosed with silicosis due to silica agglomerates.
Methods: 91 patients diagnosed with silicosis due to silica agglomerates were included, 53 with simple silicosis (SS), 38 with complicated silicosis (CS) and 23 healthy unexposed as a control group (CG). All were men. Main age 40.1 ±7.7 (SS), 41 ± 6.2 (CS) and 36.4 ±8.3 (CG). Cell subsets from blood samples were analyzed by flow cytometry.
Results: The main subsets of leukocytes in peripheral blood, such as neutrophils and monocytes, progressively increased in patients with SS and CS compared with the CG. However, in the case of lymphocytes the opposite was observed, so that the percentage of lymphocytes in the GC was 31.3±8.2, 25.6±7.6 (SS) and 22.6±5. 8 (CS) with statistically significant differences. Analyzing the main subsets of lymphocytes, the following differences were observed in patients with silicosis compared to CG: i) a significant decrease in the percentage of memory B cells (30±13.6 [CG], 19.1±9, 4 [SS], 21.1±12.2 [CS]) and an increase in plasma cells (0.07±0.06 [CG], 0.11±0.08 [SS], 0.1± 0.04[CS]; ii) a significant reduction in the proportion of naïve Th cells (32.5±13.5 [CG], 23.5±10.1 [SS], 25.8±9.6 [CS]); iii) a significant increase in memory Th cells (43.6±13.2 [CG], 54.4±14.6 [SS], 53.3±12.5 [CS]).
Conclusions: Some subsets of lymphocytes are altered and could be targeted as possible new avenues of intervention to treat the disease.

Delineating the immunological responses in people admitted to the ICU with direct and indirect lung injuries using single-cell RNA sequencing

Priyanka Hastak[1], Christopher R Andersen[2;3], Zong-Hong Zhang[1], Aayushma Lohani[1], Chansavath Phetsouphanh[1], David van Bockel[1], Swosti Shrestha[1;3], Frances Bass[2;3], Naomi Hammond[2;3], Nicodemus Tedla[1], Anthony Kelleher[1], Sarah C Sasson[1]
[1]Kirby Institute, Sydney, Australia; *[2]The George Institute for Global Health, Sydney, Australia*; *[3]Royal North Shore Hospital, Sydney, Australia*

Purpose: Acute lung injury (ALI) is characterized by acute inflammation in the lungs, with mortality of up to 46% in severe cases. There are two types of ALI, (i) direct lung injury, commonly caused by community acquired pneumonia (CAP); (ii) indirect lung injury caused by conditions including burns, pancreatitis, and non-thoracic trauma. While the immunopathology of direct lung injuries such as COVID-19 CAP, is relatively well understood, the complexities of immune dysregulation in indirect lung injuries remains poorly elucidated. This study aims to define the common and divergent inflammatory pathways associated with direct and indirect ALI.
Methods: Our cohort (N=33) included participants with (i) Direct ALI (N=11) caused by COVID-19 CAP. Criteria for CAP included symptoms of lower respiratory tract infection and radiological evidence as well as mechanical ventilation of less than 72 hours (ii) Indirect ALI (N=9) secondary to non-thoracic trauma with no secondary infection; (iii) ICU controls (N=13) or participants with no infection or lung inflammation within 72 hours of mechanical ventilation. We conducted serum cytokine profiling using the Luminex platform and single cell RNA sequencing on live CD45+ cells from peripheral blood on the BD Rhapsody Express system.
Results: Cytokine profiling demonstrated upregulation of IL-1R and IL-6 in the trauma compared to ICU controls. In contrast, IL-7, CCL-5 and IL-4 were found to be elevated in COVID-19 CAP compared to ICU controls. Transcriptomic analysis of peripheral blood revealed a large population of activated $CD4^+$ T cell expressing TNF-α and IFIT3 in the trauma group, whereas MAIT cells were predominant in COVID-19 CAP. Pathway analysis of these immune cells highlighted the upregulation of adaptive pathways such as IFN-γ signalling, TNF-α and MAPK signalling in COVID-19 CAP compared to trauma group.
Conclusion: This study highlights the divergent aetiologies and the immune landscape in direct and indirect lung injuries. Further delineation of the underlying mechanisms driving these distinct inflammatory pathways may lead to novel and or repurposed therapeutics. The COVID-19 pandemic demonstrated the success of immunomodulatory therapies in a subtype of CAP, promoting the potential to determine if similar translational strategies can be applied to treat other forms of ALI.

Recent thymic emigrants in SARS-CoV-2 infection and post-COVID-19

Xiaobo Huang[1], Suvi Jokiranta[1], Kirsten Nowlan[1], Nelli Heikkilä[1], Anu Kantele[2], Olli Vapalahti[3], Eliisa Kekäläinen[1]
[1]Department of Bacteriology and Immunology, Translational Immunology Research Program, Faculty of Medicine, University of Helsinki, Helsinki, Finland; *[2]Human Microbiome Research Program, Faculty of Medicine, University of Helsinki, Helsinki, Finland*; *[3]Zoonosis Unit, Department of Virology, Medicum, University of Helsinki, Helsinki, Finland*

Purpose: In severe COVID-19 thymic function and output are reduced. Naive T cells are affected in patients with post-acute sequelae of COVID-19 (PASC). Recent thymic emigrants (RTEs) are the youngest naive T cell population in the circulation, and represent thymic output. We examined the CD4+ RTEs and CD4+/CD8+ naive T cells in the blood of COVID-19 patients with and without PASC to check the thymic function in SARS-CoV-2 infection.
Methods: We recruited COVID-19 patients (n = 42) and collected blood at 1-3 timepoints. PBMCs were isolated, stained for FACS and analyzed. We divided the samples into acute (<30 d from symptom onset), convalescent (30-120 d) and recovered (>120 d) phases. We surveyed the patients for persisting impaired olfaction as proxy for PASC (n = 5 PASC+, n = 16 PASC-).
Results: We found that the proportions of naive CD8+ ($p = 0.049$) and Ki-67+ naive CD8+ T cells ($p < 0.001$) were negatively correlated with time since COVID-19 symptom onset. RTEs or CD4+ naive T cells did not show significant correlation. These findings were further proven using paired analysis, where the proportion of naive CD8+ T cells was higher in the acute than the convalescent disease phase ($p = 0.004$) and the proportion of Ki-67+ naive CD8+ T cells was higher in the acute ($p = 0.008$) and convalescent ($p = 0.0211$) phases than the recovered phase. We found a higher proportion of Ki67+ CD4+ naive T cells in the convalescent disease phase in PASC+ than PASC- individuals ($p = 0.031$). None of the other cell populations showed significant differences.
Conclusion: We found that CD8+ naive T cells and their proliferation were proportionally higher in acute disease than in convalescence. This is consistent with acute viral infection and, along with the stable RTE populations, suggests normal thymic function. The age-related findings of proportionally lower CD8+ naive T cells and higher CD4+ RTE proliferation are likely related to lymphopenia during COVID-19. The finding of higher proportions of proliferation in CD4+ naive T cells in PASC patients is preliminary, with a small cohort. Further research with larger sample sizes is required.

Effect of long-term cryopreservation on peripheral blood mononuclear cell viability and immune cell subset frequency

Taliha Inan[1;2], Cagla Nigde[1;2], Asli Korkmaz[1;2], Sinem Gunalp[2], Duygu Sag[1;2;3]
[1]Department of Genomic Sciences and Molecular Biotechnology, Izmir International Biomedicine and Genome Institute, Dokuz Eylul University, Izmir, Turkey; *[2]Izmir Biomedicine and Genome Center, Izmir, Turkey*; *[3]Department of Medical Biology, Faculty of Medicine, Dokuz Eylul University, Izmir, Turkey*

The aim of this study is to investigate the viability and the percentages of different immune cell subsets in peripheral blood mononuclear cells (PBMCs) after long-term cryopreservation and subsequent thawing to determine the optimal conditions for long-term storage of PBMCs. PBMCs were isolated from buffy coats using double gradient centrifugation and cryopreserved in a solution containing 50% RPMI, 40% FBS and 10% DMSO; 80% FBS and 20% DMSO; or 90% FBS and 10% DMSO. Cells were stored at -80°C and preserved in liquid nitrogen for up to 10 months. Flow cytometry analysis was performed on PBMC samples thawed at 1 month, 4 months and 10 months after cryopreservation. Monoclonal fluorescent antibodies targeting various immune cell surface markers were used for surface marker staining and analyses. The highest cell viability was observed when the PBMCS were stored in 90% FBS and 10% DMSO. The percentages of lymphoid and myeloid cell subtypes in PBMCs remained stable over the 10-month storage period. Percentages of cells positive for surface markers such as CD3, CD4, CD8, CD14, CD25, CD45, CD56 and HLADR showed stable levels, while slight fluctuations were observed in the percentages of CD15, CD16, CD19 and FOXP3 positive cell populations during long-term storage. Overall, the results suggest that surface marker expressions in PBMCs are effectively maintained under the indicated storage conditions.

This study demonstrates that long-term storage of frozen PBMCs is a reliable method to preserve their immunophenotypic properties.

Candida- Driven Modulation of Macrophage Polarization: Influence of Candida albicans and non-albicans species.

Florabelle Cabarrubias[1;2;3], Swagata Chakraborty[1;2;3], Tamás Takács[1;2;3], Attila Gacser[1;2;3]
[1]University of Szeged, IKIKK, Competence Centre for Molecular Biology, Bionics and Biotechnology, Szeged, Hungary; *[2]HUN-REN-SZTE Pathomechanisms of Fungal Infections Research Group, University of Szeged, Szeged, Hungary*; *[3]HCEMM-SZTE Pathogen Fungi Research Group, University of Szeged, Szeged, Hungary*

Purpose: Macrophages are key players in the innate immune system, capable of polarization into classically activated (M1) and alternatively activated (M2) macrophage phenotypes based on microenvironmental signals. *Candida* species, fungal pathogens causing candidemia, intricately interact with the host's innate immune components, including macrophages. In this study, PBMC-derived monocytes (PBMC-DMs) were co-incubated with *Candida albicans* (SC5314), *Candida parapsilosis* (CLIB 214), *Candida auris* (AR 0381), *Candida glabrata* (CBS 138) to investigate their impact on the polarization of PBMC-DMs.
Methods: After the co-incubation, PBMC-DMs were immunolabelled using macrophage-specific (CD68), M1-specific (CD86), and M2-specific (CD163) fluorophore-conjugated antibodies. Their polarization was characterized using flow cytometry via fluorescence-activated cell sorting (FACS). Additionally, IFN-γ-activated M1 macrophages were also studied for their response against these *Candida* species through phagocytosis and killing assays.
Results: The result showed that PBMC-DMs infected with *C. albicans* showed no significant differences in their polarization to M1 or M2 macrophages. On the other hand, *C. parapsilosis* infection drives polarization into M2 macrophages. M1 macrophages resulted in lower phagocytic and killing activity against *C. albicans* and *C. parapsilosis*. However, this phenomenon was only significant in the case of *C. parapsilosis.*
Conclusions: These findings suggest that interaction of PBMC-DMs with *C. parapsilosis* could potentially contribute to M2 polarization, which may lead to immune evasion and disease progression. The reduced phagocytic and killing activity of IFN-γ-activated M1 macrophages against *C. parapsilosis* suggests compromised IFN-γ signaling, which may further compromise the immune response and favor the survival and persistence of this pathogen. In addition to the existing analysis, ELISA will be conducted to quantify and detect various cytokines including TNF-α, IL-10, TGF-β, and IL-6 induced by different *Candida* species. Furthermore, functional analyses are planned for *C. auris* and *C. glabrata* to provide more comprehensive understanding of the dynamics of non-albicans species.

Immunomodulatory effect of phenylhydantoin derivatives on myeloid leukemia cells

Ana Obradović[1], Miloš Matić[1], Branka Ognjanović[1], Bojan Božić[2], Biljana Božić Nedeljković[2]
[1]*Faculty of Science, Kragujevac, Serbia*; [2]*Faculty of Biology, Belgrade, Serbia*

Purpose: Leukemia is one of the most important cancers affecting a large proportion of the population, especially children. Despite recent advances to improve the efficiency of therapy, the range of effective drugs available is comparatively limited and there is a significant need for the development of new drugs. One of the most prominent biological functions of phenylhydantoin derivatives is the antitumor effect on cells of various cancers, although they are frequently used for the clinical treatment of epilepsy and inflammation. The unique physicochemical properties, especially the increased molecular surface area for interactions, make phenylhydantoin derivatives promising agents for biomedical applications. In this study, the immunomodulatory effects of phenylhydantoin derivatives on a chronic myeloid leukemia cell line (K562) were investigated.
Methods: Cells were exposed to treatment with five different concentrations of phenylhydantoin derivatives (from 0.1 to 100 µM), while cells were treated at two concentrations 1 and 10 µM for 72 hours to determine migration potential and concentrations of IL-1β and IL-6, MMP-2 and MMP-9, as well as gene expression of COX-2 and iNOS. The antitumor effects were evaluated by the influence of treatment on cell viability, oxidative stress parameters and migration potential, while the imunomodulatory effects were evaluated by the production of IL-1β and IL-6 and the gene expression of iNOS and COX-2.
Results: The results obtained indicate an intense effect on cell viability, suggesting a significant antitumor potential. After treatment with derivatives, increased nitrite production and iNOS expression was observed, especially in concentrations of 1 and 10 µM. Decreased superoxide anion production was observed after derivatives application, also in concentrations of 1 and 10 µM. In addition, the migration potential and MMPs expression levels were significantly reduced, as were the concentrations of IL-1β, IL-6 and COX-2 gene expression in K562 cells. These data indicate a significant immunomodulatory activity of the tested phenylhydantoin derivatives in K562 cells.
Conclusion: The tested phenylhydantoin derivatives exhibit considerable antitumor potential and show immunomodulatory effects on various parameters, which makes them suitable candidates for further research with the aim of achieving more effective results in antitumor therapy with less harmful effects on healthy tissue.

The pathophysiological implications of interleukin-6 concentrations associated with COVID-19 in human trophoblasts

Miloš Matić[1], Ana Obradović[1], Milica Paunović[1], Branka Ognjanović[1]
[1]*Faculty of Science, Kragujevac, Serbia*

Purpose: Interleukin-6 (IL-6) is major pro-inflammatory cytokine with an exquisite ability to induce the acute phase response and cytokine storm. Proliferation, survival and invasion of extravillous trophoblasts on maternal tissue are essential for successful establishment of gestation. Cytokine storm is overproduction and uncontrolled release of pro-inflammatory markers, whereas IL-6 has role in regulating trophoblast phenotype and metabolism. COVID-19 represents major health issue globally, affecting hundred of millions of people worldwide in the past several years and causing the damage in various tissues. Proinflamatory cytokines are considered to be one one of the underlying mechanisms of COVID-19 inflamatory complications.
Methods: In this study was investigated the potential pathophysiological effects of concentrations of interleukin-6 present in clinical cases of COVID-19 on physiology of JEG-3 human trophoblast cells. The experiment was performed in atmospheric hypoxia (3% of O_2) conditions, correlating with oxygen environment of trophoblast in the first trimester of gestation. The cells were exposed to the series of concentration of interleukin-6 derived from clinical cases of COVID-19 patients (50 pg/ml to 500 pg/ml). The proliferation ratio, apoptosis index, inhibition of caspases, invasion potential, and the parameters of oxidative metabolism were evaluated in the study.
Results: Superoxide anion radical ($O_2^{\cdot-}$) production were significantly increased after several applied IL-6 concentrations, implying induction of intense redox imbalance. At all examined concentrations, IL-6 have stimulated the activation of caspases, executing enzymes of apoptosis, as demonstrated by an increase in Apostat fluorescence signal. The invasion capacity of JEG-3 cell was elevated at all applied concentrations, suggesting the promigratory role of IL-6. The results indicate that IL-6 in concentrations present in COVID-19 complications has disruptive effects on the optimal physiological functioning of first trimester trophoblasts in the aspects of cell survival, apoptosis level, invasion capacity and oxidative stress.
Conclusion: The obtained data suggest the potentially pathological effects of IL-6 on pregnancy progression due to inflammatory complications caused by COVID-19. The elevated levels of IL-6 induce various disturbances of trophoblast cell homeostasis and could be one of risk factors in development of pregnancy disorders, raising the concerns of infection impact regarding the effects on placenta and the offspring.

Interferon-β exposure and ARTS deficiency promote the generation of hyper-efferocytic Ly-6C+ macrophages during the resolution of inflammation

Orly Zeituni-Timor[1], Soaad Soboh[1], Hiba Yaseen[1], Senthil Kumaran Satyanarayanan[1], Maha Abu Zeid[1], Esther Silberberg[1], Sagie Schif-Zuck[1], Sarit Larisch[1], Amiram Ariel[1]
[1]*University of Haifa, Haifa, Israel*

During the resolution of inflammation, Ly-6C$^+$F4/80$^-$ monocytes differentiate to Ly-6C$^-$F4/80$^+$ macrophages that exert efferocytic properties and consequently convert to IFN-β-producing macrophages. Here, we report that exposure to IFN-β, or TGF-β, or a deficiency in the pro-apoptotic protein ARTS, results in the conversion of mature macrophages to a rejuvenated Ly-6C$^+$F4/80$^+$CCR2$^+$ phenotype. This phenotype appeared exclusively in peritoneal resolution phase macrophages and not their unchallenged peritoneal, splenic or bone marrow counterparts. Moreover, IFN-β-triggered rejuvenated macrophages were hyper-efferocytic and expressed higher levels of the efferocytic receptor CD36. Inhibition of CD36 ligation resulted in complete abrogation of efferocytosis ex vivo in both mature and rejuvenated macrophages. Altogether, our findings indicate an unprecedented phenomenon in which IFN-β promotes macrophage rejuvenation and efferocytosis that are limited by ARTS-mediated apoptosis during the resolution of inflammation.

The number of classical and non-classical monocytes are altered in the peripheral blood from patients with silicosis due to engineered stone

Alberto Gallardo García[1;2], Gema Jiménez-Gómez[2;3], Antonio León-Jiménez[2;4], Antonio Campos-Caro[2;5]
[1]Immunology Department, Puerta del Mar University Hospital, Cádiz, Spain; *[2]Biomedical Research and Innovation Institute of Cadiz (INiBICA), Cádiz, Spain*; *[3]Research Unit, Puerta del Mar University Hospital, Cádiz, Spain*; *[4]Pulmonology Department, Puerta del Mar University Hospital, Cádiz, Spain*; *[5]Genetics Area, Biomedicine, Biotechnology and Public Health Department, School of Marine and Environmental Sciences, University of Cadiz, Cádiz, Spain*

Introduction: Silicosis by engineered stone (ES-silicosis) is a new, more aggressive form of silicosis with a shorter latency period than classical silicosis, which has appeared in workers exposed to high concentrations of crystalline silica (CS) particles as a result of handling ES, leading to rapid loss of lung function. The exact role of the immune system in the disease is not fully understood. Previous findings, our patient cohort has shown neutrophilia, lymphopenia and monocytosis, highlighting the need for further investigation into these cell subsets as potential contributors to the disease development and progression.
Purpose: In this study, we aimed to characterize monocyte subpopulations in peripheral blood from patients diagnosed with ES-silicosis and compare them with healthy controls.
Patients and methods: We used flow cytometry to assess monocytic subpopulations in 9 healthy controls and 18 patients diagnosed with ES-silicosis: 9 with simple silicosis (SS) and 9 with progressive massive fibrosis (PMF). Peripheral blood mononuclear cells (PBMCs) were isolated via density gradient centrifugation. The PBMCs were washed and resuspended in a staining buffer containing a combination of antibodies including CD16 (FITC), CD19 (PERCPCy5.5), HLA-DR (APC), CD14 (APCH7), CD11c (PECy7), CD45 (V500). Debris and dead cells were gated out, and monocytic subpopulations ($CD11c^{+}HLADR^{+}$) were selected following this gating strategy: classical monocytes ($CD14^{+}CD16^{-}$), intermediate monocytes ($CD14^{+}CD16^{+}$), and non-classical monocytes ($CD14^{dim/-}CD16^{++}$). Statistical analysis was performed using the SPSS software program.
Results: Flow cytometry data analysis reveals a statistically significant increase in the median of non-classical monocytes in patients with both SS (5.81) and PMF (6.25) compared to controls (2.98), accompanied by a significant decrease in classical monocytes. The proportion of intermediate monocytes is similar across all studied groups, and there are no differences in monocytic subpopulations between patients with SS and PMF.
Conclusions: There is an alteration in the distribution of classical and non-classical monocytes in patients with ES-silicosis. This study will allow us to focus on these subpopulations for further investigation into activation and polarization in the monocyte-macrophage axis, aiming to elucidate altered inflammatory processes and the effect of potential therapeutic targets.

Cross-reactivity to microbiota shapes natural CD4+ T cell responses against neo-antigens associated with acute lymphoblastic leukemia

Mikhail Goncharov[1], Petra Bacher[1], Alexander Scheffold[1]
[1]*Immunology institute, UKSH, Kiel, Kiel, Germany*

Purpose: Chromosomal translocations are frequent drivers of ALL in both children and adults which create a small and defined repertoire of mutated neoepitopes, serving as specific targets for anti-tumor T cell responses. Microbiota has a strong impact on anti-tumor responses but the mechanistic details and the microbial species involved are poorly understood. Here we aimed to pinpoint the properties of CD4+ T cell-dependent immunity against ALL neoantigens in healthy donors and leukemia patients, as well as to investigate the potential of microbiota—directed immunity to modulate the immune responses against ALL-relevant neoantigens through cross-reactivity.
Methods: We use the Antigen-Reactive T cell Enrichment (ARTE) protocol for identification and phenotypic profiling of antigen-specific CD4+ T cells. To deeply characterize antigenic specificity, affinity, and cross-reactivity of target lymphocyte populations, we made use of state-of-the-art single-cell- RNA-seq, expansion, and re-stimulation of rare antigen-specifically activated T cell clones, as well as TCR-repertoire profiling of antigen-specific T cells.
Results: We found that most of the investigated ALL-relevant neoantigens induce a T-cell memory response in healthy donors. A fraction of healthy donors demonstrated a strong Th17-polarized immune response towards UBTF-ATXN7L3 fusion antigen. This response was driven by T cells reactive to one common intestinal microbial species. UBTF-ATXN7L3-reactive T cells from leukemia patients demonstrated the same cross-reactivity pattern.
Conclusion: Our research serves as a proof of principle for microbiota-specific immunity to affect anti-leukemia immune surveillance by means of T-cell cross-reactivity. This will be relevant for the development of new immunotherapeutic approaches same as fundamental understanding of anti-tumor immune response mechanisms.

Comparing three methods for the isolation of exosomes from plasma in subjects with overweight and 3T3-L1 cell culture

Jacqueline Noboa-Velástegui[1;2], Juan Carlos Leon Contreras[3], Jorge Castro Albarran[4], Ana-Lilia Fletes-Rayas[5], Iñaki Álvarez[2], Rosa Elena Navarro Hernandez[1;6]
[1]Universidad de Guadalajara, Guadalajara, Mexico; *[2]Departamento de Biología Celular, Fisiología e Inmnunología, Institut de Biotecnologia i Biomedicina, Barcelona, Spain*; *[3]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Ciudad de México, Mexico*; *[4]Centro Universitario de la Costa Sur, Autlán de Navarro, Mexico*; *[5]Departamento de Enfermería Aplicada. Centro Universitario de Ciencias de la Salud, Guadalajara, Mexico*; *[6]UDG-CA-701. Inmunometabolismo en Enfermedades Complejas y Envejecimiento. Departamento de Biología Molecular y Genómica, Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Guadalajara, Mexico*

Purpose: This study aimed to isolate whole exosomes from plasma and supernatant of differentiated 3T3-L1 cells using three isolation techniques.
Methods: Plasma samples were collected from 120 individuals categorized based on body adipose tissue proportion (excess defined as more than 25% in men and 35% in women). Differentiated 3T3-L1 cells were cultured in DMEM supplemented with 10% FBS (fetal bovine serum depleted of microvesicles through overnight ultracentrifugation) and 10 µg/mL insulin for 20 days at 37°C and 5% CO_2. Furthermore, another set of 3T3-L1 cells was subjected to hypoxia for 24 hours following the same culture conditions.
We employed three isolation techniques: differential centrifugation (DC), size exclusion chromatography (SEC), and a commercial kit. Exosomes were characterized using cryo-TEM, TEM, and western blot (WB) for the tetraspanins CD9 and CD81.
Results: In the three isolation techniques, cryo-TEM and TEM analysis showed similar quality, quantity, and morphology of exosomes; at the same time, no difference was observed between individuals categorized by proportion of body fat.
In a more detailed analysis, we detected increased concentrations of CD9 and CD81 in plasma exosomes isolated by SEC and the commercial kit compared to DC. However, we observed an increase in background noise in WB with SEC.
Conclusion: We emphasize the importance of selecting the appropriate methodology for exosome isolation, which depends on the specific research objectives. When prioritizing exosome quantity and content, we suggest employing SEC or a commercial kit for plasma samples when seeking higher yields of intact exosomes. However, if purity is the priority, DC is the best method. In this study, exosomes were not obtained from the supernatant of 3T3-L1 cells. Therefore, our findings highlight the use of FBS depleted of microvesicles in 3T3-L1 cell culture. We recommend increasing the supernatant volume and/or the ultracentrifugation process or, alternatively, exploring a commercial exosome isolation kit designed specifically for cell culture samples.

Activated platelets rapidly induce pro-inflammatory phenotype and function in monocytes

Nicola Dark[1], Harriet Allan[1], Timothy Warner[1], Dianne Cooper[1], Paul Armstrong[1]
[1]*Queen Mary University of London, London, United Kingdom*

Background: Increased numbers of platelet-monocyte complexes have been implicated in a range of thrombo-inflammatory diseases such as myocardial infarction, type 2 diabetes, and Covid-19, with higher numbers relating to worsened clinical outcomes. Several studies suggest that platelets may alter a monocyte's inflammatory function. However, characterisation of these phenotypic changes and their functional implications following thrombotic stimuli is yet to be fully elucidated.
Aim: To investigate platelet-monocyte complex (PMC) formation and the resulting changes in phenotype and function.
Methods: Whole blood, or isolated monocytes/peripheral blood mononuclear cells (PBMCs), were incubated with washed platelets (1:100) and collagen related peptide (CRP-A; 1µg/ml) for up to 1 hour at 37ºC to form PMCs. Cell surface immunophenotyping (22 colour, 18 parameter spectral flow cytometry panel), phagocytosis ability (using pHrodo bioparticles) and ROS generation (using CellRox dye) of the complexes were all assessed by flow cytometry and compared to unbound monocytes. Data were analysed using FlowJo v.10 and Graphpad Prism.
Results: Platelet GPVI-specific stimulation leads to a rapid increase in platelet-monocyte complex (PMC) formation, observed both in whole blood and isolated cells. These PMCs display significantly elevated surface expression of CD16, CCR2, and CXCR4 ($p<0.05$) compared to unbound monocytes, indicative of a pro-inflammatory phenotype. They also demonstrate significantly elevated ROS generation ($p<0.05$) and a heightened phagocytic capability ($p<0.05$) in comparison to unbound monocytes, possibly facilitated by the increased surface expression of CD36 ($p<0.05$), which is known to play a role in phagocytosis. Additionally, PMCs exhibit an upregulation of CD142 (tissue factor), suggesting their potential involvement in thrombosis.
Conclusion: Our findings collectively indicate that platelet GPVI-specific stimulation by CRP triggers the formation of PMCs which rapidly (< 1 hour) transition to a heightened pro-inflammatory and pro-coagulative state compared to unbound monocytes. Additional work is required to explore these changes in order to further characterise platelet-monocyte complexes and their contribution to thrombo-inflammation.

Helminth infection modulates the immune response to SARS-CoV-2 vaccination

Jinpeng Su[1;2], Youssef Hamway[1;2], Julia Schluckebier[1], Bo-Hung Liao[1], Zhe Xie[1], Walaa Jradi[1], Jennifer Robb[1], Ulrike Protzer[1;2], Clarissa Prazeres da Costa[1;2]
[1]Technical University of Munich, Munich, Germany; *[2]German Center for Infection Research (DZIF), Munich, Germany*

Purpose: *Schistosoma mansoni* is a parasitic flatworm that infects almost 250 million people worldwide. *Schistosoma* and other helminths modulate the host immune response, with significant effects on allergy, atopy and vaccine responses. The SARS-CoV-2 pandemic resulted in the advent of a number vaccine strategies, including the first licensed mRNA vaccines. The efficacy of these vaccinations in African populations, particularly amongst people with existing parasitic infections has been debated. This study aims to resolve the question of the immunogenicity and efficacy of SARS-CoV-2 mRNA vaccination in helminth-infected hosts, through the use of a mouse model.
Methods: C57BL/6 mice were infected with *S. mansoni* and vaccinated 8 weeks later with Comirnaty (5µg and 1µg), followed by a boost immunization 4 weeks later. 1 week after boost immunization, the cellular and humoral immune responses were assessed by flow cytometry of splenocytes and lung cells, ELISA of re-stimulated splenocytes and measurement of spike-specific IgG responses and SARS-CoV-2 virus-neutralizing activity in sera.
Results: Between naïve and *Schistosoma*-infected mice there were minimal differences in humoral responses with similar antibody levels and SARS-CoV-2 virus neutralization capacities. The main finding was Th2 (IgG_1)-shifted humoral response, driven by the helminth infection. Whereas CD4+ T cell responses were similar between the groups, Spike-specific poly-functional CD8+ T cells were much fewer in helminth-infected mice. This CD8+ T cell suppression was accompanied by significant differences in the lung, where helminth infection shifted dendritic cell populations towards a cDC2 phenotype and a prominent shift in lung macrophage populations was also observed. Analysis is currently underway to identify the drivers and connections between the observed phenotypes.
Conclusion: Helminth infection –has a well-documented effect on host immune responses including in vaccination. Here we have assessed for the first time the effect of *Schistosoma mansoni* infection on the response to both SARS-CoV-2 and mRNA vaccination, finding a distinctly blunted induction of CD8+ T cell responses and extensive differences in antigen presenting cell populations. These findings are important to take into account for the development of vaccinations in regions where helminth infections are endemic.

Exploring the human immune response through tonsil-derived organoids

Maria Cavaco[1], Rodrigo Pedroso[1], Diana Matias[1], Luís Graça[1]
[1]*Instituto de Medicina Molecular (iMM), Lisbon, Portugal*

Purpose: The *in vitro* study of the human germinal centre (GC) response has been challenged by the reproduction of sequential cellular interactions in different microanatomic niches, whose complexity surpasses B and T cell co-cultures. In this context, tonsil-derived organoids emerge as a physiologically relevant platform for dissecting these immune interactions. Despite being usually discarded following children's tonsillectomies, tonsils contain well-defined GC structures as secondary lymphoid organs, rendering them a valuable and readily accessible biological material. This project aims to establish tonsil organoids for studying cellular populations, their interactions and maturation/differentiation pathways while opening new avenues for further modelling the GC response with physiological significance.
Methods: To generate the organoids, biopsied palatine tonsils are dissociated down to a single cell suspension. Isolated cells are cultured at high-density onto a transwell, which promotes reaggregation while providing nutrients through the media in the outer chamber. The stimulatory antigen (e.g., bacterial toxin or vaccine) is directly loaded in the inner chamber along with the cells at the culture outset. Replicated cultures per donor are evaluated via flow cytometry and ELISA at different time points to assess cell proliferation and maturation/differentiation, as well as antibody and cytokine production.
Results: Cellular reaggregation occurs around day 2 in culture, resulting in macroscopically visible aggregates. Cytometry analysis at day 7 confirms that tonsillar organoids can sustain lymphocyte survival, proliferation and differentiation, recapitulating the cellular composition of germinal centres. Prior to culture, B cells are in higher proportion compared to T cells, whose ratio shifts following a week in culture. Nevertheless, B cells exhibit a more mature phenotype with expression of GC markers (i.e., CD27 and CD38) after the culture period, while T follicular helper cells have become activated (PD-1^{hi}). Cryopreserved tonsillar cells were shown to perform similarly to fresh cells in culture regarding viability and expression of GC markers.
Conclusion: This organotypic system recapitulates *in vivo* GC features of the adaptive immune response, holding potential for studying antigen specific responses and discriminating physiological from pathological conditions. Ultimately, this system enables the modelling of immune responses through polarization or inhibition of specific pathways.

Deciphering the pathological involvement of circulating immune complexes during viral infections

Lucas Auguste[1], Lamia Bouzi[1], Léa Domitien[1;2], Franck Mennechet[1], Edouard Tuaillon[1;2]
[1]PCCEI Univ Montpellier, INSERM, EFS, Univ Antilles, Montpellier, France, Montpellier, France; *[2]Department of Virology, Montpellier University Hospital, Montpellier, France., Montpellier, France*

In normal immune response, circulating immune complexes (CIC) consist of antibody bound to antigen participating in antigen clearance and infection resolution. In some viral infections, CIC contribute to the pathophysiology of disease by direct inflammatory mechanisms or by facilitating viral replication. The regulatory impact of CIC is typically ascribed to Fc fragments and their receptors, which are broadly distributed on immune cells. Mononuclear phagocytic cells (MPC) such as monocytes, macrophages and dendritic cells are especially involved in immune response triggered by CIC. Multiple factors may influence impact of CIC in diseases: size and composition of CIC themselves, the type of immune cells with which they will interact and their pre-activation state. However, these mechanisms remain poorly understood. In our study, we have used innovative methods and standardized protocols for qualitative, quantitative, and functional characterization of CIC.
We have developed experimental *in vitro* models to measure activation capacities of CIC on peripheral blood mononuclear cell (PBMC) or MPC. *In vitro* prepared CIC composed of adenovirus-derived-vectors and immunoglobulins trigger cell activation of PBMC and MPC, measured by expression of cells surface activation markers and cytokine secretion. Moreover, CIC size was determined after purification by PEG6000 and using Dynamic Light Scattering (DLS). Human plasma or *in vitro* generated CIC were tested in co-culture with monocytes and with or without other cells using transwell system.
When stimulated by CIC, PBMC exhibited an activation profile, characterized by CD38, CD169 overexpression. Using DLS, we were able to identify distinct peaks linked to CIC size. Datas collected in our experimental *in vitro* model suggest that activation of monocytes cells by CIC is an indirect process, other cells or cytokines are needed. Also, macrophages need pre-stimulation for stimulation by CIC.
In this study, we have developed a new model to characterized CIC and study their capacity to trigger monocyte activation *in vitro*. We are setting up a standardized procedure to better understand and predict how the structure and environment of CIC affect their immunomodulatory effect through interaction with MPCs. In addition, we provide new incite of MPC activation mechanism induced by CIC.

Unraveling glycan recognition: a cellular approach to studying lectin receptor-ligand interactions

Eleonora Nardini[1], Katarina Olesek[1], Fabio Balzarini[1], Eveline Li[1;2], Ernesto Rodriguez Camejo[1], Yvette van Kooyk[1;2]
[1]Amsterdam UMC, Amsterdam, Netherlands; [2]DC4U, Amsterdam, Netherlands

Introduction: Glycosylation, the enzymatic process attaching carbohydrates (glycans) to proteins and lipids, is crucial for cellular functions and signaling. Cancer cells exhibit altered glycosylation patterns compared to their normal counterparts, that directly contribute to hallmarks of cancer such as immune evasion and metastasis. These glycan structure changes contain biological information that glycan-specific receptors, or lectins, found in a wide range of cells, including immune cells, can decode. The interaction between altered glycans and lectin receptors may predict patient outcomes, underscoring the need to identify specific ligands. Lectin receptors are primarily classified as Type I and II single-pass transmembrane proteins, differing in orientation: Type I has a cytoplasmic C-terminus and an extracellular/luminal N-terminus, while Type II has the reverse orientation.
In this project we aim to develop cellular tools to identify lectin receptor ligands and study their triggering potential.
Methods: Utilizing Jurkat cells, we created a flexible pipeline to generate reporter cell lines for various lectin receptors. We designed constructs allowing for easy replacement of the receptors intracellular domain with activating motifs (ITAMs). Luciferase, that is regulated by the transcription factor NFAT, was used as a read out to measure activation.
Results: We produced reporter cell lines for myeloid receptors DC-SIGN and Siglec-7, examples of Type I and Type II membrane receptors. These were characterized using specific antibodies and glycan ligands. Both lines recognized and were activated by previously reported glycan structures, and by using specific antibodies. They could also distinguish subtle differences in glycan structures and were used to identify essential amino acids for their function. Co-culture with tumor cell lines demonstrated their ability to detect receptor ligands.
Conclusion: Our reporter cell lines for lectin receptors are flexible tools for identifying ligands and assessing their ability to induce signaling, offering valuable insights into receptor-ligand interactions and potential therapeutic targets.

NK Cell Regulation of Humoral Immunity in Therapeutic Vaccination

Joseph McDowell[1], Stephanie Kucykowicz[1], Jessica Davies[1], Dimitra Peppa[1], Mariana Diniz[1], Mala K Maini[1]
[1]*UCL, London, United Kingdom*

Purpose: Therapeutic vaccination attempts to boost antigen-specific immune responses but effectiveness is hampered in chronic viral infections and cancer by dysfunctional T and B cell responses. A growing body of literature suggests NK cells are critical regulators of B cell mediated immunity via effects on CD4 help in the setting of murine and human infections. In this study we are therefore examining whether manipulating NK cell regulation can enhance the humoral response to therapeutic vaccination in chronic HBV infection.
Methods: To achieve this, we utilised a mouse model of persistent low-level HBV infection (*Huang et al, Gastro, 2012*) and treated animals with clinically relevant therapeutic vaccination regimens with or without NK cell depletion. We also cocultured human differentiated follicular helper T cells (Tfh) (*Locci et al, Nat Immunol 2016*) and isolated NK cells derived from chronically infected HBV patient PBMCs prior to analysing Tfh functional capacity.
Results: Using PBMC from healthy controls and patients with chronic HBV, we found that culturing CD4 T cells with previously published lineage-inducing cytokines (Activin-A and IL12) promoted canonical Tfh marker and effector expression to overcome limitations of low circulating Tfh. Purified NK cells reduced the frequencies of these *in vitro* expanded Tfh when cocultured *in vitro*. We probed the *in vivo* impact of depleting NK cells prior to therapeutic vaccination and found this significantly enhanced the expansion of splenic Tfh as well as germinal centre (GC) B cells, allowing further studies to determine relevant pathways.
Conclusion: We have initial evidence that NK cells act to inhibit the humoral response to vaccination in a mouse model of chronic HBV infection and in a human PBMC coculture system with key mediators of the response, Tfh cells. Further work will investigate whether NK cells limit the capacity of Tfh to give adequate help to HBsAg-specific B cells and how this affects anti-HBV nAb production using PBMC and lymph node samples from donors with chronic HBV infection. By examining the receptor ligand interactions that underpin these inhibitory NK pathways we will identify specific targets that could be blocked during a therapeutic vaccine regimen to improve patient responses.

TLR7/8 agonism reshapes hepatic immunity and improves the response to bacterial infection in liver fibrosis

Dimitrios Patseas[1], Eoin Mitchell[1], Sarah Morel[1], Cathrin L Gudd[1], Prakash Ramachandran[2], Lucia A Possamai[1], Evangelos Triantafyllou[1]
[1]Section of Hepatology and Gastroenterology, Department of Metabolism, Digestion and Reproduction, Imperial College London, London, United Kingdom, London, United Kingdom; *[2]Institute for Regeneration and Repair, Centre for Inflammation Research, University of Edinburgh, Edinburgh, United Kingdom, Edinburgh, United Kingdom*

Purpose: Cirrhosis, a major healthcare burden, is characterized by liver fibrosis, immune dysregulation and impaired antimicrobial responses that contribute to increased infection risk and mortality in patients. Recent evidence has highlighted the therapeutic potential of Toll-Like-Receptor (TLR) 7/8-dual agonism (R848) in inflammatory pathologies including cancer. We therefore assessed in this study its immunomodulatory effects in a murine model of carbon tetrachloride (CCl_4)-induced fibrosis.
Methods: C57BL/6J 8-week-old male/female mice (n=6-8/group) received intraperitoneal (i.p.) injections of vehicle (oil) or CCl_4 (0,4 µl/g) twice-weekly (6 weeks) to establish fibrosis; during the 6th week, mice were treated i.p. with saline (PBS) or TLR7/8-L (R848; 1mg/kg). Liver non-parenchymal cells were assessed by flow cytometry (myeloid/lymphoid cells). In separate experiments, Escherichia coli (5 x 10^7 /20g body weight) was administered intravenously 24h before mice (n=8-11/group) were culled. Liver and spleen tissue lysates were plated on agar for colony-forming unit (CFU) quantification.
Results: Flow cytometry analyses showed that the number (cells /tissue gram) of VSIG$^-$ monocyte-derived macrophages expanded in PBS-fibrotic mice (Ctrl:33.063; PBS:123.975, p<0.0001) while TLR7/8-L administration reduced that number by ~35% (PBS:123.975; TLR7/8-L:79.398, p=0,0121). Conversely, increased dendritic cell (DC) numbers were observed in livers of TLR7/8-L-treated fibrotic-mice, compared to PBS-fibrosis (cDC1; PBS:11.193 vs. TLR7/8-L:42.184, p=0,0003; cDC2; 35.001 vs. 68.017, p=0,0225). No significant changes were observed in VSIG4$^+$ Kupffer cell numbers. TLR7/8 agonism further enhanced the numbers of CD4$^+$CD25$^-$FoxP3$^+$ T_{regs} in fibrotic mice (PBS:14.582 vs. TLR7/8-L:30.977, p=0,0005). Increased bacterial load (CFU/tissue gram) was detected in the liver and spleen of PBS-fibrotic mice, compared to vehicle-treated controls (Liver; Ctrl:145.245 vs. CCl_4:385.203, p=0,0026; Spleen; Ctrl:23.867 vs. CCl_4:66.212, p=0,0002). Notably, TLR7/8-dual agonism reduced CFUs in both tissues (Liver: PBS:385.203 vs. TLR7/8-L:217.944, p=0,0547; Spleen: PBS:66.212 vs. TLR7/8-L:24.873, p=0,0007).
Conclusion: Our findings demonstrate that, in the mouse fibrotic liver, TLR7/8 dual agonism mobilizes a reshaping of the intrahepatic immune compartment resulting in improved bacterial clearance after *E. coli* infection. Future studies are needed to better understand the immune intercellular crosstalk and underlying mechanisms of this TLR7/8-mediated immunomodulatory approach in liver fibrosis, aiming to ultimately translate TLR-targeted therapies to improve antimicrobial responses in patients with liver disease.

Induction of immunoregulatory responses at the injection site of vaccine adjuvant alum.

Nicole Roche[1], Aoife Gorman[1], Katie O'Grady[1], Dorian Dederko[1], Ed Lavelle[1]
[1]*Trinity College Dublin, Dublin, Ireland*

A key consideration in the development of vaccines is to generate formulations that are both effective and safe, this relies on a fine balance between immunostimulatory capacity and tolerability of vaccine components. The vaccine adjuvant Alum, one of the most widely used adjuvants worldwide, has a well-established track record in both of these regards. Alum excels as an adjuvant capable of promoting protective antibody responses while also maintaining a robust safety record. Alum is not an optimal adjuvant for promoting cell mediated immune responses (CMI), particularly CD8 and Th1 cells, making it unsuitable for vaccines against pathogens which require CMI for protection. Despite being utilised in many licenced vaccines over the past century, aiding in protection against many infectious diseases including Human Papilloma Virus (HPV), Hepatitis A, Hepatitis B, Polio and Diphtheria, the specific mechanisms underlying the immune stimulating properties, its robust safety record and the effects of biological sex on responses to alum have not been fully resolved.
Our hypothesis is that a combination of immunoregulatory processes rapidly initiated at the site of alum injection, including the accumulation of regulatory T cells, a switch from classically inflammatory monocytes to a more anti-inflammatory phenotype, the production of anti-inflammatory cytokines such as IL-10 and the inhibition of Th1 cell polarising cytokines such as IL-12 underlie alums robust safety while also limiting the initiation of CMI. We present data supporting this hypothesis and the role of biological sex in dictating the extent of these responses.

Investigating the salivary gland tissue microenvironment in Sjögren's disease using Imaging Mass Cytometry™

Hanne Borge[1], Stian Tornaas[1], Tamandeep Kaur Bharaj[1], Siren Fromreide[1], Ylva Bratterud Helgesen[2], Rebecca Jane Cox Brokstad[3;4], Karl Brokstad[2], Johan Gorgas Brun[5], Roland Jonsson[2], Brith Bergum[6], Malin Viktoria Jonsson[7], Silke Appel[2;6], Kathrine Skarstein[1;8]
[1]Gade Laboratory for Pathology, Department of Clinical Medicine, University of Bergen, Bergen, Norway; *[2]Broegelmann Research Laboratory, Department of Clinical Science, University of Bergen, Bergen, Norway*; *[3]Influenza Centre, Department of Clinical Science, University of Bergen, Bergen, Norway*; *[4]Department of Microbiology, Haukeland University Hospital, Bergen, Norway*; *[5]Department of Rheumatology, Haukeland University Hospital, Bergen, Norway*; *[6]Core facility for flow cytometry, Department of Clinical Science, University of Bergen, Bergen, Norway*; *[7]Department of Clinical Dentistry, Section for Oral and Maxillofacial Radiology, University of Bergen, Bergen, Norway*; *[8]Department of Pathology, Haukeland University Hospital, Bergen, Norway*

Purpose: Sjögren's syndrome (SS) is a complex autoimmune disease with destruction of glandular tissue as one of the major disease hallmarks. Novel Imaging Mass Cytometry™ (IMC™) can bring the investigation of the glandular tissue microenvironment into new dimensions by targeting multiple immune cell markers within the tissue simultaneously.
Objective: To study the immune cell subsets that are present in the microenvironment of minor salivary gland biopsies in a spatial dimension using Imaging Mass Cytometry.
Methods: Minor salivary gland biopsies from primary Sjögren's syndrome (pSS) patients and non- Sjögren's syndrome (non-SS) sicca controls were used. The patient cohort fulfilled the AECG/ACR-EULAR criteria for Sjögren's syndrome. To enable analysis of multiple patients and controls simultaneously, we created a tissue micro array (TMA) with cores taken from each individual biopsy and placed together in the same paraffine block. A tonsil was included for positive control. Region of interest was selected based on the dominating pathological structure of the gland. A section from the TMA was stained with 33 metal tagged antibodies, 3 segmentation markers and Iridium nucleic acid intercalator. The tissue was ablated with a laser beam in the Hyperion™ machine and data generated was first denoised to reduce hot pixels and artefacts, and metal spillover was compensated using Rstudio software. Further IMC downstream analysis were performed in Rstudio.
Results: The downstream analysis presented diversity in the detected immune cell subsets in the tissue among the patient and control participants. The follicular dendritic cells were detected in pSS patients with a more severe disease pattern and localized in close proximity to B cells in the larger focal infiltrates. Plasma cells were scattered interstitially and in the periphery of the infiltrates in the pSS cohort but was also detected in the non-SS control group. Further analyses are ongoing.
Conclusion: The analyzed data showed a difference between patients with a more complex and severe pSS disease compared to the patients presenting milder disease patterns.

Sources of contributed support: The IMC analysis was performed at the Flow Cytometry Core Facility, Department of Clinical Science, University of Bergen, Norway.

Transcriptomic Analysis Reveals Distinct Effect of Cigarette Smoke on Lung and Systemic Macrophage Populations

Lynne Faherty[1], William Z. Zhang[2], Mays M. Salih[3], Elektra K. Robinson[3], Elizabeth Perez[2], Kihwan Kim[2], Susan Carpenter[3], Suzanne Cloonan[1;2]
[1]School of Medicine, Trinity College Dublin, Dublin, Ireland; *[2]Division of Pulmonary and Critical Care Medicine, Joan and Sanford I. Weill Department of Medicine, New York, NY, United States*; *[3]Department of Molecular, Cell and Developmental Biology, University of California Santa Cruz, Santa Cruz, CA, United States*

Chronic obstructive pulmonary disease (COPD) is an inflammatory airway disease characterized by emphysema and chronic bronchitis and a leading cause of mortality worldwide. COPD is commonly associated with several comorbid diseases which contribute to worse patient outcomes. Cigarette smoke (CS) is the most prominent risk factor for COPD development and progression and is detrimental to effector functions of lung-resident immune cells, including phagocytosis and cytokine production. However, how CS mediates the various pathologies distant from the lung in COPD, and the biological effect of CS on systemic immune cells, is unknown.
Bone marrow cells were isolated from C57BL/6 mice exposed to CS for 8 weeks as an experimental COPD model and differentiated to bone marrow-derived macrophages (BMDMs) alongside room air (RA) controls. Alveolar macrophages (AMs) were isolated from the same CS-exposed and RA mice and bulk RNA-seq preformed. Bulk RNA-seq was also performed on BMDMs from CS and RA mice with and without LPS treatment. Gene ontology (GO) and Ingenuity Pathway Analysis (IPA)were used to perform pathway analyses and predict upstream regulators associated with the observed differentially expressed protein-coding genes induced by CS in each cell population. CS induced differential expression of genes involved in pathogen response, phagosome formation, and immune cell trafficking in AMs from CS-exposed mice compared to RA mice. Distinctly, CS induced alternative transcriptomic remodelling in BMDMs, associating with an upregulation of genes in the sirtuin signalling and oxidative phosphorylation pathways and with a downregulation of genes involved in histone and lysine methylation. Little overlap is observed in both differentially expressed protein-coding genes in BMDMs compared to AMs and their associated pathways, highlighting the distinct effects of CS on immune cells in different compartments. Additionally, BMDMs isolated from CS-exposed mice display a distinct transcriptomic signature upon stimulation with LPS compared to those from RA mice, with LPS treatment upregulating genes associated with RNA processing and splicing in BMDMs from CS mice. Our findings suggest that the systemic inflammation and symptom burden associated with COPD may arise from CS-affected bone marrow derived monocytes, which may in turn drive pathogenesis of diseases frequently comorbid with COPD.

ARID5B-mediated LINC01128 epigenetically activated pyroptosis and apoptosis by promoting the formation of the BTF3/STAT3 complex in antiphospholipid syndrome

Yuan Tan[1], Liyan Cui[1]
[1]*Peking University Third Hospital, Beijing, China*

Purpose: Alterations of the H3K4me3 mark in monocytes are implicated in the development of autoimmune diseases. Therefore, the purpose of our study was to elucidate the role of H3K4me3-mediated epigenetics in the pathogenesis of antiphospholipid syndrome (APS).
Methods: H3K4me3 Cleavage Under Targets and Tagmentation and Assay for Transposase-Accessible Chromatin were performed to determine the epigenetic profiles. Luciferase reporter assay, RNA immunoprecipitation, RNA pull-down, co-immunoprecipitation, and ChIP were performed for mechanistic studies. Transmission electron microscopy and propidium iodide staining confirmed cell pyroptosis. Primary monocytes from patients with primary APS (PAPS) and healthy donors were utilized to test the levels of key molecules. A mouse model mimicked APS was constructed with β2GPI injection. Blood velocity was detected using murine Doppler ultrasound.
Results: H3K4me3 signal and open chromatin at the *ARID5B* promoter were increased in an *in vitro* model of APS. The epigenetic factor ARID5B directly activated LINC01128 transcription at its promoter. LINC01128 promoted the formation of the BTF3/STAT3 complex to enhance STAT3 phosphorylation. Activated STAT3 interacted with the *NLRP3* promoter and subsequently stimulated pyroptosis and apoptosis. ARID5B or BTF3 depletion compensated for LINC01128-induced pyroptosis and apoptosis by inhibiting STAT3 phosphorylation. In mice with APS, β2GPI exposure elevated the levels of key proteins of pyroptosis and apoptosis pathways in bone marrow-derived monocytes, reduced the blood velocity of the ascending aorta, increased the thrombus size of the carotid artery, and the release of interleukin (IL)-18, and IL-1β, tissue factor (TF). Patients with PAPS had the high-expressed ARID5B and LINC01128, especially those with triple positivity for aPLs, and there was a positive correlation between ARID5B and LINC01128 expression. Moreover, triple-positive patients with PAPS had the significantly lower C3, C4, and PLT levels compared to non-triple-positive patients.
Conclusion: This study indicated that ARID5B/LINC01128 was synergistically upregulated in APS, and they aggravated disease pathogenesis by enhancing the formation of the BTF3/STAT3 complex and boosting p-STAT3-mediated pyroptosis and apoptosis, thereby providing candidate therapeutic targets for APS.

Neutrophil extracellular trap-associated glycosidases shape the immune response

Rebecca Chukwuanukwu[1], Jasmin Knopf[2;3;4], Martin Herrmann[2;3;4]
[1]Immunology Unit, Medical Laboratory Science Department, Nnamdi Azikiwe University, Awka, Nigeria; *[2]Department of Internal Medicine 3 Universitätsklinikum Erlangen, Erlangen, Germany*; *[3]Department of Pediatric Surgery, University Medical Center Mannheim, Heidelberg University, Mannheim, Germany*; *[4]Deutsches Zentrum für Immuntherapie (DZI), Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Erlangen, Germany*

Purpose: Formation of neutrophil extracellular traps (NETs) is an anti-microbial activity of neutrophils and this is a cell destructive process. The NET structures are formed from nuclear and cytoplasmic components that can capture and kill pathogens. Here, we investigated NETs for the expression of functionally active glycosidases.
Methods: The pertinence of glycosylation on functional activities of immunoglobulins are well established. Thus, we assessed the effect of NETs on the functional activity of immunoglobulin G (IgG). NETs generated from healthy donors and pooled human intravenous Immunoglobulins (IVIg) were utilized to assess cytokine levels produced by cells stimulated with IgG-coated beads. Thereafter, the total IgG and IgG subclasses glycosylation patterns were assessed using MALDI-TOF and LC-ESI MS, respectively.
Results: NETs contain the glycan-modifying enzymes neuraminidase, β−galactosidase and hexosaminidase which are either bound to NETs or released during NET formation. Incubation of IVIg with NETs modulates their bisection and sialylation composition as well as their cytokine induction.
Conclusion: These findings show that the immunomodulatory effect of NETs has the potential to upregulate inflammation. This can have beneficial but also undesirable consequences. Targeting the glycosidases on NETs could be used for immune intervention.

Impairment of alternative NLRP3 inflammasome pathway in peripheral blood monocytes from inflammatory bowel disease patients

Carlos Sánchez Rodríguez[1], Pablo Hurtado Blanco[1], Almudena Otalora[1], Gema Salgado Cecilia[1], Rosa Moya Quiles[1], Jose Antonio Galián Megías[1], Gonzalo Antón Ródenas[2], Manuel Muro Amador[1], Helios Martínez Banaclocha[1]
[1]Biomedical Research Institute of Murcia (IMIB), Immunology Department, Virgen de la Arrixaca Clinical University Hospital, Murcia, Spain., Murcia; *[2]Digestive pathology department, Virgen de la Arrixaca Clinical University Hospital, Murcia, Spain, Murcia*

Introduction: Inflammatory bowel disease (IBD), comprising Crohn's disease (CD) and ulcerative colitis (UC), is characterized by chronic and relapsing inflammation in the gastrointestinal tract, and some hypotheses propose that damage to the intestinal mucosa occurs as a result of dysregulated innate immune response. NLRP3 inflammasome is rapidly emerging as a crucial regulator of intestinal homeostasis. This receptor mediates the assembly of the inflammasome complex in the presence of microbial ligands, triggering activation of caspase-1 and secretion of IL-1β and IL-18, and has been implicated in the pathogenesis of IBD, but the detailed role of NLRP3 inflammasome in IBD is still debated. Actually, the concept of detrimental inflammasome signaling in IBD is being evaluated due to recent reports that IL-1β and IL-18 production can confer protection against colitis. In the present work, we found a defective NLRP3 inflammasome activation by peripheral blood monocytes from IBD patients that supports the asociation of detrimental inflammasome signaling with the development of IDB.
Methods: Human PBMCs obtained from 32 healthy donors and 16 newly diagnosed IBD patients (including CD and UC) were stained with anti-CD3, CD56, CD19, HLA-DR, CD14 and CD16 fluorescent monoclonal antibodies to isolate CD14++CD16- monocytes by fluorescent cell sorting. After isolation, $1x10^5$ monocytes were cultured in RPMI media 10% FBS during 18 hours in the presence of lipopolysaccharide to activate NLRP3 inflammasome by alternative pathway and in the presence or absence of MCC950 a known NLRP3 antagonist. Cell free supernatants were collected to quantify several cytokines by multiplex immunoassays (ThermoFisher Scientific) for Luminex platform.
Results: We found significantly decreased levels of inflammasome dependent cytokines IL-1β, IL-18 and IL-1α in the supernatants of IBD patients monocytes compared to healthy controls after LPS treatment to activate NLRP3 inflammasome. However, the release of other inflammatory cytokines not dependent of inflammasome activation (IL-6, IL-8, TNF-α) was similar comparing IBD patients and healthy controls.
Conclusions: In the present work we found an impaired NLRP3 alternative pathway activation in peripheral blood monocytes from IBD patients compared to healthy controls. This result suggest that defective NLRP3 inflammasome activation could be asociated with the development of inflammatory bowel disease.

The histone variant H2A.J shapes immune responses

Tanja Vera Kübelbeck[1], Daniela Kramer[1;2], Antonia Kolb[1], Berenice Fischer[1]
[1]Department of Dermatology, University Medical Center of the Johannes Gutenberg-University of Mainz, Mainz, Germany; *[2]Research Center for Immunotherapy, University Medical Center of the Johannes Gutenberg-University of Mainz, Mainz, Germany*

Purpose: Classical histones at promoter and enhancer regions can be replaced by histone variants, which consequently change the accessability of gene loci and therefore the overall gene expression. Multiple reports already demonstrated that histone variants control important cellular pathways like DNA repair and replication, or differentiation, however the role in immune cell responses remain largely unexplored. Previously it was found that the histone variant H2A.J, encoded by *H2AFJ*, controls inflammatory gene expression in senescent fibroblasts, however its function in immune cells and its impact on skin pathologies has not been investigated yet. In this project, we investigated the role of H2A.J in immune cell responses, with special focus on psoriasis.
Methods: *H2AFJ* mRNA and H2A.J protein level were assessed in skin biopsies from human psoriasis patients, compared to normal skin and non-lesional controls. For investigating the role of H2A.J in psoriasis *in vivo*, effects of imiquimod-induced, psoriasis-like skin inflammation was analysed by flow cytometry, gene expression analysis and ELISA from wildtype and *H2afj* knockout mice. This data was complemented by investigation of its function in T-cells and keratinocytes. For this purpose, primary cells were isolated from global *H2afj* knockout mice, activated and analyzed for changes in global gene expression.
Results: H2A.J expression is elevated in skin lesions of psoriasis patients. Moreover global deletion of H2A.J partially inhibits imiquimod-induced psoriasis-like skin inflammation, by inhibiting neutrophil and monocyte recruitment. This was likely due to the fact that H2A.J controls inflammatory gene responses in keratinocytes and $CD4^+$ T-cells.
Conclusion: With this work we discovered a new close connection between the expression of a histone variant and the immune response to the autoimmune disease psoriasis. Potentially H2A.J can be used as a biomarker for the chance to develop psoriasis. Next steps will be to unravel how H2A.J regulates the gene expression in immune cells and keratinocytes and if there is also a connection between H2A.J and other inflammatoy diseases.

The immunomodulatory functions of long noncoding RNA DANCR in melanoma

Ege Amirak[1], Fatih Sezer[1], Ryan M. O'Connell[2], H. Atakan Ekiz[1]
[1]Izmir Institute of Technology, Izmir, Turkey; [2]Huntsman Cancer Institute, Salt Lake City, Utah, United States

Cancer immunotherapy has emerged as a promising strategy for treating various malignancies, including metastatic melanoma. However, its efficacy remains variable among patients, necessitating a deeper understanding of the underlying mechanisms of tumor immune evasion. Long noncoding RNAs (lncRNAs) have recently garnered attention for their roles in gene regulation and disease pathogenesis. Among these, lncRNA DANCR (Differentiation Antagonizing Non-Protein Coding RNA) has emerged as a potential regulator of tumor progression and therapy resistance in multiple cancer types. In this study, we further investigated the roles of DANCR in melanoma immune evasion and tumor progression. Using TCGA skin cutaneous melanoma (SKCM) RNAseq data, we examined survival associations of lncRNA expression and identified DANCR as a prominent candidate (expression was categorized at the median value, n=230/grp). DANCR was found to be a poor prognosticator in SKCM, with its expression significantly associated with unfavorable outcomes. Furthermore, the analysis of previously published scRNAseq data revealed that DANCR was predominantly expressed in melanoma cells within the tumor microenvironment (TME), inversely correlating with the IFNγ response gene signature in immune-rich SKCM. In PTEN-high SKCM, low DANCR expression was associated with a positive prognosis (n > 112/group). In the literature, DANCR inhibited keratinocytes with differential expression of genes involved in PI3K signal transduction, EMT, and immunomodulation. Reduced DANCR levels decreased PD-L1 expression in nasopharyngeal cancer cells, indicating its potential as an immune checkpoint blockade therapy target. Notably, melanoma tumors responding to anti-PD-1 therapy exhibited decreased DANCR levels. Consistent with the literature, our receiver operating characteristic (ROC) analysis showed that DANCR predicted poor response to immune checkpoint blockade (ICB) in melanoma, highlighting its clinical benefit as a biomarker for treatment stratification. To evaluate these findings mechanistically and manipulate DANCR expression in melanoma cell lines we are leveraging CRISPR-dCas9 activation and inhibition system. The research, supported by TUBA-GEBIP, focuses on understudied regulatory pathways in tumor immunology and can reveal how melanoma progresses and achieves immunoevasion. Elucidating the role of DANCR in tumor immunoevasion could lead to the development of novel prognostic tools and therapy targets in melanoma and potentially other cancers.

Purpose: Phosphatases of regenerating liver (PRLs) have been proposed to regulate actin dynamics in lymphoid cells. However, the mechanism mediating this regulatory role during T cell activation, IS assembly and effector function remained unknown.
Methods: Interaction among proteins was confirmed by both SILAC proteomics and immunoprecipitation analysis. Immunological Synapse (IS) formation was evaluated by high resolution confocal microscopy and early TCR signalling was studied by western blot. Secretion capacity was assessed by IL-2 detection by ELISA and degranulation assays by FACS. Edition of PRL-1 or PRL-2 expression was performed by CRISPR/Cas9 in Jurkat (JK) and primary T cells.
Results: We showed the interaction of the PRLs with the actin regulator WD repeat containing protein 1 (WDR1). This association was dependent on filamentous (F)-actin integrity and the proper recruitment of the PRLs to cell membranes through the CAAX motif. Endogenous PRLs and WDR1 were distributed to the IS, and knockout (KO) JK cells and edited primary T cells for PRL-1 or PRL-2 showed that the PRLs were required for proper distribution of WDR1 to F-actin at the IS. Further, perturbed expression of the PRLs or WDR1 resulted in defective IS assembly with aberrant F-actin rearrangements, altered positioning of LFA-1 and deregulated IL-2 production. Interestingly, balanced expression of PRLs was required for accumulation of CD3ε at the IS and early activating signalling.
Conclusion: We contribute experimental evidences indicating that PRLs regulate early T cell signalling and are required for proper F-actin dynamics by regulating the WDR1 access to F-actin networks. As a consequence, PRLs regulate LFA-1 positioning at the IS and proper cytokine secretion.

End-Binding Protein-1 regulates the metabolic fate of CD4 T lymphocytes through the organisation of the mitochondrial network

Alvaro Gomez Moron[1;2], Silvia Requena[1], Clara Pertusa[1], Marta Lozano-Prieto[1], Camila Scagnetti[1], Diego Calzada-Fraile[1], Ana Adela Calero-Garcia[1], Manuel Izquierdo-Pastor[3], Pedro Roda Navarro[2], Noa Beatriz Martín-Cófreces[1;4]

Purpose: This work focuses on the role of End-Binding Protein-1 (EB1), a protein that regulates tubulin polymerisation and dynamics and has previously been identified as a regulator of CD3 vesicle trafficking to the immune synapse. However, the regulatory role of EB1 in T cell metabolism after T-cell receptor activation is unknown.
Methods: EB1-silenced Jurkat T-cells, either transiently or stable clones and $CD4^+$ T lymphocytes were used to analyse the distribution of mitochondria and the cytoskeleton in the immune synapse by confocal microscopy and the mTOR signalling pathway, which regulates cellular processes such as cell survival and metabolism, was studied by Western blotting. Metabolic assays were also performed to investigate the mitochondrial respiration and glycolytic capacity, and the role of EB1 in cell death induced by activation through the Fas/FasL system was investigated by flow cytometry.
Results: EB1-silenced cells exhibit impaired polarisation of mitochondria and the actin and tubulin cytoskeleton towards the synapse site, as well as a defective metabolic responsiveness in activated T cells, suggesting a relevant link between the cytoskeleton and metabolism in response to TCR stimulation.
Conclusion: By linking the tubulin cytoskeleton and mitochondria during $CD4^+$ T cell activation, this work highlights the importance of EB1 in this context to regulate cell asymmetry, apoptosis and metabolic functions such as glycolysis and mitochondrial respiration.

Exploring the role of calcium ion channels during mycobacterial infection

Priya Ghosh[1;2], Jacqueline Eich[2], Tobias Dallenga[2], Ulrich E. Schaible[2], Avinash Sonawane[1]
[1]Department of Biosciences & Biomedical Engineering, Indian Institute of Technology Indore, Indore, India; *[2]Research Center Borstel-Leibniz Lung Center, Borstel, Germany*

Tuberculosis (TB) is considered a significant health concern, ranking among the top ten leading causes of adult mortality globally, highlighting the urgent need for continued attention and action to address this life-threatening disease. *Mycobacterium tuberculosis* **(***Mtb***)** is a highly competent pathogenic bacteria that proliferates within host cells as a prerequisite for progression to active TB by escaping the immune system of its victim through several approaches. Recently modulation of calcium ion (Ca^{2+}) channels has surfaced as an emerging immune invading mechanism for *Mtb*. Ca^{2+} channels belong to the vanilloid subfamily among the TRP superfamily. These ion channels are predominately expressed in immune cells, where they are co-localized within the endosomal-lysosomal continuum. Out of various ion channels, Ca^{2+} specific ones are involved in the regulation of cellular and lysosomal Ca^{2+} homeostasis affecting lysosome trafficking and autophagic flux. Despite the role of ion channel-mediated Ca^{2+} in lysosomal biogenesis and trafficking with putative relevance for host immune responses. Nevertheless, how Ca^{2+} channels are regulated in immune cells during mycobacterial infection remains poorly understood. We found that Ca^{2+} channel expression is modulated upon mycobacterial (*M. bovis* BCG) infection in murine macrophages and loss of function experiments resulted in dysfunctional lysosomes, lysosomal storage phenotype, and interference with phagosome maturation. Employing Ca^{2+} channel modulators to explore their role in mycobacterial infection of the endo-lysosomal continuum revealed upregulation of EEA1 and Rab5 but downregulation of Rab7. Ca^{2+} channel agonist followed by mycobacterial infection increased the number of acidic vesicles by promoting endo-lysosome fusion and consequently, reduced intracellular mycobacterial burden. In contrast, Ca^{2+} channel antagonist reduced acidic vesicle formation. Thus, our findings demonstrate that the Ca^{2+} channel plays a critical role in host cell responses against intracellular mycobacteria but can be modulated by mycobacteria to alter cellular Ca^{2+} homeostasis and putatively, phagolysosome formation to promote mycobacterial infection.

Interplay of cytoskeleton and membrane morphology during formation of immunological synapse

Ondřej Ballek[1], Valerie Tahtahova[1], Dominik Filipp[1]
[1]*Institute of Molecular Genetics of the Czech Academy of Sciences, Prague, Czech Republic*

T-cells are key players of adaptive immunity, however is not fully understood how membrane distribution of critical molecules and membrane architecture itself influence their responses to antigens. Since contact between T-cells and APCs was found to involve microvilli, we propose that changes in surface morphology control the early events of T-cell activation. Specifically, we aim to understand how these events are driven by cytoskeleton.
Using advanced microscopy, we visualized formation of immunological synapse (IS) *in vitro* and observed robust accumulation of plasma membrane at the contact site between T-cells and APC. Cryo-TEM microscopy further revealed previously uncharacterized ultrastructural details of IS, which is actually formed by a surprisingly complex meshwork of membrane protrusions intertwined within the cavity of the interacting cells. This observation supports our assumption that increased membrane surface area within forming IS, including signalling proteins, appropriate geometry of microvilli and cytoskeleton, provide the optimal microenvironment for initial recognition of cognate antigen during T-cell:APC interaction.
Since we previously studied the critical role of spatio-temporal organization and dynamics of Lck and other signalling molecules in proximal TCR signalling, we have begun to focus on identifying their potential linkers to cytoskeletal network. We discovered α-actinin-1 and 4 as cytoskeletal components of Lck-RACK1 complexes, which are transiently formed during the initiation of T-cell activation and depend on Lck kinase activity. 3D-high resolution live-cell imaging revealed that in α-actinin-1/4 dKO T-cells, Lck was spatially arrested at IS periphery early after the start of synapse formation in contrast to Lck even distribution in WT controls. As expected, such disorganization resulted in reduced responsiveness of T-cells, indicating that α-actinins contribute to the stability of the forming IS.
Taken together, our data adds new pieces of the puzzle showing the importance and complexity of the interplay of cytoskeleton, membrane morphology and signalling molecules during IS formation.

Analysis of TAM receptor expression in patients with Sjögren's disease

Irene Sarkar[1], Hanne Borge[2], Kirsten Lassing[1;3], Aleksandra Petrovic[1], Tamandeep Kaur Bharaj[2], Alireza Molai[1], Richard Davies[1], Magdalena Alfredsen[1;4], Johan Gorgas Brun[5;6], Roland Jonsson[1], Kathrine Skarstein[2;7], Silke Appel[1;8]
[1]Broegelmann Research Laboratory, Department of Clinical Science, University of Bergen, Bergen, Norway; *[2]Gade Laboratory for Pathology, Department of Clinical Medicine, University of Bergen, Bergen, Norway*; *[3]Department of Life Science and Technology - Biology and Medical Laboratory Research, Van Hall Larenstein, University of Applied Sciences, Leeuwarden, Netherlands*; *[4]Centre for Diabetes Research, Department of Clinical Science, University of Bergen, Bergen, Norway*; *[5]Department of Rheumatology, Haukeland University Hospital, Bergen, Norway*; *[6]Department of Clinical Science, University of Bergen, Bergen, Norway*; *[7]Department of Pathology, Haukeland University Hospital, Bergen, Norway*; *[8]Flow Cytometry Core Facility, Department of Clinical Science, University of Bergen, Bergen, Norway*

Purpose: Receptor tyrosine kinases Tyro3, Axl, Mer (TAM) and their ligand Gas6 are involved in the phagocytosis of apoptotic cells, and defects in their signaling have been linked to various autoimmune diseases. Their association with Sjögren's disease (SjD) has also been investigated but their exact involvement remains elusive. We here analyzed expression levels of Tyro3, Axl, Mer and their ligand Gas6 in patients with SjD to explore if potential defects in clearance of apoptotic cells might be involved in SjD.
Methods: ELISA was used to examine plasma concentrations of the soluble forms of Tyro3, Axl, Mer and free Gas6 from 20 SjD patients and 20 age-matched healthy controls. mRNA levels were analyzed in peripheral blood mononuclear cells (PBMCs) from the same cohort by RT-PCR. We further analyzed TAM receptor expression of PBMCs from 16 SjD patients and 8 healthy controls using multi-color flow cytometry. In addition, immunohistochemistry was used to evaluate the expression of TAM receptors and their ligand Gas6 in labial salivary gland tissue from 8 SjD patients and 4 non-SjD sicca controls.
Results: While there were no significant differences in plasma, a significant decrease in the mRNA levels of Tyro3 and Mer were observed in patients. This significant decrease could not be confirmed at the protein level using flow cytometry, even though patients tended to have lower expressions of Tyro3 and Mer in most cell populations analyzed. In addition, we observed a significant reduction in the frequencies of different dendritic cell subsets in patients. In labial salivary glands, a slightly higher expression of Axl was observed in SjD patients than controls. Moreover, macrophages and dendritic cells were detected in higher numbers in patients compared to controls.
Conclusion: We found alterations in TAM receptor expression in SjD patients compared to healthy controls and non-SjD sicca controls, but further research is needed to understand their role in the pathogenesis of the disease.
Sources of contributed support: Flow cytometry analysis was performed at the Flow Cytometry Core Facility, Department of Clinical Science, University of Bergen, Norway. Financial support: Broegelmann Foundation, Western Norway Regional Health Authorities (grant nr. 912065) and Meltzer Foundation.

Purpose: Sepsis is a life-threatening, multifactorial disease with a dysregulated host response. Neutrophils and Neutrophil Extracellular Traps (NETs) have been shown to contribute to the pathogenesis of sepsis, although the exact pathomechanism is not yet fully understood. Changes in the glycosylation of the Fc glycan of immunoglobulin G (IgG) have also been reported for sepsis. In this study we investigated the possible contribution of neutrophils/NETs to the alteration of IgG N-glycans in a mouse model of sepsis.
Methods: To examine the changes in N-glycosylation of IgG in a murine sepsis model in C57/BL6 and BALB/c mice over time, we employed mass spectrometry and specific lectin ELISAs. In addition, we analyzed the IgG subclass distribution, cytokine expression and activity of neutrophil elastase (NE) as a marker for NETs. Finally, we depleted neutrophils from the circulation of the mice using an antibody and assessed the IgG N-glycosylation using lectin ELISAs.
Results: Over the time course of the experimental sepsis, we detected an increased activity of NE as a surrogate for NETs and neutrophil-associated cytokines such as the keratinocyte chemoattractant (KC). With regard to N-glycosylation of IgG, we observed an increase in fucosylated and α1,3-galactosylated N-glycans and a decrease in sialylation, but not for all subclasses analyzed. After depletion of the neutrophils from the circulation, the exposure of fucose and α2,6-linked sialic acid was changed over time.
Conclusion: Induction of sepsis leads to increased activity of NE, expression of neutrophil-associated cytokines and changes in the N-glycosylation pattern of IgG, all of which are associated with inflammation. Depletion of neutrophils alters the exposure of the aforementioned N-glycans, indicating a role for neutrophils/NETs in these glycosylation pattern changes.

Using biorthogonal (CLICK) chemistry to measure nutrient uptake flux in single immune cells.

Connor Corrigan[1], Luuk Reinalda[2], Sander van Kasteren[2], David Finlay[1]
[1]Trinity College Dublin, Dublin, Ireland; *[2]Leiden university, Leiden, Netherlands*

Nutrient uptake and utilisation are critical for the regulation of appropriate immune responses. Traditional technologies such as Seahorse-analysers and metabolomics rely on large numbers of pooled cells to measure metabolism. While these methods have revealed novel findings about immune cell metabolism, there is now a pressing need to accurately measure the metabolism of immune cells at the single cell level.
We have developed a new technology to accurately measure nutrient uptake, the first rate-limiting step for cellular metabolic pathways, using a biorthogonal chemistry (CLICK-chemistry) based approach. This involves using a minimally modified nutrient, containing a CLICK handle, that is taken up by the cell by the normal route. A fluorophore is then attached to the CLICK-nutrient after transport has occurred. This is achieved using a CLICK-reaction. This allows for fluorescence-based quantification of uptake into individual cells using flow cytometry.
This CLICK approach has been used to develop an accurate assay for SLC1A5 amino acid uptake; SLC1A5 is the major glutamine transporter in immune cells. Using this assay, we have demonstrated the metabolic heterogeneity of complex immune populations including splenocytes and developing thymocytes.
Current assays for measuring the uptake of fatty acids (FA) into cells rely upon BODIPY tagged fatty acid molecules. However, BODIPY is a highly hydrophobic molecule and has been show to have altered subcellular localisation characteristics. We have used CLICK-based technology to measure FA uptake using minimally modified oleic acid analogues, alkyne-oleic acid and Sterculic acid (StA). Uptake of both CLICK-FA was measured into diverse immune cell subtypes with single cell resolution. The highest uptake was observed in immune cells with known preferences for FA as fuels and those with highest expression of FA transport proteins such as CD36, such as macrophages and cDC1. Data using CD36-KO mice show that CD36 contributes to CLICK-FA uptake but other transport mechanisms are also involved.
Using multiple CLICK-based probes and configurations it is possible to perform 3 CLICK reactions in each individual immune cell. Using this we have simultaneously measured SLC1A5 uptake, FA uptake and rates of protein synthesis (using a CLICK-puromycin) providing 3-dimensional metabolic flux analysis in each individual cell.

Spatiotemporal cellular dynamics related to germinal center reaction in regional lymph node of COVID-19 lungs based on in-situ hybridization at single-cell resolution

YoungMin Woo[1;2], Taehwan Oh[1], Jung Joo Hong[1;2]
[1]Korea Research Institute of Bioscience and Biotechnology, Cheongju, Chungcheongbuk, South Korea; *[2]Korea University of Science & Technology, Daejeon, South Korea*

In severe cases of acute respiratory syndrome coronavirus 2 (SARS-CoV-2), the integrity of lymph node structures may be compromised, making the recovery process in convalescent subjects a vital area of study. Our study aims to unravel the nuances of structural recovery, dynamics of germinal center (GC), and their role in sustaining long-term immune memory in non-human primates recovered from SARS-CoV-2. Here, we employed the Xenium In-situ (10x Genomics) to analyze the composition of immune cells and the structure of mediastinal lymph nodes in the lung of macaques with COVID-19, tracking changes from the primary infection through to recovery and subsequent infection. Significant observations within lymphoid follicles include an increase in GC B cells during convalescence, and helper T and plasma cells during reinfection. In the paracortex area, reinfection leads to a decrease in NK cells but an increase in helper T and conventional dendritic cells. In the medulla, a reduction in macrophages is observed, accompanied by increased helper T, GC B, and plasma cells during reinfection. This study not only enhances our understanding of GC formation during COVID-19 recovery but also provides insights into immune cell repopulations within draining lymph nodes following reinfection. Such insights could be instrumental in refining vaccine approaches and developing targeted therapeutic strategies.

Phosphatase of regenerating liver-1 regulates the activity of Lck during early T cell receptor signalling.

Carlos Carrasco Padilla[1], Oscar Aguilar Sopena[1], Alvaro Gomez Moron[1], Raúl Torres Ruiz[2], Sandra Rodriguez Perales[2], Noa Martín Cófreces[3], Pedro Roda Navarro[1]
[1]Department of Immunology, Ophthalmology and ENT, School of Medicine, Universidad Complutense de Madrid and 12 de Octubre Health Research Institute (imas12), Madrid., Madrid, Spain; *[2]Molecular Cytogenetics and Genome Editing Unit, Human Cancer Genetics Program, Centro Nacional de Investigaciones Oncológicas (CNIO), Madrid., Madrid, Spain*; *[3]Immunology Service, Instituto de Investigación Sanitaria del Hospital Universitario La Princesa, IIS-Princesa, UAM, Madrid, Spain, Madrid, Spain*

Purpose: Activity of the Src kinase Lck has been proposed to be regulated by trafficking to signalling competent sites via the endosomal recycling compartment. We speculated that phosphatases of regenerating liver (PRLs), proteins trafficking through endosomal compartment and proposed to regulate Src kinases in cancer, might regulate Lck activity during initial T cell activation.
Methods: To study Lck regulation by PRLs, the PRL-1/2 expression were knocked out (KO) by using CRIRPR/Cas9 editing in the Jurkat cell line. Traffic of the active state of Lck (aLck) was evaluated, by measuring the phosphorylation of the activating tyrosine residue 394 (pY394-Lck). Lck activity was measured by initial ZAP70 phosphorylation upon TCR stimulation.
Results: A strong compensated expression of PRL-1 was found in PRL-2 KO, while PRL-2 KO showed a weak PRL-1 overexpression. PRL-1 KO reduced CD71 expression in plasma membrane and aLck traffic to CD71 compartment and cortical F-actin, a potential T cell activation site. Although PRL-2 KO reduced CD71 expression in plasma membrane, the aLck traffic was not affected. Evaluation of aLck levels in KOs and in cells overexpressing fluorescent-fusion PRL-1 and PRL-2 proteins indicated that catalytic activity and localisation of PRL-1 to plasma membrane promoted the aLck. Due to PRL-1 promoting role for Lck activity, PRL-1 KO hampered the delivery of aLck to nascent cognate interactions and early Lck activity. PRL-2 KO heightened Lck activity during later stimulation, a phenotype, probably originated from PRL-1 overexpression or from regulatory role of PRL-2 in Lck activity at later signalling. Moreover, immunoprecipitation revealed the interaction of PRL-1 and Lck in resting and stimulated cells, supporting an aLck regulation by PRL-1.
Conclusion: We propose PRL-1 is a regulator of CD71 expression at plasma membrane and is required for proper traffic of aLck to TCR signalling competent sites and for the initial TCR emanating signals. Although PRL-2 also regulate CD71 expression at the plasma membrane, our data points to PRL-2 as negative indirect regulator of aLck and ZAP70 signalling at later events during TCR stimulation. At any event, we propose that balance expression of PRLs, might contribute to appropriate TCR emanating signalling by regulating Lck activity.

Vesicle transport inhibitors induce weak Nur77 expression in murine iNKT and B cells, potentially leading to false positive signals

Yavuz Mercan[1;2], Gerhard Wingender[2]
[1]*Izmir International Biomedicine and Genome Institute, Dokuz Eylül University, Izmir, Turkey*; [2]*Izmir Biomedicine and Genome Center, Izmir, Turkey*

The Golgi transport inhibitors monensin and brefeldin A are widely used to facilitate the cytokine measurement in stimulated cells by intracellular cytokine staining. They block the intracellular vesicle transport at the trans-Golgi (monensin) or cis-Golgi (brefeldin A) network and accumulate cytokines intracellular which normally would have been secreted. Lymphocyte activation down-stream of the T cell receptor (TCR) or B cell receptor (BCR) can alternatively be measured by the rapid expression of the transcription factor Nur77 (NR4A1). However, Nur77 is also involved in endoplasmic reticulum (ER) stress-induced apoptosis. Given that vesicle transport inhibitors can induce ER stress, we hypothesized that the use of monensin or brefeldin A could also induce the expression of Nur77. Therefore, we incubated mouse splenocytes with monensin or brefeldin A with or without PMA/ionomycin stimulation and analysed Nur77 expression in conventional T cells, invariant Natural Killer T (*i*NKT) cells, and B cells by flow cytometry. PMA/ionomycin stimulation induced a strong expression (approx. three-log increase) of Nur77 in the majority of analysed T and B cells (>70% Nur77+ cells). However, the incubation of splenocytes with only monensin or brefeldin A for four hours *in vitro* also induced a weak expression (approx. 1/2-log increase) of Nur77 in approx. 4-8% of the *i*NKT cells and B cells. The increase of the Nur77-signal in conventional T cells did not reach statistical significance. Similar data were obtained with mouse mononuclear cells from mesenteric lymph nodes (mLNs). The direct link between ER stress and Nur77 expression is currently explored. In summary, our data indicate that the widely used vesicle transport inhibitors monensin and brefeldin A can induce a weak expression of Nu77 in *i*NKT and B cells in the absence of antigenic activation. As such a weak Nur77-expression could be wrongly interpreted as a sign of cell stimulation, our data highlight a source of potential false positive signal.

Maternal microbial metabolites in the fetal intestine and their effects on immunomodulation and epithelial function

Roselydiah Makunja[1], Arina Maltseva[1], Tiina Pessa-Morikawa[1], Masuma Khatun[2], Ville Koistinen[3;4;5], Olli Kärkkäinen[4;6], Niko Paalanne[7], Kati Hanhineva[3;4;5], Terhi Ruuska[7;8], Mikael Niku[1]
[1]Veterinary Biosciences, University of Helsinki, Helsinki, Finland; *[2]Department of Obstetrics and Gynecology, University of Helsinki, Helsinki, Finland*; *[3]Food Sciences Unit, Department of Life Technologies, University of Turku, Turku, Finland*; *[4]Afekta Technologies Ltd, Kuopio, Finland*; *[5]Institute of Public Health and Clinical Nutrition, School of Medicine, Kuopio, Finland*; *[6]School of Pharmacy, University of Eastern Finland, Kuopio, Finland*; *[7]Research Unit of Clinical Medicine, University of Oulu, Department of Pediatrics and Adolescent Medicine, University of Oulu, Oulu, Finland*; *[8]Biocenter Oulu, Oulu, Finland*

Purpose: Maternal microbial metabolites, transported across the placenta, may play a crucial role in modulating the development of the intestinal immune system already during the fetal development. Using non-targeted LC-MS/MS (QTOF) metabolomics, we have shown that 2200 metabolites were significantly less abundant in fetuses and placentae of germ-free (GF) mice compared to specific pathogen free (SPF) mice. Approximately 150 metabolites were undetectable in GF fetal tissues. Many of these metabolites showed strong correlations with the expression of genes related to host-microbe interactions, innate immunity, and intestinal epithelial barrier in fetal intestine of SPF mice.
Methods: We have created a new LC-MS/MS dataset comparing the fetal metabolomes across mammalian species, including human newborn meconium and amniotic fluid, and fetal intestines from mice, pig, and cattle. The new, more precise Orbitrap data enables the identification of many of the previously unannotated metabolites, using MS/MS libraries in MS-DIAL 5 and structure prediction by substructure annotation in the Sirius software. Integration with our previous data from mice allows us to identify potential microbial metabolites with immunomodulatory roles in the large mammalian dataset. To asses if these metabolites activate aryl hydrocarbon receptor (AhR), an essential sensor of microbial metabolites, we use human hepablastoma cell line HEPG2. Effect of these metabolites on immune responses and the intestinal epithelium are studied using macrophage-like cells derived from THP-1 and U937 and the Caco-2 cell line. As an efficient in vivo model of intestinal immune system development, we will use GF zebrafish embryos.
Results and conclusions: We observed many known immunomodulatory microbial metabolites in the newborn and fetal intestinal samples, including indoles, serotonin, glutamyl dipeptides and bile acids. In addition, we detected multiple metabolites which have not been previously explored in this context, but are likely modulated by the maternal microbiota, based on significantly lower levels in GF mice. Our observations suggest that the development of the intestinal immune system in humans and other large mammals is modulated by a rich array of maternal microbial metabolites already before birth.

Development of an Immunoassay for Quantification of Soluble Human CD40L (CD154) in Plasma Samples

Kathrine Pedersen[1], Nick Stub Laursen[2], Annette Gudmann Hansen[1], Yaseelan Palarasah[3], Steffen Thiel[1]
[1]*Department of Biomedicine, Aarhus University, Aarhus, Denmark*; [2]*Commit Biologics ApS, Aarhus, Denmark*;
[3]*Department of Molecular Medicine, University of Southern Denmark, Odense, Denmark*

Purpose: Autoantibody production by autoreactive B cells are central aspects in autoimmune diseases such as Systemic Lupus Erythematosus (SLE). Signaling through the CD40-CD40L pathway provides a fundamental co-stimulatory signal for B cell activation. Dysregulation of the CD40L:CD40 axis is associated with inflammatory and autoimmune diseases and increased levels of soluble CD40L (sCD40L) in the blood is implicated in many diseases involving cardiovascular diseases, autoimmune diseases as well as some types of cancer. Thus, sCD40L could serve as a valuable marker of disease; however, to do so, it is of utmost importance to be able to precisely measure and quantify sCD40L levels in a human blood sample.
Methods: We have developed a sandwich-type time-resolved immunofluorometric assay (TRIFMA) for quantification of sCD40L in plasma and serum samples. This was done by generating 29 different monoclonal mouse anti-human CD40L antibodies. From these, we selected the optimal combination of a capture and detection antibody to produce an sCD40L assay. To test the robustness of the assay, we tested the influence of the sample type (comparing different blood collection tubes for serum and plasma sampling), the influence of freeze-thaw cycles, the influence of circadian rhythm on the samples, as well as the influence of sample centrifugation.
Results: We successfully developed an immunoassay for quantification of sCD40L. We found a very similar level of sCD40L in paired EDTA plasma and serum samples (linear correlation, R_2=0.995). In blood samples from 100 healthy blood donors, 61 had a level of sCD40L below the detection level of the assay, while 39 samples had ranging levels of sCD40L from 1.14 to 33.14 ng/mL.
Conclusion: We present a time-resolved immunofluorometric assay (TRIFMA) based on paired monoclonal antibodies, and show high specificity, sensitivity, and homogeneity. The assay presented uses Eu^{3+}-labelled streptavidin in the detecting step, which provides for consistent assay readouts and a broader dynamic range than seen in standard enzyme-linked immunosorbent assays. This assay paves the way for specific and consistent quantification of sCD40L in human plasma and serum samples, allowing for the use of sCD40L as a trustworthy marker of disease.

Similarly reshaped cytokine profile in malignant and autoimmune hematologic disorders

Nino Nanava[1;2], Sophia Metreveli[1], Nino Kikodze[1], Giorgi Giorgobiani[1], Tinatin Chikovani[1], Nona Janikashvili[1]
[1]Tbilisi State Medical University, Tbilisi, Georgia; *[2]Ken Walker International University, Tbilisi, Georgia*

Purpose: Deregulated immune system plays a crucial role in pathophysiology of hematologic diseases particularly autoimmune disorders like immune thrombocytopenia (ITP) and malignancies such as lymphomas and leukemias. Multiple studies have separately indicated a proinflammatory state in ITP and in hematologic malignancies (HM) in which inflammatory cytokines influence the proliferation of both normal and pathogenic cells. In our study we examined pro- and anti-inflammatory cytokines and their ratios in patients with HM and ITP.
Methods: We quantified the concentrations of plasma cytokines TNF-a, IL-17, IL-6, IL-4 and IL-10 in HM and ITP patients and age-matched healthy individuals to compare cytokine production and cytokine ratios. Statistical analysis was performed using Prism Graph Pad and SPSS software. Mann-Whitney U-test was used to compare different study groups: ITP and HM patients and controls.
Results: Our analysis revealed elevated concentrations of TNF-a, IL-6 and IL-4 in both ITP and HM patients compared to the age-matched healthy controls. Conversely, IL-17 level was significantly reduced regardless of the pathology. There was no alteration in IL-10 levels within any patients groups. We observed significantly decreased ratio of TNF-a/IL-6 in HM patients, while this tendency was insignificant in ITP group. However, TNF-a/IL-4, IL-17/IL-4, IL-17/IL-10, TNF-a/IL-6, IL-17/IL-6 and IL-10/IL-6 ratios were significantly reduced regardless the pathology.
Conclusion: Cytokines as major inflammatory mediators instigate the similarly reshaped immune microenvironment in different pathologies. Better understand of cytokine profile similarity or heterogeneity in HM and ITP will serve to identify new effective therapeutic targets for hematologic diseases.

This study was funded by Shota Rustaveli National Science Foundation of Georgia (Grant# PhD_F_17_20 and PhD_F_17_50 received by Nino Nanava and Sophia Metreveli).

Implications of PD-1/PD-L1 pathway as a new immunological paradigm for juvenile idiopathic arthritis

Lata Singh[1], Manisha Supriya[1], Sahar Choudhary[1], Narendra Kumar Bagri[1]
[1]*All India Institute of Medical Sciences, Delhi, India*

Background: Juvenile Idiopathic Arthritis (JIA) is the most common pediatric arthritis disease affecting children below the age of 16 characterized by persistent pain and swelling of joints. It is a group of heterogeneous T-cell mediated autoimmune disease with symptoms of premature aging of the immune system that can lead to significant joint deformities which can cause deterioration of bones, tendons and ligaments and hampering the growth of children through adulthood.
Objectives: The aim of the study was to determine the expression of PD-1, PD-L1, and CTLA-4 in subsets of JIA patients, elucidating their underlying immunomodulatory mechanisms.
Methods: The expression of PD-1, PD-L1, CTLA-4 and FOXP3 was determined by flow cytometry in blood and synovial fluid of 43 JIA patients. ELISA was also performed on all JIA patients to measure the level of soluble form of PD-1, PD-L1, and CTLA-4 in blood samples. The patients' demographic data and treatment will be recorded. JIA will be classified according to the ILAR criteria. JIA activity will be assessed using the JADAS-10 tool.
Results: There was male preponderance (28/43; 65.11%) in our study. Among 43 patients, 12 patients were diagnosed with oligoarticular JIA, 12 with polyarticular JIA, 5 with systemic JIA, 13 patients had enthesitis-related arthritis and one psoriatic arthritis. Expression of PD-1 on CD3+ CD4+ T-cell and CD3+ CD8+ T-cell was found more in synovial fluid than peripheral blood of the patients using flow cytometry. Positivity of PD-1 was different in all the JIA groups. Expression of PD-L1 was decreased in SF and PB of JIA patients as compared to PD-1 expression.
Conclusion: Our finding showed the expression of PD-1/PD-L1 pathway that might provide the elucidation of disease pathogenesis, and the development of potential targeted therapeutic strategies in JIA which may be more specific as compared to conventional disease modifying anti-rheumatic drugs (c-DMARDS).

Crosstalk between innate immune system and bone metabolism is influenced by cell-free DNA quantity and mediated by cyclic GMP-AMP synthase

Patrik Škubica[1], Bhaswarupa Banerjee[1], Marketa Husakova[2], Pavlina Dankova[1]
[1]*Department of Anthropology and Human Genetics, Faculty of Science, Charles University, Prague, Czech Republic*;
[2]*Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic*

Background & Objectives: The ability of blood monocytes (PBM) to differentiate into osteoclasts is a crucial link between innate immunity and bone metabolism, particularly significant in autoimmune-related chronic inflammation, where heightened osteoclast generation/activity leads to pathological bone resorption. Circulating cell-free DNA (ccfDNA) has immunomodulatory properties and its abundance increases during chronic inflammation. While inflammatory cytokines are known to influence osteoclast differentiation, the potential role of ccfDNA in this process remains unknown. This study aimed to investigate the role of serum ccfDNA in osteoclasts differentiation from PBM and the effect of quantitative and qualitative properties (nuclear versus mitochondrial origin) of ccfDNA on osteoclastogenesis.
Methods: To measure nuclear (nc-) and mitochondrial (mt-) ccfDNA content in sera of 47 human subjects, ccfDNA was isolated and quantified using absolute qPCR of single-copy and *MT-ND2* genes. Concentration was calculated from Cp values using control standard curves prepared from whole blood. Pools of sera with varying ccfDNA content were used to culture PBM isolated from healthy individuals (N=25). Two *in vitro* experimental models were employed: 1) serum pools digested by deoxyribonuclease I alongside their undigested counterparts were applied on PBM during osteoclastogenesis, and 2) PBM were cultured in undigested sera after pre-inhibition with G140, a selective inhibitor of cyclic GMP-AMP synthase (cGAS). At the end of culture, osteoclasts were identified by histological staining and counted.
Results:
In contrast to mt-ccfDNA, the number of differentiated osteoclasts positively correlated with nc-ccfDNA concentration in undigested sera ($r=0.51$; $p<0.01$). Osteoclastogenesis decreased 1.8-fold after culturing PBM with sera treated with deoxyribonuclease I ($p<0.0001$), and 1.7-fold in culture where PBM were pre-inhibited with G140 ($p<0.05$). The trend towards a greater effect of ccfDNA digestion by deoxyribonuclease I compared to cGAS inhibition by G140 reflects higher concentration of nc-ccfDNA present in pooled sera specifically used for digestion experiments ($p<0.05$).
Conclusion: These results suggest novel connection between innate immunity and bone metabolism and indicate that serum nc-ccfDNA co-stimulates differentiation of monocytes into osteoclasts in presence of osteoclastogenic signals, at least partially via cGAS. Further study of this phenomenon could provide useful insights for treatment of autoimmune diseases.

Memory T lymphocytes, especially tissue-resident memory T lymphocytes (Trm), are central to immunological memory, yet their residency mechanisms across diverse tissues remain elusive. Here, we present a comprehensive analysis of tissue-specific epigenetic imprints on memory T lymphocytes. Utilizing 58 "reduced representation bisulfite sequencing" (RRBS) datasets encompassing 22 distinct tissue-derived and blood-borne human memory CD4+ and CD8+ T-cell populations, we investigate the methylome profiles. Our findings unveil a nuanced landscape of tissue-specific and shared differentially methylated regions (DMRs) within Trm populations across various tissues. Notably, Trm cells in different tissues exhibit distinct hypo- and hyper-methylated DMRs, highlighting the orchestrated nature of their residency. These DMRs encompass key genes encoding chemokine receptors, integrins, effector functions, and transcription factors. Importantly, we observe enrichment of tissue-specific transcription factor binding sites in hypomethylated DMRs, suggesting their regulatory role. The substantial correlation between DMRs and gene expression may significantly contribute to tissue-specific recruitment, maintenance in steady state, and effector gene expression upon reactivation, including cytokine expression memory. Our study underscores the significance of epigenetic imprinting in shaping immune memory and provides novel insights into Trm dynamics in secondary immune responses. By utilizing tissue-specific DMR signatures, we have demonstrated, for the first time, the mobilization of Trm and their consequential role in systemic secondary immune reactions. This work advances our understanding of memory T lymphocyte residency and opens avenues for deciphering the intricate interplay between epigenetic regulation and immunological memory.

Phospho-flow based immunometabolic biomarkers for pharmacodynamic evaluations: translation from bench to bedside

Bas Smal[1], Diana Pereira[1], Matthijs Moerland[1;2], Lisa van Schijndel[1]
[1]Centre for Human Drug Research, Leiden, Netherlands; *[2]Leiden University Medical Centre, Leiden, Netherlands*

Pharmacodynamic evaluation of investigational drugs targeting immunometabolic pathways is technically challenging, which hampers early clinical evaluation of such compounds. Though various functional assays are described in the public domain, the clinical application of these assays is limited since most work is based on immortalized cell lines, with a completely different immunometabolic profile. We aimed to identify, develop, and validate functional human cell-based pharmacodynamic biomarkers, focused on key junctions in immunometabolic pathways, for future implementation in early phase clinical pharmacology studies.
Human peripheral blood mononuclear cells (PBMCs) were isolated from healthy human donors. PBMCs were challenged *ex vivo* by nutrient starvation or immunometabolic modulating compounds such as dorsomorphin and rapamycin. Pharmacodynamic effects on immune cells were evaluated, such as cell viability and apoptosis, but also more in-depth evaluation such as phosphorylation of mTOR (T2446), RPS6 (S235/236), Acetyl-coA (S79) and AMPK (Thr172) by phospho-flow. Staining's for monocytes and lymphocytes were included allowing differentiation between PBMC cell subsets. Cultures of 24 hours were prepared in media with serum for unstimulated and compound conditions, while glucose- and FBS-deprived media were used for starvation conditions.
Starvation induced cell death in lymphocyte and monocyte populations resulting in 10 to 20% viability drop compared to the unstimulated conditions. A mild increase in apoptosis was observed for all conditions compared to unstimulated. Rapamycin at 200nM strongly inhibited phospho-RPS6 and phospho-mTOR on monocytes, while no inhibitory effect was observed on lymphocytes. Dorsomorphin only strongly inhibited phospho-mTOR in monocytes upon starvation, while no effect was observed on lymphocytes or unstimulated monocytes.
Starvation resulted in a strong increase in phospho-AMPK and a mild increase in phospho-Acetyl-coA. Interestingly, starvation strongly induced phospho-RPS6 while it suppressed phospho-mTOR. Lymphocytes appeared to be unresponsive to all test conditions, even to the well documented control compounds. This may be explained by the naive state of lymphocytes derived from healthy donors.
Monocytes showed a robust response to all test conditions, indicating a clear difference in metabolic activity between monocytes and lymphocytes.

Based on the technical and physiological insights obtained in these experiments, cell-based immunometabolic assays can be selected for pharmacodynamic evaluation of investigational compounds targeting these pathways.

Purpose: T cell function can be inhibited by transmembrane inhibitory receptors. Different inhibitory receptors have different signalling pathways. However, their intracellular distribution remains unclear. These receptors play a crucial role as primary therapeutic targets in cancer immunotherapy. This study investigates how five co-inhibitory receptors, CTLA-4, PD-1, LAG3, TIM3 and TIGIT, differ in their subcellular localisation.
Methods: Confocal and TIRF microscopy were used to study the subcellular and interfacial distribution of inhibitory receptors in murine T cells. APEX2, which catalyses the biotinylation of proximal proteins, was used to elucidate the inhibitor-receptor-containing vesicles by proteomic analysis. Immunoprecipitation was used to detect the trafficking regulators that interact with the inhibitory receptors. Immunofluorescence was used to study the co-localisation of inhibitory receptors and cellular compartment markers.
Results: We observed that a significant amount of CTLA-4, PD-1, LAG3, TIM3 and TIGIT were localised in the intracellular vesicles. TIRF imaging confirmed the distinct spatio-temporal patterns of the above inhibitory receptors. The distinct clustering of the lumenal proteomes containing CTLA-4, LAG3, and TIM3 is visualised by t-SNE analysis. Furthermore, immunoprecipitation revealed that different inhibitory receptors bind to common sorting complexes such as AP-1, AP-2 and ESCPE-1. CTLA-4 distribution was most pronounced, preferentially associated with lysosomal vesicles and the ESCPE-1 machinery.
Conclusion: The five inhibitory receptors were shown to have different subcellular distributions when compared using a variety of metrics, including intracellular clustering, dynamics of plasma membrane insertion, spatial and temporal distribution on the cell surface, and molecular protein neighbourhood. In the absence of evidence supporting the existence of distinct vesicle subtypes to account for the differing distributions of inhibitory receptors, we propose that these distributions are influenced by different trafficking patterns through a shared collection of vesicular compartments. This comprehensive examination of the subcellular distribution of five inhibitory receptors in juxtaposition with one another provides the basis for studying their molecular trafficking and their potential therapeutic applications.

The effects of the hypoosmolar environment developing in hyponatremia on immune system cells

Muhammed Ali Kızmaz[1], Abdulmecit Yildiz[2], Abdurrahman Simsek[1], Demir Kaan Demir[1], Tugce Bozkurt[1], Yusuf Cesmeci[2], Aysegul Oruc[2], Alparslan Ersoy[2], Elif Gullulu[2], Mehmet Sezen[2], Ferah Budak[1]
[1]Department of Immunology, Faculty of Medicine, Bursa Uludağ University, bursa, Turkey; *[2]Department of Internal Medicine, Division of Nephrology, Faculty of Medicine, Bursa Uludag University, bursa, Turkey*

Purpose: Hyponatremia or hypotonicity is characterized by a plasma sodium concentration of less than 135 mEq/L due to the relative or absolute increase in water concentration in the extracellular environment. While the effects of a hypoosmolar environment, especially on astrocytes surrounding neurons and the resulting clinical manifestations, are known, the effects of a hypotonic environment on the immune system remain unclear. This study aims to elucidate the effects of a hypoosmolar environment resulting from hyponatremia on immune system cells.
Method: The study included 20 symptomatic hyponatremia patients suspected of being corrected with water restriction. Serum and urine osmolarities of all patients were analyzed. Peripheral blood samples were obtained from all patients before and after treatment. Lymphocyte, monocyte, and granulocyte subsets were evaluated using a flow cytometer. Additionally, serum concentrations of cytokines including IL-4, IL-5, IL-6, IL-9, IL-17A, IL-21, IL-22, TGF-β, Taurine, and TNF-α were assessed using the ELISA method.
Results: According to the flow cytometry results, the levels of pE2 (pre-effector memory 2) and E (effector) cells, which can produce high levels of inflammatory molecules such as perforin and granzyme B among the CD8+ T cell subsets, increased, while the levels of pE1, EM1 (effector memory 1), and EM4 cells, which have a lower ability to produce these molecules, decreased. There is a pro-inflammatory profile in terms of memory CD8+ T cells in the hypoosmolar environment. An increase in Th1 and Tc1 cells was observed in hyponatremia. A significant increase in Th22/Tc22 cells and a trend of increase in Th17/Tc17 cells were observed. In ELISA analyses, an increase in Th2, Tc2, Th17, and Tc17-associated cytokines was observed during the disease. After treatment, IL-5, IL-6, IL-10, IL-17A, and TGF-β levels decreased, while Taurine levels increased.
Conclusion: According to all analyses, there is a trend of increase in Th17,22 and Tc17,22 cells, which may have pathogenic effects enhancing inflammation. The increase observed in Th22 and Tc22 cells may be a response to tissue damage caused by the stress condition in which the cells are located. ELISA results indicate that, in addition to the pro-inflammatory profile, it also affects type 2 responses.

Functional dissection of RNA modification Pseudouridine in T cells

Vanshika Malviya[1], Thi Cuong Pham[1], Susan Schlenner[1]
[1]*KU Leuven, Leuven, Belgium*

Gene expression is regulated at multiple levels and their orchestrated action is crucial for cell differentiation, homeostasis and function. To this end, RNA undergoes extensive chemical modification, the sum of which is referred to as the epitranscriptome. Of all RNA modifications, pseudouridylation - the conversion of uridine into Pseudouridine is most prevalent. Despite their conservation and causative function in various human diseases, mammalian epitranscriptomics research is only emerging. Pseudouridine is introduced by 13 non-redundant Pseudouridine synthases (PUS). The abundance of Pseudouridine along with the dynamic expression of PUS suggests this modification as a regulatory layer in processes where transcriptomic/proteomic rewiring is necessary such as T cell development and functional differentation.

To dissect the role of pseudouridylation, we use *in vivo* pooled CRISPR screening. To this end, hematopoietic stem cells from $CD4^{Cre}$ $Cas9^{fl\text{-}STOP}$ mice are transduced to express sgRNAs targeting the PUS and then transplanted into lethally irradiated recipient mice. Subsequently, T cell subsets from the engrafted mice are subjected to NGS to assess gRNA representation. Underrepresented gRNAs indicate that knockouts of these PUS have negative consequences for the respective T cell subset and hence identify essential PUS for T cell-relevant pathways.

We identified PUSL1 as potentially ‘essential’ in different T cell subsets - from double-positive T cells in the thymus to regulatory T cells in the small intestine. Our preliminary data suggests PUSL1-mediated pseudouridylation to be crucial in T cell development and activation/function, making it a strong candidate for further characterization.

Using arrayed CRISPR/Cas9 screening *in vitro* and *in vivo* combined with scRNA-seq, we seek to further understand PUSL1-mediated pathways crucial for T cell development and function. Thus, paving the way for further epitranscriptomics research in immunology.

Investigation of the effects of bevacizumab treatment on the immune system in age-related macular degeneration

Ali Eren Iskin[1], muhammed ali kızmaz[1], Abdurrahman Simsek[1], Tugce Bozkurt[1], Tugba Senbuz[1], Elif Kaçmaz[2], Gamze Uçan Gündüz[2], Mehmet Baykara[2], Ferah Budak[1]
[1]Department of Immunology, Bursa Uludag University Faculty of Medicine, Bursa, Turkey; *[2]Department of Ophthalmology, Surgical Sciences, Bursa Uludag University Faculty of Medicine, Bursa, Turkey*

Purpose: Age-related macular degeneration (AMD) is characterized by a progressive decrease in central visual acuity in patients aged 50 years and older, manifested by pigmentary and atrophic changes in the macula. Bevacizumab, used in the treatment of wet AMD, blocks angiogenesis by binding to all subgroups of VEGF and is usually used intravitreally. In this study, we aimed to investigate the effects of Bevacizumab, which is used in the treatment of wet AMD, on immune system cells.
Method: Patients with wet AMD (n: 18) who were admitted to and/or followed up at the Department of Ophthalmology, Uludag University, Faculty of Medicine, Bursa, and who were to receive Bevacizumab treatment and cataract surgery patients (n: 10) as the control group were included in the study. Peripheral blood samples were collected from patients with wet AMD before Bevacizumab treatment and after 3 injections. Peripheral blood samples were also collected from patients with cataract.
Results: $CD4^+CD27^+CD28^+$ EM_1 T-cell frequency was significantly lower in AMD patients compared to cataract patients (p:0.006), while $CD4^+CD27^-CD28^-$ EM_3 T-cell frequency was significantly higher (p:0.018). B10 cells in AMD patients were found to be higher than in cataract patients (p:0.026). On the other hand, it was observed that $CD4^+CD279^+$ exhausted T cells increased (p:0.012) and $CD62L^{low}CD16^{high}$ neutrophil levels decreased (p:0.029) in AMD patients after Bevacizumab treatment.
Conclusion: In AMD patients, EM_3 T-cells, which can produce inflammatory mediators such as IFN-γ at high levels, increased, while EM_1 T-cells, which exhibit low effector activity, decreased. In addition, the high level of regulatory B10 cells in AMD patients indicates that the immune system is trying to stabilize homeostasis. The administration of 3 doses of Bevacizumab in the treatment of AMD seems to mediate the regulation of inflammatory responses by directing proinflammatory T-cells, which were high before treatment, to exhaustion. Similarly, the levels of activated $CD62L^{low}CD16^{high}$ neutrophils, which can produce cytokines such as IL-1β, decreased after treatment. Taken together, the data suggest that an inflammatory state is present in patients with AMD and that Bevacizumab treatment improves these inflammatory processes.

Role of Irisin in Autosomal Dominant Polycystic Kidney Disease

Ali Eren Iskin[1], abdulmecit yildiz[2], Abdurrahman Simsek[1], muhammed ali kızmaz[1], Tugce Bozkurt[1], aysegul oruc[2], alparslan ersoy[2], Ferah Budak[1]
[1]Department of Immunology, Bursa Uludag University, Faculty of Medicine, BURSA, Turkey; *[2]Bursa Uludag University, Faculty of Medicine, Department of Internal Medicine, Division of Nephrology, BURSA, Turkey*

Purpose: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited cause of end-stage renal failure in adults. It is seen with a frequency of 1/400 to 1/1000 in the population. PKD1 and PKD2 gene mutations are observed in 85% and 15% of affected families, respectively. Decreased intracellular 5′ AMP activated protein kinase (AMPK) activity is one of the most important features of the disease and drugs that increase AMPK activity are being tried in treatment.
Irisin is a protein identified in muscle tissue that causes energy expenditure by converting white adipose tissue into brown adipose tissue. Irisin is a myokine formed from fibronectin type III domain-containing protein 5 (FNDC5) by degradation as a result of AMPK activation and is negatively correlated with oxidative stress and inflammation.
In this study, irisin levels in early stage ADPKD were compared with healthy control group.
Methods: A total of 90 early stage ADPKD patients and 70 healthy controls were included in the study. All patients were recruited from the Turkish Society of Nephrology Cystic Kidney Disease Study Group Data Sheet and had a positive family history. Patients with GFR-EPI less than 60 ml/min and patients with active infection were excluded. Sera from ADPKD patients and healthy controls were portioned and stored at -20°C until the study date. Irisin protein level was determined by ELISA kit (BT LAB, China).
Results: In patients with ADPKD, irisin level (ng/ml) was found to be significantly lower than in healthy controls ($p<0.001$) (Figure 1). In addition, a significant inverse correlation was observed between irisin levels and blood urea nitrogen (BUN, mg/dL) and creatinine (mg/dL), while a significant positive correlation was found with glomerular filtration rate (GFR, ml/min) in ADPKD.
Conclusion: In our study, we showed that irisin levels were significantly lower in ADPKD. This decrease may be related to low AMPK activation, which is a phenotypic feature of the disease. In future studies, the relationship between oxidative stress and inflammation and irisin should be investigated.

Dissecting the immune microenvironment in a High Grade Serous Ovarian Cancer murine model following Platinum treatment and epigenetic modulation

Michele De Luca[1], Francesca Basso[2], Barbara Belletti[2], Mario Paolo Colombo[3], Delia Mezzanzanica[1], Gustavo Baldassarre[2], Elena Jachetti[3]
[1]Unit of Integrated Biology of Rare Tumors, Department of Experimental Oncology, IRCCS Fondazione Istituto Nazionale dei Tumori, Milan, Italy; *[2]Division of Molecular Oncology, IRCCS CRO National Cancer Institute, Aviano, Italy*; *[3]Molecular Immunology, Department of Experimental Oncology, IRCCS Fondazione Istituto Nazionale dei Tumori, Milan, Italy*

Purpose: High Grade Serous Ovarian Cancer (HGSOC) is a challenging disease characterized by TP53 mutations and defects in DNA repair (dDR). Debulking surgery and platinum-based chemotherapy is the standard care. The introduction of PARP inhibitors (PARPi) as first-line maintenance treatment for patients with dDR changed patients' prognosis, but eventually resistance occur. dDRs alter immune response, suggesting that tumor immune microenvironment (TiME) can be exploited in HGSOC therapy. G9a/GLP histone methyltransferase, overexpressed in HGSOC, negatively regulates gene expression, promotes DNA damage repair and perturbs the TiME. This study aims to dissect HGSOC TiME contribution in response to PT/PARPi, and the involvement G9a inhibitors (G9ai) in harnessing the TiME through combinatorial therapy.
Methods: TP53-PTEN-KO ID8 murine ovarian cancer cells were injected *i.p.* in syngeneic C57BL/6 mice. 4 days after ID8 injection, mice were treated with saline, PT, G9ai and their combo three times/week and sacrificed at 11 or 21 days of treatment. Treated tumor-free mice were used as control. Flow cytometry analysis of ascites, spleen, lymph nodes and bone marrow was performed to assess modulation of myeloid and lymphoid cell populations.
Results: No significant differences were noted in tumor-free mice receiving the different treatments. In tumor-bearing mice, the major changes were observed in ascites, whose volume decreased in the combo-treated mice. Most alterations in TiME are noticeable at early treatment and related to the expansion of regulatory T cells (Tregs), mast cells (MCs), and type 1 dendritic cells. Here, Tregs coproduce IL-10 and IL-17. We also found an increase of $Ki67^{+}OX40^{+}CD8^{+}$T cells and Granzyme B producing $CD49b^{+}$NK, as if these cells were early activated after the combo. No significant changes were observed in the other tissues considered. Conversely, immune cells are drastically reduced in combo-treated mice at late time-point, suggesting that early modifications can shape tumor growth.
Conclusion: In our *in-vivo* model, the PT-G9ai combo therapy shapes the TiME towards activation. The possible skewing of Tregs into a Th17-like phenotype and the concomitant accumulation of MCs, that can counteract Treg suppressive activity fostering Treg-Th17 differentiation, suggest of deeply investigating the MC-Treg-Th17 network in our setting.

Role of autophagy in antitumor activity of human NK cells

Piera Filomena Fiore[1], Ignazio Caruana[2], Nicola Tumino[1], Maria Teresa Bilotta[1], Sergio Forcelloni[1], Francesca Nazio[3], Lorenzo Moretta[1], Paola Vacca[1]
[1]Bambino Gesù Children's Hospital, rome, Italy; *[2]University Hospital of Würzburg, Würzburg, Germany*; *[3]University of Rome Tor Vergata,Rome, Italy*

Purpose: Natural killer (NK) cells are cytotoxic lymphoid cells that play a crucial role against different tumors. Indeed, NK cells are considered a great promise in cellular immunotherapy. On the other hand, cancer cells can inhibit NK cell function by creating a hostile microenvironment. Consequentially, tumor microenvironment (TME) results in tumor resistance and decreased efficacy of NK cell-based immunotherapy. Autophagy is a self-degradation process crucial for maintaining cellular homeostasis. Although it has been shown that autophagy regulates the immune system, its role in human NK cell biology remains to be clarified. Autophagy is activated by stress and physiological conditions such as nutrient deprivation, hypoxia, cell differentiation, or activation. In TME, the NK cells are subjected to stress conditions. Thus, regulating autophagy may affect the NK anti-tumor activity and improve cellular stress response in the tumor microenvironment.
Methods: To evaluate the autophagic flux in different NK functional states, the expression of genes involved in the critical steps of autophagy was analyzed in NK cells isolated from peripheral blood (pb-NK) and expanded NK cells (ex-NK) upon cytokine stimulation. To investigate autophagy on NK cell homeostasis and cytotoxic activity, the autophagic flux was manipulated by drugs and genetic manipulation of the autophagy-related gene (ATG).
Results: NK-activating cytokines can modulate the autophagic status. Indeed, deprivation of pro-survival and pro-cytotoxic cytokines induces autophagy in both pb-NK and ex-NK cells. However, pharmacological and genetic modulation of autophagy can affect the NK cytotoxic activity.
Conclusion: Autophagy influences the NK anti-tumor performance, modulating their cell cytotoxicity. The regulation of autophagy represents a crucial tool to counteract the inhibitory effect of low pro-survival factors in the TME. The modulation of autophagy in NK cells represents a novel strategy to boost NK cell-based cancer immunotherapy.

Investigating the role of E3 ubiquitin ligase Pellino1 in B cell antigen uptake

Pratiti Nanda[1], Nawal Khan[1], Theresia Allo Anginan[1], Dessi Malinova[1]
[1]*Queen's University Belfast, Belfast, United Kingdom*

Long-term protective antibody responses depend on B cell activation through a specific interaction between the B cell receptor and its cognate antigen. Upon binding, the BCR-antigen complex is also internalised resulting in antigen processing and presentation via MHC class II to initiate T cell responses. The process of BCR-antigen internalisation – while essential for normal immune function – is also crucial to prevent hyperactivation. Thus, internalisation influences BCR signalling and vice versa, but the regulators of this critical interconnection remain unknown.
A recent genome wide CRISPR screen identified E3 ubiquitin ligase Pellino1 (Peli1) as a novel regulator of BCR trafficking. This project aims to identify the targets of Peli1 in B cells, determine its role in BCR uptake and signalling events. We demonstrate increased BCR uptake and antigen presentation in primary and Ramos B cells upon Peli1 knockout – the first example of negative regulation of the BCR by an E3 ubiquitin ligase. Despite increased antigen presentation, murine germinal centre responses upon immunization were significantly reduced.
Using SILAC mass spectrometry, we have identified specific cellular pathways coordinated by Peli1 in human Ramos B cells, including endocytic and structural proteins, metabolic regulators and signalling components. Subsequently, via the Seahorse assay we have validated novel roles of Pellino1 as a metabolic regulator in B cells with Peli1 knockout cell lines exhibiting increased basal metabolism, maximal mitochondrial respiration, and upregulation of known metabolic regulators such as GSK3α/β via western blot. Finally, we have seen increased intracellular Ca^{2+} signalling upon Pellino1 knockout.
Taken together our findings highlight an important role of Pellino1 in B cell metabolism and signalling, with a potential to bridge the gap between BCR signalling and endocytosis. Its role as a negative regulator of B cell activation opens further research questions and therapeutic potential in malignancy and autoimmunity.

AKNA is a novel RNA-binding protein that localizes to the centrosome and regulates the germinal center reaction

Lisa Kifinger[1;2], Gesine Behrens[1;2], Rosa Schmitz[1], Anneli Petes[1], Kai Höfig[2], Juliane Merl-Pham[2], Stefanie Hauck[2], Joao Guimaraes[3], Henning Urlaub[4], Magdalena Götz[1;2], Vigo Heissmeyer[1;2]
[1]Biomedical Center Munich, Ludwig-Maximilians-University, Munich, Germany; *[2]Helmholtz Zentrum, Munich, Germany*; *[3]Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal*; *[4]Max Planck Institute for Biophysical Chemistry, Göttingen, Germany*

The presence of RNA at the centrosome has been known for a long time, and more recently also RNA-binding proteins have been found associated with this organelle, but a functional role remained unclear. These RNA-binding proteins might be involved in transporting RNAs to the centrosome, where local translation can occur. The AKNA gene has been implicated in several diseases including microcephaly and Sjögren's syndrome. Originally, the AKNA protein was proposed to localize to the nucleus, and since it harbors an AT-hook, it was thought to interact with AT-rich DNA or potentially also RNA. A recent study revealed that AKNA is rather a cytosolic, centrosomal protein that regulates microtubule organization during neurogenesis.
In this study, we establish that AKNA is a novel RNA-binding protein. We show that the AT-hook localizes the protein into the RNA/protein-adducts containing interphase after orthogonal organic phase separation (OOPS) of UV-crosslinked cells. Furthermore, individual-nucleotide crosslinking and immunoprecipitation (iCLIP) in immune cells suggests binding of AKNA to mRNAs encoding for proteins of the cytoskeletal machinery and actin-nucleation complex. The strong upregulation of AKNA early during lymphocyte activation and the localization to the centrosome in B and T cells during immune synapse formation suggest an importance for adaptive immunity. Indeed, in mixed lymphocyte reactions, AKNA is required in antigen-presenting cells (APCs) for effective T cell activation and proliferation. Upon immunization of AKNA knockout mice, we find an impaired germinal center reaction, which depends on tightly controlled interactions between lymphocytes with APCs to generate high-affinity antibody-producing plasma cells and memory B cells. Currently, we study how AKNA regulates B cell-T cell interactions and immune synapse formation via its RNA-binding activity. In ongoing experiments, we aim to decipher previously unrecognized immune regulatory mechanisms by centrosomal RNA-binding proteins.

Deficiency in nitric oxide production by myeloid cells during LPS-induced inflammation in naked mole-rats H. glaber

Ekaterina Gorshkova[1;2], Ekaterina Gubernatorova[1], Svetlana Purtova[1], Olga Averina[2], Michael Adrianov[2], Mikhail Vyssokikh[2], Marina Drutskaya[1;3], Sergei Nedospasov[1;2;3]
[1]Engelhardt Institute of Molecular Biology, Russian Academy of Sciences, Moscow, Russian Federation; *[2]Belozersky Institute of Physico-Chemical Biology, Lomonosov Moscow State University, Moscow, Russian Federation*; *[3]Sirius University of Science and Technology, Sirius, Russian Federation*

Naked mole-rat (NMR) is a long-lived rodent highly resistant to cancer and age-associated disorders. The immune system of NMR possesses a unique cellular composition with the prevalence of myeloid cells. It was reported that NMR macrophages activated with lipopolysaccharide (LPS) and interferon-gamma exhibit reduced nitric oxide (NO) production *in vitro* as compared to mouse macrophages. Moreover, upon classical macrophage activation genes involved in arginine metabolism demonstrate different expression patterns between the two species. We hypothesized that under inflammatory conditions NMR myeloid cells located in the blood and tissues also have limited capacity for NO induction due to species-specific metabolic adaptations.
To address inflammation-induced species-specific profile of NO metabolism in vivo, we tested two doses of LPS (1.5 or 30 μg/g) in a model of acute systemic inflammation. Blood cellular composition as well as intracellular NO production 24 h following LPS administration were assessed by FACS. Also, the expression of nitrogen metabolism-associated genes and cytokines was analyzed in the spleen, liver and kidney.
NMR demonstrated sickness behavior such as reduced locomotion and food intake, especially pronounced for the high-dose group in correlation with an increase in inflammatory cytokine gene expression in the spleen and the liver. The percentage of $CD11b^+$ $CD14^+$ in the blood was elevated 24 h after LPS challenge in both species. However, intracellular NO levels changed significantly in $CD11b^+$ blood cells 24 h after LPS administration in mice, but not in NMR. Relative expression of *Nos2* increased in a dose-dependent manner in murine liver and spleen, while only high dose LPS upregulated *Nos2* in NMR liver. Interestingly, relative expression of *Gatm* in NMR liver remained unchanged in LPS-treated group, unlike in mice. Since AGAT is a consumer of arginine as a substrate for the first step of creatine synthesis, its expression during inflammation in NMR may imply the predominance of other pathways of arginine utilization than iNOS-catalyzed reactions.
Our findings suggest that the naked mole-rats can tolerate higher doses of LPS due to metabolic adaptations that are associated with altered iNOS activation in myeloid cells.

Combining single-cell short and long-reads sequencing for dissecting immune cell states

Azahara Fuentes-Trillo[1], Mariacristina De Luca[1], Davide Bolognini[1], Luca Seffin[2], Luca Basso-Ricci[3], Alessandro Aiuti[3;4], Serena Scala[3;4], Cecilia Dominguez[1]
[1]Human Technopole, Milan, Italy; *[2]Vita-Salute San Raffaele University, Milan, Italy*; *[3]San Raffaele Telethon Institute for Gene Therapy (SR-TIGET), Milan, Italy*; *[4]IRCCS San Raffaele Scientific Institute, Milan, Italy*

PURPOSE: T-cell populations are heterogeneous cell types with unique cell states that shape adaptive immunity. T-cell differentiation stages can be studied in detail through the characterization of gene expression signatures, where single-cell technologies offer unprecedented resolution. Although short-read data has been widely used to study these signatures at the gene level, alternative splicing and polyadenylation have not been dissected yet thoroughly at single-cell resolution. To address this, we here combine both short and long-read single-cell technologies to characterize transcript-level expression across T-cell states.
Methods: We isolated the following T-cell subpopulations: αβ CD8+ naïve, central memory, effector memory, terminal effectors, and γδ T-cell populations from healthy donor peripheral blood mononuclear cells (PBMCs). We performed 5' scRNA-seq using short-read and long-read sequencing on those sorted populations and total PBMCs. We annotated assembled transcripts, systematically compared high-quality cells across technologies and performed differential gene/transcript expression and differential transcript usage (DTU) analysis.
Results: The number of genes and UMI counts detected per cell was highly correlated between short and long-reads data and we observed reproducible prediction of cell identities with the classifier CellTypist. Transcript categorization from long-reads using *gffcompare* revealed above 70% of reads with complete matches against known transcripts in the GENCODE database, indicating low presence of artifacts. Using this set of annotated transcripts, we were able to detect DTU events. Some of these are well characterized, such as the one affecting the *PTPRC* gene, encoding CD45, which is alternatively spliced between naïve and memory T-cell states.
Conclusion: With the addition of the transcript-level expression layer, we have started to build a comprehensive map of post-transcriptional events across fine-grained cellular states. As a proof of concept, we have compared the protein expression of CD45 against transcript expression in specific sorted T-cell subsets, adding depth to our understanding of this key locus. Furthermore, we studied patterns of transcript usage transcriptome-wide in the continuum of unsorted T cells from peripheral blood. In the long run, this type of analysis holds the promise to not only unravel dynamics of transcript-level expression but also uncover novel isoforms in the context of development or disease.

Dissecting immune cell states in healthy and CMV-infected newborns through single-cell sequencing technologies

Altea Gjurgjaj[1], Azahara Fuentes-Trillo[1], Mariacristina De Luca[1], Luca Seffin[2], Luca Basso-Ricci[2], Andrea Ronchi[3], Lorenza Pugni[3], Alessandro Aiuti[2], Carlo Pietrasanta[3], Serena Scala[2], Cecilia Dominguez[1]
[1]Human Technopole, Milan, Italy; *[2]San Raffaele Telethon Institute for Gene Therapy (SR-TIGET), IRCCS San Raffaele Scientific Institute, Milan, Italy*; *[3]NICU, Department of Woman, Child and Newborn, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy*

Purpose: The adaptive immune system begins to develop in prenatal life but only fully matures years after birth. Unique features, such as lower cytotoxicity or tolerogenic bias, have been reported to characterize neonatal adaptive immunity. Nonetheless, the mechanisms controlling these processes are poorly understood. Neonates encounter a myriad of microorganisms post-birth with diverse outcomes that shape their immune system. Congenital Cytomegalovirus (cCMV) infection, the most common congenital infection (0.2-2.0% of newborns globally), can lead to permanent disabilities, such as hearing loss and neurological deficits. Previous reports have shown that neonatal responses to CMV include activation of natural killer cells and T cells, however, there is a lack of comprehensive evaluation of the immune response in these subjects.
Methods: Here, we present an in-depth analysis of the neonatal immune cell landscape and its changes in cCMV using single-cell genomics (CITE-seq and scV(D)J-seq) to deeply characterize peripheral blood cell phenotypes and antigen receptor features (healthy n = 10; cCMV n = 2). We assessed the frequency and the phenotype of immune cell subpopulations in healthy and CMV-infected neonates compared to adult controls. To this end, we employed automated and manual cell type annotation, differential composition, and differential gene expression analysis.
Results: Our preliminary data indicate that naïve populations within the T and B cell compartments are more prevalent in neonates, as expected. Interestingly, we also find that naïve cells across age groups show differential activation of specific gene programs. In the cCMV neonates, apart from naïve lymphocytes, we also detect the presence of effector memory cytotoxic T cells, which are not evident in their healthy counterparts, opening the possibility to dissect antigen-driven responses in early life.
Conclusions: Overall, we have generated deep molecular profiles of cellular subpopulations in neonates, both healthy and cCMV-infected. We have identified gene signatures unique to neonatal cell states and activated cell states in congenital infection. Future work will on the one hand be focused on increasing our cohort size across age groups and on the other hand on dissecting the role of neonatal specific gene programs in steady state and upon viral infection.

Alterations in the natural autoantibody network during pregnancy in Hashimoto's thyroiditis

Szabina Erdő-Bonyár[1;2], Diána Simon[1;2], Ahmed Badawy[1;2], Anna Bajnok[2;3;4], Ákos Várnagy[2;4], Kálmán Kovács[2;4], Emese Mezősi[2;5], Tímea Berki[1;2]
[1]Department of Immunology and Biotechnology, Clinical Center, Medical School, University of Pécs, Pécs, Hungary; *[2]National Laboratory on Human Reproduction, University of Pécs, Pécs, Hungary*; *[3]Szentágothai Research Centre, University of Pécs, Pécs, Hungary*; *[4]Department of Obstetrics and Gynecology, Clinical Center, Medical School, University of Pécs, Pécs, Hungary*; *[5]First Department of Internal Medicine, Clinical Center, Medical School, University of Pécs, Pécs, Hungary*

Purpose: Hashimoto's thyroiditis (HT) stands as a prevalent autoimmune disorder predominantly observed in women of reproductive age. Although HT is classically considered a T cell-mediated disorder, the presence of pathological anti-thyroid autoantibodies indicates the dysfunction of B cells, which may result in the imbalance of the natural autoantibody (nAAb) network. The regulatory role of nAAbs in tolerance induction has been described, thus the network may also be important in the establishment of the immunological tolerance to the fetus. Consequently, we aimed to investigate nAAbs in pregnant women with HT (HTP) and healthy pregnant women (HP).
Methods: Serum levels of nAAbs in HTP and HP against mitochondrial citrate synthase (CS), heat shock proteins (Hsp60 and Hsp70) were measured using in-house developed ELISA, while anti-cytokine autoantibodies were measured by a Milliplex multiplex immunoassay. Serum samples of patients with Hashimoto's thyroiditis (HT) and healthy, non-pregnant women (HC) were also collected as controls.
Results: We found that nAAb levels of IgM against CS were higher, while levels against Hsps were lower in HP than in HC. Additionally, IgG nAAb levels against Hsps were elevated in HT compared to HC but decreased during the pregnancy of HT patients. An increase in anti-cytokine autoantibodies against TNFα, IFNγ and IL-8 was determined in the first trimester in HP compared to HC, which was not observed in HTP.
Conclusion: We hypothesize that in pregnancy, the physiological nAAb network exhibits a moderate plasticity to regulate immune response and tolerance, which is disturbed in HTP. Our results also support the regulatory role of autoantibodies in the availability and activity of Th1 cytokine IFNγ and inflammatory cytokine TNFα which are considered to be central players in early pregnancy.

Validation of inflammatory markers' association with rheumatic heart disease in an African cohort

Taariq Salie[1], Zahra Parker[1], Timothy Spracklen[1], Liesl Zuhlke[2;3], Mpiko Ntsekhe[4], Mark Engel[1;2]
[1]Cape Heart Institute & Dept of Medicine, University of Cape Town, Cape Town, South Africa; *[2]SA Medical Research Council, Cape Town, South Africa*; *[3]Children's Heart Disease Research Unit, University of Cape Town, Cape Town, South Africa*; *[4]Cardiac Clinic, Groote Schuur Hospital & Dept of Medicine, UCT, Cape Town, South Africa*

Introduction: Rheumatic heart disease (RHD) is a significant contributor to premature morbidity and mortality in sub-Saharan Africa and the global south. Literature supports prompt diagnosis of early stages of RHD with appropriate treatment strategies to prevent disease progression; however, the optimal approach to doing so is contested. Using mass spectrometry and machine learning (ML) algorithms, we recently identified inflammatory proteins likely to be involved in the pathogenesis of ARF/RHD. If validated, these proteins present an opportunity to improve early recognition of ARF/RHD, by incorporating them in the development of a bedside diagnostic tool. Here we document the validation of the previously identified inflammatory proteins in people with severe RHD utilizing immunological assays .
Methods: Serum levels of adiponectin (ADIPOQ), complement C7, gelsolin (GSN) and ficolin-3 (FCN-3) were measured using commercial sandwich ELISA in people with severe RHD (n=70) and healthy controls (n=59). ELISA was performed and quantified according to the manufacturer's instructions, in duplicate; the mean of the duplicates was used for statistical purposes. Statistical analysis was performed using GraphPad Prism 10.0.2 (GraphPad Software, USA). Nonparametric Mann-Whitney and Kruskal-Wallis tests were used to compare differences in protein concentration between the experimental groups. For all results, p-values less than 0.05 were considered significant.
Results: Three proteins (ADIPOQ, C7, GSN) were significantly increased in RHD cases in comparison to controls (p-value: <0.05 respectively). Two of the proteins (ADIPOQ and C7) confirmed the *in-silico* predicted findings of an association with RHD, while GSN contrasted with the negative correlation suggested by the mass spectrophotometry. The fourth protein, FCN-3, showed no significant difference between cases and controls despite a high ranking in our prior ML algorithm.
Conclusions: Preliminary data emanating from this study presents proteins may serve as potential markers for the development of a diagnostic tool that could identify individuals at risk for RHD. The data presented here also provides further evidence that *in-silico* derived data requires laboratory-based validation.

Functional analysis of elongation factor 1 alpha 1 in M1 macrophage differentiation

Eri Shimura[1], Ayako Shigenaga[2], Tadashi Ando[3;4], Ryo Ishihara[1], Takeshi Baba[1], Fumiyuki Yamakura[5]
[1]Faculty of Medicine, Juntendo University, Inzai City, Chiba, Japan; *[2]Institute of Health and Sports Science & Medicine, Juntendo University, Inzai City, Chiba, Japan*; *[3]Department of Applied Electronics, Tokyo University of Science, Katsushika-ku, Tokyo, Japan*; *[4]Research Institute for Science and Technology, Tokyo University of Science, Noda, Chiba, Japan*; *[5]Faculty of Health Science, Juntendo University, Bunkyo-ku, Tokyo, Japan*

Purpose: This study investigates the role of elongation factor 1 alpha 1 (EF1α1) in the differentiation of M1 macrophages. We identified EF1α1 as a protein associated with signal transducer and activator of transcription 1 (STAT1) by co-immunoprecipitation using an anti-STAT1 antibody. Although it is widely recognized that STAT1 is essential for the differentiation of M1 macrophages, the mechanisms underlying its interaction with EF1α1 are not yet fully elucidated. Furthermore, the significance of this interaction in the differentiation and functional capabilities of M1 macrophages remains unclear. Therefore, the purpose of this study is to clarify the biological significance and functional roles of the STAT1-EF1α1 interaction, thereby enhancing our understanding of the regulatory mechanisms governing M1 macrophage differentiation.
Methods: Murine RAW 264.7 macrophages were cultured with lipopolysaccharide (LPS) and interferon-gamma (IFN-γ) for 24 hours to induce M1 macrophage differentiation. Immunoprecipitation using an anti-STAT1 antibody was then performed to explore interactions of STAT1 with other proteins following stimulation. Simultaneously, RAW cells were transfected with EF1α1-targeting siRNA to reduce its expression. After a similar 24-hour exposure to LPS and IFN-γ, transcriptional levels of key genes associated with M1 macrophage differentiation, including EF1α1, were measured using quantitative polymerase chain reaction (qPCR). This experimental setup enabled evaluation of the effects of EF1α1 downregulation on the STAT1 pathway and related inflammatory markers in differentiated M1 macrophages.
Results: RAW 264.7 cells treated with LPS and IFN-γ for 24 hours demonstrated increased expression of M1 macrophage markers. Immunoprecipitation using anti-STAT1 antibodies showed co-precipitation with EF1α1, confirming their association. Additionally, EF1α1 silencing via siRNA led to a pronounced decrease in the mRNA levels of iNOS and NF-κB expression.
Conclusion: The findings of this study suggest the potential interaction between STAT1 and EF1α1 during the differentiation process of M1 macrophages. Additionally, silencing EF1α1 significantly affected the expression of key inflammatory markers such as iNOS and NF-κB, indicating a possible role of EF1α1 in the regulatory pathways of M1 macrophage activation. Further analyses are underway to elucidate EF1α1's role in M1 macrophage differentiation and function.

Ageing impacts the innate immune response to vaccine adjuvants

Alexandra Sanchez-Martinez[1], Gabriella Chappell[2], Anita Milicic[2], Christine Rollier[1]
[1]*University of Surrey, Guildford, United Kingdom*; [2]*University of Oxford, Oxford, United Kingdom*

Immunosenescence encompasses the changes in the immune system with age. Although most commonly associated with a decline in adaptive immunity, immunosenescence also affects innate immunity, which plays a key role in priming robust adaptive responses. These immune alterations can result in a decreased ability to fight infections and reduced vaccine efficacy in later age. Vaccine adjuvants can improve the immune response induced by immunisation; consequently, designing and testing novel adjuvants and understanding their mechanism of action becomes imperative to develop more effective vaccines, particularly for older people.
Purpose: This study aims to assess the effect of ageing on the innate immune response (e.g., the NLRP3 and TLR4 pathways) to vaccine adjuvants using in vitro models of human macrophages from older and younger individuals.
Methods: Fresh peripheral blood mononuclear cells were isolated from healthy younger (20-30 y.o.) and older (>65 y.o.) donors. CD14+ monocytes were then differentiated into macrophages by exposure to macrophage colony-stimulating factor (M-CSF) for seven days. After day 7, these monocyte-derived macrophages (MDMs) were stimulated for 6 h in vitro with different vaccine adjuvants. Control cells were stimulated with LPS and Nigericin. Cell viability was measured using the Cytox96 nonradioactive cytotoxicity assay, and secretion of IL-1β, IL-18 and TNF-α monitored using ELISA.
Results: Human monocyte-derived macrophages (HMDM) from older donors released more IL-1β when exposed to QuilA saponin, Aluminium Hydroxide (Al_2OH_3) or adjuvant combinations MPLA+QuilA and MPL-A+Al_2OH_3 compared to younger individuals. A similar trend was seen in HMDM from older donors when stimulated with LPS+Nigericin. MPL-A alone promoted lower release of IL-1β in older donors compared to younger donors. Interestingly, the adjuvants and LPS+Nigericin stimulation induced lower levels of cell death in HMDM from older donors.
Conclusion: These findings suggest that adjuvants that can activate the NLRP3 inflammasome elicit a more pronounced inflammatory response in older adults. Also, we observed a potentially defective response to TLR4-mediated signalling in the context of ageing, indicating that the choice of adjuvant may need to be tailored to the recipient age bracket. Further assays are necessary to validate the increased NLRP3 activation in older adults and its potential impact on vaccine effectiveness.

Protective effect of cortistatin upon thymic regression

Marina García-Frutos[1], Marta Caro[1], José L. Ruiz[2], Natividad Martin-Morales[3;4], Francisco O'Valle[3], Mario Delgado[1]
[1]Institute of Parasitology and Biomedicine López-Neyra (IPBLN-CSIC), Granada, Spain; *[2]Bioinformatics Unit. Institute of Parasitology and Biomedicine López-Neyra (IPBLN-CSIC), Granada, Spain*; *[3]Department of Pathology, School of Medicine, University of Granada, Granada, Spain*; *[4]Biomedical Research Centre (CIBM), Granada, Spain*

Thymic involution is a hallmark of immunosenescence, the innate and adaptive immune dysfunction that accompanies aging and causes ineffective responses to infections/vaccines, cancer and autoimmunity. Age-related thymus degeneration plays a key role in this process, due to the decline in T-cell production and the imbalance of T-cell proportions, leading to a decreased capacity to sustain immune competence. Additionally, thymus undergoes transient involution as a result of acute insults such as infections, stress or chemotherapy; these effects can be especially detrimental considering the context of an aged-involuted thymus in the elderly population.
Although various cytokines/chemokines, growth factors and neuropeptides/hormones have been proven to regulate thymic regression, the identification of new factors and mechanisms involved in this critical process is an urgent need. The aim of this work is to investigate the role of cortistatin, an immunomodulatory neuropeptide with potential effects in thymic function, in both acute and chronic thymus involution, by mainly using a model of aged cortistatin-deficient mice exposed to systemic infection.
We firstly confirmed the expression of cortistatin in the four main mouse thymocytes populations (CD4+CD8+, CD4+CD8, CD4-CD8+ and CD4-CD8-),and of the cortistatin-receptors SSTR2 and GHSR in thymocytes. Cortistatin deficiency was associated with accelerated age-related thymic atrophy (along 6-24 months), with involvement of changes in CD4/CD8, CD25/CD44 thymocyte populations. Remarkably, we found that 6-month-old cortistatin-deficient mice showed comparable thymic weight/cellularity than that showed by 12-month-old wild-type mice. RNA-sequencing analysis comparing cortistatin-deficient and wild-type thymocytes of 3-/6-/12-month-old mice revealed 450-900 differentially expressed genes, with an enrichment in ribosome biogenesis, ncRNA metabolic and cellular senescence processes.
Moreover, the earlier thymic regression related to cortistatin deficiency may lead to impaired responses to immune challenges. Using an experimental polymicrobial sepsis model, we found that 12-month-old cortistatin-deficient mice showed enhanced thymic involution, dysregulated inflammatory response, more severe clinical/histopathological signs and increased mortality compared to wild-type mice. Furthermore, systemic administration of cortistatin for 4-5 weeks in aged mice appeared to revert thymic involution (higher weight/cellularity, reduced thymocyte apoptosis), and improved immune response to sepsis caused by subsequent polymicrobial infection. Overall, cortistatin seems to play a beneficial role in immunosenescence by attenuating thymic regression.

How an acute stress impacts immunity in elderly patients?

Manon Chauvin[1], Jamila Dhiab[1], Martin Larsen[1], Eric Pedruzzi[1], Hélène Vallet[1;2], Jacques Boddaert[2], Delphine Sauce[1]
[1]Sorbonne Université, Inserm U1135, CIMI-Paris, Pitié-Sâlpétrière, Paris, France; *[2]AP-HP, Unité péri-opératoire gériatrique, Paris, France*

Purpose: Our society faces a major challenge with the management of the health and socio-economic burden caused by aging of the population (older than 75 years). As society ages, the incidence of physical limitations is dramatically increasing, which reduces the quality of life and increases healthcare expenditures. In western society, ~20% of the population over 60 years is confronted with moderate or severe physical limitations. This fragility results in a higher morbidity and mortality where the deleterious role of inflammation is often debated. In this context, we used hip fracture (HF) as an acute stress model that accelerates the progressive course of aging. Nowadays, this trauma, which affects around 1.6 M patients worldwide, is still associated with poor clinical outcomes in the elderly (20-30% one-year mortality; 50% inability to walk). This emphasizes the value of assessing biological factors that may predict clinical outcome after HF.
Our aim is to decipher mechanisms taking place during this medical situation, by comparing immunity from patients with different clinical outcomes (autonomy or death) in order to decrypt the respective pathways involved.
Methods: We analyze longitudinally immunological parameters evocating of the Immune Risk Phenotype in sequential pre- and post-surgical samples collected from HF patients over 75 years of age. Clinical outcomes (death and capacity to walk) were collected retrospectively. The different markers, such as white blood cells count, circulating T- B- & NK-cells (naïve/ memory/activation status), CMV responsiveness, and inflammatory molecules were screened by flow cytometry and Luminex to determine the immune status of such patients.
Results: The study revealed that HF is associated with a profound impairment of immunity. Comparing healthy elderly individuals and HF elderly patients, we found a transient T-cell leucopenia and an acute hyper-inflammation early post fracture. Among this signature, we pinpoint a central role of neopterin (an immune activation marker) which predicts the loss of autonomy and death.
Conclusion: Both innate and adaptive immunity are affected transitory during this medical event which leads to different immune trajectories. The identification of these pathways could result in the development of new therapeutic strategies for better care of the geriatric population.

Shorter supplementation of vitamin D is associated with an inflammatory and senescent immune profile in older people

Maike Mangold[1;2], Dicle Celik[1;2], Valentin Vetter[3], Ilja Demuth[3;4], Beate Kruse[1;2], Manuela Dingeldey[1;2], Andreas Thiel[1;2], Julian Braun[1;2]
[1]Si-M / "Der Simulierte Mensch" a science framework of Technische Universität Berlin and Charité - Universitätsmedizin Berlin, Berlin, Germany; *[2]Berlin Institute of Health at Charité – Universitätsmedizin Berlin, Immunomics - Regenerative Immunology and Aging, Berlin, Germany*; *[3]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Department of Endocrinology and Metabolic Diseases (including Division of Lipid Metabolism), Biology of Aging working group, Berlin, Germany*; *[4]Charité - Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, BIH Center for Regenerative Therapies, Berlin, Germany*

Purpose: Vitamin D is discussed to positively influence several health aspects and sufficient vitamin D levels may help to enhance healthy ageing. Ageing is associated with increased inflammation and immune senescence, comprising changes in the immune cell composition. The risk to develop vitamin D deficiency is particularly high in older individuals. Therefore, the aim was to evaluate the association between vitamin D and immune cell composition in a well characterized cohort of older people.
Methods: Cross-sectional analysis of 24 immune cell populations of 840 participants (mean age = 75.8 years) of the Berlin Aging Study II (BASE-II, mean follow-up of about 7.4 years as part of the GendAge study) was performed using flow cytometry. Blood was sampled across all seasons. All donors were stratified into different groups of serum vitamin D sufficiency, and confounding factors like season of blood collection, morbidity, and vitamin D supplementation were considered by applying strict matching strategies. The participants were predominantly healthy and only n = 23 were vitamin D deficient.
Results: Seasonal changes in vitamin D levels and immune parameters, particularly CD4+ T cells and CD8+ memory T cells (CD8+ CD45RA-), were demonstrated. Independent of season or morbidity, the number of inflammatory monocytes (CD14+ CD16+) was higher with increasing vitamin D levels. Intermediate monocytes (CD14++ CD16+), CD8+ naïve T cells (CD8+ CD45RA+ CCR7+) and CD8+ memory T cells were positively associated with vitamin D levels and even stronger with morbidity. Morbidity was higher in supplemented participants. Short-term supplemented donors (supplementation started between baseline and follow-up) exhibited higher amounts of CD8+ T_{EMRA} (CD8+ CD45RA+ CCR7-), inflammatory and intermediate monocytes as well as decreased CD4/CD8 ratio.
Conclusion: A direct association between vitamin D sufficiency and immune ageing cannot be confirmed. Contradictory, in short-term supplemented donors, a tendency towards an inflammatory and senescent immune profile was detectable. It cannot be excluded that supplementation because of newly diagnosed diseases is linked to this observation as a secondary effect. This study sheds light on the associations between vitamin D, seasonality, morbidity, and immune cell variations during healthy ageing.

Cross-talk between overweight and immunosenescence in healthy adults

Yana Todorova[1], Radoslava Emilova[1], Milena Aleksova[1], Vesselina Koleva[2], Maria Nikolova[1]
[1]National Center of Infectious and Parasitic Diseases, Sofia, Bulgaria; *[2]Acibadem City Clinic Tokuda Hospital, Sofia, Bulgaria*

Purpose: Several studies have demonstrated that obesity and high body mass index (BMI) accelerate inflammaging and are associated with a higher risk of cardiovascular diseases, diabetes type II, and neoplastic processes. The aim of the study was to evaluate whether overweight affected some markers of T-lymphocyte senescence.
Methods: Peripheral blood samples from 29 clinically healthy individuals (12 male and 17 female) aged 21 to 55 were analyzed. Participants were distributed in two groups according to CDC weight category: group A (healthy weight; n=18), BMI (mean, ±SD) 21±2.4 and group B (overweight; n=11), BMI 29±4 (p=0.0001). The percentage distribution of lymphocytes, T-, B-, and NK cells, naïve (CD45RO-CD27+), memory (CD45RO+CD27-) and effector (CD45RO-CD27-) CD4 and CD8 T lymphocytes, proapoptotic (CD57+CD27-) CD8 T, T cells with inhibitory potential (TIGIT+) and activated (HLA-DR+CD38+) T lymphocytes were analyzed by multicolor flow cytometry (FACSCanto II, FACSDiva 6.1.2).
Results: Group A and B participants were similar in age (mean, ±SD) 33±7 and 36±10 (p>0.05). The higher BMI was associated with a higher absolute count of leucocytes (mean, ±SD) 7200±1200 vs 5800±1000 (p=0.006), lymphocytes 2340±474 vs 2026±360 (p=0.05) and B-cells 306±133 vs 209±104 (p=0.02). Group B was characterized with decreased percentage of naïve CD8+ T cells, accumulation of effector memory CD4+ T-cells (23±14 vs 35±10, p=0.03; 38±12 vs 29±10, p=0.05) and elevated proportion of TIGIT+CD8+ T lymphocytes with decreased proliferative potential (42±15 vs 27±9, p=0.01). The BMI inversely correlated with percentage of naïve CD4+ T cells (Rho= -0.48, p=0.005) and was associated with elevated expression of TIGIT+ on helper T-cells (Rho= 0.36, p=0.05).
Conclusion: Our results suggest that a high BMI may accelerate the process of immune ageing, most probably through ongoing inflammation inducing the activation, differentiation, and depletion of CD4 and CD8 T -lymphocyte clones.

Beyond the obstruction: immunological perspectives on aortic stenosis and coronary artery disease

Pablo Alvarez-Heredia[1], Jose Joaquín Domínguez-del-Castillo[2], Irene Reina-Alfonso[1], Monica Espinar-Garcia[1], Isabel Maria Vallejo-Bermudez[1], Carmen Gutiérrez[1], Fakhri Hassouneh[1], Alexander Batista-Duharte[1], Rafael Solana Lara[1;3], Ignacio Muñoz[2], Alejandra Pera Rojas[1;3]
[1]*GC01 - Immunology and allergy. Maimonides Biomedical Research Institute of Cordoba (IMIBIC), Cordoba, Spain*; [2]*Cardiovascular Surgery Unit. Reina Sofia University Hospital, Cordoba, Spain*; [3]*Immunology service. Reina Sofia University Hospital, Cordoba, Spain*

Purpose: It has been shown that the process of aortic valve calcification that occurs in aortic stenosis (AS) shares similarities with the systemic vascular atherosclerotic process leading to coronary artery disease (CAD), indicating a common pathogenesis. Moreover, traditional cardiovascular risk factors like hypertension, hypercholesterolemia, smoking, or diabetes are associated with both AS and CAD. The progression of AS and CAD, like atherosclerosis, involves inflammatory processes, highlighting the complex immunological interplay between these conditions.
Methods: We performed an immunological characterization of both innate and adaptive immune populations in peripheral blood from sex/age matched AS patients (n=58), CAD patients (n=20) and healthy donors (HD, n=55).
Results: Our analysis revealed distinct immune profiles between AS and CAD cohorts. CAD patients exhibited an overall increase in the frequencies of terminally differentiated effector memory T cells (CD4, CD8 and TcRγδ) when compared to AS and HD individuals (p<0.001). Additionally, both frequencies and absolute numbers of CD14+CD16+ monocytes and CD56bright NK cells were increased in CAD patients (p<0.01). In contrast, AS patients exhibited an increased CD4:CD8 T cell ratio compared to CAD patients and HD (p<0.01). Furthermore, AS patients had higher frequency of $CD4+CD28^{null}$ and $CD8+CD28^{null}$ T and an enhanced expression of CX3CR1 and CD57 surface markers in all T cell subsets (p<0.01) in comparison with HD and CAD patients. Moreover, we found lower absolute numbers of dendritic cells (DCs) and their subsets ($p < 0.01$) in AS when compared to CAD patients and HD.
Conclusion: Although AS and CAD share the same pathogenic mechanisms, our research reveals significant differences regarding the immune populations present in the peripheral blood of these patients. Our analysis suggests that CAD patients exhibit an expansion of immune populations associated with inflammation. On the other hand, AS patients show higher level of immunosenescence than CAD patients. These differences suggest the necessity to further investigate the role played by the immune system in the atherosclerotic progress, which varies between these diseases.

Role of β2 integrins on dendritic cells in immunosenescence

Christoph Hieber[1], Yanira Zeyn[1], Nadine Röhrig[1], Evelyn Montermann[1], Matthias Bros[1], Stephan Grabbe[1]
[1]*Department of Dermatology, University Medical Center Mainz, Mainz*

Purpose: This study aims to investigate the multifaceted impact of age-related changes (immunosenescence) in dendritic cells (DC) on the immune system. Specifically, we aim to elucidate the intricate role of β2 integrins, in modulating immune cell function and intercellular communication within the context of aging. By employing a mouse model with a DC-specific knockdown of β2 integrins, we seek to delineate the mechanisms underlying age-associated alterations in DC function (intrinsic effects) and their consequential effects on other leukocytes (extrinsic effects).
Methods: We generated a mouse strain with a DC-specific conditional knockdown of β2 integrins (CD18cKO) by breeding mice with a floxed CD18 gene locus (CD18fl/fl) with CD11c-Cre (DC-restricted expression of Cre recombinase) mice. Leukocytes derived from old (>52 weeks) and young (8-12 weeks) CD18 cKO and WT (CD18fl/fl) mice were compared. Immunophenotyping of primary DC and other immune cells was conducted by flow cytometry, cytokine detection and metabolic assays. Additionally, bone marrow-derived DC (BMDC) were assessed for genotype- and age-dependent effects on DC function, including antigen presentation and T cell activation. Moreover, single-cell RNA sequencing (scRNA-Seq) of spleen cells was performed to better understand the observed intrinsic and extrinsic effects and to find underlying mechanisms.
Results: In old CD18cKO mice, primary DC exhibited lower activation marker expression but increased cytokine production as compared to wild type and young mice. This pattern was also observed in the according BMDC cultures. Furthermore, old CD18cKO BMDC induced stronger IFN-γ production in T cells after three days of co-culture. Additionally, β2 integrin deficiency increased mitochondrial metabolism in BMDC, regardless of age. Moreover, stimulated splenic T cells and B cells from aged CD18cKO mice showed elevated activation marker expression and cytokine production indicative of DC-dependent regulation of either cell type under basal conditions. ScRNA-Seq revealed age- and genotype dependent alterations in immune cell frequencies and gave insight to potential mechanisms of the observed differences.
Conclusion: These findings highlight the significant role of β2 integrins in regulating immune cell function, particularly in the context of immunosenescence. Understanding the mechanisms underlying age-related immune dysregulation could offer insights into therapeutic interventions aimed at restoring immune homeostasis in elderly.

Homelessness and Low Socioeconomic Status Drive Broad Immune Dysregulation and Impair Vaccine Induced Immunity to SARS CoV2

Conor Reddy[1], Ailbhe Herity[1], Matt McElheron[2], Adam Dyer[2], Nicole Roche[3], Jean Dunne[4], Barry Moran[3;5], Jean Fletcher[3], Nollaig Bourke[2], Cliona Ni Cheallaigh[1]
[1]Trinity Translational Medicine Institute, Dept Clinical Medicine, Dublin, Ireland; *[2]Dept Medical Gerontology, Trinity Translational Medicine Institute, Dublin, Ireland*; *[3]School of Biochemistry and Immunology, Trinity Biomedical Sciences Institute, Dublin, Ireland*; *[4]Department of Immunology, St James' Hospital, Dublin 8, Dublin, Ireland*; *[5]Flow Cytometry Core Facility, Trinity Biomedical Sciences Institute, Dublin, Ireland*

Purpose and Methods: Sharp social gradients in disease outcomes observed during the Covid-19 pandemic have renewed interest in the social-to-biological processes underlying health inequalities. The linked studies, Assessing Effects of SES-Associated Psychosocial Stress on Vaccine Induced Immunity to SARS CoV-2 (AESS-Vax, n=164) and Premature Ageing in long Term Homeless Adults- Immune (PATH-I, n=59) were designed to examine psychosocial adversity as a potential biological conduit for the socioeconomic determination of health and ageing. Detailed sociodemographic, health and medical data were recorded in both studies along with psychosocial inventories of stress and wellbeing. Blood samples were collected at time of recruitment and in AESS-Vax, at multiple timepoints following vaccination with BNT162b2 (Pfizer-BioNTech). Serum and plasma samples were banked for multiplex cytokine analysis, quantification of anti-SARS CoV-2 antibodies and for confirmation of CMV serostatus. Peripheral Blood Mononuclear Cells (PBMCs) were isolated for immunophenotyping and functional analysis by spectral cytometry. Whole blood samples taken 4-6 weeks and 12-16 weeks after a third dose of BNT162b2 were used to conduct Interferon-Gamma Release Assays (IGRA) to profile antigen-specific responses.

Results:

- Total Anti-SARS CoV2 Spike antibodies are significantly lower in low SES individuals with no history of infection 6-8 and 12-16weeks after vaccination.
- IFN-γ production following stimulation with Spike peptides and whole Spike protein was higher in High SES participants 4-6 weeks and 12-16 weeks following a third dose of vaccine.
- Eight circulating cytokines are significantly elevated in homeless versus housed participants (TNF-a,IL-1B, IFN-g,IL-12p70, IL-18, IL-4, IL-10,IL-2)
- Low SES participants had diminished naïve T cell populations, enlarged TEMRA populations and higher expression of surface markers indicative of T cell exhaustion and Immunosenescence.

Conclusions:

- SES and housing status are associated with diminished humoral and cell-mediated immunity to SARS CoV2 after vaccination with BNT162b2.
- Homeless participants display elevated levels of circulating proinflammatory cytokines and cytokines resembling patterns seen in accelerated, immune driven ageing. Associations are independent of age and sex.
- T Lymphocyte populations in low SES participants display a more mature phenotype, possibly affecting functionality and responses to novel antigens. Further analysis of T cell function and of myeloid immunophenotype will follow.

Metabolic heterogeneity between tissue-resident NK cells

Carrie Corkish[1], David Finlay[1]
[1]*Trinity Biomedical Sciences Institute, Dublin, Ireland*

Numerous studies have now concluded that cellular metabolism is crucial for effective Natural Killer (NK) cell responses using *ex vivo* or *in vitro* approaches. However, the degree to which this is true of NK cell responses *in vivo* is less well understood. Recent studies have demonstrated large discrepancies between the metabolic parameters of immune cells measured *in vitro* compared to those measured *in vivo*. This study aimed to understand the metabolic configurations of NK cells in their in vivo niche and how in vivo metabolic features change following immune stimulation.
High-resolution quantitative proteomic analysis was performed on splenic NK cells that were activated *in vivo* and isolated for analysis directly *ex vivo.* Analysis of these proteomes revealed that a robust metabolic response was induced following *in vivo* activation. This included the increased expression of nutrient transporters, such as the amino acid transporters Slc1a5 and Slc7a5, increased expression of machinery for glycolytic and glutamine-metabolism pathways, aswell as increased expression of electron transport chain components and other mitochondrial proteins.
Next, I used single cell flow-based metabolic analyses, developed in the Finlay lab and by others, to confirm what we see at the proteomic level. I have also applied these single cell technologies to explore potential metabolic heterogeneity of tissue-resident NK cells based on the tissue of residence. Tissue-resident NK cells were studied from the spleen, uterus, bone marrow, adipose tissue, salivary gland, liver and lung.
The data shows that tissue resident NK cells differ substantially in their metabolic configuration dependant on their tissue location, both basally and upon challenge with virus and/or bacteria. The data show that the activities of two key amino acid transporters, Slc1a5 and Slc7a5, are quite distinct in NK cells residing in different tissues. I then studied the impact of deleting either of these amino acid transporters, specifically in NK cells, on the homeostasis/function of NK cells is different tissues.
This study is revealing the in vivo metabolic features of tissue resident NK cells across a range of tissues, and how these metabolic configurations change to respond to immunological challenge.

Work is supported by the Irish Research Council.

Divergent roles for STAT4 in shaping differentiation of cytotoxic ILC1 and NK cells during gut inflammation

Gianluca Scarno[1], Julija Mazej[2], Mattia Laffranchi[2], Chiara Di Censo[3], Irene Mattiola[4], Arianna Maria Candelotti[2], Giuseppe Pietropaolo[2], Helena Stabile[2], Cinzia Fionda[2], Giovanna Peruzzi[5], Stephen R Brooks[6], Wanxia Li Tsai[7], Yohei Mikami[8], Giovanni Bernardini[2], Angela Gismondi[2], Silvano Sozzani[2], James Di Santo[3], Christian Vosshenrich[3], Andreas Diefenbach[4], Massimo Gadina[7], Angela Santoni[2], Giuseppe Sciumè[2]
[1]Memorial Sloan Kettering Cancer Center, New York, United States; *[2]Dipartimento di Medicina Molecolare, Sapienza University of Rome, Rome, Italy*; *[3]Innate Immunity Unit, Institut Pasteur, Université Paris Cité, Paris, France*; *[4]Laboratory of Innate Immunity, Institute of Microbiology, Infectious Diseases and Immunology, Charité-Universitätsmedizin Berlin, Berlin, Germany*; *[5]Center for Life Nano- & Neuro-Science, Istituto Italiano di Tecnologia, Rome, Italy*; *[6]Biodata Mining and Discovery Section, Office of Science and Technology, National Institute of Arthritis, Musculoskeletal and Skin Diseases, NIH, Bethesda, United States*; *[7]Translational Immunology Section, Office of Science and Technology, National Institute of Arthritis, Musculoskeletal and Skin Diseases, NIH, Bethesda, United States*; *[8]Division of Gastroenterology and Hepatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

Purpose: Natural killer (NK) cells and type 1 innate lymphoid cells (ILC1) play pivotal roles in host defense and tissue homeostasis, relying on the transcription factor STAT4 for effector functions. Our study aims to elucidate the role of STAT4 in regulating the effector differentiation of NK cells and ILC1 within the intestinal microenvironment during inflammation.
Methods: In this study we generated a novel mouse model enabling the deletion of *Stat4* in *Ncr1*-expressing cells. We then utilized the widely adopted mouse model of intestinal inflammation, namely dextran sulfate sodium (DSS)-induced colitis, to study the effects of STAT4 deletion in large intestinal lamina propria (lilp) *Ncr1*-expressing cells in colitis settings. Additionally, we employed single-cell transcriptomic analysis to deconvolute how *Stat4* deletion shapes the transcriptomic programs of lilp NK/ILC1.
Results: Deletion of *Stat4* in *Ncr1*-expressing cells had detrimental effects on colitis severity, with increased weight loss and colitis score in $Ncr1^{iCre}$ $Stat4^{fl/fl}$ mice, compared to wt $Stat4^{fl/fl}$ littermates. At cellular and molecular level, we showed that STAT4 is necessary for the terminal differentiation of NK cells, as well as for driving the effector responses of both NK and ILC1. Intriguingly, this deficiency paradoxically amplifies the generation of cytotoxic ILC1 during intestinal inflammation. Transcriptomic analyses reveal a distinct gene expression profile in Stat4-deficient ILC1, characterized by the upregulation of gene modules typically regulated by STAT5. This dysregulated transcriptional landscape translated into aberrant effector differentiation, particularly evident upon IL-2 stimulation. Furthermore, STAT4 expression in NCR+ innate lymphocytes limited the severity of colitis by curtailing the pathogenic production of IL-13 from CD4+ T cells within the large intestine.
Conclusion: Our study elucidates the intricate regulatory network orchestrated by STAT4 in governing the effector functions of NK cells and ILC1 in the intestinal milieu. These findings not only highlight shared and distinct mechanisms of STAT4-mediated transcriptional control but also underscore potential therapeutic avenues for modulating innate lymphocyte responses in the context of inflammatory bowel disease.

Oxysterols modulate iNKT cell function

Cristhiane Favero de Aguiar[1], Emily Smith[1], Cathal Keane[1], Carrie Corkish[1], David Finlay[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Invariant NKT (iNKT) cells are a distinct subtype of lymphocytes characterized by their reactivity to lipids presented by CD1d. They are relatively unique amongst T cells because of their ability to rapidly produce a variety of cytokines, while also having cytotoxic capabilities. The tumour microenvironment (TME) is known to be suppressive and affects immune cells in different ways. Lipids and other metabolites are increased in the TME and can induce immune cell dysfunction.

Oxysterols are a family of oxidized derivatives of cholesterol whose levels are elevated in some tumors and are known to impact immune cell function. In our work we investigated how oxysterols affect iNKT cell function. Splenic iNKT cells were activated ex-vivo in the absence/presence of two different oxysterols: 25-hydroxycholesterol (25-HC) and 27-hydroxycholesterol (27-HC). We found that both oxysterols inhibited iNKT cell cytokine production. We Investigated the molecular mechanisms underlying the immunosuppressive effects of these oxysterols, including effects on metabolism and signalling pathways. Oxysterol can modulate of two families of transcription factors, SREBP and the LXR. However, neither PF429242 (pharmacological inhibitor of SREBP activation) or GW3965 (a synthetic LXR agonist) affected iNKT cell function in our short-term ex-vivo activation model.

We also analysed the activity of mTORC1 by staining the phosphorylated S6 ribosomal protein (rpS6) and protein synthesis via puromycin incorporation as metabolic readouts. While neither oxysterol affected the rate of protein synthesis, oxysterols impaired the phosphorylation of S6 ribosomal protein. These data suggest that oxysterols might be affecting iNKT cell metabolic signalling.

The lipid microenvironment in the plasma membrane is crucial for signal transduction. Because the presence of oxysterols can change the membrane fluidity, we investigated if alterations in the membrane order might be responsible for the effects on iNKT cell function. The analysis of Di-4-ANEPPDHQ staining showed increased membrane disorder on oxysterol-treated cells, suggesting that a disturbed membrane is underlying the reduced function of iNKT cells.

Understanding the specific role of 25HC and 27HC in inhibiting different immune cells' functions may pave the way for the development of novel pharmacological interventions aimed at modulating immune responses in various pathological conditions.

Novel FFAR2 agonist prevents development of type 1 diabetes in C57BL/6 mice

Natalija Jonić[1], Ivan Koprivica[1], Dragica Mićanović[1], Tamara Saksida[1], Bojan Jevtic[1], Graeme L Fraser[2], Dorde Miljkovic[1], Ivana Stojanović[1]
[1]*Institute for Biological Research "Siniša Stanković" - National Institute of the Republic of Serbia, Belgrade, Serbia*; [2]*EPICS Therapeutics, Gosselies, Belgium*

Type 1 diabetes (T1D) is a chronic autoimmune disease that usually develops in early childhood. The recent market approval of the anti-CD3 monoclonal antibody (teplizumab) is a major advance in protecting at-risk patients from the onset of T1D. In addition to the presence of autoantibodies, T1D-prone individuals exhibit alteration in the gut microbiota and the intestinal immune response. As intestinal epithelial and immune cells express receptors for free fatty acids (FFAR), and it was shown that stimulation of FFAR2 can down-regulate inflammation during Crohn's disease, we have tested the efficacy of the novel agonist for FFAR2 (Cpd1) in the prevention of T1D induced by five injections of low-dose of streptozotocin in C57BL/6 mice. Oral application of Cpd1 (applied from the 1st day of T1D induction for 20 days in total) resulted in a significant reduction of T1D incidence and lowered mean glycemia levels in the treated mice. Accordingly, these mice had lower insulitis in the pancreas and higher insulin production. *Ex vivo* analysis on the 8th day post T1D induction showed higher proportions of innate lymphoid cell type 3 (ILC3) that produced IL-2 within the small intestine (SI) lamina propria of Cpd1-treated mice. The increase in IL-2 correlated with higher Treg proportions detected on day 12 in the SI lamina propria. Similar findings were observed in NOD mice, a spontaneous T1D model, treated with Cpd1 on a daily basis (from 8 weeks until 12 weeks of age). Cpd1 increased the presence of ILC3 in the SI lamina propria of NOD mice, and more specifically, the proportion of Nkp46^{-} ILC3. In total, these results demonstrate that Cpd1 increased the population of ILC3 and Treg by activating FFAR2, thereby modulating the anti-inflammatory immune response and protecting the pancreas from the imposed damage.

Cobalt exposure enhances group 2 innate lymphoid cell apoptosis in vitro

Hsiang-Han Su[1], Chia-Chi Lin[1], Jau-Ling Suen[1]
[1]*Graduate Institute of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan*

Purpose: ILC2 is an environmental sensor that can aggravate allergic diseases by expressing type-2 cytokines, but it also participates in tissue repair by secreting Amphiregulin. The homeostasis of ILC2 in the body regulates the inflammatory status of the mucosal site, which is where most environmental pollutants are encountered. Heavy metals are harmful environmental pollutants that can accumulate in the human body through bioaccumulation. Cobalt is primarily absorbed through the lungs and digestive tract and its exposure is associated with allergic contact dermatitis and occupational asthma. When inhaled, cobalt-containing dust can lead to a pathological response in the lung parenchyma. However, the direct effects of cobalt exposure on immune toxicity are still unclear. This study investigates the impacts of cobalt exposure on ILC2, including cell proliferation, apoptosis, and function *in vitro*.
Method: We expanded ILC2s *in vitro* and treated them with varying concentrations of $CoCl_2$ (less than 1 μM levels). We then stimulated the cells with rmIL-33 and analyzed the cell numbers of ILC2s using Cell Counting Kit-8. We also used flow cytometry to measure the Ki-67 proliferative activity and Annexin-V^+ apoptosis. Additionally, we measured the type-2 cytokine expression abilities of ILC2s using enzyme-linked immunosorbent assay. Finally, we evaluated the expression of tissue repair-related genes by Real-time PCR analysis.
Results: ILC2 cells treated with 0.1 or 1 μM $CoCl_2$ exhibited a significant decrease in cell count and proliferation capability. Upon stimulation with rmIL-33, there was a significant increase in the number of apoptotic ILC2 cells after 6-hour $CoCl_2$ treatment. However, no significant changes were observed in the expression levels of the *Areg* gene, which is associated with tissue repair, and *Mapk1* gene, which is related to cell proliferation, in ILC2 cells.
Conclusion: Cobalt treatment *in vitro* increases ILC2 apoptosis without affecting their function. This may lead to decreased tissue repair in inflamed mucosal sites. However, the mechanism and health implications of cobalt exposure requires further investigation.

Purpose: Our initiative aims to propose a standardized terminology and provide a basis for subsequent studies of the role of human Natural killer (NK) cells in health and disease.
Methods: Our comprehensive analysis, based on a joint consensus of 20 leading laboratories specializing in NK cell research, integrates proteomic (CITE-seq) and transcriptomic data (scRNAseq) from a total of 224,689 NK cells isolated from 718 donors. Our study starts in the blood of healthy donors and expands by analyzing the heterogeneity of NK cells in 3 healthy tissues (tonsil, lung, and intestine). Finally, we analyze the distribution of NK cell subsets in tumor tissues and blood from 22 cancer types.
Results:
- Three prominent NK cell subsets:
Our analysis delineates three distinct NK cell subsets: NK1, NK2 and NK3. Their gene profiles extend beyond the peripheral blood of healthy individuals and reveal the heterogeneity of NK cells in different tissues. Our results describe the unique molecular features, key transcription factors, major biological functions, significant metabolic traits, cytokine responses of each subgroup, and ontogenetic origins of NK cells leading to distinct transcriptional trajectories.
- Two distinct NK cell trajectories:
Our study documents for the first time unique transcriptional pathways for the NK1 and NK2 populations.
- Relationships between NK cells and other innate lymphoid cells:
The different ILC subsets identified in tonsils, lungs, and intraepithelial lymphocytes show different relationships with the three NK subsets. For example, the NK2 subset shows similarities with the precursors of innate lymphoid cell precursors.
- Composition of the NK compartment in pathological conditions:
The distribution of NK cell subsets in 22 tumor types varies by tumor type and shows no strict correlation with the distribution in blood.
- A user-friendly classification system:
We have developed a classification system that is available through an easy-to-use web portal. It is both intuitive and robust and facilitates the accurate categorization of NK cell populations in different samples.

Analysis of the mechanisms regulating ILC2 immune checkpoints expression and function in the tumor microenvironment

Cecilia Ciancaglini[1], Silvia Santopolo[1], Paola Vacca[1], Lorenzo Moretta[1], Linda Quatrini[1]
[1]*IRCCS Bambino Gesù Children's Hospital, Rome*

Background: ILC2s are a subset of innate lymphoid cells involved in the type 2 immunity. ILC2s are mainly resident at mucosal barriers and are specialized in the secretion of type 2 cytokines IL-4, IL-5, and IL-13 in response to IL-33, IL-25 and TSLP. Although the expression of immune checkpoints has been reported on ILC2, little is known about their regulation and function in these cells. We found that ILC2 in the tumor microenvironment (TME) display higher levels of immune checkpoints expression, compared to ILC2s freshly isolated from healthy donors' peripheral blood. In particular, we observed that ILC2 in the pleural effusions from lung cancer patients express PD1 and CTLA4. These data suggest that the TME regulates ILC2 response through these receptors. The immune checkpoint ligands are released as soluble molecules in the TME and expressed on the membrane not only of tumor cells but also of immune cells such as macrophages.
Purpose: The aims of my project are to study the molecular mechanisms involved in the expression and function of PD1 and CTLA4 in ILC2 and to investigate the contribution of tumor-resident macrophages in this regulation.
Methods: To achieve the objectives of the project, we performed in vitro experiments using primary activated ILC2 cultures as a model reproducing ILC2 phenotype in the TME. We performed co-culture experiments with monocytes-derived macrophages (MoM) in presence and absence of immune checkpoint inhibitors (ICI). We analysed ILC2 phenotype, cytokine production and gene expression by RNA sequencing.
Results: We identified the targets of PD1 and CTLA4-mediated inhibition in ILC2. We found that ILC2/MoM co-culture results in a reduction of PD1 and an increase of CTLA4 expression. We also demonstrated that MoM downregulate the expression of type 2 cytokines by ILC2.
Conclusions: Collectively our data show that MoM are able to limit ILC2 effector functions and suggest that the immune checkpoints PD1 and CTLA4 play a distinct role in controlling ILC2 response in the TME.

Role of the transcription factor Foxo1 in the differentiation of naïve CD4 T lymphocytes

Théo Level[1], Charlotte Guillou[1], Aurélie Durand[1], Léa Giraud[1], Nelly Bonilla[1], Cédric Auffray[1], Bruno Martin[1], Bruno Lucas[1]
[1]*Institut Cochin INSERM U1016 CNRS 8104, Paris, France*

Following activation by antigen presenting cells in the periphery, naïve CD4 T cells (CD4 T_N cells) can differentiate into a variety of well documented T-helper (TH) cell subsets, such as TH1, TH2, TH17 or induced regulatory (iTreg) T cells, characterized by their cytokine production profiles and specific effector functions. The immunological context in which CD4 T_N cells are immersed at the time of their activation is known to guide TH cell lineage commitment and thereby to adjust the quality of T-cell responses to the nature of the stimuli. We recently observed that Foxo1-deficient CD4 T_N cells are prone to differentiate into TH1 and TH2 cells *in vitro*, even in the absence of exogenous polarizing cytokines in the culture medium (IL-12 for TH1 polarization and IL-4 for TH2 polarization). In line with these results, higher percentages of memory CD4 T cells from the secondary lymphoid organs of $Foxo1^{TKO}$ mice compared with control mice are able to produce IFN-γ (TH1) and IL-13 (TH2) *ex vivo*. The aim of the present project is to decipher the mechanisms underlying the enhanced differentiation of CD4 T_N cells into TH1 and TH2 effector cells in the absence of Foxo1 expression. Indeed, inadequate responses might lead to immune disorders such as asthma, allergy or autoimmune diseases. To answer this question, we performed RNA-seq and ATAC-seq of Foxo1-deficient CD4 T_N cells to determine their transcriptomic signature and compare it with the transcriptomic signatures of the different TH cell subsets in the literature by using Ingenuity Pathway Analysis and GSEA. The results obtained suggest that the $Foxo1^{TKO}$ CD4 T_N cells are already commited towards the Th1/Th2 cell lineages. It is currently accepted that IL-2 promotes the differentiation of naïve CD4 T_N cells into Th1/Th2 cells while inhibiting Th17-cell development. Interestingly, our latest results strongly suggest that Foxo1 deficiency makes CD4 T_N cells more sensitive to IL-2, by promoting STAT5 signaling pathway.

Preliminary results of the fluctuation of peripheral follicular T cells and their subsets in lupus nephritis

Eleni Moysidou[1], Michalis Christodoulou[1], Georgios Lioulios[2], Vasiliki Nikolaidou[3], Aliki Xochelli[3], Pantelis Sarafidis[1], Eleni Frangou[4;5;6], Asimina Fylaktou[3], Maria Stangou[1]
[1]1st Department of Nephrology, Hippokration Hospital of Thessaloniki, School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece; *[2]Department of Nephrology, 424 General Military Hospital, Thessaloniki, Greece*; *[3]Department of Immunology, National Peripheral Histocompatibility Center, Hippokration Hospital of Thessaloniki, Thessaloniki, Greece*; *[4]Department of Nephrology, Limassol General Hospital, State Health Services Organization, Limassol, Cyprus*; *[5]Department of Basic and Clinical Sciences, University of Nicosia Medical School, Nicosia, Cyprus*; *[6]Laboratory of Autoimmunity and Inflammation, Biomedical Research Foundation of the Academy of Athens, Athens, Greece*

Purpose: Follicular T (TF) cells are implicated in the pathogenesis of Lupus Nephritis (LN) by mediating the selection of high-affinity B cells in germinal centers. They classically reside in secondary lymphoid organs; however, T cells with similar markers can be detected in the blood, the exact origin and function of which have not yet been specified. Herein, we describe the population of circulating TF cells in patients with LN and their association with disease hallmarks.

Methods: Peripheral blood was collected from 25 LN patients (LN) and 25 healthy controls (HC). Flow cytometry was performed to assess cTF (CD4+CD45RA$^-$CXCR5+) cells, and their subsets, defined as cTF1 (CD4+CD45RA$^-$CXCR5+CXCR3+CCR6-), cTF2 (CD4+CD45RA$^-$CXCR5+CXCR3-CCR6-), cTF17 (CD4+CD45RA$^-$CXCR5+CXCR3-CCR6+) and cTF-ICOS+ (CD4+CD45RA$^-$CXCR5+ICOS+).

Results: Here are presented preliminary results analyzed in 15 LN patients (age = 38±8yrs) compared to 9 HC (age = 31.5±7yrs). The percentage and total number of cTFH cells were similar between LN and HC [11(0.6-22.4) % and 41.6(3.4-412.7) cells/μL, vs. 8.8(1.9-12.1) % and 43.5(13.3-69.6) cells/μL, respectively]. cTFH-ICOS+, cTFH1 and cTFH2 cells were upregulated in LN compared to HC [0.9(0-5.2) vs. 0.256(0-1) cells/μL, 6.7(0.2-25.9) vs. 1.9(0.4-13.3) cells/μL, and 9.88(0-14.5) vs 1.82(0.46-32) cells/μL, respectively], while the cTFH17 compartment was obviously condensed [6.58 (0.79-213.8) vs 16.9(0.6-29.2) cells/μL, respectively]. Increased SLEDAI-2K score (>6) was associated with increased cTFH [75(14-413) vs. 34(3-99) cells/μL], cTFH1 [12.45(2-26) vs. 3(0.2-18) cells/μL], cTFH2 [10.38(5-14) vs. 2.27(0-11) cells/μL], cTFH17 [23.8(0.8-214) vs. 1.6(1-44) cells/μL], and cTFH-ICOS+ [1.13(0.5-5.19) vs. 0.552(0-1.18) cells/μL]. Increased levels of proteinuria were characterized by increased cTFH1 [12.4(2.08-25.88) vs. 6.7(0.2-18.17) cells/μL] but reduced cTFH17 [3.7(0.8-42.3) vs. 6.6(1.06-213.8) cells/μL] and cTFH-ICOS+ [0.22(0-5.19) vs. 0.9(0-3.7) cells/μL].

Conclusion: Most of the subtypes of cTFH were increased in active LN patients, while proteinuria levels were associated with increased cTFH1 but reduced cTFH17 and cTFH-ICOS+, suggesting the involvement of different pathogenic mechanisms and the possibility of an appealing therapeutic target for LN.

Regulatory T cells (Tregs) are critical in regulating the immune response. In vitro induced Treg cells (iTregs) have significant potential in clinical medicine. However, applying iTregs as therapeutics is complicated due to their poor stability and variable suppressive activity. To gain a better understanding of the molecular characteristics specific to iTregs, a data-independent proteomics analysis was performed. A group of Treg signature proteins was identified, including FOXP3, EOS, IL2RA, CTLA4, PDCD1, IKZF3, LAG3, RUNX1 and HIC1, all consistent with the known molecular characteristics of Tregs. These Treg signature proteins were validated using targeted proteomics and TaqMan assay. In addition, we discovered that Leupaxin (LPXN) is upregulated in response to Treg differentiation. The LPXN deficient cells showed impaired expression of Treg protein markers, FOXP3, EOS, and IKZF3 and reduced ability to suppress effector cells. Collectively, this study characterized the proteomic signature of human iTregs and identified a novel role of LPXN in the development and suppressive activity of Tregs. Our data provides a resource for further research into Treg cell biology.

Aryl hydrocarbon receptor signalling contributes to the enhanced ability of human gut-topic T-cells to acquire a Trm phenotype.

Joshua McGuire[1], Beverley Rodger[1], Harjod Singh Assi[1], James Lindsay[1], Andrew Stagg[1]
[1]*Blizard Institute, The Faculty of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom*

Purpose: Memory precursor T-cells recruited into tissues become tissue resident memory cells (T_{RM}) under the influence of local cues; some precursors show pre-commitment to a T_{RM} fate. The human intestine contains T_{RM} which play a key role in inflammatory bowel disease (IBD). Modulation of the immune system by environmental factors is pivotal to IBD onset and natural history. Here we test the hypothesis that the aryl hydrocarbon receptor (AHR), a key environmental sensor responsive to dietary and microbial ligands, regulates the generation of T_{RM} from gut-tropic circulating precursors.
Methods: Peripheral blood mononuclear cells were obtained from healthy human donors and conventional (αβTCR+) T-cells FACS purified into: naïve (CD45RA+), gut-tropic memory (CD45RA-β7integrin+) and non-gut memory (CD45RA-β7-) fractions. Expression of *AHR* and its target gene *CYP1A1*, as well as genes associated with T-cell residency, were quantified by qRT-PCR. Generation of T_{RM}-like cells (CD69+CD103+) was assessed following sequential culture in IL-15 and TGFβ, with or without the AHR antagonist CH223191.
Results: All sorted populations expressed AHR, but mean relative expression was significantly higher in memory (both β7+ and β7-) compared with naïve populations (0.0081 vs 0.0027, p = 0.0002; n=6). In contrast, expression of *CYP1A1*, indicative of active AHR signalling, was significantly greater in gut-tropic (β7+) than β7- memory cells (4.5x10-5 vs 1.7x10-5, p = 0.02; n=6). Expression of *CYP1A1* was similar in naïve and β7- memory cells. CD69+CD103+ T_{RM}-like cells with reduced expression of the tissue egress genes *S1PR1* and *KLF2*, were generated from memory T-cells *in vitro*. Significantly more β7+ than β7- memory cells acquired a T_{RM}-like phenotype (CD8+: 23% vs 11%, p=0.02 & CD8-(CD4+): 3.8% vs 1.1%, p =0.007; n= 5). The generation of T_{RM}-like cells was significantly reduced by AHR antagonism (β7+CD8+: 8.79% in CH223191 vs 23% in vehicle, p=0.02 & β7+CD8- (CD4+): 0.33 vs 3.92, p =0.007, n= 5) with corresponding preservation of tissue egress gene expression.
Conclusion: AHR signalling enhances the generation of human T_{RM}-like cells *in vitro*. Memory T-cells expressing β7 integrin, with the potential to traffic to the intestinal mucosa, have a more active AHR signalling pathway and enhanced T_{RM} potential.

Regulatory T cells (Tregs) are responsible of the maintenance of immunological homeostasis and self-tolerance. Unlike other T helper cells, Tregs suppress immune responses via contact dependent and humoral factor-mediated mechanisms. However, abnormalities in Treg numbers, frequencies, and suppressive function can trigger autoimmune diseases while Treg accumulation in tumors suppresses anti-tumor immunity. The aim of this study was to perform an in-depth characterization of early human induced Treg cell differentiation by high-dimensional single-cell mass cytometry. For this purpose, a panel of 25 markers was designed and validated in Tregs, differentiated *in vitro* from naïve human umbilical cord blood derived $CD4^+$ T cells. The expression of these markers was further studied in Tregs compared to activated control Th0 cells over time. Our results revealed that Tregs cluster distinct from Th0 control cells. Tregs upregulated the key transcription factor Foxp3 and several co-stimulatory and -inhibitory molecules (i.e. CCR4, CCR7, CXCR3, TIM3, CD73, PD1, CD137 and CD103) during early human Treg cell differentiation. In summary, our study provides valuable insights into the phenotypic characteristics of human induced Tregs during early differentiation, and their potential therapeutic applications.

Unraveling the contribution of B cells on the differentiation of specific CD4+ T cells using a novel MHC class II multimer platform

Christine Kreher[1], Daniela di Blasi[1], Dorina Roem-Haagsma[1], Britt Windhouwer[1], Veronique Konijn[1], Gerard van Mierlo[1], Laura Kummer[1;2], Koos van Dam[2], Eileen Stalman[2], Joep Killestein[3], Luuk Wieske[2;4], Taco Kuijpers[5], Filip Eftimov[2], Zoé L E van Kempen[3], Theo Rispens[1], Marieke van Ham[1;6], Anja ten Brinke[1]
[1]Sanquin Research and Landsteiner Laboratory, Amsterdam UMC, University of Amsterdam, Amsterdam, Netherlands; *[2]Department of Neurology and Neurophysiology, Amsterdam Neuroscience, Amsterdam UMC, location AMC, University of Amsterdam, Amsterdam, Netherlands*; *[3]Department of Neurology, Amsterdam UMC, Vrije Universiteit, Amsterdam, Netherlands*; *[4]Department of Clinical Neurophysiology, St Antonius Hospital, Nieuwegein, Netherlands*; *[5]Department of Pediatric Immunology, Rheumatology and Infectious Disease, Amsterdam UMC, Location AMC, University of Amsterdam, Amsterdam, Netherlands*; *[6]University of Amsterdam, Swammerdam Institute for Life Sciences, Amsterdam, Netherlands*

CD4+ Tfh-B-cell interaction is necessary to induce affinity-matured plasma and memory B cells, resulting in a high-affinity antibody response. Vice versa B cells might also affect the phenotypic differentiation of CD4+ T cells in the lymph node. Recently, we found that CD4+ T cells in multiple sclerosis (MS) patients on B cell depleting (anti-CD20) therapy upregulated the activation markers HLA-DR and CD38 after second SARS-CoV2 vaccination compared to untreated MS controls [Verstegen *et al.* JNNP 2024]. We aim to unravel the role of B cells in the formation and phenotypic differentiation of specific CD4+ T cell responses by performing *ex vivo* deep-phenotyping on spike-specific CD4+ T cells 7 days after second SARS-CoV2 mRNA vaccination in MS patients with or without anti-CD20 therapy. Major histocompatibility complex (MHC) class II tetramers or dextramers might be used to detect antigen-specific CD4+ T cell responses directly *ex vivo*. However, the current reagents are often limited in the signal intensity and binding affinity to the antigen-specific T cell receptor. Therefore, we developed novel peptide-specific MHC class II multimers based on Ig Fc-fusion protein framework to optimize the detection of antigen-specific CD4+ T cells. We proved that our multimers stained antigen-specific CD4+ T cells with much higher signal intensity and specificity than commercial reagents. Besides, multimers of the MS dominant HLA type HLADRB1 15:01 conjugated with spike peptide 866-880 showed specific staining in HLADRB1 15:01 positive donors compared to negative ones. Furthermore, no staining was observed in COVID19 naïve individuals. Using these MHC class II multimers, spike-specific CD4+ T cells are sorted from MS patients, either untreated (n=7) or on anti-CD20 therapy with (n=7) or without an anti-RBD IgG response (n=7). During sorting, proteomic data on memory and T helper phenotype of the spike-specific CD4+ T cells is acquired. In combination with single cell RNA-sequencing data of these sorted cells, we expect to obtain insight in the effect of lack of B cell interaction on the CD4+ T cell differentiation during a recently developed immune response.

Thymic cell competition relies on efficient bone marrow contribution to prevent T cell acute lymphoblastic leukemia

Rafael Paiva[1], Bruna Sabino Oliveira[1], Sara Azenha[1], Vera Martins[1]
[1]*Instituto Gulbenkian de Ciência, Oeiras, Portugal*

T lymphocytes differentiate in the thymus from hematopoietic progenitors of bone marrow origin, which progressively lose multipotency, commit to the T cell lineage and differentiate. This is a process characterized by high cell turnover and, at steady state, mouse thymocytes are all virtually replaced every 4 weeks. We have shown that thymus turnover is partly regulated by cell competition involving thymocytes at the double negative (DN) 2 and 3-early stages of differentiation. Specifically, young DN2 and DN3-early with a shorter time of thymus residency outcompete and replace old DN3-early with longer times of thymus residency. If thymus seeding by competent progenitors is temporarily impaired, thymocytes can self-renew and autonomously maintain thymopoiesis. However, such property bears a heavy burden on the organism because it causes T cell acute lymphoblastic leukemia (T-ALL). Here, we show that thymus autonomy and T-ALL can be triggered as result of inefficient bone marrow reconstitution of γ_C-deficient mice. Interestingly, the risk of T-ALL was inversely proportional to the level of engraftment of the bone marrow, i.e. the lower the efficiency of wild type bone marrow engraftment, the higher the incidence of T-ALL. Our data reveal that aberrant thymocytes, probably the precursors of leukemia, emerge very early, and we establish a safe threshold for the input of healthy HSPCs and bone marrow reconstitution capable of inhibiting thymus autonomy. Altogether, our data reveals the leukemogenic potential of thymocytes upon bone marrow correction of γ_C-deficiency, and the requirements to prevent such unwanted outcome.

DNA methylation profiles guide development and differentiation in T cells in the thymus and in the periphery, but epigenetic recoding of proliferation only occurs after full maturation

Frederik Hamm[1], Dania Hamo[1], Marcel Finke[1], Mingxing Yang[1], Cornelia Peitsch[1], Anne Schulze[1], Julia K. Polansky[1]
[1]*Berlin Institute of Health @ Charité Universitätsmedizin Berlin, Berlin, Germany*

Epigenetic mechanisms are known drivers of T lymphocyte development and function. This is attributed to epigenetic changes on gene regulatory elements like promoters and enhancers, which control the expression patterns of their target genes and with this, imprint cell type-specific transcriptional profiles. In addition, in previous studies, we also observed a progressive DNA methylation loss in the heterochromatic parts of the genome in human T cells from the peripheral blood, as a lasting epigenetic record of undergone proliferation episodes. Here, we addressed the epigenetic remodeling of the DNA methylome during the thymic development of T cells, which so far has not been clarified in detail.
We generated genome-wide DNA methylation profiles of well defined, human ex vivo isolated thymocyte populations at various stages of T cell development. We observed two waves of epigenetic remodeling taking place: the first from the early double-negative stages to phases of TCR rearrangement and the second one after finishing TCR rearrangement to the mature state. Although cells during TCR rearrangement undergo a series of phenotypic and transcriptomic changes, the DNA methylome during this phase is stable, until the next major rearrangement to the mature state. Furthermore, we did not observe significant loss of DNA methylation in the heterochromatin throughout thymic development, although cells undergo episodes of strong proliferation. This finding is in stark contrast to proliferating mature cells from the periphery, which display a clear loss of heterochromatic DNA methylation, which we could identify to be driven by DNA replication speed. Cells displaying increased proliferation-induced loss of heterochromatic DNA methylation were predisposed to memory differentiation, indicating that the proliferation history of cells influences their further developmental fate.
Taken together, we could show that remodeling of the DNA methylome occurs during thymic T cell development as well as during memory generation in the periphery, however, proliferation episodes seem to be only imprinted into the DNA methylome after full maturation. Then, however, cells with an accumulated proliferation history being recorded in their DNA methylome, are predisposed for further differentiation into memory phenotypes.

T cell-intrinsic PKD3 fine-tunes the development into CD8+ central memory T cells

Jiří Koutník[1], Grzegorz Sumara[2], Michael Leitges[3], Gottfried Baier[1], Kerstin Siegmund[1]
[1]Institute of Cell Genetics, Medical University of Innsbruck, Innsbruck, Austria; *[2]Nencki Institute of Experimental Biology, Polish Academy of Sciences, Warszawa, Poland*; *[3]Division of BioMedical Sciences, Memorial University of Newfoundland, St. John's, Canada*

The orchestration of a T cell response is tightly balanced, with both proper T cell activation as well as memory development being critical to ensure protection from pathogens without leading to autoimmunity.
Recently, we have identified Protein Kinase D3 (PKD3) as a novel regulator of this process. Thus, T lymphocytes from conventional PKD3-deficient mice are hyper-reactive upon polyclonal stimulation *in vitro* or immunization *in vivo*. However, this might be explained by the mice's substantial skewing in their T cell compartment towards an effector/memory phenotype, already under steady-state conditions.
In our current study, we have complemented our initial observations with mouse models that either lack, or overexpress a constitutive active form of PKD3, specifically in the T cell compartment. Combining these model systems, we surprisingly observed T cell-intrinsic PKD3 to be dispensable for the cell's activation. Moreover, we were able to specify that the strongly skewed T cell compartment of PKD3$^{-/-}$ mice is largely caused T cell-extrinsically, whereas T cell-intrinsic PKD3 specifically fine-tunes the development into CD8^{+} central memory T cells.

Mixed phenotype acute leukemia: a case report

Beatriz Fernandez Perea[1], Maria del Carmen Barrera Aguilera[1], Juan Francisco Gutiérrez-Bautista[1], Lucía Ballesta Alcaraz[1], Ana Marin[1], Mónica Bernal[1], Jose Ramón Vilchez[1], Pilar Jimenez[1]
[1]*Hospital Universitario Virgen de las Nieves, Granada, Spain*

Mixed phenotype acute leukemia is a rare form of leukemia that combines two different types: acute myelocytic leukemia (AML) and acute lymphoblastic leukemia (ALL). This leukemia has an aggressive profile, and presents a disjunctive in treatment, as there is no standardized treatment protocol.
We present a case of an 18-year-old female patient with a lymphocyte percentage of 80% without associated leukocytosis, maintained for 20 days. Immunophenotyping by cytometry showed an immunophenotypic pattern compatible with **type B acute lymphoblastic leukemia with 87% of blast cells.** Negative CD10 expression is characteristic of the pro-B subtype, although this is usually associated with NG2 and CD15 expression. The MPO study was negative.On the other hand, the expression of myeloid markers and CD66c is characteristic of B-ALL associated with the t(9;22) BCR-ABL1 translocation, which was negative by FISH. On the other hand, massive sequencing tests showed a **monosomy of chromosome7** associated with a deletion in the IKZF1 gene. This finding, more characteristic of acute myeloid leukemias, presented the possibility of an acute leukemia of mixed phenotype.
In addition, in the massive sequencing, genetic alterations were found in chromosome 8 and 12. As addedinformation of the study by Optical Mapping, a t(2;9)(p11.1;p24.1) and another t(12;12)(p13.31; p12.1) of uncertain significance were detected.
Treatment with PETHEMA LAL 2019 is decided, since the result of MPO- CMF has more weight in the diagnosis of B-ALL than the possibility of leukemia of mixed etiology.
The morphological smear in Hematology after treatment shows 4% undifferentiated blasts and post- chemotherapy agranulocytosis and in the CMF 0.04% of EMR B-lymphoblasts: CD19+, CD10-, CD34+, CD20-, CD73/CD304+, CD81+, CD38 weak.
Currently the patient is awaiting unrelated BMT, responding well to chemotherapy treatment.

The role of toll-like receptor agonists in modulating thymocyte development in fetal thymus organ culture

Elise Helena Armulik[1], Artur Stoljar[1], Uku Haljasorg[1], Pärt Peterson[1], Martti Laan[1]
[1]*Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia*

The microenvironment of the thymus represents a unique phenomenon, where even in physiological conditions there is a constitutive production of pro-inflammatory mediators, like toll-like receptor (TLR) induced cytokines and type I IFNs. This type of tonic inflammation is believed to play a crucial role in thymocyte development; nevertheless, a comprehensive understanding remains elusive.
Using the fetal thymus organ culture (FTOC) system, we aimed to determine how introducing additional exogenous toll-like receptor agonists like CpG ODN (TLR9), LPS (TLR4) and Gardiquimod (TLR7) would affect the development of different thymocyte populations. Additionally, we examined the impact of IFNα1, a product of TLR-mediated signaling, on thymocyte development. For this purpose, we harvested the thymi from E16.5 or E17.5 C57BL/6J mouse embryos, cultivated them in FTOC with various stimulants, and analyzed the samples at multiple time-points.
By using qPCR, we were able to observe several stimuli-induced alterations in gene expression, proving that the mediators are able to affect thymocyte development in the FTOC system. For analyzing functional changes in the thymus, we employed a 17-color spectral flow cytometry panel, enabling simultaneous assessment of over 40 different thymic cell populations. We saw numerous changes across various thymocyte populations, including an increase of CD4SP and CD8SP mature 1 (CD3+CD5+CD69+MHCI+) and mature 2 (CD3+CD5+CD69-MHCI+) subsets, induced by both CpG ODN and IFNα1. Additionally, CpG led to a significant rise in CD4SP cells undergoing negative selection (CD3+CD5+Foxp3-CD69+Helios+); and at the same time induced a negative trend in the Treg population (CD3+CD5+Foxp3+CD25+). What's more, when incubating thymi with anti-IFNα1 antibodies we detected trends in some T-cell populations that were opposite of IFNα1 and CpG treatment.
Our experiments provide insight into how various thymocyte populations respond to an augmented inflammatory environment induced by different TLRs. This data also suggests that manipulation of the thymic pro-inflammatory microenvironment has a potential to modulate the developmental fate of thymocytes, and thus consequently affect the peripheral T cell pool.

Urinary immune cells in ANCA-associated vasculitis: a marker of disease relapse?

Arlena Carney[1], Conor Finlay[1], Mark Little[1], Amrita Dwivedi[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Background: Immune cells are detectable in the urine of healthy individuals, and their numbers increase during infection or inflammation, particularly during renal inflammation. ANCA-Associated Vasculitis (AAV) is an autoimmune disease that follows a relapsing-remitting disease course and commonly affects the kidneys. Measurement of urinary immune cells as a non-invasive prognostic marker has been demonstrated in another autoimmune renal disease, lupus nephritis. This work seeks to define the urine immune cell phenotype during a period of stable remission and enumerate these populations for comparison to a healthy control group.
Methods: Urine was collected from patients recruited to the RITA Ireland Vasculitis Biobank (n=51). Healthy controls were recruited from Trinity Translational Medicine Institute (n=12). Patients with positive urine cultures were excluded from analysis. Cells were isolated from the urine and stained with fluorescent conjugated antibodies for CD45, CD3, CD16, CD14 and CD15 for subsequent analysis by flow cytometry using the BD FACS Canto II. Counting beads were used to allow estimation of absolute cell counts. All samples were gated on live cells to mitigate excess autofluorescence from urine.
Results: 41 patients across 51 encounters were included. The cohort was 54% female and 46% male, with a median age of 68 years. It was found that patients with AAV in remission presented with a statistically higher number of CD45+ cells in their urine (median 18,800 cells/ml) when compared to healthy controls (median 5,540 cells/ml) (p=0.0002). Of these leukocytes, neutrophils were the most common subset in both remission patients (median 16,300 cells/ml) and healthy controls (1,665 cells/ml) (p=0.0009). T cells were significantly higher in patients in remission (median 669 cells/ml) than in healthy controls (median 111 cells/mls)(p=0.0003). Classical monocytes were the most common monocyte subset identified, with a median of 602 cells/ml in remission patients and 26.2 cells/ml in healthy controls (p=0.0032).
Conclusion: Despite being in clinical remission, AAV patients have significantly elevated numbers of T cells, monocytes and neutrophils in their urine when compared to healthy controls. This could indicate persistent subclinical renal inflammation and marks the potential for use of urinary immune cells as a non-invasive marker of disease progression in AAV.

Vacuolated lymphocytes in pleomorphic mantle cell lymphoma, case report

Alberto Gallardo García[1], Jorge Mannelli[1], Daniel García-Cuesta[1], Maria Paz Garrastazul-Sánchez[1], Raquel de la Varga-Martínez[1]
[1]*Servicio de Inmunología, UGC Hematología e Inmunología, Hospital Universitario Puerta del Mar, Cádiz, Spain*

Introduction: Mantle cell lymphoma (MCL) is a subtype of non-Hodgkin lymphoma derived from the malignant transformation of B lymphocytes in the mantle zone of lymph nodes. One of its variants, the pleomorphic variant, resembles diffuse large B-cell lymphoma and carries a less favorable prognosis. While cytoplasmic vacuoles are common in various conditions (infections, cancer, metabolic diseases) their occurrence in lymphoproliferative syndromes is rare.
Objectives: We report a case of pleomorphic variant MCL with cytoplasmic vacuoles to elucidate its characteristics and peculiarities to facilitate appropriate differential diagnosis.
Case description: A 65-year-old male presenting significant weight loss underwent medical examination revealing lymphadenopathy and splenomegaly. Anemia and thrombocytopenia were noted on blood count. White blood cell count was $3{,}56x10^9$/l, with a normal absolute lymphocyte count of $1{,}45x10^9$/l. The peripheral blood smear revealed vacuolated lymphocytes with a mature appearance, prompting a bone marrow (BM) aspiration. The cytomorphology of the BM showed significant infiltration of atypical lymphocytes, most of which had large vacuoles. Flow cytometry (FC) detected infiltration by 16% of large-sized and complex B cells positive for CD19, CD20, CD79b, CD5 and bright kappa light chain being negative for CD23, CD200, and CD10. BM biopsy confirmed massive infiltration by atypical lymphocytes displaying pleomorphic features and vacuolated cytoplasm with the expression of CD20, CD5, and cyclin D1. Molecular studies confirmed clonality and the presence of the CCND1/IGH t(11;14). The patient was diagnosed with pleomorphic variant mantle cell lymphoma (MCL). Treatments involving chemotherapy, ibrutinib, and splenectomy were received. Despite treatments, subsequent assessments revealed positive minimal residual disease and multi-organ lymphoma infiltration. The patient passed away six months post-diagnosis.
Conclusions: In this case, the vacuoles were a key finding that raised suspicion for an underlying lymphoproliferative disorder. They may be seen in a variety of entities, including lysosomal storage diseases and neoplastic disorders. However, there are very few cases described regarding its presence in B lymphoproliferative syndromes. Therefore, the presence of vacuoles in lymphocytes should prompt further investigation in the diagnosis and prognosis of lymphoproliferative disorders.
Clinical findings, morphology, FC, and genetic testing were necessary to reach the diagnosis of mantle cell lymphoma.

The impact of T-cell responses on vascular inflammation and thrombosis

Reiner Mailer[1]
[1]*Clinical Chemistry and Laboratory Medicine, Hamburg, Germany*

Purpose: Pro-inflammatory T cells that recognize liver-derived apolipoprotein B-100 (ApoB100), the protein component of low-density lipoprotein particles, aggravate atherosclerosis development. However, the intrahepatic differentiation of ApoB100-specific T-cell subsets in liver patients and healthy controls was previously unknown. In addition, the pro-thrombotic function of stimulated T cells via inorganic polyphosphate (polyP) - a ubiquitously found, negatively charged biopolymer, which activates coagulation factor XII, has not been analysed so far. Thus, we investigated the contribution of hepatic T-cell responses to vascular inflammation and the contribution of T-cell stimulation to thrombotic diseases.
Methods: We analysed intrahepatic T-cell differentiation in hypercholesterolemic mice and identified ApoB100-specific T cells by activation-induced marker expression in liver disease patients and controls. To validate our findings, we applied a transient liver damage model and performed repetitive transfers of TCR-transgenic T cells into ApoB100-transgenic mice. We used a polyP-binding probe in immunofluorescence microscopy and flow cytometry for the detection of polyP on the surface of stimulated T cells and assessed their pro-thrombotic activity via chromogenic cleavage assays, real-time thrombin generation and FeCl3-induced thrombosis models.
Results: We previously showed that hypercholesterolemia promotes CD4+ T-cell stimulation intrinsically by enhanced T-cell antigen receptor signalling and extrinsically by increased liver inflammation. We found that intrahepatically differentiated T-cell subsets relocate to the atherosclerotic vasculature in adoptive transfer experiments. Consistently, increased populations of pro-inflammatory ApoB100-specific T cells were present in blood from non-alcoholic fatty liver disease patients or cardiovascular disease patients in comparison to healthy controls. However, repetitive ApoB100 recognition in the absence of inflammation promoted the generation of IL-10-secreting regulatory T type 1 cells in healthy subjects. Moreover, we revealed that stimulated T cells accumulate polyP and that plasma membrane-bound polyP on their surface activates factor XII, enhanced thrombin generation in vitro and increased the thrombus formation in a venous thrombosis model in vivo.
Conclusion: Liver damage triggers pro-inflammatory ApoB100-specific T-cell responses and stimulated T cells promote polyP-driven thrombus formation, indicating a role of antigen-specific T cells in vascular inflammation and thrombosis.

Red Complex Pathobionts on Osteoclast-Like Cell Maturation

Arzu Beklen[1;2], Muhammed Allippara[3], Katariina Nurmi[1], Pirkko Pussinen[3;4], Mari Ainola[1], Kari K. Eklund[1;5]
[1]*Faculty of Medicine, Clinicum, Translational Immunology Program, University of Helsinki, Helsinki, Finland*; [2]*Eskisehir Osmangazi University, Faculty of Dentistry, Eskisehir, Turkey*; [3]*Department of Oral and Maxillofacial Diseases, University of Helsinki, Helsinki, Finland*; [4]*Institute of Dentistry, University of Eastern Finland, Kuopio, Finland*; [5]*Department of Rheumatology, Helsinki University Hospital, Helsinki, Finland*

Purpose: Osteoclasts, arising from mononuclear cells, are characterized as multinucleated giant cells. Apart from host-related factors, bacteria in periodontal disease also play a role in bone degradation by promoting the differentiation of osteoclasts from monocyte/macrophages. Cathepsin K and Tartrate-Resistant Acid Phosphatase are osteoclast markers. Osteoclasts destroy connective tissues and contribute to destruction of tooth supporting tissue. Our study investigated the impact of periodontal pathobionts from the "red complex" - *Porphyromonas gingivalis*, *Treponema denticola*, and *Tannerella forsythia* - on the maturation of osteoclasts.
Methods: To generate osteoclasts, we isolated human primary blood mononuclear cells from peripheral blood and cultured them in the presence of macrophage colony-stimulating factor and receptor activator of nuclear factor-κB ligand to induce monocyte-to-osteoclast differentiation. Throughout the differentiation process, the cells were exposed to lipopolysaccharides (LPS) obtained from pathobionts of the red complex. mRNA expression of cathepsin K and tartrate-resistant acid phosphatase were assessed on days 1, 3, 7, and 14 using qRT-PCR.
Results: The expression of cathepsin k (*CTSK*) and tartrate-resistant acid phosphatase (*TRAP*) were significantly upregulated on day 14 marketing the osteoclast maturation. Furthermore, cells stimulated with lipopolysaccharides (LPS) from *T. denticola* and the combination of pathobionts from the red complex exhibited a significant augmentation in *CTSK* and *TRAP* gene expression by day 14 compared to unstimulated cells.
Conclusion: Among red complex pathobionts, especially *T. denticola* LPS enhanced the maturation of osteoclast-like cells thereby potentially contributing to the pathogenesis of periodontal disease.

CD8 regulatory T cells inhibit antigen-specific CD4 T cell responses during respiratory infection with Bordetella pertussis

Caroline Sutton[1], Caitlín Ní Chasaide[1], Kingston Mills[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Infection with the respiratory pathogen *Bordetella pertussis*, the causative agent of whooping cough, relies on both humoral and cellular immune responses for control and elimination of the bacteria from the respiratory tract. IL-17 and IFN-γ producing CD4 T cells, as well as γδ T cells, along with antigen-specific antibody responses are required for the elimination of the pathogen. However, the role of CD8 T cells during infection is less well characterised. We found that when compared with lymph node or spleen, CD8 T cells from the respiratory tract of naïve mice had high surface expression of PD1 and LAG-3, and produced IL-10, but did not express FOXP3, suggesting that they were inducible or Tr1-type regulatory T cells. Depletion of CD8 T cells from cultures of lung and nasal tissue immune cells from mice infected with *B. pertussis* significantly enhanced antigen-specific CD4 T cell responses. Furthermore, addition of CD8 T cells purified from the lung and nose of naïve or infected mice inhibited antigen-specific IL-17 and IFN-γ production by CD4 T cells purified from *B. pertussis* infected mice. Using an antibody that depletes CD8 T cells, we demonstrated that mice lacking CD8 T cells at the time of infection had significantly lower bacterial burdens, compared with mice treated with an isotype control antibody. This suggests that in contrast to CD4 T cells which mediate protective immunity, CD8 T cells inhibit the clearance of the bacteria from lung and nasal tract. Our findings identify a previously unknown suppressive role for CD8 T cells in the control of antigen-specific CD4 T cells responses that control respiratory infection with *B. pertussis*.

Deficiency of the Interleukin-36 Receptor Antagonist (DITRA) disrupts dermal immune homeostasis predisposing to severe psoriatic disease.

Paloma Narros Fernandez[1], Shrikanth Chomanahalli Basavarajappa[1], Heather Loughnane[1], Larissa Bless[1], Yasmina Hernandez Santana[1], Patrick T. Walsh[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Deficiency of the Interleukin-36 Receptor antagonist (DITRA) is a rare autoinflammatory disease which commonly manifests with severe recurrent episodes of Generalized Pustular Psoriasis (GPP). Loss of function mutations in the *IL36RN* gene results in unopposed IL-36 cytokine dependent signalling which orchestrates severe psoriatic inflammation. Indeed, GPP has recently been shown to be successfully treated with Anti-IL-36R monoclonal antibodies. Despite such advances, there remain some key questions concerning how loss of a functional IL-36R antagonist predisposes to GPP. These include identifying the triggers which initiate psoriatic flares and what are the impacts, if any, of such mutations on skin homeostasis.

To address these questions, we investigated the consequences of IL-36 receptor antagonist deficiency using *il36rn-/-* mice, which we, and others, have demonstrated recapitulate the severe psoriatic inflammation observed in DITRA patients. Here, we show through RNAseq analysis, that in overtly healthy mice, prior to disease onset, there is a defined pattern of altered global gene expression in the skin, indicating disrupted skin homeostasis. The most significantly altered gene encodes the chemokine, Ccl27, which is decreased in *Il36rn-/-* mouse skin, at both the mRNA and protein level. Indeed, stimulation of primary mouse keratinocytes with IL-36 cytokines *in vitro* resulted in decreased *Ccl27* expression. Altered *il36rn-/-* skin homeostasis also occurred in association with dysbiosis of the skin microbiome as detected through shotgun metagenomic sequencing. This dysbiosis was characterized by a significant outgrowth of the skin commensal bacteria, *Cutibacterium acnes*. Importantly, intradermal administration of recombinant Ccl27, prior to the induction of psoriasiform inflammation, significantly reduced the enhanced severity of disease observed in *il36rn-/-* mice demonstrating a central role for this chemokine in regulating the predisposition to increased disease severity. Furthermore, RNAseq analysis of skin biopsies from GPP patients also revealed decreased *CCL27* expression in non-lesional, as well as lesional skin, when compared to healthy skin, indicating that this chemokine may also play a key instructive role among DITRA patients.

Together these data identify a novel mechanism through which IL-36 receptor antagonist deficiency alters dermal homeostasis and predisposes to increased severity of psoriatic disease observed in DITRA patients.

Ectopic lung germinal centres support functional affinity maturation despite their disordered structure

Stephane Guillaume[1], William Foster[1], Michelle Linterman[1], Alice Denton[2]
[1]*Babraham Institute, Cambridge, United Kingdom*; [2]*Imperial College London, London, United Kingdom*

Tertiary lymphoid structures form *de novo* in response to allergy or infection, in the inflamed sites of autoimmune diseases and even adjacent to solid cancers. However, whether these structures are functionally competent and can support antibody affinity maturation is unknown. Elucidating key differences between classic and ectopic germinal centres may inform how we can improve vaccine programs and medical interventions to enhance humoral protection.
B cells undergo vigorous selection within germinal centres to improve their B cell receptors and generate high-affinity serum antibodies for protection against repeated infections. Concurrent germinal centre reactions in both lymphoid and non-lymphoid sites represent an evolutionarily inefficient duplication of efforts; we hypothesised that the less stringent assembly and organisation of tertiary lymphoid structures will result in impaired somatic hypermutation, thereby producing more broadly reactive antibodies.
Intranasal inoculation of mice with NP-KLH in combination with an allergic adjuvant house dust mite induced synchronised germinal centre kinetics in the lung and lung-draining lymph node. This novel inoculation protocol allowed us to index-sort NP-binding germinal centre B cells or memory B cells at days 21 and 42 post-inoculation and directly compare mutation rates between the lung and lung-draining lymph node.
Single B cell receptor sequencing revealed that despite their spontaneous and disordered assembly, lung germinal centres supported the same degree of somatic hypermutation and affinity maturation as the lung-draining lymph node. This shows that ectopic germinal centres are functionally capable of supporting B cell receptor diversification to enhance local protection at peripheral non-lymphoid sites. This has implications for the optimal site of vaccination in scenarios when lymph node germinal centres are less capable of supporting humoral immunity and tertiary lung lymphoid structures form easily – for example in human infants and toddlers.

The HLA-G Levels of Cord Blood- and Wharton's Jelly-Derived Mesenchymal Stem Cells from Early to Late Passages

Sule Karataş[1], Ayse Erol Bozkurt[1], Figen Abatay Sel[1], Mediha Süleymanoğlu[1], Beril Yaşa[2], Hayriye Şentürk Çiftçi[1], Fatma Savran Oğuz[1]
[1]Istanbul University, Istanbul Faculty of Medicine, Medical Biology Department, Istanbul, Turkey; *[2]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medical Sciences, Department of Child Health and Diseases, Istanbul, Turkey*

Mesenchymal stem cells (MSCs) are known to secrete various molecules, including soluble factors, into their surrounding environment, often referred to as the supernatant when cultured in vitro. One of the molecules that MSCs can secrete is the human leukocyte antigen-G (HLA-G). This research aimed to investigate the levels of HLA-G in human cord blood (CB) and Wharton's Jelly (WJ)-derived MSCs for their immunomodulatory function from early to late passages in cell culture supernatant.
The levels of HLA-G in the supernatant of MSCs at each passage were determined using ELISA. WJ-MSCs were passaged from P0 to P7, and supernatants were collected at each passage. When comparing the HLA-G levels between P0 passage and increasing passage numbers (P1-P7), a significant increase was observed at P5 passage ($p<0.05$). When P1 passage was compared with all other passages, HLA-G levels were significantly increased from P2 to P7 ($p<0.05$). CB-MSCs were passaged from P0 to P3, and their HLA-G levels were examined. When comparing HLA-G levels with increasing passage numbers from P0, a significant decrease was observed in P1 and P3 passages ($p<0.05$).
In conclusion, MSCs are known for their immunomodulatory properties, and HLA-G is one of the key molecules involved in this process. Higher levels of HLA-G are generally associated with stronger immunomodulatory effects. Based on the information provided, it appears that the levels of HLA-G increase with passage number in Wharton's Jelly MSCs, with a significant increase observed at P5. This suggests that P5 MSCs may have higher immunomodulatory potential compared to earlier passages.

Investigating the mechanism of human peripheral helper T cells (Tph) generation.

Linh-Huyen Truong[1], Rachel Anscombe[1], Feng Liu[1], Liye Chen[1]
[1]*Botnar Research Center, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom*

Purpose: Peripheral helper T (Tph) cells have been recently identified and shown to be associated with disease severity and treatment response in autoimmune diseases and cancer. Recent studies defined Tph cells as CD4+CXCR5-PD1+CXCL13+ cells. The generation of Tph cells was enhanced by the high dosage of CD28 signaling and IL2 limiting condition. How Tph cells are generated in tissue where CD28 signaling is not that high and how they maintain survival in the IL2 starvation condition are unsolved questions. Herein, we analyzed single-cell RNA-sequencing data of Tph cells from tissues of different diseases and in vitro models to investigate the cellular mechanism of Tph generation.
Methods: scRNA-seq data from tissue in breast cancer, psoriasis and rheumatoid arthritis were analyzed. Tph cells were *in vitro* generated from MACS-isolated bulk memory CD4+ T cells, FACS-isolated CD161+/CD161 cells, Th17 memory cell sin an anti-CD3-coated plate supplemented with TGF-b, IL-2 neutralizing antibodies (IL2i) and soluble anti-CD28. In some conditions, cells were supplemented with IL-7 or IL-15 to mimic the tissue milieu. After 5 days, cells were collected and phenotypically analyzed by flow cytometry.
Results: Tph cells from the tissue across diseases highly express KLRB1 (CD161). The sorted CD161+ cells were prone to give rise to Tph cells in conditions lacking CD28 signaling or limiting IL2. Tph cells carrying features of Th17 tissue-resident cells are also found in psoriasis. Sorted Th17 from memory CD4+ cells could produce CXCL13 in the presence of TGFb and IL2i. IL-2 neutralizing antibody enhanced Tph generation but dampened cell proliferation and survival. Either IL-7 or IL-15 rescued the IL-2i effect and promoted cell proliferation but only IL-7 could preserve CXCL13 production while IL-15 suppressed it.
Conclusion: Tph cells could be generated from memory CD4+ T cells. The generation of Tph from CD161+ memory cells is more efficient than CD161- ones, likely due to their differences in the dependence on CD28 and IL-2 signaling. IL-7, but not IL-15, is more likely the cytokine driving the survival of Tph cells in the IL2-limiting condition in the tissue.

Tissue-specific immunity in the human fetus by γδ T cells

Guillem Sanchez Sanchez[1;2], Isoline Verdebout[1;2], Yohannes Tafesse[1;2], Moosa Rezwani[2;2;3], Céline La[2], Panagiotis Vitsos[1;2;3], Aurélie Detavernier[2], Stanislas Goriely[2], Maria Papadopoulou[1;2], David Vermijlen[1;2;3]
[1]Department of Pharmacotherapy and Pharmaceutics, Université Libre de Bruxelles (ULB), Brussels, Belgium; *[2]Institute for Medical Immunology (IMI), Gosselies, Belgium*; *[3]WEL Research Institute, WELBIO Department, Wavre, Belgium*

Accumulating evidence indicate that γδ T cells are key players in early life immunity and physiology. We recently showed that human fetal γδ thymocytes (both the phosphoantigen-reactive Vγ9Vδ2 and nonVγ9Vδ2 subsets) are committed to either a type 1, a type 3 or a type 2-like effector fate that possess thymic-egress potential and display a wave-like pattern depending on gestation age. However, it is not clear what the tissue fate is of the different effector types in the human fetal immune system neither their potential tissue-specific roles.
Therefore, we decided to investigate fetal γδ T cell biology in different peripheral tissues by coupled single cell (sc) RNA/TCR sequencing and multiparametric flow cytometry. Interestingly, a tendency towards atomization of the previously described thymic effector clusters was observed in addition to the appearance of tissue-specific cell-states. In contrast to our previous observations in fetal thymus, Vγ9Vδ2 T cells were differentially enriched among the effector modules in the distinct peripheral tissues. Finally, sc TCR analysis showed that certain TCR sequences are more prone to be associated to particular transcriptomic profiles in peripheral tissues and revealed the existence of niche-specific CDR3 motifs.

Thus, human fetal γδ T cell cells appear to acquire tissue-specific specialization both at TCR and functional level. This knowledge provides a basis to study the role of these cells in human early life immunity and physiology.

School (MHH), and Institute of Pathology, RWTH Aachen University / UKA, Germany, Aachen, Germany*; *[6]Genomics and Immunoregulation, Life & Medical Sciences (LIMES) Institute, University of Bonn, Bonn, Germany*

Purpose: Organ transplantation provides unique access to human tissue material and enables the application of high-end techniques to identify novel cellular and molecular biomarkers associated with disease progression and clinical outcomes.
Methods: Using SeqWell scRNA Sequencing combined with broad immune phenotyping and Luminex multiplex protein array (n=50) we transcriptionally and immunologically defined and compared immune cell subsets in the human end-stage lung parenchyma (Par.) and lung-draining lymph nodes (LN): Par. Emphysema (Emph, n=6), Par. Fibrosis (Fib, n=6), Par. PAH (n=1), Par. tum. free (tumor-free lung tissue of lung cancer patients (n=5)), LN Emph (n=4), LN Fib (n=5).
Results: We found compartment and disease-specific alterations in the transcriptional profile of immune cell subsets such as tissue-resident vs circulating T cells, monocytes, and granulocytes in Par. and LN. We also defined disease-specific cell-cell interaction networks as an important characteristic of end-stage tissue microenvironment. These data were supported by cytometry analyses. Finally, we measured differences in the concentrations of chemokines, cytokines, and growth factors, which could potentially drive end-stage lung cell alterations in a compartment- and disease-specific manner.
Conclusion: The discovery of novel disease- and compartment-associated cellular and molecular biomarkers may pave the way to understanding the end-stage disease progression paving the way to improved therapeutic and diagnostic options.

Tissue-Specific Imprinting Shapes Conventional Dendritic Cell Functionality in Tumors and Non-Malignant Tissues

Anna Celant[1], Giulia Protti[1], Giuseppe Rocca[1], Francesco Andreata[1], Giulia Stucchi[1], Alessia Donato[1], Marco Galli[1], Ilaria Fontana[1], Stefano Cozzi[1], Laura Marongiu[1], Metello Enzo Innocenti[1], Francesca Granucci[1]
[1]*Università degli Studi di Milano-Bicocca, Milan, Italy*

The tumor microenvironment (TME) is a complex ecosystem comprising diverse cell populations, including immune cells, that play pivotal roles in cancer development and response to therapies. Conventional dendritic cells (cDCs) are crucial antigen-presenting cells influencing adaptive immunity and tumor progression, but their adaptations within the TME remain unclear. Here, by performing an in-depth single-cell analysis, we investigated cDC subsets across human tumors, including both immunologically cold and hot malignancies, and delineating their functional states and tissue-specific plasticity. Our integrated analyses across tumors revealed four cDC phenotypes: cDC1s, cDC2s, CCR7$^+$ DCs, and CD207$^+$ DCs.
CD207$^+$ DCs, enriched in tumor tissues, exhibit a unique transcriptional profile linked to inflammatory responses and type 1 immunity. Strikingly, in immunologically hot cancers, CD207$^+$ DCs are enriched in the early stages of the disease and correlate with improved patient survival. These features were not observed in immunologically cold tumors.
We also investigated the transcriptional alterations in cDC subsets infiltrating hot and cold tumors, showing that cDC2 were the most impacted by the different tumor microenvironments. In detail, in hot tumors, their transcriptomes exhibited upregulation of genes involved in chemokine-mediated immune cell trafficking and antigen presentation, likely promoting immune cell recruitment.
Furthermore, tissue-specific imprinting influences cDC2 plasticity not only within tumors but also in non-malignant tissues, as they were found to have the greatest number of differentially expressed genes (DEGs) among DC subsets when comparing normal tissues, indicating a non-negligible role of tissue imprinting in shaping cDC2 functionality.
Collectively, our findings illuminate cDC adaptations in both tumoral and steady state conditions, particularly highlighting their functional plasticity and role in immune cell recruitment, driven by tissue imprinting and paving the way for tailored immunotherapies. Understanding the interplay between cDC2s and the TME holds promise for enhancing therapeutic strategies and advancing precision oncology, as they could emerge as fire starters for cold tumors.

PD-1 Pathway in Rheumatoid Arthritis: Applying the brakes on synovial inflammation.

Hannah Costello[1], Aoife O'Rourke[1], Carl Orr[2], Douglas Veale[2], Ursula Fearon[1], Mary Canavan[1]
[1]Trinity Biomedical Sciences Institute, Dublin, Ireland; *[2]St. Vincent's University Hospital, Dublin, Ireland*

Purpose: In rheumatoid arthritis (RA), ongoing synovial inflammation causes degradation of cartilage and bone, leading to joint damage and disability. Co-stimulation signals are positive regulators of T cell activation in the RA joint. However, the role of negative regulators of T cell responses, have been less well described. PD-1 is an immune checkpoint, which functions to restore tolerance by binding PD-L1 expressed on antigen presenting cells such as dendritic cells. The role of PD-1 is well studied in the context of cancer, but less is known about the PD-1 pathway in autoimmunity.
Methods: Peripheral blood mononuclear cells (PBMC) and synovial fluid mononuclear cells (SFMC) were isolated from RA patients. Cells were stained with a panel of multicolour flow cytometry antibodies to assess cell frequency, activation, maturation, and metabolism. Samples were processed on the Cytek Aurora and analysed using FlowJo software.
Results: Firstly, we identified an accumulation of PD-1+ T cells (CD4 and CD8) in RA synovial fluid compared to RA blood. Within the inflamed joint, we also determined that PD-1+ CD4+T cells and PD-1+ CD8+ T cells do not display an exhausted phenotype; instead producing more TNF-α and significantly higher levels of IFN-γ (CD4; **$p<0.05$**) than their negative counterparts. PD-1+ T cells in the RA joint also produce significantly more proinflammatory cytokines then PD-1+ cells within the circulation, suggestive that the unique inflamed joint microenvironment may drive the accumulation of pathogenic PD-1+ T cells in the joint. Next, to determine if PD-1 signalling was likely to occur in the joint, we investigated if the ligand for PD-1 was available in the joint. Specifically, we found that PD-L1- cells were significantly more abundant in the RA joint compared to PD-L1+ antigen presenting cells **($p<0.05$**) including cDC1 **($p<0.05$**) and cDC2 **($p<0.05$**). Although PD-L1+ APCs are rare in the RA joint, they displayed significantly higher expression of co-stimulation markers CD80 and CD40 **($p<0.05$**).
Conclusions: PD-1+ T cells are enriched at the site of inflammation in RA, displaying a proinflammatory phenotype. This inhibitory pathway is unlikely to be engaged due to the lack of tissue specific PD-L1 in the joint.

Inflammatory CD1c+ CD163+ dendritic cells are enriched in the inflamed joint and contribute to rheumatoid arthritis pathology

Hannah Costello[1], Aoife O'Rourke[1], Carl Orr[2], Douglas Veale[2], Ursula Fearon[1], Mary Canavan[1]
[1]Trinity Biomedical Sciences Institute, Dublin, Ireland; *[2]St. Vincent's University Hospital, Dublin, Ireland*

Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease that develops because of a break in tolerance to otherwise harmless self-antigen. Given the important role dendritic cells (DC) have in maintaining immunological tolerance and immunogenicity, we hypothesised that DC may contribute to ongoing synovial inflammation in the joints of RA patients. While we previously identified an accumulation of cDC1 and cDC2 in the RA joint, the contribution of DC3 to synovial inflammation and joint destruction remains unknown. DC3 are a newly identified population of inflammatory DC, co-expressing the markers CD1c and CD163, thought to contribute to tissue specific inflammation. While they have been studied in the context of osteoarthritis and systemic lupus erythematosus, their role in RA is unknown.

Methods: Peripheral blood mononuclear cells (PBMC) and synovial fluid mononuclear cells (SFMC) were isolated from RA patients. Cells were stained with a panel of multicolour flow cytometry antibodies to assess cell frequency, activation, maturation, and metabolism. Samples were processed on the Cytek Aurora and analysed using FlowJo software.

Results: While circulating DC3 have been identified in SLE, the role of DC3 in RA remains unclear. Firstly, we identified an enrichment in the frequency of DC3 within the peripheral blood of RA patients compared to healthy controls **($p<0.05$)** paralleled with higher levels of CD80, PD-L1 and CD40 **($p<0.05$)** –indicative of increased DC maturation and activation in the periphery. Furthermore, upon examination at the site of inflammation – we identified a significant enrichment of DC3 in RA synovial fluid compared to peripheral blood **($p<0.05$)**. Synovial DC3 display heightened levels of CD80, CD40 and PD-L1 (**$p<0.05$**) further suggesting that inflammatory DC3 are strategically placed to reactivate synovial T cells. Importantly, DCs utilise a variety of metabolic pathways to generate energy to support their immune function. We identified that synovial DC3 significantly upregulate the expression of GLUT-1 **($p<0.05$)** concomitant with an increase in fatty acid uptake receptor CD36, – suggestive that both carbohydrate and fatty acid metabolism may support the long-term survival and function of DC3 in the RA joint.

Conclusion: DC3 are enriched in RA and may present a new therapeutic target for suppressing synovial inflammation.

The Role of Immunological Memory in Synovial Inflammation in Rheumatoid Arthritis.

Aoife O'Rourke[1], Rebecca Stokell[1], Hannah Costello[1], Carl Orr[2], Douglas Veale[2], Ursula Fearon[3], Mary Canavan[1]
[1]Translational Immunopathology, Trinity Biomedical Sciences Institute, Dublin, Ireland; *[2]St. Vincent's University Hospital, Dublin, Ireland*; *[3]Molecular Rheumatology, Trinity Biomedical Sciences Institute, Dublin, Ireland*

Purpose: Lifelong protective immunity requires a sufficient number of diverse naïve T cells (TN) that are ready to expand and differentiate when faced with antigenic challenge. The generation of memory T cells is also essential. Given that joint swelling arising from Rheumatoid Arthritis (RA)tends to flare in the same previously affected joints, and involvement of a formerly unaffected joint is rare, we hypothesis that local tissue memory may mediate disease flare.
Methods: Peripheral blood and synovial fluid mononuclear cells from RA patients were isolated using density gradient centrifugation and cultured overnight in the absence/presence of PMA and Ionomycin, alongside Brefeldin-A (Golgi blocker). The samples were stained with a 20-colour flow cytometry panel to assess memory T cell frequencies and their activation capacities. All samples were processed on the Cytek Aurora cytometer and analysed using FlowJo software.
Results: Upon examination of RA synovial fluid, a small but distinct population of $CD4^+$ and $CD8^+$ TN cells are present. Interestingly, following antigen stimulation $CD4^+$ synovial TN cells produced significantly higher levels of IFNγ($P<0.001$), TNFα($P<0.01$), IL-17A($P<0.01$) and GM-CSF($P<0.001$) compared to peripheral blood. Similarly, $CD8^+$ TN cells from the site of inflammation produced significantly higher levels of IFNγ($P<0.0001$) and GM-CSF($P<0.01$). Synovial TN cells demonstrated greater polyfunctionality properties compared to peripheral blood TN cells, as demonstrated by their ability to coproduce multiple proinflammatory cytokines simultaneously. This suggests that TN cells residing within the joint are primed to become more inflammatory upon stimulation compared to their peripheral blood counterparts. Furthermore, we demonstrated that this enhanced inflammatory profile is supported by altered cellular bioenergetics. The expression of GLUT1 is decreased in synovial TN cells compared to peripheral blood, concomitant with a significant increase in CD36 expression, suggestive that synovial TN cells utilise fatty acid metabolism to support their pro-inflammatory functions. These results suggest synovial TN cells are primed by inflammatory mediators within the joint microenvironment to support T cell activation and differentiation.
Conclusion: Naïve T cells present in the RA synovium are primed to respond more potently to antigenic stimulation and may utilise fatty acid metabolism to support these pathogenic functions.

PD-L1-expressing eosinophil-mediated regulation of immunity and pulmonary inflammation

Daniel Ivers[1], Alexander Lawrence[1], Heike Hawerkamp[1], Vincent Kelly[2], Conor Finlay[3], Christian Schwartz[4], Padraic Fallon[1;3]
[1]School of Medicine, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland; *[2]School of Biochemistry & Immunology, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland*; *[3]Trinity Translational Medicine Institute, Trinity College Dublin, Dublin, Ireland*; *[4]Institute of Clinical Microbiology, Immunology and Hygiene, Universitätsklinikum Erlangen and Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany*

Purpose: Eosinophilia presents as a defining feature of aberrant type 2 inflammation across a range of disease states, particularly in allergic asthma. Despite extensive research, questions remain as to the functional role of eosinophils in the regulation or genesis of inflammation in tissues such as the lung. We previously reported that expression of programmed death-ligand 1 (PD-L1) on distinct cell populations acts as a checkpoint on type 2 immunity to maintain immune homeostasis in the lung. During allergic lung inflammation in mice models, we have explored the function of PD-L1 expressing eosinophil populations associated with the development of tissue inflammation and associated tissue damage.
Methods: Mice were subjected to three distinct acute or chronic models of allergic lung inflammation; *Nippostrongylus brasiliensis* infection, intranasal challenge with house dust mite (HDM: *Dermatophagoides pteronyssinus*) or Interleukin-33. Flow cytometry was used to identify distinct eosinophil populations; $CD45.2^+$ $CD11b^+$ $F4/80^-$ $SiglecF^+$. Histology and NanoString gene expression analysis were performed. Bone marrow (BM) chimera mice were generated - ΔdblGATA/WT and ΔdblGATA/PD-$L1^{-/-}$ - for eosinophil-specific targeting of PD-L1.
Results: Distinct subpopulations of eosinophil were evoked in the lungs of wildtype mice, with kinetic differences in PD-L1 expression following *Nippostrongylus brasiliensis* infection and intranasal challenge with IL-33 or HDM. HDM-induced lung sensitisation evoked marked pulmonary pathology and inflammation, with a distinct alteration in type 2 immune cells, in BM chimeras with eosinophil-specific deletion of PD-L1. Analysis of PD-L1 deficient chimeric mice revealed changed frequency in programmed cell death protein 1 (PD-1) expressing $CD4^+$ T-cell populations, including Th2 and Treg cells.
Conclusion: Allergic lung inflammation induces recruitment of distinct PD-L1 expressing inflammatory eosinophils, with functional roles in ameliorating allergic type 2 inflammatory responses in mice models. Absence of PD-L1 expressing eosinophils contribute to marked changes in PD-1^+ innate and adaptive type 2 cells and Treg cells in aberrant lung inflammation. The potential suppressor/regulatory roles for PD-$L1^+$ eosinophils recruited to the allergic lung, acting as a checkpoint in pulmonary inflammation will be described.

Memory T cells play a crucial role in orchestrating efficient immune responses against pathogens. Here, we present compelling evidence demonstrating the critical role of bone marrow resident memory T cells (TRM) in conferring long-term immunity. Our findings highlight the significance of bone marrow memory T cells in shaping systemic immune responses, particularly in the context of SARS-CoV-2 and vaccination. Our investigations reveal that human bone marrow professional memory T cells, despite expressing activation markers, maintain a resting state, suggesting a unique mode of long-term immune memory storage. Notably, the bone marrow harbors an enrichment of pathogen-specific $CD4^+$ memory T cells, providing sustained memory for systemic pathogens. Expanding upon this, we demonstrate the mobilization of TRM from the bone marrow into the bloodstream following secondary immune reactions to MMR (measles-mumps-rubella) vaccination. Importantly, we observe that TRM recognizing other antigens are not mobilized, unless they cross-react with the vaccine, underscoring the significance of cross-reactivity in TRM mobilization. These mobilized TRM significantly contribute to systemic immune memory, as evidenced by their representation among newly generated circulating memory T-cells post-vaccination. Furthermore, we unveil the presence and significance of preexisting SARS-CoV-2-reactive memory $CD4^+$ T cells within the bone marrow, even in individuals with no prior exposure to the virus or its vaccines. These bone marrow resident memory T cells, abundant and polyfunctional, play a crucial role in shaping systemic immune responses to SARS-CoV-2, potentially contributing to the establishment of long-lasting immunity. Collectively, our findings underscore the importance of cross-reactive bone marrow resident memory T cells in providing robust and enduring immunity against pathogens. Understanding their role enhances our comprehension of immune memory and informs the development of strategies to bolster protective immunity.

Abnormalities of skeletal muscle regeneration and macrophage polarization in Nakajo-Nishimura syndrome.

Naoya Kase[1], Akira Niwa[1], Nobuo Kanazawa[2], Megumu Saito[1]
[1]Department of Clinical Application, Center for iPS cell research and application (CiRA), Kyoto University, Kyoto city, Kyoto, Japan; *[2]Department of Dermatology, Hyogo Medical University, Nishinomiya city, Hyogo, Japan*

Nakajo-Nishimura syndrome (NNS) is an autoinflammatory disease with skeletal muscle atrophy caused by homozygous point mutations in the *PSMB8* gene encoding the β5i subunit of the immunoproteasome. To elucidate the mechanism of skeletal muscle atrophy in NNS, we analyzed knock-in mice ($PSMB8^{G201V}$) in which the patient mutation was introduced and found that the efficiency of skeletal muscle regeneration was significantly lower than that in wildtype mice. The proliferative efficiency of satellite cells in $PSMB8^{G201V}$ during regeneration was also significantly lower. However, satellite cells grown in ex vivo culture showed no difference in growth rate between wildtype and $PSMB8^{G201V}$. Moreover, infiltrating macrophages during skeletal muscle regeneration showed abnormal anti-inflammatory polarization and decreased production of inflammatory cytokines in $PSMB8^{G201V}$, suggesting that they contribute to the decreased proliferation efficiency of muscle satellite cells. However, the production of inflammatory cytokines by bone marrow-derived macrophages was rather increased in $PSMB8^{G201V}$, indicating an autoinflammatory phenotype. These results suggest that $PSMB8^{G201V}$ macrophages acquire a specific phenotype during skeletal muscle regeneration and contribute to reduced efficiency of muscle regeneration.

Marine sulphated polysaccharides stimulate innate immunity to fight infection in a model of post-traumatic immunosuppression

Maëva Guillonneau[1], Marwan Bouras[2;3], Alexander Kettner[4], Marion Davieau[2], Mélanie Petrier[2], Cynthia Fourgeux[2], Cédric Jacqueline[2], Antoine Roquilly[2;3], Karim Asehnoune[2;3], Pierre Rocheteau[1;4]
[1]Olgram, Brehan, France; *[2]Nantes Université, CHU, INSERM, Center for Research in Transplantation and Translational Immunology, UMR 1064, Nantes, France*; *[3]CHU Nantes, INSERM, Nantes Université, Anesthesie Reanimation, CIC 1413, Nantes, France*; *[4]Olgram, Plan-les-Ouates, Switzerland*

Ventilator-associated pneumonia (VAP) is the most frequent nosocomial infection in intensive care units, particularly affecting patients with severe traumatic brain injuries. Indeed, head injury generates a systemic inflammatory response (SIRS), which is then accompanied by a compensatory anti-inflammatory response (CARS) aiming at the restoration of immune homeostasis. If the CARS persists, it leads to systemic immunosuppression promoting secondary infections. At the cellular level, the mechanisms are a decrease in the capacity of dendritic cells and monocyte-macrophages to present antigen to effector cells, a decrease in the number and capacity of secretion of pro-inflammatory cytokines by effector cells (NK, T cells).
Among the emerging immunostimulant therapeutics, marines sulfated polysaccharides (SPs) are a relevant research axis. Current studies suggest that sulfated polysaccharides primarily exert immunomodulatory effects by promoting macrophage, T cells, and NK cell proliferation, increasing cytokine release, and regulating the immune system through feedback of anti-inflammatory cytokines. SPs from *Ulva Lucinulata* have shown their immunostimulant effects *in vitro* and *in vivo* in animals.
In our study, we investigated the immunostimulatory potential of SPs in a preclinical mouse model of secondary pulmonary infection after traumatic brain injury. We studied the effects of this compound on the main functions of innate immune cells in the lung. In our model of post-trauma immunosuppression, we were able to demonstrate that SPs improved the general condition of the mice and their resistance to infection. In the lung, SPs partially restored the number of NK cells and their IFNγ expression, as well as macrophages and their phagocytosis activity, in the context of an infectious challenge.
In conclusion, our results strongly suggest that SPs restores the ability to recruit immune cells to the lung during post-traumatic immunosuppression and protects against systemic infection. The growing interest in the effects of algal polysaccharides is a strong indication of their potential relevance as a new therapeutic modality. The fact that they target the host immune system rather than the pathogen is also a key factor in limiting the development of bacterial resistance to antibiotics.

Signaling pathways and differentially expressed genes associated with placental pathology in antiphospholipid syndrome

Anush Martirosyan[1], Susanna Ghonyan[1], Eva Kriegova[2], Anna Petrackova[2], Jakub Savara[2], Gayane Manukyan[1]
[1]*Laboratory of Molecular and Cellular Immunology, Institute of Molecular Biology NAS RA, Yerevan, Armenia*;
[2]*Department of Immunology, Faculty of Medicine and Dentistry, Palacky University and University Hospital, Olomouc, Czech Republic*

Purpose: Antiphospholipid syndrome is an autoimmune thrombophilia defined by the presence of circulating antiphospholipid antibodies (aPL). Obstetric morbidity is the hallmark of APS. Heterogeneous pregnancy complications, including placental pathology, have been increasingly studied in the past years but still continue to present a formidable clinical and scientific challenge.
Methods: We performed RNA-seq analysis of the mid-pregnancy placenta from mice with well-established APS and healthy controls animals, followed by validations with morphological staining.
Results: The GO function and KEGG pathway enrichment analyses revealed that the biological functions of differentially regulated genes are highly associated with the regulation of developmental processes, cell cycle, proliferation and cellular senescence. Disturbed tissue homeostasis presumably was driven by aPL-activated signaling through p53, PI3K/AKT pathways and motor proteins, as evidenced by KEGG pathway analysis. These alterations were accompanied with metabolic adaptations, including shifts in carbon, pyrimidine and energy metabolism. Also, we evidenced differential regulation of genes involved in pathways for oxygen binding and HIF-1 hypoxia-related pathways. This observation was supported by the presence of nucleated red blood cells in a labyrinth, identified in histological sections of APS placenta, which might reflect hypoxia of the fetus. Microscopic examination of APS placenta sections also revealed vascular wall thinning and areas with fibrin depositions.
Conclusion: Altogether, we identified a number of regulatory mechanisms that separately or combine are capable of contributing to placental insufficiency. Our data indicate that altered mechanosensitive capacity of cells may define defect trophoblast functioning and survival, influenced by the levels of shear stress they encounter.

Mast cells and their adipokine receptors: a role of specific ligands in expression shift

Paulina Żelechowska[1], Magdalena Wiktorska[2], Elżbieta Kozłowska[1], Justyna Agier[1]
[1]Department of Microbiology, Genetics and Experimental Immunology, Center for Molecular Research of Civilization Diseases, Medical University of Lodz, Poland, Lodz, Poland; *[2]Department of Molecular Cell Mechanisms, Medical University of Lodz, Poland, Lodz, Poland*

Purpose: Mast cells (MCs) are significant sensor and effector cells of the immune system involved in various physiological and pathological conditions. A primary function of MCs is modulating inflammatory processes since MC-derived molecules exert pro-, anti-inflammatory, and regulatory effects. Even though MCs may affect different phases of acute and chronic inflammation, emerging data indicates that they contribute to low-grade inflammatory reactions associated with obesity. This phenomenon is strongly regulated by adipokines synthesized by adipocytes and various immune cells in adipose tissue. Despite adipokines being viewed as crucial for regulating body metabolism, mounting evidence shows they are also critical for immunological mechanisms and inflammatory responses. Adipokines mediate their actions through specific receptors widely distributed in many cell and tissue types. However, limited data are available on their expression in mast cells (MCs) and, consequently, adipokine's significance in the modulation of MC activity. This study aimed to evaluate the constitutive and adipokine-induced expression of receptors for key adipokines (leptin, adiponectin, and chemerin) in MCs.
Methods: Experiments were conducted *in vitro* using freshly isolated peritoneal MCs from female albino Wistar rats. Flow cytometry evaluated adipokine receptors' constitutive and adipokine-induced expression (LEPR, ADIPOR1, ADIPOR2, and CMKLR1).
Results: Tissue MCs constitutively express receptors for leptin, i.e., LEPR, adiponectin, i.e., ADIPOR1 and ADIPOR2, and chemerin, i.e., CMKLR1. We also observed that LEPR, ADIPOR1, ADIPOR2, and CMKLR1 expression levels in MCs change in response to stimulation by their specific ligands.
Conclusion: Our findings suggest that adipokines leptin, adiponectin, and chemerin may influence the activity of tissue MCs in various processes, especially during inflammation. These observations support the thesis on the role of MCs in chronic low-grade inflammation associated with increased adiposity. This insight could open new avenues for understanding and managing inflammation-related conditions.

UTERINE NATURAL KILLER CELLS IN WOMEN WITH RECURRENT PREGNANCY LOSS AND IMPLANTATION FAILURE

Nilgun Akdeniz[1], Burcin Karamustafaoglu Balcı[2], Esin Cetin Aktas[1], Vuslat Yilmaz[3], Abdullah Yılmaz[1], Cemil Akgul[2], Gunnur Deniz[1]
[1]Istanbul University, Aziz Sancar Institute of Experimental Medicine, Department of Immunology, Istanbul, Turkey; *[2]Istanbul University, Istanbul Faculty of Medicine, Department of Surgical Medical Sciences, Department of Reproductive Endocrinology, Istanbul, Turkey*; *[3]Istanbul University, Aziz Sancar Institute of Experimental Medicine, Department of Neuroscience, Istanbul, Turkey*

Although the functions of uterine natural killer (NK) cells are still unclear, they are thought to play an important role in the early stages of pregnancy. In this study, we aimed to investigate peripheral blood and endometrial NK cell functions in recurrent pregnancy loss. Patients who applied to Istanbul University, Istanbul Faculty of Medicine, Infertility Outpatient Clinic with recurrent pregnancy loss (n=20) and people who applied due to recurrent miscarriage but had children (n=10) constituted the control group. In cells isolated from peripheral blood and endometrium, lymphocyte subsets and NK cell cytotoxic activity (expression of perforin, granzyme and CD107a) were evaluated by flow cytometry. Uterine $CD3^+$ T lymphocyte ratio decreased significantly compared to peripheral blood in both controls and recurrent pregnancy losses ($p<0.01$, $p<0.001$, respectively). Similarly, uterine $CD19^+$ B lymphocytes were significantly lower in recurrent pregnancy losses compared to peripheral blood ($p<0.01$ $p<0.0001$, respectively). It was found that both blood and uterine NK cell ratios were significantly higher in recurrent pregnancy losses compared to the control group ($p<0.0001$). When evaluated in terms of perforin/granzyme, decreased uterine NK ratios and an increased CD107a expression were observed in both groups compared to peripheral blood ($p<0.0001$, $p<0.001$, respectively). In the control group, uterine NK CD107a expression was significantly reduced compared to peripheral blood ($p<0.05$). The altered numbers and functional properties of peripheral and uterine NK cells in recurrent pregnancy loss indicate that these cells may play a role in the pathogenesis of the disease.

Characterization of the immune cell signature in pulmonary hypertension associated with chronic lung diseases

Bernhard Reiter[1;2], Katharina Jandl[2;3], Ayu Hutami Syarif[1], Sophia Auner[4], Konrad Hoetzenecker[4], Grazyna Kwapiszewska[1;2], Leigh M Marsh[1;2]
[1]Otto Loewi Research Centre, Graz, Austria; *[2]Ludwig Bolzumann Institute for Lung Vascular Diseases, Graz, Austria*; *[3]Otto Loewi Research Centre, Division of Pharmacology, Medical University of Graz, Graz, Austria*; *[4]Department of Thoracic Surgery, Medical University of Vienna, Vienna, Austria*

Rational: Chronic lung diseases (CLD), such as chronic obstructive pulmonary disease (COPD) and pulmonary fibrosis (PF), are highly heterogeneous severe conditions, which are associated with a decreased quality of life and increased mortality. The presence of pulmonary hypertension (PH) in CLD, which is caused by a progressive remodelling of the pulmonary arteries (PA), is associated with worse patient prognosis. In the idiopathic form of PH (WHO Group 1) the immune system has been shown to have an important role in this remodeling process. However, the extent of the immune involvement in PH which is associated with chronic lung diseases (Group 3) remain unclear. In this study we therefore investigate the immune cell profile of PH associated with CLD, such as COPD and PF.
Methods: PA were isolated from human end-stage PH-COPD(n = 14), PH-PF(n = 9) and control lungs from transplantations and cancer-free tissues (n = 9). The immune cell characterization was performed using several multicolour flow cytometry panels and analysed bioinformatically. Additionally, adjacent PA and lung tissues were embedded for further histological analysis.
Results: Principal component analysis (PCA) revealed an altered immune cell profile in the PA of PH-COPD and PH-PF compared to control, with the strongest separation between controls and PH-COPD. The immune composition in PH-PF were more heterogeneous and partially overlapped with the PH-COPD, indicating overlaps in the immune profile, but separated from the control in Principal Component (PC) 3. The separation of the PC1 is mainly driven by lymphocyte populations and macrophages and neutrophilic granulocytes, while the PC3 is driven by monocytes. Both CLD possessed an increased abundance of CD4 and CD8 lymphocytes and monocytes, and a decrease in neutrophil granulocytes and macrophages. Work is ongoing to determine immune cell localization and association of immune cell signatures with clinical and histological parameters, as well as single cell RNA-sequencing analysis to gain further information of immune and structural cell activation.
Conclusions: Our initial data indicates that there is an altered inflammatory profile between control and CLD-PH, and by understanding the immune profile in PA of CLD we can lay the foundations for future immunomodulatory PH treatments.

The Jak inhibitor filgotinib concentration-dependently suppresses immune responses in precision cut intestinal tissue slices ex vivo

Klaudia Maria Grieger[1], Valerie Beneke[1], Vanessa Neuhaus[1], Susann Dehmel[1], Ulf Kulik[2], Benjamin Gundert[3], Heiko Aselmann[3], Christina Hesse[1], Armin Braun[1], Katherina Sewald[1]
[1]Fraunhofer Institute for Toxicology and Experimental Medicine, Hannover, Germany; *[2]Hannover Medical School (MHH), Hannover, Germany*; *[3]KRK clinicum Siloah, Hannover, Germany*

Purpose: The global burden of inflammatory bowel disease (IBD) is reportedly increasing worldwide. Yet, the pathogenesis of the disease remains incompletely understood. Current treatments focus on controlling the abnormal inflammatory reactions in the intestine. Among new therapeutics, the Janus kinase (JAK) pathway has gained attention, with selective inhibition by drugs like filgotinib. It has shown promise in reducing inflammation and symptoms associated with IBD. The aim of this study was to investigate the effect of the JAK1 inhibitor filgotinib in patient-derived primary intestinal tissue slices *ex vivo*.
Methods: Precision cut intestinal slices (PCIS) were prepared from ileum and colon resections of IBD and non-IBD patients and treated with the T cell mitogen Concanavalin A ± filgotinib for 24h. We assessed tissue viability (LDH-assay), cytokine release (ELISA), and PCIS morphology (H&E-staining).
Results: IBD and non-IBD-derived intestinal tissue slices maintained viability in culture and presented typical intestinal morphology (e.g. crypts, villi, immune and epithelial cells). *Ex vivo* treatment with Concanavalin A upregulated the secretion of pro-inflammatory and T cell specific cytokines such as IL-6, IL-2 and IL-17A after 24h. This induction was inhibited by filgotinib (10 and 100 µM) in a dose-dependent manner. Of note, no increase in LDH release was observed in treated PCIS, indicating no adverse effects of filgotinib on the tissue´s viability in the applied concentrations. The effects of filgotinib were comparable in both ileal and colonic intestinal tissue slices.
Conclusion: Our data highlights anti-inflammatory effects of filgotinib in primary intestinal tissue slices *ex vivo*. These effects involve modulation of various T cell-associated cytokines implicated in JAK-STAT pathways. PCIS can be used to further elucidate potential JAK1 inhibitors and their mode of action in the context of IBD treatments.

Compartmentalized immune response in sepsis

Stavroula Litsiou[1], Stephan Culemann[1], Claudia Waskow[1;2]
[1]*Leibniz-Institut für Alternsforschung - Fritz-Lipmann-Institut (FLI), Jena, Germany*; [2]*Institute of Biochemistry and Biophysics, Faculty of Biological Sciences, Friedrich-Schiller University, Jena, Germany*

Imbalanced immune response to infection leads to sepsis, though little is known on the compartmentalized alterations of cell numbers and microenvironment across vital organs.
We use the Peritoneal Contamination and Infection (PCI) model to track the displacement of neutrophils (PMN), Ly6Chi monocytes (Mono), DC, tissue resident macrophages (TRM), T and B cells by flow cytometry in 5 organs: peritoneum (PeC), liver, spleen, blood and bone marrow (BM).
At 6h post PCI, PMN and Mono egress from spleen and BM and infiltrate PeC and liver. In contrast, B cells abandon PeC and liver – but not BM – and migrate towards spleen. PMN and B cell, but not Mono relocation is also reflected in blood counts. In a healthy liver and blood the majority of immune cells positively correlate with each other, a dependency lost upon sepsis. Inter-organ correlations are scarce, but distinct between the conditions. During sepsis B cells in spleen negatively correlate with B cells and DC in PeC and in liver Kupffer cells positively correlate with Mono, suggesting fine-tuned intra- and interorgan mechanisms responsible for compartmentalized cell flow patterns.
From all cells, PMN and Mono in liver and BM as well as B cells in spleen (but no cell from blood) were the most informative with 73-80% accuracy in distinguishing between healthy and septic mice.
PMN and Mono migration suggest PeC and liver as focal points to fight pathogens. Bacteria spreading confirms the highest load in these 2 organs with spleen and BM being less affected. As anticipated, in vivo phagocytosis occurred predominantly in PeC and liver, but only by TRM and PMN – not Mono.
We measured a total of 200 secreted mediators and identified both a unique and a shared secreted protein signature in all 5 tissues. 8 factors including known and novel targets classify apart with up to 100% accuracy healthy from septic mice.
In conclusion, we report a highly compartmentalized immune response aligning with bacteria translocation in acute sepsis. Distinct infiltration patterns and newly formed intra- and interorgan cell dependencies suggest a complex crosstalk between immune cells and secreted mediators.

Association of autoantibodies with pregnancy outcomes

Chistina Tsigalou[1], Elisabeth Stavropoulou[1], Konstantinos Nikolettos[2], Alexandros Karvelas[1], Theocharis Konstantinidis[1], Grigorios Trypsiannis[3], Nikolaos Nikolettos[2], Panagiotis Tsikouras[2]
[1]Laboratory of Hygiene and Environmental Protection, Democritus University of Thrace, Greece and Master in Food, Nutrition and Microbiome, Alexandroupolis, Greece; *[2]Department of Obstetrics and Gynaecology, Democritus University of Thrace, Greece, Alexandroupolis, Greece*; *[3]Department of Medical Statistics, Democritus University of Thrace, Greece, Alexandroupolis, Greece*

Purpose: The impact and aetiologies of rheumatic diseases are multifactorial and mostly still unclear. Autoantibodies could be found in all autoimmune diseases such as Sjögren's disease (SJ), as well as in non-autoimmune disorders. The aim of this study was to determine the level of autoantibodies in pregnant women and explore their clinical significance.
Methods: This is a 3-year prospective study performed at the University Obstetrics-Gynecology Department of Democritus University of Thrace during the period of June 2020-June 2023. The data were collected from 79 pregnant woman and 70 controls. The testing for antinuclear autoantibodies (ANAs) and anti-dsDNA was performed by using conventional indirect immunofluorescence assay (IIF) at dilution ratios of 1/80, 1/160, 1/320, and 1/640, with a cutoff for positivity set at 1/80 for ANA and dilution ratio of 1/10 for anti-dsDNA. The ENA screen (Extractable nuclear antigens) was performed by ELISA for the following antigens: Anti-SSA(Ro), Anti-SSB(La), Anti-Sm, Anti-SmRNP, AntiJo-1, Anti- Scl-70. In case of positivity (cut-off value >1), specific ELISA kits for each autoantibody were employed. The aPL (anti-phospholipid abs) both IgG and IgM types (ACA), were measured by ELISA Statistical analysis of the data was performed using IBM Statistical Package for Social Sciences (SPSS), version 19.0 (IBM Corp., Armonk, NY, USA).
Results: ANA-positivity was significantly more frequent among pregnant (11/79) than healthy controls (3/70) (13.9% vs 4.3%, p=0.044; OR=3.61, 95% CI=0.97-13.53). Among them 7 (8.9%) had titer 1/80, 3 (3.8%) 1/160 and 1 (1.3%) 1/320. Considering the of immunofluorescence pattern of the 11 ANA positive: 5 (45.5%) had Homogeneous pattern, 4 (36.4%) had Dense Fine Speckled 70 (DFS-70) pattern, and 2 (18.2%) had fine speckled pattern. In relation to the diagnosis, ANA-positive were correlated with death fetus (2 of 5 patients, 40.0%), RSA (3 of 11 patients, 27.3%), spontaneous abortion (2 of 11 patients, 18.2%), missed abortion (2 of 29 patients, 6.9%) or other disease.
Conclusion: Our results indicate that alterations in the levels of autoantibodies are more frequent in pregnancy in comparison to controls**.** Pregnancies complicated by rheumatic diseases should be approached interdisciplinary, by teams of experienced professionals.

Ointment in the flies: augmentation and synergy of host defense peptide against AMR bacteria in epithelial and systemic infection

Patrick Lennard[1], Pieter Hiemstra[2], Julia Dorin[1], Peter Nibbering[2]
[1]*University of Edinburgh, Edinburgh, United Kingdom*; [2]*Leiden University Medical Center, Leiden, Netherlands*

Host defence peptides (HDPs) show promise in combating multidrug-resistant (MDR) bacteria; however, their use is limited by their restricted activity in physiological conditions and the development of resistance. Synthetic antibacterial and anti-biofilm peptides (SAAPs), based on HDP sequences, have been developed to bypass these limitations. The leading candidate, SAAP-148, shows promise in its direct activity against MDR bacteria, but its efficacy in robust tissue models of infection and *in vivo* remains to be explored. As HDPs are unlikely to advance clinically as monotherapies, the synergistic employment of SAAP-148 required clarification likewise. Here, we have assessed the ability of SAAP-148 to: prevent infection in 3D culture models of skin and bronchial respiratory epithelium; synergise with novel nonpeptide antibacterial agents against MDR bacteria; and deter *Staphylococcus aureus* lethality in *Drosophila melanogaster* as an *in vivo* model of infection. We demonstrated that SAAP-148 application on 3D skin and bronchial respiratory epithelial models up to 24 hours prior to infection with MDR *S. aureus* or *Pseudomonas aeruginosa* prevented the colonization of skin but not airway tissue models. In addition, SAAP-148 synergises with the nonpeptide antibiotic halicin against MDR bacteria in skin models, and the agents act additively in airway tissue models. In systemic infection of *Drosophila*, SAAP-148 and halicin synergistically inhibited the growth and lethality of *S. aureus* and *Providencia rettgeri* during early stages of infection, where neither agent alone effectively limited infection. Further, the response of infected *Drosophila* depleted of endogenous HDPs highlights the potential of SAAP-148 and halicin to synergise with native peptides against bacterial infection. Together, these results support the efficacy of SAAP-148 as a prophylactic agent against MDR epithelial infections, and as a synergistic treatment in combination with halicin against both epithelial infections *in vitro* and systemic infections *in vivo*.

Exploring red blood cells as a novel tolerogenic approach for factor VIII inhibitors employing immuno-dominant FVIII derived peptides presented on MHC class II

Mariarosaria Miranda[1], Eelke Brandsma[1], Paul Kaijen[1], Floris Van Alphen[1], Robin Van Bruggen[1], Karin Fijnvandraat[2], Sebastien Lacroix-Desmazes[3], Jan Voorberg[1]
[1]Sanquin, Amsterdam, Netherlands; *[2]University of Amsterdam, Amsterdam, Netherlands*; *[3]Centre de recherche Des Cordeliers, Paris, France*

Purpose: The primary challenge in the treatment of hemophilia A is the development of neutralizing antibodies (inhibitors) against factor VIII (FVIII). Immune tolerance induction (ITI) is the standard approach to eradicate anti-FVIII antibodies. Since ITI is efficient in only 60-80% of cases, within the EDUC8-consortium we are pioneering innovative methods to reduce the immunogenicity of biotherapeutics. Here, we utilized bioinformatics and proteomic-based peptide presentation assays to identify promiscuously presented FVIII peptides for potential use in immuno-tolerogenic approaches. To this end, we are exploring red blood cells (RBCs) as innovative antigen delivery system to modulate the immune response.
Methods: A data-set of naturally processed FVIII peptides was generated by incubating human FVIII with immature monocytes-derived DCs from HLA-typed healthy donors. Special attention was given to the identification of HLA-DP4-FVIII derived peptides, as these alleles are highly prevalent in the Caucasian population.
Results: We have developed a novel mass spectrometry-based protocol for investigating HLA-DR and HLA-DP antigen presentation using specific monoclonal antibodies. Through this method, we identified approximately 2000 HLA-DR and 1000 HLA-DP presented peptides. Notably, our analysis revealed over 100 HLA-DR and 14 HLA-DP4 presented peptides derived from FVIII. Two HLA-DR presented FVIII peptide from the A2 and C1 domain respectively were fused to a cell-penetrating peptide and incubated with RBCs. Flow cytometry demonstrated their dose-dependent binding to RBCs, which was confirmed by imaging flow cytometry. Macrophages efficiently endocytosed FVIII peptide-treated RBCs, as observed via confocal microscopy. Utilizing immunopeptidomic approaches, we established the functional presentation of RBC-derived peptides on MHC class II molecules on macrophages. Specifically, the TAT-A2 FVIII peptide exhibited efficient processing and presentation on HLA-DR molecules on macrophages. Importantly, incubation of TAT-C1 FVIII-treated RBCs loaded macrophages with a FVIII-specific T cell hybridoma led to a significant increase in IL-2 production, suggesting the potential of peptide-loaded RBCs for immune system modulation.
Conclusion: Our data provide an inventory of promiscuously presented FVIII-derived peptides which guide the development of novel tolerogenic approaches for FVIII inhibitors employing RBCs as carrier.

Impact of commonly used immunosuppressants on Treg phenotype and function

Daniel Acevedo[1;2], Joaquim Coloma[1;2], Yiyi Luo[1;2], Alexandru Vlagea[2], Ana Esteve-Solé[1;2], Laia Alsina[1;2;3]
[1]Clinical Immunology and Primary Immunodeficiencies Unit, Allergy and Clinical Immunology Department, Hospital Sant Joan de Déu, Esplugues de Llobregat, Barcelona, Spain; *[2]Clinical Immunology Unit, Hospital Sant Joan de Déu-Hospital Clínic, Barcelona, Spain*; *[3]Department of Surgery and Surgical Specializations, Facultat de Medicina i Ciències de la Salut, Universitat de Barcelona, Barcelona, Spain*

Purpose: Inborn errors of immune dysregulation are a heterogeneous group of disorders with clinical variability that affect genes involved in the regulation of the immune system. Those presenting with a phenotype caused by loss of tolerance mechanisms leading to autoimmunity, autoinflammation, lymphoproliferation, and/or severe atopy have come to be recognized as having Primary Immune Regulatory Disorders (PIRD) since 2020. Currently, high-potency nonspecific immunosuppressant treatments such as steroids or cyclosporine are being used to control these manifestations. Such treatments have multiple side effects and add many complications to the chronically affected organs in these patients, which is accentuated by the fact that these treatments must be used for long periods of time. With the aim of applying targeted therapies to control immune dysregulation in these patients and minimize side effects, new treatments are being tested. These new therapies include: JAK-STAT pathway inhibitors (Ruxolitinib), PI3K/AKT/mTOR pathway inhibitors such as sirolimus and others.
Methods: exposure of PBMCs of healthy controls to 4 commonly used immunomodulators at different concentrations (RAPA 20ng, 100ng, 500ng; Tacrolimus 5ng, 10ng, 15ng; Mycophenolic acid 5ng, 10ng, 15ng and Ruxolitinib 0.1uM, 0.3uM, 1uM) to assess the mechanistic impact of the drugs on Treg cells. Different regulatory cell populations beyond classical CD25hiCD127lowFoxP3+ Treg cells, such as Tr1, CD8+CD122+PD-1+, CD8+CD28-CD56+ cells and expression of suppression markers such as TIM-3, TIGIT, GITR are explored by multiparametric flow cytometry.
Results: preliminary results (n=2) show a different impact depending on drug, dose and study population. For Tr1 cells, ruxolitinib at 0.3uM appears to increase the cell population dramatically compared to the other drugs. For the CD8 regulatory compartment, mycophenolic acid tends to increase this cell population while rapamycin tends to decrease it. Finally, the classical Treg populations together with the expression of suppression markers do not show relevant changes.
Conclusion: Although some drugs at specific doses tend to increase or decrease certain regulatory populations, further replicates and suppression trials will be conducted to uncover the mechanism by which these commonly used immunomodulators impact on Treg function and phenotype.

In situ reprogramming of dendritic cells for immunomodulation of FoxP3+ regulatory T cells

Elisa Blickberndt[1], Ari Waisman[1]
[1]*Institute of Molecular Medicine, Mainz, Germany*

The purpose of this project is to investigate the tolerance mechanisms observed in mice with experimental autoimmune encephalomyelitis (EAE), a murine model for multiple sclerosis (MS), after applying a non-inflammatory mRNA coding for myelin oligodendrocyte glycoprotein (MOG). This mRNA has been developed by Krienke et al. and it is specifically taken up by CD11c+ cells where the MOG peptide is then expressed on MHCII. When applied in mice with an active EAE, there is a decrease in MOG-specific T cells and an increase in regulatory T cells in the spleen. This project focuses on the mechanisms leading to the tolerance induction as well as the cells involved.
In order to investigate the impact that the priming phase of EAE has on the tolerance induction, we will apply the mRNA in mice with an adoptive transfer EAE.
Additionally, we will analyze the cells involved in the observed tolerance induction, the mRNA will be applied in mice with an active EAE and the gene expression profile of the Tregs that infiltrate the CNS will be analyzed. To do so, a novel single cell sequencing technique called “zman sequencing” will be applied (Kirschenbaum et al., 2024). Zman sequencing allows to introduce time stamps by injecting anti-CD45 antibodies coupled to different fluorophores at different time points. When performing single cells sequencing of the CNS, it can be differentiated which cells infiltrated at which time point. This technique is especially interesting to apply in this context since it allows us to cover multiple days during the course of EAE.
Currently, we focus mostly on the establishment of this technique in EAE. We could show the exclusion of labeling of the long-term CNS-resident microglia population even during neuroinflammation at the onset, peak and recovery phase of the disease. Additionally, we could show that time stamps up to 48 hours before opening mice could still be detected by flow cytometry. These findings highlight the applicability of zman sequencing in EAE.

Induction of neonatal Fc receptor-mediated tolerance to therapeutic factor VIII in Hemophilia A

Alejandra Reyes-Ruiz[1], Sandrine Delignat[1], Victoria Daventure[1], Aishwarya Bhale[2], Krishnan Venkataraman[2], Jordan D Dimitrov[1], Sebastien Lacroix-Desmazes[1]
[1]Institut National de la Santé et de la Recherche Médicale, Centre de Recherche des Cordeliers, CNRS, Sorbonne Université, Université de Paris, Paris, France; *[2]Centre for Bio-Separation Technology (CBST), Vellore Institute of Technology (VIT), Tamil Nadu, India*

Introduction: Development of inhibitory anti-factor VIII (FVIII) antibodies after replacement therapy with FVIII is a serious problem in hemophilia A patients.
Purpose: Foster a complete tolerance towards FVIII in Hemophilia A through the transplacental delivery of either Fc-fused FVIII, Fc-fused FVIII domains or Fc-fused immunodominant FVIII-derived peptides.
Methods: Binding of Fc-fused molecules to Fc neonatal receptor (FcRn) was evaluated at pH6 and pH7.4 by SPR and ELISA. Intracellular routing of the constructs was investigating by confocal microscopy, using human placental cells (BeWo) and human endothelial cells (HMEC-1) transfected with FcRn-EGFP. To evaluate the transplacental delivery, pregnant FVIII-KO mice were injected at day 17.5 of gestation with Fc-fused proteins. Foetuses were collected 4h later and the protein concentration was quantified by ELISA. In some mice, *in vivo* imaging on the mothers' organs, placenta, and fetuses were performed. For tolerance experiments, naïve pregnant FVIII-KO mice were injected from day 16 to 18 of gestation with different molecules, the progeny was weakly treated with FVIII. Anti-FVII antibodies were evaluated in the mice circulation.
Results: The FcRn mediates the transplacental delivery of Fc-fused FVIII (FVIII-Fc) but at insufficient levels (0.03±0.01nM) to foster FVIII-specific tolerance. The low transplacental delivery of FVIII-Fc in FVIII-KO mice is due to an impairment on the FcRn-mediated recycling of FVIII-Fc. Indeed, FVIII-Fc bound to FcRn at neutral pH, which reduced its release from FcRn in the extracellular space and favor its degradation in lysosomes. Masking the C1 and C2 domains of FVIII-Fc abrogated its binding to FcRn in neutral conditions. Accordingly, mutations in the C1 and C2 domains of FVIII-Fc prevented its binding to the FcRn at pH 7.4. Such improvement in the FcRn-mediating recycling had an impact on its transplacental delivery (the FVIII^{C1C2}Fc mutant showed a 8.7-fold increased in contrast to FVIII-Fc). In comparison with FVIII-Fc (0.03±0.01 nM), the transplacental delivery of domains-Fc (0.5-1 nM) and peptides-Fc (3-8 nM) were higher.
Conclusion: Due to their good placental crossing capacities, the FVIII^{C1C2}Fc mutant, domains-Fc and the peptides-Fc seem to be good candidates to improve the FVIII (entire, domains or peptides) delivery to the fetuses and favor induction of FVIII-specific tolerance.

Getting dynamic insights into the regulation of autoreactive germinal centers using serial intravital microscopy

Layla Pohl[1], Thomas R. Wittenborn[1], Cecilia Fahlquist-Hagert[1], Lisbeth Jensen[1], Ali Shahrokhtash[2], Donato Sardella[1], Alain Pulfer[3], Kristian Savstrup Kastberg[1], Duncan Sutherland[2], Santiago F. Gonzalez[3], Ina Maria Schiessl[1], Søren Egedal Degn[1]
[1]Department of Biomedicine, Aarhus University, Aarhus, Denmark; *[2]Interdisciplinary Nanoscience Center (iNANO), Aarhus University, Aarhus, Denmark*; *[3]Institute for Research in Biomedicine, Faculty of Biomedical Sciences, Università della Svizzera Italiana, Bellinzona, Switzerland*

Purpose: Germinal Centers (GCs) are dynamic and transient microanatomical structures, giving rise to antibody-producing plasma cells. Upon antigen exposure, GC responses are initiated and eventually shut down again when antigen has been cleared. In autoimmune diseases, however, GCs persist. How autoreactive GCs escape the mechanisms of shutdown under ongoing inflammation is unclear. T-follicular regulatory (Tfr) cells are known regulators of GC responses, hence investigating their involvement in the persistence of autoreactive GCs is crucial. Splenic autoreactive GCs are of special interest as the spleen is critical to clearance of circulating immune complexes and apoptotic debris, and splenomegaly represents a hallmark of autoimmunity. To our knowledge, long-lasting GC dynamics in the spleen have not been investigated yet.
Method: An abdominal imaging window over the spleen was used to capture autoreactive GC dynamics over two weeks during both their emergence and their shutdown. A TLR7 agonist, R848 (Resiquimod), was administered and paused to induce the respective initiation and shutdown of autoreactive GCs. To identify and follow the same GCs during two weeks, intravital labeling of follicular dendritic cells (CD35-iFluor647) was utilized. Foxp3-GFP-DTR mice were used to visualize T-regulatory cells, and Tfr cells were identified based on their localization in GCs.
Results: The initiation of an autoimmune response caused an increased spleen weight and expansion of GCs, whereas the shutdown of an autoimmune response caused a decreased spleen weight and contraction of GCs. Serial intravital imaging of the spleen revealed different Tfr cell influx patterns during autoreactive GC initiation and shutdown, while only perturbing mouse body weight and systemic inflammation minimally.
Conclusions: Longitudinal tracking of individual autoreactive GCs allows visualization of autoimmune responses without disturbing normal physiology. This involves capturing the progression and shutdown of autoimmune responses. Serial intravital imaging of GCs in the spleen, combined with different murine transgenic reporter models is a promising new research tool to study dynamic long-lasting cellular mechanisms contributing to either the progression or shutdown of (autoreactive) immune responses.

Central Tolerance Mechanisms in a CNS1-/- Rat Model

Artur Stoljar[1], Martti Laan[1], Pärt Peterson[1]
[1]*Institute of Biomedicine and Translational Medicine, Tartu, Estonia*

Central tolerance is crucial for preventing autoimmunity, with Aire playing a key role. Aire deficiency leads to autoimmune polyendocrinopathy candidiasis ectodermal dystrophy (APECED). Although CNS1's role in Aire regulation is documented in mice, its function and the impact of its deletion across species are not well understood. This study aims to elucidate the role of CNS1 in Aire expression and to characterize the autoimmune phenotype in CNS1 knockout (CNS1-/-) rats.
CNS1-/- rats were created via CRISPR/Cas9, using two guide RNAs to delete the CNS1 sequence, including NF-κB sites. These rats were used to characterize the effect of CNS1 deletion on Aire expression and the development of autoimmune phenotype by analysing the immune organs, skin, blood plasma, and adrenal glands using flow cytometry, real-time PCR, LIPS, immunefluorescence microscopy, histological examinations, and transcriptome analysis.
Our findings confirm the absence of Aire protein in immune tissues and thymic evaluations revealed altered tissue-specific protein expression, inflammatory mediation, and regulatory T-cell differentiation. CNS1-/- rats exhibited an APECED-like phenotype characterized by hair loss, nail dystrophy, and the presence of anti-interferon autoantibodies. Transcriptomic and histological analysis of the skin revealed an upsurge in inflammation cell markers and Jak-Stat pathway genes, alongside tissue damage and most hair follicles in knockout rats arrested in the telogen phase of the hair cycle, indicative of an alopecia-like condition. Additionally, blood plasma analysis suggested adrenal gland dysfunction, potentially hinting at Addison's disease due to elevated potassium and decreased corticosterone levels.
Our research confirms CNS1's vital role in modulating Aire expression across different species and unveils the CNS1-/- rat as a novel model for exploring Aire's regulatory mechanisms, central tolerance origins, and the onset of alopecia and possibly Addison's disease.

The role of thymic B cells in central T cell tolerance

João Augusto Freitas[1], Dario Zebcevic[1], Christine Federle[1], Nadia Khouja[1], Amina Sayed[1], Ludger Klein[1], Iliana Siamishi[1]
[1]*Institute for Immunology, Biomedical Centre Munich, Ludwig Maximilian University of Munich, Planegg, Germany*

Central T cell tolerance is essential for maintaining immune homeostasis and preventing autoimmunity. Traditionally, medullary thymic epithelial cells and dendritic cells are considered the key thymic antigen presenting cells (APCs) that promote the deletion (negative selection) or Treg cell differentiation of autoreactive thymocytes. We previously showed that the thymus also harbors a distinct population of B cells expressing Aire and exhibiting characteristics akin to activated B cells such as elevated CD80 and MHCII levels. These potent APC features of thymic B cells suggest that they may play a crucial role in central T cell tolerance. To elucidate how thymic B cells contribute to shaping the T cell receptor (TCR) repertoire, we compared the TCR repertoire of mature 'conventional' CD4 thymocytes and thymic Foxp3+ Treg cells from B cell-deficient and -sufficient mice. This comparison revealed a substantial number of TCR clonotypes whose deletion or diversion to the Treg repertoire required the presence of B cells, indicating a significant contribution of thymic B cells to both modes of central tolerance. In summary, our findings suggest a more prominent role of thymic B cells in shaping the T cell repertoire than previously appreciated.

Purpose: There is a strong relationship between metabolic state and immune tolerance through a direct control exerted on immune cells by specific intracellular nutrient-energy sensors. An increased "metabolic work load" represents a novel issue linking metabolism with loss of self-immune tolerance. In this context, several dietary interventions have been shown to influence disease progression of experimental autoimmune encephalomyelitis (EAE), the experimental model of Multiple Sclerosis. Our approach aims at dissecting at the cellular level the mechanism of action of different dietary regimens, such as Free Diet (FD) and Caloric Restriction (CR), to alter disease progression and immune cell homeostasis, in relapsing remitting Multiple Sclerosis (RR-MS) subjects.
Methods: We evaluated the impact of FD and CR on the immunophenotype of different subsets of circulating immune cells and their correlation with clinical/nutritional status and patient reported outcomes (PRO) in RR-MS subjects during DMF treatment. We also investigated the effect of different dietary regimens (FD and CR) on the metabolic asset of conventional T (Tconv) cells (measurement of glycolysis and oxidative phosphorylation) from RR-MS subjects after starting first line drug treatment.
Results: We observed that CR improves the clinical/nutritional status of RR-MS subjects and modulates different immune T cell subsets. Moreover, CR is able to reduce glycolytic capacity of pro-inflammatory Tconv cells compared to FD-RR-MS subjects.
Conclusions: Overall, these data suggest that modulation of metabolic state via calorie restriction is able to improve the outcome of RR-MS and efficacy of first line drug treatment.

Impact of CCR4 ligands on Treg cells in islet autoimmunity

Gianmarco Spata[1], Linda Hammann[2], David Anz[2], Carolin Daniel[1;2;3], Isabelle Serr[1;3]
[1]*Research Unit Type 1 Diabetes Immunology, Helmholtz Diabetes Center at Helmholtz Zentrum, Munich, Germany*; [2]*Division of Clinical Pharmacology, Department of Medicine IV, Ludwig-Maximilians-Universität München, Munich, Germany*; [3]*German Center for Diabetes Research (DZD), Munich, Germany*

Type 1 Diabetes (T1D) is an autoimmune disease defined by the selective destruction of pancreatic beta-cell cells leading to insulin deficiency. Exact mechanisms are still poorly understood, but regulatory T-cell (Treg) impairments have been shown to promote aberrant immune activation thereby triggering islet autoimmunity. Chemokine ligand (CCL) 22 and CCL17 are important mediators of T-cell trafficking with anti- and pro-inflammatory properties respectively. CCL22/CCL17 transduce signals to Tregs via the Chemokine receptor (CCR) 4, highly expressed on Tregs. CCL22-CCR4 interaction leads to Treg migration and prolonged dendritic cell (DC)-Treg crosstalk resulting in immune suppression. However, functional effects of CCL22 and CCL17 signalling on Tregs apart from migration remain incompletely understood especially in the setting of islet autoimmunity.
To approach this experimentally, our preliminary data show trends towards reduced levels of serum CCL22 in autoimmune prone non-obese diabetic (NOD) mice compared to disease-free Balb/c mice (149.22 ± 36.14 vs. 198.88 ± 72.10 pg/ml; p=0.08) while in the pancreas, both CCL22 and CCL17 levels were increased (CCL22: 2.96 ± 0.27 vs. 1.57 ± 0.50 ng/g protein; CCL17: 4.36 ± 2.96 vs. 1.55 ± 1.09 ng/g protein). This was accompanied by increased frequencies of CCR4+ Tregs in the pancreas of insulin autoantibody (IAA) positive NOD mice compared to IAA negative NODs (32.01 ± 8.29% vs. 20.66 ±5.04%; p=0.0044), suggesting a possible active recruitment of the Tregs to the pancreas via the CCL22/17-CCR4 axis.
In our next steps, we will make use of gain- and loss-of-function mouse models to specifically analyse the role of the single components of the axis in Treg ontogenesis, including Treg induction in presence/absence of DCs deriving from the models. In parallel, we will employ different mouse models for islet autoimmunity and perform in depth analysis of CCR4+ Treg phenotypes with multiparametric conventional and spectral flow cytometry technologies. These studies will provide insights into the impact of CCR4 ligands on Treg cells and their relevance for T1D development, with the overarching goal to identify critical new targets for the future development of novel Treg targeting strategies.

Peripheral mast cell-derived RANKL is a prerequisite for lymphocyte egress from distant lymph nodes

Konstantinos Katsoulis-Dimitriou[1], Anne Dudeck[1]
[1]*Institute for Molecular and Clinical Immunology, Magdeburg, Germany*

Purpose: Mast cells (MCs) are innate sentinel cells populating tissues at the interface to the environment such as skin, lung and intestine, and act as key initiators of vasoactivation and immune cell infiltration upon inflammatory insult. The receptor activator of NFκB (RANKL) is most well-known for its role in bone resorption, but recent studies have shown that it is an important immune regulator. We recently identified MCs as a prominent source of RANKL. However, the relevance of MC-derived RANKL in skin inflammation is completely unknown
Methods: Using a mouse line with a conditional RANKL knockout in connective tissue type MCs, we defined the relevance of MC-derived RANKL in DNFB-induced contact hypersensitivity, a mouse model for allergic contact dermatitis.
Results: Surprisingly, mice lacking MC-derived RANKL displayed massive lymphocyte hyperplasia in inguinal lymph nodes (LN) 24h after DNFB challenge, accompanied by profound blood lymphopenia. Despite delayed lymphocyte egress and even increased immune cell infiltration at 48h after challenge, skin inflammation remained markedly dampened in absence of MC-derived RANKL. Strikingly, MC depletion and reconstitution with RANKL deficient MCs only locally in the ear skin resembled the early inguinal LN hyperplasia, blood lymphopenia and reduced lymphocyte infiltration to inflamed skin. An i.v. administration of Sphingosine-1-phosphate (S1P) after induction of skin inflammation was able to restore timely lymphocyte egress demonstrating an organ-spanning RANKL-S1P axis.
Conclusion: In the absence of MC-derived RANKL, lymphocytes do not timely egress from LNs after the induction of skin inflammation, which leads to massive LN hyperplasia and profound blood lymphopenia. Moreover, when lymphocytes finally egress, they infiltrate the ear skin with a delay that leads, possibly because of the dys-primed inflammatory microenvironment, to diminished inflammation and ameliorated symptoms of CHS. Consequently, MC-derived RANKL is a prerequisite for lymphocyte egress from distant LN, through a mechanism involving the induction of S1P signaling.

Understanding the molecular recognition of Bacteroides fragilis glycosphingolipids by Natural Killer T-cell receptor

Praveena Thirunavukkarasu[1], Sungwhan Oh[2;3], Heebum Song[4], Ji-Sun Yoo[3], Da-Jung Jung[3], Deniz Erturk-Hasdemir[2], Yoon Soo Hwang[4], Changwon C. Lee[2], Jérôme Le Nours[1], Hyunsoo Kim[4], Jesang Lee[4], Richard S. Blumberg[5], Seung Bum Park[4], Dennis L. Kasper[2], Jamie Rossjohn[1;6]
[1]Infection and Immunity Program & Department of Biochemistry and Molecular Biology, Biomedicine Discovery Institute, Monash University, Melbourne, Australia; *[2]Department of Immunology, Blavatnik Institute of Harvard Medical School, Boston, United States*; *[3]Center for Experimental Therapeutics and Reperfusion Injury, Department of Anaesthesiology, Perioperative and Pain Medicine, Brigham and Women's Hospital, Boston, United States*; *[4]CRI Center for Chemical Proteomics, Department of Chemistry, Seoul National University, Seoul, South Korea*; *[5]Division of Gastroenterology, Hepatology and Endoscopy, Department of Medicine, Brigham and Women's Hospital, Boston, United States*; *[6]Institute of Infection and Immunity, Cardiff University School of Medicine, Cardiff, United Kingdom*

The human gut microbiota comprises more than 50% of *Bacteroides* species that produce small diffusible molecules like sphingolipids that play a key role in modulating the host's immune responses. In particular, *Bacteroides fragilis* produces glycosphingolipids similar to α-galactosylceramides termed as 'BfaGCs' that can activate type I Natural Killer T (NKT) cells. While they share key chemical similarities with the type I NKT cell marker antigen, α-galactosylceramide (KRN7000), they possess distinctive structural features including short sphinganine chains, branching and functional groups, implying a basis for their unique immunomodulatory properties. The co-culture assay performed with bone marrow-derived dendritic cells and NKT cells in the presence of specific BfaGCs indicated that branching in their sphinganine chain is a critical determinant of NKT cell activation. As such, the strong stimulators measured by their IL-2 release were the compounds that contained the branched sphinganine chains. Our structural studies on two such CD1d-presented BfaGCs in complex with the type I NKT TCR revealed the TCR adopted a parallel docking topology atop the F'-pocket of CD1d in recognising the presented BfaGCs. Interestingly, the terminal sphinganine branching of the BfaGCs mediated unique interactions within the F'-pocket of CD1d, providing a mechanism for their differing agonistic properties. The NKT TCR recognised the CD1d presented stimulatory and non-stimulatory BfaGCs with nanomolar affinities. Thus, BfaGCs were demonstrated to be bonafide CD1d ligands that function as immunomodulatory mediators influencing the host's defence in the context of NKT cells. Together, this study highlights the structural and molecular-level paradigm of existing symbiotic relationship between the microbes producing these endogenous lipids and the host.

Impact of microbiota from preterm infants on the immune system and infection susceptibility

Justine Smout[1;2], Diego Ortiz[2;3], Mangge Zou[1], Till-Robin Lesker[3], Dorothee Viemann[2;4;5], Till Strowig[2;3], Jochen Huehn[1;2]
[1]Department of Experimental Immunology, Helmholtz Center for Infection Research, Braunschweig, Germany; *[2]Cluster of Excellence RESIST (EXC 2155), Hannover Medical School, Hannover, Germany*; *[3]Department of Microbial Immune Regulation, Helmholtz Centre for Infection Research, Braunschweig, Germany*; *[4]Department of Pediatrics, University Hospital Würzburg, Braunschweig, Germany*; *[5]Center for Infection Research, University Würzburg, Braunschweig, Germany*

Purpose: The neonatal period is characterized by a higher susceptibility to infection, particularly in preterm infants, for whom infection and subsequent sepsis remain significant clinical problems worldwide. Early-life host-microbe cross-talk plays a key role in the development and maturation of the mucosal and systemic immune system, exerting a major influence on lifelong immune homeostasis and disease susceptibility. However, detailed information on how age-related programming and microbiota-dependent imprinting influence an individual's immune status and lifelong susceptibility to infectious diseases is lacking in humans. Our study aims to explore the immunomodulatory effects of the preterm microbiome on the host and its potential protective role against infection.
Methods: Germ-free female mice were colonized with feces from preterm infants before mating, and their offspring were analyzed to validate the humanized mouse model and assess the impact of the preterm infant-derived microbiota on the immune status under homeostasis using high-dimensional flow cytometry. Additionally, neonatal mice were infected with enteropathogenic *Escherichia coli* (EPEC) to assess the consequences of early-life infection on immune cell subset composition within lymphoid organs and the gut.
Results: Colonization with preterm infant fecal samples induced significant alterations in $CD4^+$ T cell subset distribution, particularly in the intestine, and to a lesser extent in secondary lymphoid organs, during steady-state conditions. Three weeks after neonatal infection with EPEC, distinct preterm microbiota backgrounds exhibited differential impacts on susceptibility and recovery from gastrointestinal infection, as evidenced by differences in recovery trajectories, organ burden, and immune cell populations.
Conclusion: Overall, our results support evidence that different microbial communities have sustained effects on the neonatal immune system under homeostasis. It enhances our understanding of the complex interplay between microbiota composition and host defense in gastrointestinal infections, emphasizing the complexity of early-life immune system education. Future research should investigate specific microbial species associated with reduced infection incidence and improved outcomes in newborns, emphasizing the potential of probiotics as preventive interventions.

Host glycosylation shapes intestinal microbiome and immune response in Inflammatory Bowel Disease

Cláudia Rodrigues[1;2], Joana Gaifem[1], Márcia S. Pereira[1;2], Maria Francisca Alves[1;2;3], Mariana Silva[1;2], Nuno Padrão[1;4], Inês Alves[1], Aonghus Lavelle[5], Harry Sokol[5;6;7], Salomé S Pinho[1;2;4]

Inflammatory Bowel Disease is a group of chronic debilitating disorders from the gastrointestinal tract, comprising Crohn's disease (CD) and ulcerative colitis (UC). It is caused by the interplay of the host's genetic predisposition and abnormal immune response to an altered gut microbiota driven by several environmental factors.
The currently available therapies for IBD are ineffective, being associated with several side effects. Thus, an improved understanding of the causes leading to the loss of gut microbial equilibrium (dysbiosis) and mucosal inflammatory response is crucial for a better clinical management of IBD. Cellular glycosylation displays a key role in IBD immunopathogenesis. The epithelial glycocalyx, a complex layer of glycans/sugar-chains at the cell surface, is a major interface between host and gut microbiota. In this study we aim to unveil the impact of an altered host glycocalyx in the microbiota profile and in the initiation of intestinal inflammation. For that, we have resorted to a glycoengineered mouse model, deficient in complex glycans. Colitis was induced by dextran sulfate sodium (DSS) and disease score was monitored daily. The intestinal glyco-immune profile was characterized at baseline and after disease induction. Faecal microbiota was analysed by 16S rRNA sequencing. Firstly, we observed that the increase susceptibility to severe colitis in glycoengineered mice is concomitant with a dysbiotic gut microbiota and decreased levels of SCFAs at baseline. Interestingly, the analysis of immune profile demonstrated that glycoengineered mice exhibited a proinflammatory immune response characterized by the impairment in innate immune response. Alteration in complex glycans was associated with an increased frequency of dendritic cells and increased levels of IL-6 and TNFα on colonic mucosa at steady state. Overall, our results highlight the role of glycans as essential elements that shape gut immunity and intestinal microbiome.

The Microbiome-Spine Axis: Exploring Pathology, Autoimmunity, and Research Gaps through a Narrative Review

Muaz Rashid[1;2], Hugo Serra Pereira[2;3], Salman Keraidi[1;2], Nicolas Wipf[1;2], Ahmad Issa Alissa[1;2], Aubrie Sowa[1;2], Jake McDonnell[2], Stacey Darwish[2;4], Joseph Butler[1;2]
[1]School of Medicine, University College Dublin, Dublin, Ireland; *[2]National Spinal Injuries Unit, Mater Misericordiae University Hospital, Dublin, Ireland*; *[3]School of Medicine, Trinity College Dublin, Dublin, Ireland*; *[4]Department of Orthopaedics, St. Vincent's University Hospital, Dublin, Ireland*

The microbiome's relevance in human health and patient care is becoming increasingly discussed amid the rising prevalence of chronic illnesses. It is well known that the gut microbiome has a complex relationship with our immune system; helping it to mature and prevent overactivation. Microbiome research to date focuses predominantly on its relationship with the GI tract while largely ignoring any impact on the rest of the body. Our review aims to lay a foundation of knowledge to fill this gap in the literature, specifically concerning the microbiome and its relation to spinal health.
Through this narrative review, it was found that with disruptions, specific bacterial families such as Bacteroidaceae and Rikenellaceae are allowed to proliferate and are associated with increased onset of ankylosing spondylitis (AS). Dysbiosis was also seen to alter the cytokine microenvironment and subsequently increase gut wall permeability, causing immune overactivation, and improper cell function. Ultimately these changes result in a heightened state of inflammation, leading to increased susceptibility to autoimmunity and in particular AS and seronegative arthropathies.
Overall, the available literature discussing the microbiome and its relation to spine health still has significant gaps in knowledge. It was found that most studies focus solely on the bacterial composition but ignore fungal and viral components of the microbiome; which was demonstrated through their predominant usage of 16s RNA sequencing. The sheer quantity of confounding factors surrounding microbial compositions also makes for poor generalizability of results to the greater population. These limitations all serve to add constraints to a comprehensive understanding of the microbiome's true significance and underscore the severe need for standardized and organized research approaches.
In conclusion, this narrative review hopes to equip clinicians with a broad understanding of how the microbiome, and its disruption, have specific implications for spinal health; an incredibly complex and novel topic. By building on the current literature and integrating this knowledge into practice, we hope to implement more patient-specific practices in the treatment of spinal pathologies and ultimately improve and optimize patient care in a field in which the microbiome is not currently at the forefront of pathology.

Involvement of gut and oral Microbiome in the development of allergy to non-specific Lipid Transfer Proteins

Paula Álvarez Romero[1], Laura Carrero[1;2], Ana Navas[1;2], Nadine Blanco Toledano[1;2], Berta Ruiz León[1;2], Aurora Jurado Roger[1;2]
[1]Maimonides Biomedical Research Institute of Córdoba (IMIBIC)/ University of Córdoba, Córdoba, Spain; *[2]Reina Sofía University Hospital, Córdoba, Spain*

Purpose: Co-sensitisation to non-specific Lipid Transfer Protein (nsLTP) from olive pollen (Ole e 7) and peach (Pru P 3) is a usually phenomenon observed in the Mediterranean basin and particularly in areas of extensive olive tree crops, without a clearly established underlying cross-reactivity between proteins. The aim of this study was to analyse other possible causes related to this phenomenon, including the interaction between microbiome and the immune system.
Methods: Gut and oral microbiome profile of 110 patients sensitised to Ole e 7 with or without sensitisation to Pru p 3 (by sIgE > 0.35 kU/L in ImmunoCAP 250) was explored, together with the expression of Toll-like receptor (TLR) pathway in oral mucosa by NanoString and circulating T-cell subpopulations by flow cytometry.
Results: Oral microbiota of monosensitised patients was characterised by a preponderance of TM7_3 and Clostridia classes, whereas that of bisensitised patients was characterised by the preponderance of an unknown genus from Actinomyces, by the Micrococcaceae family belonging genus Rothia and by an unknown genus from Gemellaceae family. Regarding gut microbiota, we found that in monosensitised patients, it was characterised by the preponderance of Betaproteobacteria class. By contrast, the gut microbiota of bisensitised patients was characterised by the preponderance of Bacteroides genus and the bacterial species *Bacteroides uniformis*. When we performed a logistic model including microbiome, immunological and TLR variables, we found that the presence of circulating Tregs $CD39^{+}$, the expression of TLR3 in oral mucosa and the preponderance of Rothia genus and Gemellacea family in oral microbiota and Bacteroides genus, Butrycimonas genus and Bilophila genus in gut microbiota were the most important variables to determine the sensitisation to Ole e 7 and Pru p 3 with an area under the curve of 0.882, an accuracy of 81.4%, a sensibility of 87.5% and a specificity of 76.3%.
Conclusions: The microbiome of patients monosensitised to Ole e 7 and patients bisensitised to Ole e 7 and Pru p 3 is different and its interaction with the immune system could be determinant to develop sensitisation to multiple nsLTPs.

IMMUNOMETABOLIC STATE IN A PORCINE MODEL AFTER SUPPLEMENTATION OF THE MIXTURE OF LACTOBACILLI ISOLATED FROM HUMAN MILK

Rosa Elena Navarro Hernandez[1], David-Roman Sanchez-Chipres[2], Ana-Lilia Fletes-Rayas[1], Anaid Maciel-Rivera[3], Jacqueline-Alejandra Noboa-Velastegui[1], Perla-Monserrat Madrigal-Ruiz[1], Dalia-Alejandra Madrigal-Ruiz[1], Blanca-Rosa Aguilar-Uscanga[3]
[1]Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara, Guadalajara; *[2]Universidad de Guadalajara. Centro Universitario de Ciencias Biológico Agropecuarias, Zapopan, Jal., Mexico*; *[3]Centro Universitario de Ciencias Exactas e Ingenierías. Universidad de Guadalajara, Guadalajara, Mexico*

Purpose: The porcine model *vs*. human analogy reveals significant findings regarding the diversity of its intestinal microbiota and the presence of *lactobacilli*, which are relatively stable in both species' adult stages but fluctuate during the piglet and infant stages. In this context, previous reports show that piglets from the same litter and newborn human twins can differ concerning their intestinal microbiota, manifesting in their metabolic homeostasis. In a porcine piglet model, this study examined the immune-metabolic state after supplementation with a mixture of *lactobacilli* isolated from human milk.
Methods: We included 16 piglets *of Sus scrofa domesticus*, evaluated their body weight, and classified them as control (n = 8) without supplying a mixture of Lactobacilli and treatment (n = 8) supplying a mixture of *Lactobacilli* and treatment (n = 8) with a mixture of *Lactobacilli*. *Lactobacilli* were isolated from human milk. A mixture of three (*Lactoplantibacillus plantarum, Limosilactobacillus reuteri, and Lactobacillus fermentum*) was formulated with 109 CFU/mL and provided as a supplement at the treatment group in the experimental diet throughout 30 days. Piglet blood samples were collected on day 1 and day 30 for immune-metabolic profiling after they were euthanized and necropsied on day 30. Adipose and intestinal segments were collected, flushed with cold PBS, and fixed in 10% neutral buffered formalin. Tissue samples were then sliced into 5 µm sections and stained with hematoxylin and eosin stain to determine intestinal villus height and crypt depth morphology. Images of adipose and intestinal sections were taken using an OPTIKA microscope/LEITZ-WETZLAR photo-camera.
Results: At day 30, the piglets of the treatment group showed minor diameter adipocytes, increased serum levels of chemerin, decreased levels of glucose, insulin, triglycerides, VLDLc, CRP, and ESR, and a smaller number of monocytes circulating compared to the control group. The duodenum/jejunum/colon *villus* and height-to-Lieberkühn crypt depth ratio in the control group was reduced compared to the treatment group, while the ileum was inverse.
Conclusion: These data suggest that the mixture of *Lactoplantibacillus plantarum, Limosilactobacillus reuteri, and Lactobacillus fermentum* isolated from human milk contributes to a healthy immune-metabolic state in the piglet porcine model *Sus scrofa domesticus*.

Intestinal-derived short chain fatty acid modulates alveolar macrophage response to *Streptococcus pneumoniae*

Kate Roche[1;2], Craig McEntee[2], Suzanne Cloonan[3], Susan Carpenter[4], Analía Rial[5], Jose A. Chabalgoity[5], Ed Lavelle[2], Natalia Muñoz-Wolf[1]
[1]Translational and Respiratory Immunology Lab, Clinical Medicine Tallaght, School of Medicine, Trinity College Dublin, Dublin, Ireland; *[2]Adjuvant Research Group, School of Biochemistry and Immunology, Trinity College Dublin, Dublin, Ireland*; *[3]Clinical Medicine Tallaght, School of Medicine, Trinity College Dublin, Dublin, Ireland*; *[4]Molecular, Cell and Developmental Biology Department, University of California Santa Cruz, Dublin, United States*; *[5]Laboratory for Vaccine Research, Hygiene Institute, School of Medicine, Universidad de la República, Montevideo, Uruguay*

Lower respiratory tract infections are a leading cause of mortality worldwide. *Streptococcus pneumoniae* is a major human respiratory pathogen responsible for 30-50% of community acquired pneumonia cases and over a million deaths every year. Alveolar macrophages are resident phagocytes in the lower airways with a key role against pneumococcal infection as they promote early bacterial clearance and co-ordinate downstream inflammatory responses.
While many factors influence susceptibility to respiratory infections, the intestinal microbiota has emerged as a key regulator of respiratory immune processes. The immunological crosstalk between the intestinal and lung compartments is known as the gut-lung axis of immune regulation. The intestinal microbiota influences this crosstalk in different ways; one such mechanism is the production of immunomodulatory microbiota-derived metabolites, namely short chain fatty acids (SCFA). SCFAs are exclusively produced by the microbiota through the saccharolytic fermentation of dietary fibre in the gut. Millimolar concentrations of SCFAs are metabolised in the colon where they have potent immunomodulatory properties and reach the portal circulation at sub-millimolar levels. Intestinal dysbiosis and low SCFAs have been linked to macrophage dysfunction and susceptibility to pneumococcal pneumonia. The SCFA acetate (C2) and propionate (C3) protect against pneumococcal pneumonia by enhancing alveolar macrophage function. However, the role of the four carbon SCFA butyrate remains to be explored in this context.
Here we investigated how butyrate modulates susceptibility and alveolar macrophage function during *S. pneumoniae* infection. *In vivo* butyrate supplementation protected mice against invasive pneumococcal pneumonia. *In vitro*, butyrate increased IL-1β secretion in long-term cultures of *ex vivo* alveolar macrophage (MexAM) stimulated with the TLR2 agonist Pam3CSK4. Preliminary experiments in murine foetal liver-derived alveolar macrophage (FLAM) showed that butyrate enhanced the expression of *Nlrp3* and *Tnfa* upon *S. pneumoniae* infection or stimulation with Pam3CSK4. Collectively this evidence points towards a role of butyrate in enhancing alveolar macrophage function and increasing resistance against pneumococcal pneumonia. Our data highlights the therapeutic potential of dietary interventions and modulation of the gut microbiota as means to increase resistance to invasive pneumococcal pneumonia.

Purpose: The bacterial strains residing in the anaerobic environment of the colon have been shown to produce short-chain fatty acid (SCFA) essential for preserving homeostasis in the gut, and in the host more broadly. The reduction in the abundance of butyric acid (BA)-producing bacteria associated with multiple sclerosis (MS). Hence, our study aimed to isolate the bacterial strains with the high capacity to produce BA from the feces of healthy donors and to test the effects of supplementation in a mice model of MS.
Methods: By using different media in anaerobic conditions and measuring BA by HPLC we selected *Faecalimonas* sp. NGB245 strain. To overcome the sensitivity of this strict anaerobe to oxygen, the NGB245 overnight culture (NGB245-postbiotic) was used as the supplement. Myelin oligodendrocyte glycoprotein peptide/complete Freund's adjuvant/pertussis toxin-induced experimental autoimmune encephalomyelitis (EAE) in C57BL6 mice was used as a model of MS. Mice consumed NGB245-postbiotic in a 16h/day (instead of the water, ad libitum) regime during the 15 days. The control group of EAE mice consumed PYG medium enriched with cellobiose and starch, used for the NGB245 cultivation, in the same regime. The effects of NGB245 strain on EAE symptoms, immunological responses, and microbiota properties were analyzed by flow cytometry, ELISA, microscopy, and new-generation sequencing, respectively.
Results: NGB245 strain was selected for the study based on the high production of BA (15mM). The supplementation with NGB245-postbiotic alleviated daily clinical scores, maximal clinical scores, and the duration of the EAE in comparison to the control group. This was associated with the lower abundance of Th1 and Th17 cells, myeloid dendritic cells, inflammatory monocytes, macrophages, and activated microglia, but a higher level of myeloid-derived suppressor cells in the CNS of treated EAE mice. These immunomodulatory effects were associated with the higher diversity of microbiota in the colon.
Conclusion: These results support the idea of targeting the microbiota in autoimmune diseases to preserve the homeostatic functions of the immune system and microbiota and thus restrain the autoimmune process development.

Examining the Role of the Microbiome-Immune Axis in the Development of Systemic Lupus Erythematosus

Johannes Skræp[1], Thomas R. Wittenborn[2], Cecilia Fahlquist-Hagert[2], Julia K. Demtröder[2], Lisbeth Jensen[2], Gudrun Winther[2], Janne K. Klitgaard[1], Miriam Rabenow[3], Diego Ortiz[3], Till-Robin Lesker[3], Till Strowig[3], Holger Brüggermann[2], Søren Egedal Degn[2]

Over the past decades, autoimmune disorders have drastically increased in incidence and, presently, affect one in ten people in the Western world. However, the etiology of these diseases remains unknown in most cases. Systemic lupus erythematosus (SLE) is an example of such an autoimmune illness. Despite improvements in both treatments and diagnostics, the limited understanding of SLE leads to inadequate treatment efficacy and thus morbidity and mortality remain high. Therefore, it is crucial to further explore the etiology and pathogenesis of these autoimmune disorders. One possible determining factor is the microbiome-immune axis. It has been postulated imbalanced microbiota composition and function (often called dysbiosis) lead to a loss of immunological tolerance and thus an increased risk of developing autoimmune conditions. Although no causal connection between dysbiosis and SLE has been discovered until today, multiple studies have found interesting correlations.
Using a transgenic lupus-prone mouse model called 564Igi, we investigated the effect on the autoimmune phenotype when altering the microbiome. Briefly, this was accomplished by exposing cohorts of 564Igi mice to environments with distinct sanitary differences or treating them with a cocktail of antibiotics to induce severe dysbiosis. The comprehensive collection of biological samples makes it possible to investigate whether a dysbiosis in the gut microbiome occurs before or after the development of the autoimmune condition and whether it depends on the autoimmune phenotype and the immunological response toward microbiome alterations. Preliminary results from comparative metagenomics provide novel insight into bacterial communities of the gut microbiome that correlate with an ameliorated or exacerbated autoimmune phenotype. Furthermore, flow cytometry and other immunological analyses indicate that a higher systemic response toward gut bacteria signifies better immune control of the gut microbiome and correlates with a more benign lupus phenotype. This suggests a complex interaction forming feedback and feedforward loops between the gut microbiome and the immune system, which also may play a significant role in the pathogenesis of SLE.

Gut bacteriome in mothers with and without gestational diabetes and their offspring: immunological parallels

Kristi Alnek[1], Aili Tagoma[1], Anu Bärenson[1;2], Oliver Aasmets[3], Helis Janson[1], Ondrej Cinek[4], Elin Org[3], Raivo Uibo[1]
[1]*Department of Immunology, Institute of Bio- and Translational Medicine, University of Tartu, Tartu, Estonia*; [2]*Children's Clinic of Tartu University Hospital, Tartu, Estonia*; [3]*Estonian Genome Centre, Institute of Genomics, University of Tartu, Tartu, Estonia*; [4]*Department of Pediatrics, 2nd Faculty of Medicine, Charles University and Motol University Hospital, Prague, Czech Republic*

Purpose: Gestational diabetes mellitus (GDM) influences both the maternal and offspring microbiomes, therefore it may play a role in shaping the onset of immune-mediated diseases. We aimed to study the gut bacteriome of mothers with and without GDM and their young children and compare these results with children's allergen-specific IgE test results, skin- and respiratory-tract-associated allergy diagnoses, HLA haplotypes and presence of diabetes-associated autoantibodies (glutamic acid decarboxylase 65 antibody (GADA), islet antigen-2 autoantibodies (IA-2A) and zinc transporter 8 autoantibodies (ZnT8A)).
Methods: Stool and blood samples were collected from 53 mothers (18 with GDM and 35 without GDM) and their children (1-2 year olds) recruited from Woman's Clinic of Tartu University Hospital. Data about children's allergy diagnoses were obtained from Electronic Health Records. The composition of stool bacterial communities was profiled by 16S rDNA sequencing. Allergen-specific IgE, diabetes-associated autoantibodies and HLA haplotypes were analysed.
Results:
No differences were observed in alpha and beta diversity between mothers with and without GDM. However, we found a negative correlation between the mother's C-peptide level and alpha diversity measures. In children, no significant difference in alpha diversity was found with allergy diagnoses, maternal GDM diagnoses, HLA haplotypes or IgE. However, the microbial richness (Shannon's index) was higher in children whose mothers had diabetes-associated autoantibodies during pregnancy. Overall bacterial structure (beta diversity) revealed a difference for clustering between children with (IgE level ≥0.7 kUA/L) and without definite (IgE level <0.7 kUA/L) allergic sensitisation.
Conclusion:
The results demonstrate that alpha and beta diversity showed no significant differences between mothers with and without GDM. However, children of mothers with diabetes-associated autoantibodies exhibited higher microbial richness and distinct clustering based on allergic sensitization status.

Gut microbiota-modulated immunological profile in mouse models of eating disorders

Radka Roubalova[1], Petra Prochazkova[1], Janet Jezkova[1], Hana Papežová[2]
[1]Institute of Microbiology of the Czech Academy of Sciences, Praha 4, Czech Republic; *[2]Charles University and General University Hospital in Prague, Praha 2, czech Republic*

Purpose: Emerging studies highlight the significant impact of the gut microbiome on neuropsychiatric disorders and offer insights into its potential to influence human behavior. The intestinal microbiota modulates the central nervous system via neuroimmune and neuroendocrine pathways and thus may promote the pathophysiology of these disorders. Loss of microbial diversity and reduced abundance of beneficial microbes are frequently described in patients with eating disorders. To gain further insight, we investigated the reactivity of the immune system in mouse models of binge eating disorder (BED) and anorexia nervosa (AN) in conventional animals and animals with depleted microbiomes.
Methods: In our study, we used conventional, ATB-treated, and germ-free mouse models of BED and AN. We collected spleens of these mice to measure immune cell populations and intracellular cytokine production by flow cytometry. In addition, the levels of assorted cytokines (IL-6, IL-10, IL-12, TNFα, IFNγ, and MCP1) were determined in the serum. To assess gut barrier function, we collected colon biopsies and determined the expression of two intestinal tight junction proteins (ZO-1, occludin) and two members of the mucin protein family (MUC2, MUC13).
Results: In mice with an induced model of eating disorder (ED), the population of CD4+CD25+FoxP3+ regulatory T cells was significantly lower than in control mice. The difference was even more pronounced in mice with an ATB-depleted microbiome. Further, CD4+IFNγ+ cells were increased in mice with ED. Again, the difference was greater in ATB-treated mice. We did not detect any difference in cytokine levels in mice with ED. We observed increased expression of ZO-1 and occludin only in germ-free, but not in conventional or ATB-treated mice in the AN model compared to control mice. We also found no significant differences in mice with the induced BED model.
Conclusion: In mouse models, we have demonstrated the influence of the microbiota on changes in the representation of the population of immune cells and the production of IFNγ in the mouse spleen. These changes may lead to a long-term disturbance in the reactivity of the immune system, which is frequently observed in patients with ED, especially in patients with AN.

Influence of the microbiome on dendritic cell phenotype and function

Willemien Miller[1], Alexandra Kazanova[1], Christina Gavino[1], Morgane Brouillard-Galipeau[1], Samantha Gruenheid[1]
[1]*McGill University, Montreal, Canada*

Purpose: The intestinal microbiome educates the immune system, in part through signaling in antigen-presenting cells including dendritic cells (DCs). Germ-free mice exhibit DC deficiency, migration impairment, and priming dysfunction, implying a relationship between microbiota and DC function. Naturally acquired, endemic *Helicobacter* species (*H.* spp.) such as *H. hepaticus* are common in many mouse colonies, whereas some facilities are *Helicobacter*-free. Although they do not cause overt disease in most immune-competent mouse strains, we hypothesized that *H.* spp. could be a source of low-level inflammation, resulting in immune reprogramming and leading to phenotypic differences between *H.* spp.-positive and *H.* spp.-negative mice.
Methods: We generated bone marrow-derived dendritic cells (BMDCs) from *H.* spp.-positive mice and from genetically identical mice rendered *H.* spp.-free through mouse rederivation. BMDCs were stimulated for 6 hours (or not) with ultra-pure lipopolysaccharide (LPS). We measured expression of molecules MHC-I and MHC II (Signal 1 of antigen presentation) and CD80, CD86 and PD-L1 (Signal 2), the "activating" epigenetic mark of trimethylation at lysine 3 of histone 4 (H3K4me3) and metabolic changes via flow cytometry. Multiplex ELISA was used to measure secreted cytokines (Signal 3) and in vitro methods were used to assay BMDC antigen presentation.
Results: Surface expression of molecules related to Signal 1 and Signal 2 of antigen presentation were increased both at steady state and after LPS stimulation in BMDCs derived from *H.* spp.-positive in comparison with *H.* spp.-free mice and this correlated with the abundance of H3K4me3. The presence or absence of *H.* spp. also altered metabolic phenotype of BMDCs upon LPS stimulation.
Conclusion: The presence of *Helicobacter* in the gut microbiome influences BMDC phenotype and may alter BMDC function. We anticipate epigenetic changes involved in BMDC phenotypic and functional changes, which will require in-depth epigenetic profiling. Future directions also include fecal microbiota transplant experiments and *Helicobacter* infection models followed by BMDC characterization using our established pipeline.

PD-L1 exaggerates obesity-induced dysbiosis

Viviane Schmidt[1], Roman Gerlach[1], Padraic Fallon[2], Christian Schwartz[1;3]
[1]Institute of Clinical Microbiology, Immunology and Hygiene, Universitätsklinikum Erlangen and Friedrich-Alexander-Universität (FAU) Erlangen-Nürnberg, Germany, Erlangen, Germany; *[2]School of Medicine, Trinity Biomedical Sciences Institute, Trinity College, Dublin, Ireland*; *[3]FAU Immunomedicine (FAU I-MED), Erlangen, Germany*

Purpose: Obesity has grown into a major global health concern. The gut microbiome plays an important role in obesity and shaping of the immune system. However, many aspects of these interactions are only beginning to be understood. Here, we investigated the mechanisms how regulators of the immune system influence the gut microbial composition and its impact on diet-induced obesity.
Methods: Obesity was induced in mice using a high fat diet (HFD). Cell-specific function of the immune checkpoint protein programmed death-ligand 1 (PD-L1) was investigated using knockout mice as well as wild type mice treated with αPD-L1. Body weight was recorded weekly and faecal pellets were collected biweekly. We analysed the gut microbial composition by 16s rRNA sequencing. Germinal centres in the Peyer's Patches of mice were analysed using FACS analysis.
Results: The gut microbial composition of mice on HFD changed drastically in the first two weeks after onset of HFD to a more obesity-like phenotype, characterised by an increase of the *bacillota:bacteroidota* ratio. Interestingly, the early changes in microbial composition had long-lasting effects. This shift was more pronounced in wild type mice on HFD than in mice with a constitutive deletion of PD-L1. While no differences in the amount of germinal centre B cells could be observed, antibody production in the Peyer's Patches was impacted by diet and genotype.
Conclusion: Our results demonstrate that PD-L1 influences the gut microbial composition during diet-induced obesity by ameliorating the increase of the obesity-characteristic *bacillota:bacteroidota* ratio, possibly by impacting formation of tolerance. Further studies will elucidate the mechanisms how PD-L1 affects the microbial composition and development of obesity.

Mechanisms of action of microbial-derived indoles on inflammation parameters in rheumatoid arthritis

Leona Ehnes[1;2], Carolin Brandl[3], Stefan Wirtz[4], Arne Gessner[5], Isabel Wank[5], Andreas Hess[5], Georg Schett[1], Mario Zaiss[1;2]
[1]Department of Internal Medicine 3, Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Erlangen, Germany; *[2]Deutsches Zentrum Immuntherapie, Erlangen, Germany*; *[3]Strahlenklinik, Universitätsklinikum Erlangen, Erlangen, Germany*; *[4]Department of Internal Medicine 1, Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Erlangen*; *[5]Institute of Experimental and Clinical Pharmacology and Toxicology, Friedrich-Alexander University Erlangen-Nürnberg (FAU, Erlangen, Germany*

Purpose: Rheumatoid arthritis (RA) is a chronic and progressive autoimmune disease mainly affecting the musculoskeletal system, with inflammation causing pain and destruction of joints. Recent studies reveal the role of gut microbiota in the genesis of the disease (gut-joint axis). Thereby, indoles, gut bacteria-derived metabolites of tryptophan, in particular indole-3-proioic acid (IPA), show a positive impact on the immune, nervous, gastrointestinal and cardiovascular system in various pre-clinical and clinical studies in mammals. Furthermore, the aryl hydrocarbon receptor (AHR) activated by IPA, shows a modulating effect on immune and inflammatory responses.
Methods: Mice with collagen-induced arthritis (CIA) were orally treated with IPA and antibiotics preclinical. Targeted metabolomics analyzed serum of early RA patients and untreated CIA mice. 16s RNA sequencing examined murine intestinal content and Flow cytometry presented different B cell populations in mesenteric lymph nodes.
Results: First, concentration of IPA in serum of new onset RA patients was significantly reduced compared to controls of healthy individuals. CIA mice had significantly lower IPA serum levels already on day five after immunization. Second, it was shown that IPA treatment significantly attenuated the course of CIA and restored microbial dysbiosis in the intestine. In addition, *in vivo* B cell activation- and proliferation-markers in the mesenteric lymph nodes were significantly downregulated following nutritional IPA intervention. The direct effects of IPA on B cells were further confirmed *in vitro*. Depletion of IPA producing gram-positive bacteria through targeted antibiotic treatments exacerbated arthritis scores in animal models and significantly reduced IPA serum concentration. Of note, these effects could be compensated through combined antibiotics and IPA treatment. Further, Aryl hydrocarbon receptor (AhR) specific intestinal epithelial knockout mice were used to analyse the role of AhR in the protection of IPA on arthritis scores. Thus, villin cre AhR fl/fl mice showed exacerbated arthritis scores along with significantly lower serum IPA serum concentration.
Conclusion: In conclusion, our study defines a novel approach on how gut derived indoles, specifically IPA, influences arthritis disease.

Gut microbiota protects mice from acute colitis by improving intestinal barrier function

Michal Kraus[1;2], Zuzana Jacková[1;3], Eliška Krčmářová[2;3], Tomáš Thon[1;3], Lenka Súkeníková[2;3], Jiri Hrdy[2], Miloslav Kverka[1]
[1]Czech Academy of Sciences, Institute of Microbiology, Prague 4, Czech Republic; *[2]Charles University, First Faculty of Medicine, Prague 2, Czech Republic*; *[3]Charles University, Faculty of Science, Prague 2, Czech Republic*

Purpose: Gut microbiota drives inflammation by shaping the function of intestinal barrier and stimulating the immune system of intestinal mucosa. Our aim was to analyze the mechanisms of how microbiotas from two different animal facilities influence the development of acute experimental colitis.
Methods: We induced acute colitis in conventional BALB/c mice originating from the animal facility of the Institute of Microbiology (IMIC) or the First Faculty of Medicine (FoM), and in ex-germ-free mice colonized with intestinal content from either facility. Colitis was induced by intrarectal administration of 2,4,6-trinitrobenzenesulfonic acid (TNBS) dissolved in 50 % ethanol, with (hapten-type) or without (toxic-type colitis) skin presensitization. The severity of colitis was assessed by Wallace's score and measurement of colon length. Intestinal microbiota was analyzed by 16S rRNA sequencing, gut barrier function was analyzed by a fluorescein isothiocyanate dextran (FITC-Dx) permeability assay, and immune system activity was measured by flow cytometry in cells from the spleen and mesenteric lymph nodes.
Results: IMIC mice were significantly more resistant to both types of TNBS colitis and had more bacteria of the *Verrucomicrobiae* and *Campylobacteria* classes in their feces. IMIC mice had significantly less permeable gut barrier, and significantly fewer effector memory T cells and lower percentages of IFNγ-, IL-17- and TNFα-producing $CD4^+$ T cells in both the spleen and mesenteric lymph nodes even before the colitis induction. While microbial consortia in the colonized ex-germ-free mice resembled these of the conventional mice, there were no significant differences in either sensitivity to colitis or T cells subsets.
Conclusion: We conclude that early life colonization with the *Verrucomicrobiae* and *Campylobacteria* promotes development of the gut barrier and decreases immune system reactivity, resulting in resistance to acute intestinal inflammation in mice.

GBP2 engages Galectin-9 for immunity against Toxoplasma gondii

Daniel Degrandi[1], Elisabeth Kravets[1], Veronica Raba[1], Imke Bradtmöller[1], Klaus Pfeffer[1]
[1]*Institute of Medical Microbiology and Hospital Hygiene, Heinrich Heine University Düsseldorf, Düsseldorf, Germany*

Guanylate binding proteins (GBPs) are large interferon-inducible GTPases, executing essential host defense activities against *Toxoplasma gondii,* an invasive intracellular apicomplexan protozoan parasite of global importance. *T. gondii* establishes a parasitophorous vacuole (PV) which shields the parasite from the host's intracellular defense mechanisms. Murine GBPs (mGBPs) recognize *T. gondii* PVs and assemble into supramolecular mGBP homo- and heterocomplexes that are required for the disruption of the membrane of PVs eventually resulting in the cell-autonomous immune control of vacuole-resident pathogens. We have previously shown that mGBP2 plays an important role in *T. gondii* immune control. Here, to unravel mGBP2 functions, we report Galectin-9 (Gal9) as a critical mGBP2 interaction partner engaged for immunity to *T. gondii*. Interestingly, Gal9 also accumulates and colocalizes with mGBP2 at the *T. gondii* PV. Furthermore, we could prove the requirement of Gal9 for growth control of *T. gondii* by CRISPR/Cas9 mediated gene editing. These discoveries clearly indicate that Gal9 is a critical factor for the mGBP2 coordinated cell autonomous host defense mechanism against *T. gondii*.

Stimulation of Natural Killer cell responses by different activating ligands

Luca Kröll[1], Mina Sandusky[1], Maren Claus[1], Sabine Wingert[1], Michèle Saretzki[1], Carsten Watzl[1]
[1]*Leibniz Research Centre for Working Environment and Human Factors (IfADo), Dortmund, Germany*

Purpose: Natural Killer (NK) cells are part of the innate immune system and serve an important role in the early response against viral infections and in tumor immunosurveillance. Their activation depends on the stimulation of a broad range of receptors, which have overlapping and potentially redundant functions. Here, we aim to identify cause-effect relationships between the stimulation of distinct receptors and subsequent NK cell effector functions including cytokine secretion, cytotoxicity, and serial killing.
Methods: To stimulate human NK cells, we utilized NIH3T3 cells, an embryonic mouse fibroblast cell line that is not recognized by human NK cells. NIH3T3 cells were transfected to express defined ligands for activating NK cell receptors. To characterize different aspects of NK cell activity upon exposure to these targets, a combination of flow cytometry, ELISA, chromium-release and xCelligence killing assays is employed.
Results: We generated NIH3T3 cells stably expressing the NKp30 ligand B7H6, the 2B4 ligand CD48, the DNAM-1 ligands PVR (CD155) or Nectin-2 (CD112), the NKG2D ligand MICA, the CD16 ligand CD20 (in combination with anti-CD20 antibodies Rituximab or Obinutuzumab), or the LFA-1 ligand ICAM-1 (CD54). These cells were validated by comparing respective ligand expression levels with commonly employed human tumor cell lines. Upon incubation with pre-stimulated NK cells, target cells expressing B7H6, MICA or CD20 could effectively induce degranulation, while no significant differences were observed between the NIH3T3 wt control and remaining targets. Similar results were obtained in chromium-release assays. On the other hand, xCelligence assays revealed significantly enhanced target cell killing solely against NIH3T3-B7H6 cells.
Outlook: In the next steps of this ongoing project, we will finalize our analysis of which NK cell receptors can induce NK cell cytotoxicity. Furthermore, supernatants obtained from co-cultures of pre-stimulated NK cells with the different targets will be assessed regarding cytokine secretion by ELISA. Additionally, we will investigate NK cell adhesion to target cells and generate NIH3T3 cells expressing combinations of defined ligands.

Potent induction of trained immunity by Saccharomyces cerevisiae b-glucans

Patricia Vuscan[1], Breda Kischkel[1], Maria Tintoré[1]
[1]*Department of Medicine, Radboud University Medical Center, Nijmegen, Netherlands*; [2]*AB Biotek Human Nutrition & Health, Barcelona, Spain*

Candida albicans cell wall component b-glucan has been extensively studied for its ability to induce epigenetic and functional reprogramming of innate immune cells, a process termed trained immunity. We show that a high-complexity blend of two individual b-glucans from Saccharomyces cerevisiae possesses strong bioactivity, resulting in an enhanced trained innate immune response by human primary monocytes. The training required the Dectin-1/CR3, TLR4, and MMR receptors, as well as the Raf-1, Syk, and PI3K downstream signaling molecules. By activating multiple receptors and downstream signaling pathways, the components of this b-glucan preparation are able to act synergistically, causing a robust secondary response upon an unrelated challenge. In in-vivo murine models of melanoma and bladder cell carcinoma, pre-treatment of mice with the b-glucan preparation led to a significant reduction in tumor growth. These insights may aid in the development of future therapies based on b-glucan structures that induce an effective trained immunity response.

Hyper-glycolytic monocytes in obesity have an increased oxidative stress and IL-8 response

Janina Berg[1], Veselina Radusheva[2], Isabel Karkossa[3], Martin von Bergen[3], Matthias Blüher[4], Kristin Schubert[3], Manuela Rossol[1]
[1]*Molecular Immunology, Faculty of Health Sciences, BTU Cottbus-Senftenberg, Senftenberg, Senftenberg, Germany*; [2]*Division of Rheumatology, Department of Endocrinology, Nephrology, Rheumatology, Leipzig University, Leipzig, Germany*; [3]*Department of Molecular Toxicology, Helmholtz Centre for Environmental Research, Leipzig, Germany*; [4]*Helmholtz Zentrum München at the University of Leipzig and University Hospital Leipzig, Leipzig, Germany*

Obesity is associated with chronic low-grade inflammation and immune system dysfunction, which increases susceptibility to infection and serious disease outcomes. Monocytes are the precursors of the well-studied adipose tissue macrophages but little is known about functional alterations of monocytes in people with obesity. Aim of the study is to analyse the immunometabolic and functional responses of monocytes from individuals with obesity.
Monocytes were isolated from the blood of healthy human donors and people with obesity, and characterized using proteomics and analysis of cellular metabolism and immunological functions.
Monocytes from people with obesity showed a distinct proteomic profile. Activation of monocytes with lipopolysaccharide (LPS) led to the upregulation of metabolism pathways as well as phagocytosis and migration. Using the Seahorse analyzer, we found a pronounced hyper-glycolytic phenotype in resting monocytes from people with obesity compared to lean donors. After LPS activation, monocytes of people with obesity showed an enhanced glycolytic response. In addition, LPS-stimulated monocytes of people with obesity showed an increased IL-8 secretion and a prolonged production of reactive oxygen species, suggesting a dysregulated immune response.
In summary, the proteomic analysis as well as cytokine release data confirmed a dysregulated LPS-response in monocytes from people with obesity, which potentially increases the risk for infections. Targeted interventions focusing on monocytes might be beneficial and longitudinal studies investigating the dynamic changes in immunometabolism during the progression of obesity could provide valuable insights into potential targets.

Functional characterization of guanylate binding proteins in the host defense against chlamydia and toxoplasma infection

Veronica Raba[1], Katja Mölleken[2], Johannes Hegemann[2], Daniel Degrandi[1], Klaus Pfeffer[1]
[1]*Institute of Medical Microbiology and Hospital Hygiene, Heinrich Heine University Düsseldorf, Düsseldorf, Germany*;
[2]*Institute for Functional Microbial Genomics, Heinrich Heine University Düsseldorf, Düsseldorf, Germany*

Purpose: Guanylate binding proteins (GBPs) are interferon (IFN)-inducible mediators of cell-autonomous host resistance against intracellular pathogens and potent activators of canonical and non-canonical inflammasome pathways, leading to the processing of pro-inflammatory cytokines (IL-1β, IL-18) and inducing pyroptosis. The murine GBP family comprises eleven protein members (mGBP1-11) critically involved in the defense against protozoa, bacteria, and viruses. Upon infection with intracellular pathogens, GBPs are recruited to pathogen-containing compartments, significantly contributing to the immune response against *Toxoplasma gondii* and *Chlamydia trachomatis*. *In vivo* studies have revealed an increased susceptibility of mGBP2- and mGBP7-deficient mice to *T. gondii*, underscoring their importance in parasite control. In *vitro analyses* showed that mGBPs accumulate at *T. gondii* vacuoles, disrupting their integrity and restricting *Toxoplasma* replication.
Methods: To investigate the role of mGBPs in inflammasome activation and pyroptosis induced by *T. gondii* and *C. trachomatis*, we utilized mouse embryonic fibroblasts (MEFs) stably transduced with mGBP1-10. We analyzed the secretion of IL-1β and IL-18 and evaluated lactate dehydrogenase (LDH) release to assess the extent of pyroptosis after IFNγ stimulation and *T. gondii* / *C. trachomatis* infection. The activation of inflammasome components was determined by Western Blot analysis, facilitating a comprehensive examination of the molecular pathways involved.
Results: MEFs expressing mGBP1-10 exhibited increased LDH release and higher concentrations of IL-1β and IL-18 responding to *T. gondii* or *C. trachomatis* compared to control MEFs. Despite high sequence identity among mGBPs, distinct differences in effector function were observed. For instance, mGBP6-overexpressing MEFs exhibited a decreased cell death rate with high cytokine levels (hyperactivation), whereas mGBP9 led to enhanced cell death with normal cytokine release.
Conclusion: Our findings reveal the critical role of mGBPs in host defense against intracellular pathogens by modulating inflammasome pathways and inducing pyroptosis. These observations indicate that mGBPs regulate inflammasome assembly, either through direct interactions with its components or by mediating the lysis of pathogen-containing vacuoles, exposing them to the host cell cytosol. The differential effects of individual GBPs in the activation of the immune response highlight the complexity of their regulatory mechanisms and the necessity for further research to fully understand their contributions to cell-autonomous immunity.

Localization of phosphatidylserine binding site in the globular domains of C1q

Alexandra Kapogianni[1], Gabriela Radulova[1], Ginka Cholakova[1], Stoyan Iliev[2], Anela Ivanova[2], Vanya Bogoeva[3], Ivanka Tsacheva[1]
[1]Sofia University "St. Kliment Ohridski", Faculty of Biology, Department of Biochemistry, Sofia, Bulgaria; *[2]Sofia University "St. Kliment Ohridski", Faculty of Chemistry and Pharmacy, Department of Physical Chemistry, Sofia, Bulgaria*; *[3]Institute of molecular biology "Rumen Tzanev", Department Molecular biology of cell cycle, Sofia, Bulgaria*

Purpose: C1q is the key component of the classical pathway of the Complement system. Beside its classical function, C1q plays a crucial role in maintaining homeostasis, by partaking in the clearance of apoptotic cells. This occurs by the binding of C1q to phosphatidylserine (PS), which is externalized during apoptosis. The goal of this study was to characterize the PS binding site in the globular domains of C1q.
Methods: A quantitative ELISA was used to determine the binding activity of C1q and its globular fragments (ghA, ghB, ghC) to the physiologically relevant phospholipid 1-palmitoyl-2-oleoyl-sn-glycero-3-phospho-L-serine (POPS)**.** Fluorescence spectroscopy was used to determine the dissociation constants of the complexes formed between C1q and POPS as well as between the protein fragments and POPS. Simulation of the C1q-PS interaction was performed by molecular dynamics. The interaction was studied in the presence and absence of physiological concentration of extracellular Ca^{2+}.
Results: ELISA showed a dose-dependent interaction of C1q, ghA and ghB with POPS with significant difference in the presence and absence of Ca^{2+}. The fluorescent measurements confirmed the binding activity of C1q, ghA, ghB and also of ghC. The dissociation constant (KD) of each protein was calculated with C1q having the highest affinity (KD- 0.16 μM), followed by ghB (KD- 0.9 μM), ghA (KD- 1.2 μM) and ghC (KD- 1.5 μM). Molecular dynamics analysis supported the experimental data, revealing that amino acids in ghA and ghB interact with POPS.
Conclusion: Data from the aforementioned methods helped with the formation of a holistic view regarding the structure of the PS binding site. The three globular fragments of C1q globular domain contribute in a different way to the interaction with PS. The first contact of C1q with POPS is due to the glycosylated AA Asn-124 from ghA, followed by other residues from both ghA and ghB.

Innate immune sensing of self-RNA by RIG-I-like receptors

Felix Bender[1], Katharina I. Maser[1], Gunther Hartmann[1], Thomas Zilliger[1;2]
[1]*Institute of Clinical Chemistry and Clinical Pharmacology, Bonn, Germany*; [2]*Department of Biomedicine, Aarhus, Denmark*

Melanoma Differentiation-Associated Protein 5 (MDA5) is a cytosolic pattern recognition receptor of the RIG-I-like receptor (RLR) family that senses long double-stranded RNA (dsRNA) and, upon activation, induces type I interferon (IFN). Besides its role in antiviral immunity, sensing of insufficiently modified self-RNA by MDA5 has been implicated in autoinflammatory diseases. However, presence and characteristics of endogenous MDA5 agonists under healthy conditions have not been extensively studied so far.
To address this, we utilized a transient overexpression model of MDA5 in 293T cells and showed that MDA5 responds to endogenous dsRNA in a dose-dependent manner. Using mtRNA-free cells, we found while mtRNA makes up the bulk of MDA5 agonists in total RNA, nuclear-encoded RNA is the major source for accessible MDA5 ligands within cultured cells. In line with this, we found significant levels of nuclear-encoded cytosolic dsRNA in human and murine cells by immunofluorescence staining with an anti-dsRNA antibody. To identify these cellular dsRNAs, we developed a method for targeted, sequence-independent isolation and sequencing of full-length long dsRNAs. This method will be applied to map dsRNA regions in RNA isolated from cells and tissue and will be complemented by a genome-scale CRISPR knockout screen as well as proximity-labeling based APEX-Seq.
Our findings suggest that cells express MDA5-activating dsRNAs even in non-pathological conditions, and a portion of these is accessible to MDA5. Further experiments will be needed to address the exact identity of these stimulatory RNAs, especially in comparison to ligand sources under pathological conditions, their regulation to prevent autoimmunity or a possible physiological role in priming of innate immunity.

Profiling the circulating pathogen-associated molecular patterns and damage-associated molecular patterns in patients with end-stage liver disease

Omar Abdelrahman[1], Mark Robinson[1]
[1]*Maynooth University, Maynooth, Ireland*

Purpose: Low grade systemic inflammation is hypothesised to directly contribute to organ failure in patients with liver cirrhosis (an irreversible scarring of the liver). While elevated circulating interleukin (IL)6 and C-reactive protein (CRP) are commonly observed in patients with liver cirrhosis, it is unclear what causes this low grade systemic inflammation. Various pathogen-associated molecular patterns (PAMPs) and damage-associated molecular patterns (DAMPs) are detectable in patient samples, however, to date studies have investigated individual PAMPs and DAMPs in isolation. We hypothesise that profiling multiple PAMPs and DAMPs simultaneously may correlate better with low grade systemic inflammation and clinical outcomes in cirrhotic patients.
Methods: We profiled circulating PAMPs (lipopolysaccharide (LPS) and lipoteichoic acid (LTA)), and DAMPs (cell-free DNA (cfDNA), IL-1a, heat shock protein 70 (HSP70), cytochrome C and high mobility group box 1 (HMGB1)), in serum samples of cirrhotic patients with liver failure, undergoing assessment for liver transplant, and healthy controls. These were correlated with clinical and biochemical parameters associated with low-grade systemic inflammation and clinical outcomes.
Results: All the PAMPs and DAMPs investigated were elevated in a variable proportion of the cirrhotic patients with liver failure, in comparison to the healthy controls. When assessing all PAMPs and DAMPs in combination, the cirrhotic patients segregated into three groups. The first group showed minimum evidence of circulating PAMPs or DAMPs, and clustered together with the healthy controls. The second cluster included only cirrhotic patients who had elevated levels of two or three PAMPs or DAMPs, while the third cluster included cirrhotic patients with highly elevated levels of more than three of the assessed PAMPs or DAMPs. These patient clusters correlated with important clinical outcomes such as ascites, Charleson Comorbidity Index, and hospital length of stay.
Conclusions: Low grade systemic inflammation contributes to the transition to liver failure in patients with chronic liver disease. Our results indicate that while individual PAMPs or DAMPs are highly variable between patients, simultaneous assessment of multiple PAMPs and DAMPs can segregate patients and identify individuals as high-risk of adverse clinical outcomes.

Exploring monocyte activation, migration, and terminal differentiation in inflammatory arthritis

Niamh O'Dowd[1;2], Seán Dixon[1;2], Dumitru Anton[1;2], Sonia Sundanum[2], Carl Orr[2], Douglas Veale[2], Ursula Fearon[1;2], Viviana Marzaioli[1;2]
[1]Molecular Rheumatology, Trinity Biomedical Sciences Institute, TCD, Dublin 2, Ireland; *[2]EULAR Centre of excellence, Centre for Arthritis and Rheumatic Diseases, St Vincent's University Hospital, UCD, Dublin 4, Ireland*

Purpose: Monocytes emerge as pivotal players in the pathogenesis of Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA), where nuanced differences in activation, differentiation to DC, and function within both systemic circulation and local inflammatory sites have been observed. This study aims to delineate the divergent patterns of monocyte activation/priming, and differentiation into DCs, macrophages, and osteoclasts in RA vs PsA, offering insight into unique immunopathogenic signatures characterising the two diseases.
Methods: Monocyte subsets (Classical, Intermediate, Non-Classical) frequency and expression of activation markers and chemokine/differentiation receptors were analysed by flow cytometry in PBMCs from healthy controls (HC), RA and PsA patients. CD14+ monocytes were magnetically isolated from blood and differentiated into monocyte-derived-macrophages (Mo-MAC), -dendritic cells (Mo-DC), -osteoclasts (Mo-OC), and dendritic cell-derived osteoclasts (DC-OC) with specific cytokines, and differentiation was assessed by flow cytometry and TRAP staining.
Results: The frequencies of the three monocyte subsets showed no significant disparities between HC and RA/PsA, however an increase in activation markers CD40 and CD80 in PsA/RA *vs* HC, and CX3CR1 and CCR7 in RA>PsA>HC in classical and intermediate monocytes was observed, with a distinct co-expression profile observed for RA *vs* PsA by SPICE analysis. This hyper-inflammation in RA and PsA translated into a decrease in endocytic activity and enhanced cytokine production (TNFα and IL1β) in response to TLR stimuli. To evaluate whether this hyper-activation translated into a higher ability of monocyte differentiation into terminal cells, the frequencies of receptors implicated in monocyte differentiation were measured, demonstrating that IL4R, GMCSFR,RANK and MCSFR were higher in RA/PsA *vs* HC. In accordance, *in vitro* differentiation of CD14+ monocytes into terminal cells, demonstrated an increased differentiation of Mo-DC and Mo-MAC in RA>PsA>HC monocytes (evidenced by higher CD209 and CD64), and increased osteoclast formation and multinucleated cells in PsA>RA>HC for both Mo-OC and DC-OC in TRAP stained cells; thus suggesting cells from RA and PsA patients might prefer different routes of differentiation based on their environment.
Conclusion: Altogether, these findings indicate that differential monocyte hyper-activation and inflammation predisposes RA and PsA monocytes to selectively differentiate into terminal cells, potentially accounting for patient response to therapy.

The tuberculosis plasma milieu induces signatures of inflammation, neutrophil recruitment, and interleukin-10 family-mediated immunomodulation in monocytes

Hubert Senanu Ahor[1], Monika M. Vivekanandan[1], Difrey Minadzi[2], Isaac Acheampong[2], Wilfred Aniagyei[1], Augustine Yeboah[2], Millicent Lamptey[2], Dorcas Owusu[2], Ernest Adankwah[2], Julia Seyfarth[1], Richard O. Phillips[1], Marc Jacobsen[1]
[1]Department of General Pediatrics, Neonatology and Pediatric Cardiology, Medical Faculty, University Hospital Duesseldorf, Heinrich-Heine University, Duesseldorf, Germany; *[2]Kumasi Centre for Collaborative Research in Tropical Medicine (KCCR), Kumasi, Ghana, Kumasi, Ghana*

Phenotype changes of immune cells in peripheral blood are characteristic of human tuberculosis and immunopathology seen in blood plasma plays a central role in suppressing T-cell responses in a subgroup of tuberculosis patients. In previous studies, we described changes in the phenotype of monocytes in acute tuberculosis patients and identified causative effects of the aberrant plasma milieu. Therefore, in this study, we aimed to characterize the functional implications of plasma effects on monocyte function in tuberculosis disease.
Using our established in vitro plasma-reference monocyte assay, we investigated the effect of plasma samples from patients with tuberculosis and healthy contacts (controls) on heterologous monocytes by conducting total mRNA sequencing. Affected pathways were confirmed by analyses of selected candidate proteins on plasma-treated monocytes and monocytes from tuberculosis patients and controls.
Among the transcripts induced by tuberculous plasma, we identified an enrichment of pathways involved in inflammation, recruitment of granulocytes/monocytes, and immunomodulation. Several chemokines and chemokine receptors were increased in tuberculous plasma-treated monocytes, suggesting the recruitment of granulocytes (via G-CSF, CXCL1, CXCL2, CXCL8) and monocytes. Monocytes from tuberculosis patients showed an inflammatory phenotype with increased expression of chemokine receptors (CCR1, CCR2, CCR5), as previously described. Interestingly, members of the Interleukin (IL)-10/-20 family (such as IL-10, IL-19, and IL-24), as well as IL-10 and IL-20 receptor chains were increased in tuberculosis plasma-treated monocytes.
These results suggest that monocytes and changes in the plasma milieu play a central role in tuberculosis immunopathology. Both inflammatory perturbations and immune modulation are promoted by monocytes, which may contribute to the immunosuppression of T-cell responses in patients with tuberculosis.

Dissecting structure and function of the macrophage testraspan MS4A4A

Alessia Troilo[1;2], Jiazhi Lin[1], Riccardo Albanesi[1], Raffaello Viganò[3], Eleonora Capezzali[4], Viviana Valeri[4], Francesca Brambilla[3], Pierluigi Mauri[3], Dario Di Silvestre[3], Luca Mollica[1], Benedetta Savino[1;2], Carlo Pucillo[4], Massimo Locati[1;2], Elena Monica Borroni[1;2]
[1]Department of Medical Biotechnologies and Translational Medicine, University of Milan, Segrate, Italy; *[2]IRCCS Humanitas Research Hospital, Rozzano*; *[3]Proteomics and Metabolomics Institute for Biomedical Technologies, Segrate, Italy*; *[4]Department of Medicine, University of Udine, Udine, Italy*

Membrane-spanning 4A (MS4A) proteins are emerging as a new class of immune cell regulators, but the molecular mechanisms underpinning their biological functions are currently poorly characterized. In the recent years, we focused our attention on MS4A4A, which shows a pattern of expression restricted to mast cells and macrophages, both in human and mice. MS4A4A expression is induced during macrophage differentiation and is detected in tissue resident macrophages and in some body districts (CNS, colon, lungs, skin). In vitro MS4A4A expression is increased in "alternative activated" macrophages (i.e. IL-4, glucocorticoids) and is found highly expressed in some pathological settings (rheumatoid arthritis) and in tumor-associated macrophages (colon carcinoma, lung adenocarcinoma, melanoma). Here, we aim to reveal the role of MS4A4A in macrophage biology, achieving a deeper mechanistic understanding of its function in macrophages and disclosing its contribution to immune responses.
Our preliminary data showed no difference during bone marrow-derived macrophage (BMDM) generation from wild-type (WT) and Ms4a4a knock-out (KO) animals. However, MS4A4A deficiency impaired the expression of anti-inflammatory genes in BMDM after stimulation with IL-4, suggesting that this protein is involved in the acquisition of an alternative phenotype. To define MS4A4A contribution in macrophage polarization, RNA sequencing of WT and KO BMDM has been performed. To deeper investigate the biological relevance of the defect in "alternative activation" observed in Ms4a4a-KO macrophages, cytokines production, extracellular vesicles secretion and uptake and calcium fluxes upon different stimuli has been evaluated. As other tetraspan proteins, MS4A4A forms omo- and ethero-complexes. Indeed, recent publications identified several partners for MS4A4A, including MS4A4A itself, MS4A6A, MS4A7, TREM2 and Dectin-1 and they showed that MS4A4A influences macrophage functions by regulating membrane distribution and signaling properties of its partners. Interestingly, using a split-ubiquitin two-hybrid approach and mass spectrometry-based immunoprecipitation proteomics, we identified new possible partners for MS4A4A, including the γ signaling chain of Fcγ receptors, Toll-Like Receptor 2, and calcium/calmodulin-dependent 3',5'-cyclic nucleotide phosphodiesterase 1A. Furthermore, we are computationally characterizing MS4A4A structure and dynamics aiming to understand its function in macrophages, also by means of an extensive molecular docking calculations campaign with some families of endogenous and exogenous bioactive compounds.

Using Drosophila melanogaster (fruit fly) to investigate the role of two novel immune-induced peptides, IBIN and IBIN-like.

Matthew Maasdorp[1], Susanna Valanne[1], Laura Vesala[1], Petra Aaltonen[1], Aino Malin[1], Tiina Salminen[1], Dan Hultmark[2], Mika Rämet[1]
[1]Tampere University, Tampere, Finland; *[2]Umeå University, Umeå, Sweden*

Expanding our understanding of innate immune system mechanisms remains an important task for developing vaccines and drugs against both infectious diseases and inflammatory conditions. While mammals possess both innate and adaptive immune systems, complicating the study of the role of innate immunity, insects such as the fruit fly *Drosophila melanogaster* rely only on innate immunity. In this project, we work to determine the roles of two novel short peptides in *Drosophila*, IBIN and IBIN-like. Expression of both is highly upregulated when flies are infected with a wide range of pathogens. Our work shows at times opposing roles for these peptides in the immune response, through regulation of key immune processes, including the Toll pathway. While the short sequences of these peptides and their genes makes tracing their evolutionary histories challenging, our analysis shows that IBIN and IBIN-like are part of a gene family conserved in insects separated by approximately 100 million years of evolution.
The fruit fly model is highly suited to immunology research due to lower genetic redundancy compared to mammalian models. Despite this, a high percentage of disease relevant genes are conserved between flies and humans. This has, in the past, resulted in key immunology findings being made in the fly, including the discovery of Toll receptors, leading to the description of TLRs in mammals. *Drosophila* researchers have a wide range of genetic tools at their disposal, and fast generation times, reduced ethical constraints, and low cost of maintenance enable experiments with large numbers and therefore high power, making this an excellent model for screening work.

Investigating the molecular mechanism of tumor necrosis factor-related apoptosis-inducing ligand-induced macrophage polarization: Transcriptomic analysis of key signaling molecules

Serhat Songoren[1;2], Sinem Gunalp[1], Ahmet Bursalı[1], Gökhan Karakülah[1;2], Duygu Sag[1;2;3]
[1]*Izmir Biomedicine and Genome Center, Izmir, Turkey*; [2]*Department of Genomic Sciences and Molecular Biotechnology, Izmir International Biomedicine and Genome Institute, Dokuz Eylul University, Izmir, Turkey*; [3]*Department of Medical Biology, Faculty of Medicine, Dokuz Eylul University, Izmir, Turkey*

Macrophages can be polarized into pro-inflammatory M1 and anti-inflammatory M2 macrophages. TNF-related apoptosis-inducing ligand (TRAIL), a member of the TNF superfamily, can trigger cell death or initiate survival pathways by binding to death receptors DR4 or DR5. We have recently shown that TRAIL promotes the polarization of human macrophages towards the M1 phenotype. However, the molecular mechanism of this effect is not known. In this study, to uncover the molecular mechanism, we analyzed the signaling molecules associated with M1 polarization in primary human monocyte-derived macrophages treated with TRAIL. Primary human monocyte-derived macrophages were stimulated with 200 ng/ml soluble TRAIL for 8 hours and the changes in the molecules associated with M1 polarization was analyzed by RNA-seq and qPCR. Of all M1 macrophage markers obtained from RNA-seq data, the expression rates of genes relevant to M1 polarization that reached significant expression levels were examined. It was shown that TRAIL stimulation increased the expression of STAT1, TRAF1, NFkB1, and MAPK11 in primary human macrophages. qPCR confirmation analyses showed that although the expression levels of all the signaling molecules showed an increase after TRAIL stimulation, only the increase in MAPK11 reached statistical significance. In conclusion, our study demonstrates that TRAIL stimulation leads to upregulation of MAPK11 gene expression in primary human macrophages, suggesting that TRAIL may promote M1 polarization through the MAPK signaling pathway.

Viral envelope protein fragments can modulate innate immune cell signaling via formylpeptide receptors

Heiko Heilmann[1], Lukas Busch[1], Celine Buchmann[1], Islam Mohamed[2], Adrian Theiß[1], Stefan Lohse[3], Bernd Bufe[1]
[1]University of Applied Sciences Kaiserslautern, Zweibrücken, Germany; *[2]Saarland University Medical Center, Institute of Virology, Homburg, Germany*; *[3]Leibniz Institute for New Materials, Saarbrücken, Germany*

Formylpeptide receptors (FPRs) comprise a small family of immune receptors that are capable of interacting with structurally diverse peptide ligands. In addition to their well-established role as pattern recognition receptors for bacterial pathogens, recent mouse studies provide clear evidence that FPRs play an important role for the outcome of influenza A and dengue virus infection. Additional interactions with peptide fragments from envelope proteins of HIV-1, Ebola- and different coronavirus strains have also been reported. Interestingly, spike protein fragments from SARS-CoV-2 were shown to directly trigger innate immune responses and cardiovascular signaling. Given that FPRs are expressed in multiple other cell types where they have a complex role in immune defense, a modulation of FPRs by breakdown products of spike protein fragments might help to explain some aspects of the COVID-19 pathophysiology. However, systematic studies that investigate the interaction between spike protein fragments, FPRs and responses of innate immune cells are lacking.
Using high-throughput calcium imaging, we first identified six regions in the spike protein ectodomain of SARS-CoV-2 that can specifically interact with FPR1, FPR2 and FPR3 in nanomolar to low micromolar concentrations. Experiments with primary human neutrophils revealed that these peptides also triggered calcium signaling and other immune responses such as chemotaxis, MMP-9 protease release and NETosis via FPRs. Interestingly, peptides from the conserved membrane proximal region in the spike protein were capable to competitively inhibit FPR1 calcium signaling, while they initiated calcium flux via the receptor subtype FPR2. Systematic structure function studies of these peptides revealed that their precise signaling pattern and resulting neutrophil responses can significantly differ depending on peptide length and strain specific amino acid composition. Moreover, the analysis of physicochemical properties revealed hidden common features in FPR ligands that are also found in envelope proteins of other viruses. In line with these predictions, tests of synthetic peptide pools from the envelope proteins of four different viruses were found to strongly activate all FPR subtypes suggesting that an activation of FPRs via viral envelope protein fragments is an underrated general mechanism of unrelated viruses modulating innate immune responses.

Itaconate drives mtRNA-mediated Type I interferon production via inhibition of succinate dehydrogenase

Shane O'Carroll[1], Christian Peace[1], Juliana Toller-Kawahisa[1], Alessia Zotta[1], Emily Day[1], Alex Hooftman[1], Sara Charki[1], Yukun Min[1], Aline Zoller[1], Anne Mcgettrick[1], Luke A.J O'Neill[1]
[1]*School of Biochemistry and Immunology, Trinity Biomedical Sciences Institute, Trinity College Dublin, Ireland, Dublin, Ireland*

Itaconate is one of the most highly upregulated metabolites in inflammatory macrophages. It has been shown to have immunomodulatory properties, although the underlying mechanisms are not fully elucidated. Here, we have investigated how itaconate regulates type I interferon production. We have found, using both pharmacological and genetic approaches, that inhibition of succinate dehydrogenase (SDH) is required for this response. SDH inhibition by itaconate leads to mitochondrial double-stranded RNA (mtRNA) release which is dependent on the mitochondrial pore VDAC1. Following this, the dsRNA sensors MDA5 and RIG-I are required for IFNβ production in response to SDH inhibition. Inhibition of SDH by itaconate therefore links TCA cycle modulation to type I Interferon production via mtRNA.

The Multifaceted Role of Lactoferrin in Covid-19

Vladimir Leksa[1]
[1]*Institute of molecular biology SAS, Bratislava, Slovakia*

Lactoferrin is an iron-binding glycoprotein present in most human exocrine fluids, particularly breast milk. Lactoferrin is also released from neutrophil granules and its concentration increases rapidly at the site of inflammation. Immune cells of both the innate and adaptive immune system express receptors for lactoferrin to modulate their functions in response to it. Based on these interactions, lactoferrin plays manifold roles in host defense from augmenting or calming inflammatory pathways to direct killing of pathogens. Complex biological activities of lactoferrin are determined by its ability to sequester iron and by its highly basic N-terminus, via which lactoferrin binds to a plethora of negatively charged surfaces of microorganisms, viruses, but also to mammalian cells, both normal and cancerous. Proteolytic cleavage of lactoferrin in the digestive tract generates smaller peptides, such as N-terminally derived lactoferricin. Lactoferricin shares some of the properties of lactoferrin, but also exhibits unique characteristics and functions. The focus of the presentation will be put on the potential therapeutic role of lactoferrin in COVID-19.

SHP1 knockdown enhances Toll-like Receptor 7 (TLR7) signalling in the plasmacytoid dendritic cell line CAL-1.

Sarah Harkin[1], Adam Dignam[1], Marion Butler[1]
[1]*Maynooth University, Maynooth, Co. Kildare, Ireland*

Purpose: The protein tyrosine phosphatase SHP1 has been widely studied for its immunoregulatory activity in immune cells, such as in growth factor receptor, toll-like receptor (TLR), T and B cell signalling pathways. SHP1 plays a positive role in type I interferon production downstream of TLR3/4, however it acts to limit TLR4-induced expression of pro-inflammatory cytokines. Mice with mutations in the SHP1 gene, known as motheaten mice, develop severe autoimmunity and inflammation. Similarly reduced phosphorylation of SHP1 has been associated with increased T cell proliferation in autoimmune diseases such as systemic lupus erythematosus (SLE). To date, the role of SHP1 in TLR7 signalling, an antiviral signalling pathway that displays altered activity in SLE, is still unknown. This study aims to uncover the function of SHP1 within this innate immune signalling pathway.
Methods: Stable SHP1 knockdown of a plasmacytoid dendritic cell line (CAL-1) which constitutively express TLR7 were generated using a lentiviral approach to investigate the impact of SHP1 deficiency on the TLR7 pathway. CAL-1 control and SHP1 knockdown cells were stimulated with the TLR7 agonist R848, and supernatants were harvested to assess cytokine levels by ELISA. In parallel, cell lysates were profiled by Western blot analysis to examine how SHP1 affects NF-κB, MAPK and IRF activation downstream of TLR7.
Results: SHP1 knockdown in CAL-1 cells enhances the production of both pro-inflammatory cytokines and type I interferons downstream of TLR7 and enables increased activation of the major transcription factors involved in this signalling pathway.
Conclusion: These findings implicate SHP1 as a negative regulator of TLR7 signalling, suggesting the potential for future investigations into SHP1 and the increased activity of TLR7 observed in SLE.

Enhanced complement activation and MAC formation accelerates to severe COVID-19

Xuebin Qin[1;2], Calder R Ellsworth[2;3], Shumei Liu[2;3]
[1]Tulane Univeristy School of Medicine, New Orleans, LA, United States; *[2]Tulane Univeristy School of Medicine, New Orleans, United States*; *[3]Tulane National Primate Research Center, Covington, United States*

The complement system, a key component of innate immunity, provides the first line of defense against bacterial infection; however, it has been implicated in being a detrimental to COVID-19 patients and accelerating lung and other tissue damage. The underlying mechanism remains unclear and requires further experimental investigation. Here, we used three knock out mice strains (1. C3-/-; 2. C7-/-; and 3.CD59-/-) to evaluate the role of complement in severe COVID-19 pathogenesis. C3 deficient mice lack a key common component of all three complement activation pathways and are unable to generate C3 and C5 convertases. C7 deficient mice lack a complement protein needed for MAC formation. CD59 deficient mice lack an important inhibitor of MAC formation. In addition to use of these knock out mice, we also used anti- C5 antibody to block and evaluate the therapeutic potential of inhibiting MAC formation. We demonstrate that inhibition of complement activation (in C3-/-) and MAC formation (in C3-/-. C7-/-, and anti-C5 antibody) attenuates severe COVID-19; whereas enhancement of MAC formation (CD59-/-) accelerates severe COVID-19. The degree of MAC deposits in the alveoli, epithelial cells, and endothelial cells of $C3^{-/-}$, $C7^{-/-}$ mice, and $CD59ab^{-/-}$ mice as compared to their control mice is associated with the attenuation or acceleration of SARS-CoV-2-induced disease. However, C3 deposits in the lungs of these infected mice did not show the same trend. Further, the lack of terminal complement activation for the formation of MAC in C7 deficient mice protects endothelial function, which is associated with the attenuation of diseases and pathologic changes. In summary, these results shed light on the importance of the pathogenic role of MAC in severe COVID-19 and demonstrate the therapeutic beneficial effect of anti-MAC on severe COVID-19.

Characterisation NKG2C NK cell receptor and genotypes in relation to human cytomegalovirus infection

Suruthimitra Okpoluaefe[1], Rafeezul Mohamed[1], Norfarazieda Hassan[1]
[1]*Advanced Medical and Dental Institute, Universiti Sains Malaysia, Kepala Batas, Malaysia*

Purpose: This study aims to characterize the immunogenetic profiles of HCMV infection in the healthy Malaysian population, specifically the NKG2C and NKG2A receptors on NK cells, and *HLA- E* on infected cells
Methods: Enzyme-linked immunosorbent assay (ELISA) is employed for the detection of HCMV IgG levels. *HLA-E* (01:01, 01:03and 01:114), and *NKG2C* (wild-type, and deletion-type) will be analysed using sequence-specific-primer polymerase chain reaction, while *HLA-E* (exon 3) and *NKG2A* (exon 2 and 5) sequences will be sequenced employing Sanger Sequencing.
Results: Our results currently indicate that HCMV seropositivity may be lower at 79.1% (n=67) than the previously reported 92% in 2012. Our results also indicate an almost equal distribution of NKG2C haplotypes; WT/WT at 53.70% (n=29), and WT/DEL at 46.30% (n=25). NKG2C DEL/DEL was not detected. It is also expected that HCMV seropositive individuals will have differential *HLA-E*, *NKG2C* and *NKG2A* genotypes.
Conclusion: Approximately 70-90% of Malaysians are expected to be HCMV seropositive, with them possessing a unique immunogenetic profile that can be harnessed for potential NK cell-based therapy and anti- tumour property.

The complex role of the human RNA helicase DDX3X during viral infections

Cathal Ryan[1], Dimitrios Anastasakis[2], Ahsan Polash[2], James Carolan[3], Markus Hafner[2], Martina Schröder[1]
[1]*Host-Pathogen Interaction Lab, Kathleen Lonsdale Institute for Human Health Research, Biology Department, Maynooth University, Maynooth, Co. Kildare, Ireland*; [2]*RNA Molecular Biology Laboratory, National Institute for Arthritis and Musculoskeletal and Skin Disease, National Institutes of Health, Bethesda, Maryland, United States*; [3]*Maynooth University, Maynooth, Co. Kildare, Ireland*

Human DDX3X is an RNA helicase with known roles in the regulation of mRNA translation, and a host factor targeted by a diverse range of viruses during infection. Although inhibition of DDX3X is explored for development of broad-spectrum antiviral drugs, DDX3X is also an immune-signalling protein in the RIG-I pathway, promoting type I interferon production and thereby exerting an anti-viral function. It is currently unknown how DDX3X's role in host mRNAs translation is impacted during viral infection and if this plays an anti-viral role separate from its immune signalling function.
Using PAR-CLIP, a technique which crosslinks and then sequences RNAs bound to immunoprecipitated proteins, we identified mRNA targets of DDX3X in uninfected and Sendai Virus-infected cells at the transcriptome level. We found that DDX3X primarily binds to the 5'-UTR and start codon in both host and Sendai Virus mRNAs, indicating a potential role in regulating translation initiation. Furthermore, Sendai Virus infection induces changes to the DDX3X-bound mRNA pool, revealing new candidates for DDX3X post-transcriptional regulation which may impact anti-viral immunity. Finally, utilising mass spectrometry, we also assessed the downstream effect of DDX3X knockdown and viral infection on the host cell proteome, linking DDX3X binding to post-transcriptional regulation of its targets. Overall, DDX3X may contribute to the dynamic of the virus-host interaction also at the level of mRNA regulation, which may be of consequence when exploring it as a potential broad-spectrum antiviral drug target.

Inflammasomes are immune complexes that, when activated, leads to the release of pro-inflammatory cytokines IL-18 and IL-1β. Type I interferons (IFNs) are involved in fighting infections and promote the expression of IFN-stimulated genes related to inflammation. Despite the significance of these cytokines in inflammation, the relationship between type I IFNs and inflammasome regulation is not well-understood. In this study, we examined RNA-sequencing data from patients with monogenic interferonopathies and identified an increase in the expression of several inflammasome-related genes. To explore the impact of type I IFN on inflammasomes, we exposed human monocyte-derived macrophages to IFN-α. We observed an increase in *CASP1* and *GSDMD* mRNA levels over time, while *IL1B* and *NLRP3* expression did not show a direct correlation with IFN-α exposure duration. IFN-α treatment decreased the release of mature IL-1β and IL-18 in response to ATP-induced NLRP3 inflammasome activation, indicating that regulation may occur at the cytokine expression level rather than directly affecting the inflammasome itself. However, further research is needed to understand the mechanisms by which IFN-α regulates NLRP3 and other inflammasomes at both the transcriptional and post-translational levels.

NKG7 control cytolytic granule maturation and granzyme B levels in NK cells

Yunjie Wu[1], Miriam Aarsund[1], Susanna Ng[2], Tuula Anneli Nyman[1], Marit Inngjerdingen[1]
[1]*University of Oslo, Oslo, Norway*; [2]*University Hospital Bonn, Bonn, Germany*

The tetraspanin NKG7 is preferentially expressed in cytolytic granules of NK cells and T cells. Lack of NKG7 reportedly leads to reduced cytotoxicity, and reduced control of tumors in vivo. We have previously shown that a subset of NK-cell derived extracellular vesicles (EVs) released in response to cytokines contain NKG7. The purpose of this study was therefore to investigate whether NKG7 impact EV biogenesis and function. We report here that cytotoxic granules in NK cells contain intraluminal vesicles positive for NKG7 as examined by transmission electron microscopy. Further, CRISPR-mediated knockdown of NKG7 in NK-92 cells led to accumulation of smaller-sized cytotoxic granules, accompanied with fewer intraluminal vesicles in the granules. In contrast, multivesicular bodies appeared morphologically normal. Immunogold labeling indicated a higher amount of granzyme B in granules of NK cells lacking NKG7. The data thus indicates that NKG7 may play a role in granule biogenesis, and that loss of NKG7 may result in a maturational block and build-up of granzymes. EVs released from NK cells lacking NKG7 were smaller, but induced tumor cell apoptosis at a comparable level to EVs from control NK cells, indicating that vesicles from the endosomal system also may contribute to tumor cell apoptosis. To further understand the biology of NKG7$^+$ EVs, we purified NKG7$^+$ EVs from NK-92 cells by immunocapture, and performed comparative proteomics profiling against bona fide CD63$^+$ EVs. We found that NKG7$^+$ EVs are enriched in granzymes, certain Rab proteins and proteins mediating vesicular fusion. These proteins were reduced in EVs derived from NK cells lacking NKG7, indicating that NKG7$^+$ EVs may be a separate, specialized subset of EVs, possibly mediating an alternative pathway of targeting cancer cells.

Ins and Outs of Autophagy in Measles Virus Infection

Mathias Faure[1;2]
[1]*CIRI Inserm U1111, Lyon, France*; [2]*Université Lyon 1, Lyon, France*

Autophagy is a highly conserved degradation pathway used as an autonomous mechanism to combat intracellular pathogens. However, many pathogens have evolved molecular strategies to avoid or subvert autophagy for their own benefit. Over the years, we have described many very complex relationships between measles virus and autophagy, because this virus can induce autophagy through several distinct inputs: upon entry, during replication, and during its propagation. This very fine interaction has allowed us to better understand how autophagy is regulated in the context of infections, and to highlight a new paradigm on how and when autophagy can be beneficial or detrimental to a pathogen. We show that during measles virus infection, molecular regulators of autophagy can be hijacked for the benefit of the virus. Nevertheless, unexpectedly, measles virus-induced autophagy can lead to the degradation of otherwise pro-viral cellular cargoes and, at the same time, anti-bacterial cargoes facilitating the establishment of secondary infection. Thus, using mechanistic and unbiased approaches reveal new ins and outs of autophagy in microbial infection.

Glutamine metabolism is essential for cytokine-induced natural killer cell training and enhanced effector function

Gearóid Conlon[1], David Finlay[1], Clair Gardiner[1], Aisling Dunne[1]
[1]*Trinity College Dublin, Dublin, Ireland*

Purpose: Natural Killer (NK) cells are innate, granular effector lymphocytes with important anti-viral and anti-cancer functions. There is increasing interest in NK cell therapies for cancer treatment, including cytokine-induced memory-like or "trained" NK cells which show enhanced effector functions upon restimulation. A clearer understanding of the mechanisms required for inducing and sustaining NK cell training may improve the efficacy of these cells as an immunotherapy.
Nutrient uptake is a crucial aspect of immune cell function and metabolism. The amino acid, glutamine, is an important nutrient that fuels oxidative phosphorylation (OXPHOS) in metabolically active cells via glutaminolysis which feeds into the tricarboxylic acid (TCA) cycle. The role of glutamine is beginning to be recognised in innate immune cell activation and training but remains largely unexplored in human cytokine-trained NK cells. Therefore, this project aims to investigate the role of glutamine uptake and metabolism in cytokine-induced NK cell training.
Methods: A proteomics data set comparing IL-2 stimulated and unstimulated NK cells was interrogated to determine if cytokine stimulation results in altered nutrient transporter expression. A novel click chemistry paired uptake assay was employed to quantify, by flow cytometry, SLC1A5-mediated glutamine transport in cytokine-trained NK cells. The role of glutamine uptake and metabolism during cytokine-induced NK cell training and subsequent activation was also investigated by analysing functional and metabolic readouts after treatment with inhibitors.
Results: Results demonstrate that SLC1A5, the major human glutamine transporter, is the most differentially expressed protein in IL-2 stimulated NK cells. Significant upregulation of SLC1A5-mediated amino acid transport was also observed in cytokine-trained NK cells (relative to untrained NK cells). Depletion of glutamine and inhibition of glutamine/glutamate metabolism impaired enhanced NK cell effector functions during cytokine restimulation and cytokine-induced training.
Conclusion: This data suggests that glutamine uptake, notably through SLC1A5, and subsequent metabolism in the mitochondria are essential events in sustaining the metabolic changes needed for enhanced NK cell effector functions during cytokine-induced activation and training.

Initial sensing of segmented filamentous bacteria and subsequent induction of Th17 responses first occur in Peyer's patches by privileged monocyte-derived phagocytes

Renan Oliveira Corrêa[1], Marie Cherrier[1], Nadine Cerf-Bensussan[1], Hugues Lelouard[2], Valérie Gaboriau-Routhiau[1;3]
[1]*Imagine Institute for Genetic Diseases, Université Paris Cité, Paris, France*; [2]*Université Aix Marseille, CNRS, INSERM, CIML, Marseille, France*; [3]*Université Paris-Saclay, INRAe, AgroParisTech, Micalis Institute, Jouy-en-Josas, France*

Segmented filamentous bacteria (SFB) are commensal members of the gut microbiota with unique features, including their tight attachment to the epithelial layer without triggering any pathological inflammation. SFB also strongly induce gut homeostatic Th17 responses, being crucial to the proper post-natal maturation of the intestinal barrier. However, the precise location where SFB is initially sensed by the host and the phagocytic population orchestrating Th17 priming are both questions still highly debated. LysoDCs are a subset of monocyte-derived cells with the strongest phagocytic activity in the Peyer's patches (PPs), sampling antigens especially by extending dendrites into the gut lumen through M cell-specific transcellular pores. Given their privileged location and effective functions, they had been highlighted as potential candidates in mediating SFB-induced immunity, although this relationship has never been directly approached. Here we describe higher accumulation of SFB-specific T lymphocytes and Th17 cells in PPs when compared to mesenteric lymph nodes (MLNs), both naturally after weaning (which correlates to the onset of SFB colonization) and following in vivo adoptive transfer of transgenic SFB-specific naïve CD4+ T cells. By preventing lymphocyte recirculation, we also show that although SFB-specific Th17 cells can be locally primed at both PPs and MLNs, they appear much earlier in the PPs, probably due to a more rapid response of the local antigen-presenting cells and the shorter time required for them to migrate to the interfollicular zone. Indeed, PPs imaging reveals SFB in proximity with and even engulfed by LysoDCs. Interestingly, we also observe LysoDCs in close interactions with RORgt+ proliferating SFB-specific T cells. We further describe that the profile of LysoDC maturation is strongly affected by weaning in a microbiota-dependent way, and that SFB alone can recapitulate this phenotype induced by a complex microbial community. Finally, we also demonstrate that amongst distinct phagocytes, only LysoDCs have the capacity to prime SFB-specific T cells ex vivo. We are currently working on a model for LysoDC depletion that will be crucial for elucidating their role in such complex scenario.

Role of type III interferons on intestinal tissue restitution

Julien Mambu[1], Kautilya K. Jena[2], Daniel Boehmer[2], Benedetta Sposito[2], Virginie Millet[1], Lionel Spinelli[1], Sarah Wurbel[1], Chloé Riquier[1], Franck Galland[1], Philippe Naquet[1], Vanessa Mitsialis[3], Katlynn Bugda Gwilt[3], Jay R. Thiagarajah[3], Katherine A. Fitzgerald[4], Scott B. Snapper[3], Achille Broggi[1], Ivan Zanoni[2]
[1]Aix Marseille Université, CNRS, INSERM, Centre d'Immunologie de Marseille-Luminy (CIML), MARSEILLE, France; *[2]Harvard Medical School, and Boston Children's Hospital, Division of Immunology, Boston, United States*; *[3]Harvard Medical School, Boston Children's Hospital, Division of Gastroenterology, Boston, United States*; *[4]Program in Innate Immunity, Department of Medicine, University of Massachusetts Chan Medical School, Worcester, United States*

During inflammatory bowel diseases (IBD), the equilibrium between inflammatory cells, epithelia, and microbiome is lost, leading to inflammation, intestinal barrier breaches, and impaired epithelial regeneration. Therefore, understanding the mechanisms by which immune mediators influence tissue repair is crucial.
Here, we investigated how interferons (IFN) influence tissue repair after damage to the intestinal mucosa driven by inflammatory or physical injury.
Indeed, Interferons, which are increased during intestinal inflammation, can significantly alter the physiology of target cells. Type III IFN, or IFN-λ, are of particular interest due to their specialized ability to stimulate epithelial cells at barrier sites. Previous studies indicated elevated levels of IFN-λ and its receptor (IFNLR) in IBD patients, sparking debate over their role in colitis.
Both during dextran sulfate sodium-induced colitis or targeted irradiation damage, we found that IFN-λ signaling in intestinal epithelial cells (IECs) delays intestinal repair. The impaired tissue repair was associated with a transcriptional program inhibiting intestinal stem cell expansion. Mechanistically, IFN-λ delays epithelial cell regeneration by inducing the upregulation of ZBP1, Caspase-8 activation, and cleavage of Gasdermin C (GSDMC), both *in vivo* and in human and mouse intestinal organoids. Cleaved GSDMC drives epithelial cell death by pyroptosis and delays the re-epithelialization of the large or small intestine after colitis or irradiation, respectively.
Hallmarks of this pathway, such as ZBP1 upregulation, Casp-8, and GSDMC upregulation and cleavage, are significantly higher in IBD patients compared to controls and correlate with disease severity.
To understand the relevance of these findings during homeostasis, inflammation and repair, we mimicked injury and repair cycles in organoids grown in 2D in air-liquid interface.
In this model, IFN-λ provided the priming signal, requiring a second stimulus to mediate cell death. We identified Z-nucleic acids as this secondary signal, which increases during inflammatory damage and recovery, *in vivo* and *in vitro*.

This study unveils a novel mechanism by which IFN-λ regulates intestinal tissue repair, offering insights into how the inflammatory response affects epithelial repair in IBDs. The clinical relevance of the ZBP1/Casp-8/GSDMC pathway activation in patient samples suggests its potential as a therapeutic target for promoting tissue repair in these diseases.

Maintenance of intestinal homeostasis is imperative to prevent the onset of inflammatory bowel disease (IBD). Intestinal homeostasis relies heavily on the intricate interplay among various cell types, including immune and non-immune cells. However, the precise mechanisms underlying the regulation of intestinal homeostasis by specific cell populations remain largely elusive. Here, we investigate the distinct roles of immune cells and stromal cells by modulating the expression levels of lamin A/C, a multifaceted regulator involved in structural, epigenetic, and transcriptional processes, in a murine model of IBD induced by dextran sulfate sodium salt (DSS).
We assessed the development of DSS-induced colitis in mice lacking lamin A/C ($Lmna^{-/-}$) specifically in immune cells (Vav1-Cre), T cells (CD4-Cre), select myeloid cells (LysM-Cre), and stromal cells (Col1a2-Cre), as well as in mice overexpressing lamin A/C in T cells ($Lmna^{++/++}$ CD4-Cre). Mice were subjected to one or two cycles of DSS administration to predominantly elicit innate or adaptive immune responses, respectively.
Our findings demonstrate that, compared to wild-type mice ($Lmna^{+/+}$), the absence of lamin A/C in T cells, myeloid cells, or stromal cells following a single dose of DSS confers protection against colitis. Notably, the protective effect appears more pronounced in mice lacking lamin A/C specifically in T cells when exposed to two doses of DSS, underscoring the pivotal role of lamin A/C in adaptive immunity during colitis. Conversely, lamin A/C overexpression in T cells exacerbates colitis following two doses of DSS administration. Furthermore, the absence of lamin A/C in all immune cells confers protection against colitis induced by either one or two doses of DSS.
In conclusion, the regulation of lamin A/C levels in immune cells and stromal cells emerges as a critical factor in the progression of colitis: its deficiency protects against colitis, whereas its overexpression exacerbates the disease, thereby highlighting lamin A/C modulation in specific immune and non-immune cell populations as a promising therapeutic target.

Effects of gluten consumption on the transcriptomic landscape of Dermatitis Herpetiformis

Helka Kaunisto[1], Esko Kemppainen[1], Teea Salmi[1;2], Päivi Saavalainen[3;4], Katarzyna Leskinen[3;4], Heli Pessa[3;4], Rebecka Venti-Holmberg[3;4], Kaisa Hervonen[1;2], Tuire Ilus[2], Katri Kaukinen[1;2], Katri Lindfors[1]
[1]Tampere University, Celiac Disease Research Group, Tampere, Finland; *[2]Tampere University Hospital, Tampere, Finland*; *[3]Folkhälsan Research Center, Helsinki, Finland*; *[4]University of Helsinki, Immunomics Research Group, Helsinki, Finland*

Dermatitis herpetiformis (DH) is a gluten-induced chronic autoimmune skin condition manifesting as itchy blisters in the extremities of the body. It is thought to develop from untreated celiac disease (CD) with both forms of the disease being gluten induced. The rash in DH resolves slowly after introduction of gluten-free diet (GFD). Although the gluten-induced transcriptomic changes of the small intestine are well studied in CD, corresponding studies have not been conducted in DH patients. Despite DH manifesting as a rash, it is though that the immune responses responsible for the skin symptoms might originate from the gut. In order to understand the skin symptoms and their relation to the intestinal symptoms, we have studied the transcriptomic landscape of DH patients during gluten challenge. Bulk 3' RNA sequencing was applied to duodenal biopsies of DH patients on GFD and after a long (3-9 months) gluten challenge, as well as to DH peripheral blood mononuclear cells (PBMCs) during a 6-day gluten challenge. In addition, T and B cell receptor sequencing is currently being carried out on the same samples, and the results will be discussed. Interestingly, the PBMCs show very little change in transcriptome during the 6-day gluten challenge, with the only gene induced by gluten on day 6 being CXCR2. The intestinal biopsies on the other hand show clear inflammatory changes, similar to the gluten-induced inflammation known from CD. In line with these changes, there is also a marked and plasma cell activation in patients consuming gluten. In this study we show, for the first time, how DH patient duodenum and PBMCs react transcriptomically to gluten challenge. Our findings indicate that the gluten induced inflammation in DH gut is similar to CD, showing that there must be other factors in play, than just the intestinal inflammation, in relaying the immune response to skin in DH patients. Although we were unable to find drastic changes in PBMCs during 6 days of gluten challenge, increase of CXCR2 expression may be closely related to skin recruitment of innate immune cells.

Allergen-displaying extracellular vesicles of probiotic Escherichia coli strain O83:K24:H31 for mucosal tolerance induction in allergy

Viktor Černý[1;2], Eliška Krčmářová[1], Stefan Heinl[3], Michael Thaler[2], Anna Schmid[2], Agnieszka Razim[2], Jiri Hrdy[1], Aleksandra Inic-Kanada[2], Ursula Wiedermann[2], Irma Schabussova[2]
[1]Institute of Immunology and Microbiology of the 1st Faculty of Medicine and General University Hospital in Prague, Prague, Czech Republic; *[2]Institut für Spezifische Prophylaxe und Tropenmedizin, Zentrum für Pathophysiologie, Infektiologie und Immunologie, Medizinische Universität Wien, Wien, Austria*; *[3]Institut für Molekulare Biotechnologie, Universität für Bodenkultur, Wien, Austria*

Mucosal tolerance is a crucial regulatory mechanism that prevents unwanted immune reactivity against innocuous elements such as the colonizing microbiota and harmless environmental antigens. Failure of peripheral tolerance to such antigens leads to allergy. The processes involved are complex and depend on numerous factors, including dose, timing and context of exposure, as well as properties of the antigen (e.g. soluble or particulate nature). The exact mechanisms are not yet fully understood, but it is clear that the commensal microbiota plays a key role in the establishment of mucosal tolerance. There is therefore a strong incentive to study the details of the interaction between the immune system, the microbiota and potential allergens in the context of the mucosa. Intervention with probiotics is a promising and widely studied way of prophylaxis and therapy of allergic diseases. However, the administration of live bacteria can be problematic, particularly in newborns or in patients with immunodeficiency. Extracellular vesicles (EVs), highly resilient nanosized lipid bilayer particles released by all living cells, could provide a much safer and more controlled alternative to probiotic bacteria, retaining the probiotic properties with reduced risks. Importantly, the ability of EVs to carry proteins, lipids and nucleic acids from the releasing cells allows them to retain the strain-specific elements responsible for the probiotic effects, making it possible to examine the details of the immunological response to potential allergens delivered in a harmless context.
In our study, we transformed the probiotic strain of *Escherichia coli* O83:K24:H31 (EcO83) with the plasmid pMS470 to enable the expression of an engineered outer membrane protein A – SpyCatcher fusion protein. Vesicles expressing SpyCatcher can be decorated with SpyTag-marked proteins, enabling the modular construction of EVs with bound allergen. We obtained crude EcO83 extracellular vesicles (EcO83-EVs) by ultracentrifugation (3h, 150,000g, 4°C; Beckman Coulter 45Ti rotor) and purified them using size exclusion chromatography (IZON automated fraction collector). We tested the ability of purified EcO83-EVs with membrane-bound ovalbumin to promote mucosal tolerance after intranasal administration in the ovalbumin-induced allergic airway inflammation model in mice.

Purpose: With a global prevalence of 4.1%, irritable bowel syndrome (IBS) has a considerable negative impact on both society and millions of individuals. The pathophysiology of IBS remains incompletely understood, but involves several factors such as low-grade intestinal inflammation, visceral hypersensitivity, changes in epithelial barrier integrity and permeability, altered gut-brain interactions, and an unfavourable composition of intestinal microbiota. There is currently no cure for IBS, but 70% of patients experience clinically significant symptom relief on a diet low in fermentable oligosaccharides, disaccharides, monosaccharides, and polyols (FODMAPs). In this study, we will explore the duodenal intestinal immune system and barrier integrity in patients with IBS at baseline and after a 12-week strict low FODMAP diet intervention.
Methods: We have used highly multiplexed Hyperion imaging mass cytometry to investigate the cellular microenvironments in duodenal biopsies from patients (n = 46) and healthy volunteers (n = 19) at baseline and patients (n = 21) after a 12-week strict low FODMAP diet. An antibody panel consisting of 37 different markers for immunologic mapping, intestinal integrity and neuro-immune communication was used. Resulting images were segmented with the Steinbock framework in order to identify single cells. Downstream single-cell analysis for a selection of our markers was performed in R with the imcRtools R/Bioconductor and cytomapper packages.
Results: Images generated from Hyperion imaging mass cytometry were successfully segmented. Several immune cell type clusters, including CD4 and CD8 T cells, B cells, macrophages, and mast cells were identified based on marker expression and unsupervised clustering in duodenal biopsies from patients with IBS and healhty volunteers at baseline and patients with IBS at 12-week follow-up.
Conclusion: With our results from a selection of markers from our antibody panel, we have laid the foundation for further single-cell analysis of the duodenal mucosa of patients with IBS before and after 12 weeks of a strict low FODMAP diet intervention. Integration of tissue analyses and clinical symptom scores before and after treatment could provide clinically relevant intestinal biomarkers to advance the treatment strategies for patients with IBS.

Understanding the anti-inflammatory effects of extracts originating in traditional Taiwanese medicine against chronic gut inflammation

Kate Sheehan[1;2], Helen Sheridan[1], Sinéad Corr[1;2]
[1]Trinity College Dublin, Dublin, Ireland; [2]APC Microbiome Ireland, Cork, Ireland

Purpose: Previous research has optimised extracts from a fern plant used within traditional Taiwanese medicine. The anti-inflammatory properties of these extracts against inflammatory bowel disease (IBD) have been identified however the underlying mechanism for this effect is yet undetermined. Here we investigated their anti-inflammatory nature within an in vitro setting, assessing impact on inflammatory responses and phenotype in macrophage cells.
Methods: The QUANTI-Blue™ assay was applied to investigate the influence compounds may have on macrophage NF-κB activation. The ability of these compounds to influence TNF-α induced cell death pathways was studied through qRT-PCR analysis, western blot, and flow cytometry. Treatment effects on M1/M2 macrophage phenotype and characteristics was also investigated through qRT-PCR, Flow Cytometry and Seahorse real-time cell metabolic analysis.
Results: Both compounds demonstrated an ability to interfere with the TNF-α – NF-κB pathway within macrophages through the QUANTI-Blue™ assay. Interference with this pathway has also been supported by these compounds dampening the expression of the pro-inflammatory protein iNOS which is under the control of the NF-κB transcription factor. To further investigate the influence on the TNF-α – NF-κB pathway in macrophages, the expression of signalling proteins involved in TNF-α induced cell death pathways was studied. qRT-PCR, western blot and flow cytometry analysis revealed the ability of both compounds to induce cell death pathways such as apoptosis and necroptosis within macrophage cells while also promoting inflammation resolution through increased efferocytosis.
Conclusions: These compounds may exert their anti-inflammatory effects through the promotion of cell death pathways while downregulating NF-κB activation within macrophage cells. We hypothesis that this feature may act to provide balance to the macrophage population within an inflamed state possibly through the upregulation of M2 macrophages capable of the efferocytosis of apoptotic bodies and necrotic cell debris. Our results so far have begun to uncover a previously uncharacterised mechanism underlying the anti-inflammatory effect of compounds originating in traditional Taiwanese medicine in the context of IBD.

Intestinal TIGITnegCD38+ memory T cells proliferate, acquire an ex-Th17/Th1* pathogenic phenotype and drive inflammation in severe Crohn's disease patients with poor outcome

Maud Heredia[1], Danielle M. H. Barendregt[1], Irma Tindemans[1], Renz C.W. Klomberg[1], Martine A. Aardoom[1], Beatriz Calado[1], Lea M.M. Costes[1], M. (Linda) E. Joosse[1], Danielle H. Inflammatory bowel disease (IBD), including Crohn's disease (CD) and ulcerative colitis, is a T-cell-driven intestinal inflammation. The defects driving loss of T-cell regulation vary between patients and remain undefined. Previously, we have shown that, in healthy individuals, 40% of circulating $CD38^+$ ($CD62L^{neg}CD4^+$) memory T cells, which are enriched for intestinal antigen specificity, express TIGIT, an inhibitory receptor modulating dendritic cell and T-cell function. $TIGIT^+CD38^+$ memory T cells have a regulatory function while $TIGIT^{neg}$ cells are enriched in inflammatory IFN-γ-producing cells. We hypothesize that $TIGIT^{neg}CD38^+$ memory T cells have an inflammatory phenotype in a subgroup of IBD patients, driving disease. In a cohort of therapy-naïve pediatric IBD patients and age-matched healthy controls, we detected increased frequencies of circulating $TIGIT^{neg}CD38^+$ memory T cells in CD patients with a more severe disease course. As anticipated, $TIGIT^{neg}CD38^+$ memory T cells showed high expression of chemokine receptors associated with pathogenic ex-Th17 non-classical Th1, or Th1* cells, defined as high producers of IFN-γ. Cultures of stimulated memory T cells isolated from healthy peripheral blood identified IL-12 as the only IBD-related, antigen presenting cell-derived, inflammatory cytokine leading to an increase in $Th1^*TIGIT^{neg}$ cell proliferation in $CD38^+$, but not $CD38^{neg}$ cells. In agreement, IL12Rβ2 mRNA expression was higher in inflamed biopsies of CD patients compared to controls, and correlated with increased intestinal inflammation. Altogether, these results argue that, in a subgroup of CD patients, increased IL-12 signalling drives reprogramming of Th17 to a proliferative, inflammatory Th1* phenotype in $TIGIT^{neg}CD38^+$ memory T cells, leading to severe, therapy resistant disease.

Enthesitis-related arthritis can be distinguished from other juvenile-idiopathic arthritis subtypes by a serum biomarker for gut-barrier dysfunction

Persephone Jenkins[1], Nora Pinar[1], Thea Jakobi[1], Ania Radziszewska[1], Vicky Alexiou[1], Claire Deakin[2], Lucy R Wedderburn[1], Coziana Ciurtin[1], Diana Matei[1], Elizabeth Rosser[1]
[1]University College London, London, United Kingdom; [2]University of New South Wales, Sydney, Australia

Introduction & Purpose: Juvenile Idiopathic Arthritis (JIA) is the most common rheumatic disease of childhood and encapsulates a heterogenous group of diseases characterised by joint inflammation persisting for at least 6 weeks. The JIA umbrella term includes subtypes with unique clinical presentations including Rheumatoid Factor positive (RF+) polyarticular-JIA, Rheumatoid Factor negative (RF-) oligoarticular/polyarticular JIA and Enthesitis-Related Arthritis (ERA). Evidence from adult inflammatory arthritis suggests that gut dysbiosis increases intestinal permeability, which may contribute to immune cell activation and subsequent joint inflammation. In this study, we aimed to explore whether increased gut permeability can also be observed in JIA.

Methods: Lipopolysaccharide Binding Protein (LBP), an acute phase protein which binds to translocated bacterial lipopolysaccharide, was used as an intestinal permeability biomarker. Concentration of LBP in venous blood serum of adolescent JIA patients (n=61) and age-matched healthy controls (HC) (n=29) was measured using a Human LBP ELISA (age range 13-23, mean age 16). JIA subtypes included were ERA (n=17), polyarticular/oligoarticular (n=31) RF- JIA, and RF+ JIA (n=14).

Results: Although there was no significant difference in serum LBP concentration between JIA patients as a whole compared to HCs, after separation by subtype, increased sera LBP concentration was found in ERA patients compared to HCs ($p=0.0262$). Further subdivision of ERA patients based on active joint count (Inactive=0, Active≥1) demonstrated this increased sera LBP was associated with active disease ($p=0.0488$ active ERA versus HCs), whilst there was no difference between inactive ERA patients and HCs.

Conclusions: This data suggests that adolescents with ERA, but not other JIA subtypes, have higher LBP levels indicating increased gut permeability. The data also suggests the increase in gut permeability in ERA is strongly driven by disease activity. This is in line with previous research showing an increased association of ERA with subclinical gut inflammation compared to other JIA subtypes.

The protective effect of L. sakei CVL-001 against DSS-induced colitis through NOD2-dependent CD103 expression in dendritic cells

Dong-Yeon Kim[1;2], Jung Joo Hong[1], Jong-Hwan Park[2]
[1]National Primate Research Centre, Korea Research Institute of Bioscience and Biotechnology, Cheongju, South Korea; [2]Laboratory animal medicine, Chonnam national university, Gwangju, South Korea

Inflammatory bowel disease (IBD) is a group of disorders characterized by chronic inflammation of the gut, predominantly including crohn's disease and ulcerative colitis. These conditions frequently cause symptoms such as diarrhea, bloody stools, and weight loss, significantly impacting daily life. Recent research has shown that an imbalance of gut microorganisms, known as dysbiosis, is linked to the development of various diseases, including IBD. This finding has increased interest in microbiome-based therapies, such as probiotics. This study investigated the protective effects and mechanisms of action of the *Lactobacillus sakei* CVL-001 strain on IBD in a mouse model. In the experiment, IBD was induced in mice using DSS, and the probiotic was administered orally to evaluate its potential impact on the disease. The results showed that administration of heat-killed (H.K.) CVL-001 exhibited a protective effect against IBD, whereas its supernatant did not. H.K. CVL-001 increased the expression of the anti-inflammatory cytokine IL-10 in the colon, as well as the population of regulatory T cells and CD103+ dendritic cells (DCs), thereby reducing inflammation. Mutations in the Nod2 gene have been found to be deeply associated with IBD. Interestingly, clinical improvement was not observed in Nod2 knockout mice fed with H.K. CVL-001. Gut immune analysis also did not show increases in IL-10 expression, regulatory T cells, and CD103+ DC expression. Treatment of bone marrow-derived dendritic cells (BMDCs) with H.K. CVL-001 induced upregulation of CD103 expression, which subsequently promoted regulatory T cell differentiation in co-culture with naive T cells, a response that was absent in Nod2 knockout BMDCs. This suggests that the protective effect of H.K. CVL-001 significantly dependent on the Nod2 signaling pathway in DCs. We generated mice with depleted Nod2 signaling in DCs using the Cre-loxP system and found that administering H.K. CVL-001 to these mice did not result in protective effects or immunological changes. Conversely, injecting Nod2-intact DCs into Nod2 knockout mice restored the protective and immunological responses. This elucidates a novel role for Nod2 signaling in IBD and proposes its potential as a candidate for the treatment of IBD.

Scrutinizing prime-boost immunization approaches during early-life to enhance immunity against respiratory pathogens

Poorya Foroutan Pajoohian[1;2], Audur Anna Aradottir Pind[1;2], Jenny Lorena Molina Estupinan[1;2], Thorunn Asta Olafsdottir[1], Dennis Christensen[3], Ingileif Jónsdóttir[1], Stefanía P. Bjarnarson[1;2]

Purpose: The strategic development of vaccine, incorporating diverse adjuvants, employing various routes of administration, and using optimal doses of vaccine has demonstrated efficacy in eliciting strong immune responses. The mucosal IgA antibody plays a crucial role in the initial defense, while systemic immunity relies on the significance of the IgG antibody. To optimize the desired immune response triggered by vaccination, the study aims to assess if heterologous route prime-boost immunization can induce strong and persistent humoral immune responses.
Methods: We immunized neonatal mice with a pneumococcal conjugate vaccine, Pn1-CRM_{197}, and two adjuvants by heterologous subcutaneous (s.c) priming with CAF01 followed by intranasal (i.n.) booster with mmCT, or two homologous immunizations, either s.c. or i.n.. Blood and saliva were collected at different time points post-immunizations and spleen, bone marrow (BM), cervical lymph nodes (CLNs), inguinal lymph nodes (ILNs), and lungs two or five weeks post-booster to assess anti-Pn1 antibody levels and ASCs.
Results: Compared to heterologous s.c./i.n. immunization, homologous s.c./s.c. immunization induced higher serum and lung IgG anti-Pn1, and homologous i.n./i.n. immunization induced higher serum IgA anti-Pn1 five weeks post-booster. Homologous s.c. immunization induced higher IgG anti-Pn1 antibody secreting cells (ASCs) in spleen, ILNs, and BM but lower IgA anti-Pn1 ASCs than heterologous immunization in CLNs and spleen. Notably heterologous immunization induced higher IgG and IgA anti-Pn1 ASCs in CLNs utilizing higher doses than homologous s.c./s.c. immunization. Generally, utilizing higher dose of vaccine in i.n. booster of heterologous immunization, yielded higher levels of anti-Pn1 IgG, IgA, and also higher number of anti-Pn1 ASCs.
Conclusion: Homologous s.c./s.c. immunization induces higher systemic IgG anti-Pn1 responses than heterologous s.c./i.n. immunization, which could be enhanced by increasing the vaccine dose in the i.n. booster that was still not comparable to what was induced after s.c./s.c. immunization. However, the heterologous s.c./i.n. immunization induced higher mucosal IgA anti-Pn1 responses. This study indicates that heterologous prime-boost immunization routes could be a promising early-life vaccination strategy, although further optimizations are needed.

Lung dendritic cell metabolism underlies susceptibility to viral infection in diabetes

Samuel Nobs[1]
[1]*Weizmann Institute of Science, Rehovot, Israel*

Diabetic patients feature a life-risking susceptibility to respiratory viral infection, including influenza and SARS-CoV-2, whose mechanism remains unknown. In acquired and genetic mouse models of diabetes, induced with an acute pulmonary viral infection, we demonstrate that hyperglycemia leads to impaired costimulatory molecule expression, antigen transport and T cell priming in distinct lung dendritic cell subsets, driving a defective antiviral adaptive immune response, delayed viral clearance and enhanced mortality. Mechanistically, hyperglycemia induces an altered metabolic dendritic cell circuitry, characterized by increased glucose-to-acetyl-CoA shunting and downstream histone acetylation leading to global chromatin alterations. These, in turn, drive impaired expression of key dendritic cell effectors, including central antigen presentation-related genes. Glucose-lowering treatment, or pharmacological modulation of histone acetylation rescues dendritic cell function and antiviral immunity. Collectively, we highlight a hyperglycemia-driven metabolic-immune axis orchestrating dendritic dysfunction during pulmonary viral infection and identify metabolic checkpoints which may be therapeutically exploited in mitigating exacerbated disease in infected diabetics.

Purpose: The key role of IL-23 signaling in the pathogenesis of some chronic inflammatory diseases has been validated by the success of IL-23 blockers in the clinics. Yet cellular targets and signaling pathways affected by this cytokine remain poorly understood. In this study, we investigated the role of IL-23 signaling in human mucosal-associated invariant T (MAIT) cells.
Methods: Immune cell populations were monitored by spectral flow cytometry and isolated by cell sorting. MAIT cells were activated with an MHC related molecule 1 (MR1) tetramer presenting the potent antigen 5-OP-RU in the presence or absence of IL-23, or its structurally related cytokine IL-12. Gene expression, protein secretion and chromatin accessibility of activated MAIT cells were analyzed using bulk and single-cell RNA-sequencing, multi-analyte profiling and ATAC-sequencing, respectively.
Results: We show that human MAIT cells are the population with the highest frequency of circulating IL-23R-positive cells. Multi-omics profiling of MAIT cells at the population and single cell levels demonstrated that stimulation with IL-23 or IL-12 drives both shared and distinct functional polarization, revealing a high level of plasticity. IL-23, in particular, affected key molecules and pathways related to autoimmunity and cytotoxic functions. Integrated analysis of transcriptomic and chromatin accessibility changes identified the AP-1 family of transcription factors as key targets of IL-23 signaling in MAIT cells. CRISPR/Cas9 mediated knockdown of BATF supported the role of this AP-1 transcription factor as a regulatory node in the IL-23 pathway in this cell population.
Conclusion: High expression of IL-23 receptors and IL-23-mediated induction of autoimmune disease-related genes suggest an important role of MAIT cells in the IL-23 signaling cascade underlying the pathogenesis of chronic inflammatory diseases.

Parkinson's disease-associated leucine-rich repeat kinase 2 polymorphism promotes neutrophil responses and enteric α-synuclein pathology during intestinal inflammation

Yuan-Kai Cheng[1], Hao-Sen Chiang[1]
[1]*Department of Life Science, National Taiwan University, Taipei City, Taiwan*

Purpose: Inflammation in the gut has been considered a trigger of Parkinson's disease (PD). However, the role of immune cells in the gut-to-brain PD pathogenesis is still unclear. In this study, we use the mice carrying mutated leucine-rich repeat kinase 2 (LRRK2), the most frequent genetic risk factor for PD, to investigate if irregulated immune responses during intestinal inflammation result in PD pathology.
Methods: LRRK2 G2019S transgenic mice, the most common LRRK2 polymorphism among PD patients, were treated with dextran sulfate sodium (DSS) to induce intestinal inflammation, the composition of immune cells and the expression of α-synuclein in the gut were examined. Neutrophils of mice were isolated and stimulated with ionomycin to study the effect of mutated LRRK2 on the function of neutrophils.
Results: LRRK2 G2019S transgenic mice showed more severe pathology and elevated α-synuclein in the colon after repeated DSS treatment. Moreover, increased expression of neutrophil extracellular traps (NETs) was also observed in the inflamed colon of LRRK2 G2019S mice. Since LRRK2 G2019S mice had a similar level of neutrophil compared to the non-transgenic mice during intestinal inflammation, the *ex vivo* study demonstrated that LRRK2 G2019S promotes the production of NETs due to the hyperactive kinase activity. The removal of NETs during DSS treatment ameliorated the inflammation and reduced enteric α-synuclein in LRRK2 G2019S mice, suggesting the disruption of intestinal homeostasis might induce the synthesis of α-synuclein in the gut.
Conclusion: This study reveals that neutrophil is likely involved in the LRRK2-mediated α-synuclein pathology during intestinal inflammation, which then initiates the gut-to-brain pathogenesis of PD.

Optimization of NKTfh cell induction in vivo for improved vaccine protocols

Jihana Achour[1], Yavuz Mercan[1], Pumla Bhekiwe Manyatsi[1], Gerhard Wingender[1]
[1]*Izmir Biomedicine and Genome Center, İzmir, Turkey*

Purpose: Vaccines are essential tools to protect humans against infections, mainly by inducing antibody production by B cells. The activation of B cells is aided by a specialist subset of T cells, called follicular-helper T (Tfh) cells. Invariant Natural Killer T (*i*NKT) cells are memory-phenotype cells that produce copious amounts of various cytokines shortly after antigenic stimulation by e.g. the model antigen αGalCer. A subset of *i*NKT cells, called follicular helper NKT (NKTfh) cells, was detected six days after the *in vivo* stimulation that was also able to support B cell responses. However, currently not enough is known about the *in vivo* development of NKTfh cells to utilize them for vaccine development.
Methods: BALB/c wild-type and IL-10-reporter ($IL10^{GFP}$) mice were injected i.v. with 2 µg of different *i*NKT cell antigens (αGalCer, OCH, C-glycoside, DB06-1). Some mice were re-challenged on days 3-5. On day 6, splenocytes were analysed for the frequency and phenotype of *i*NKT and NKTfh (CD185+ Bcl6+) cells by flow cytometry. Their cytokine profile was assessed by intracellular cytokine staining 4 h after *in vitro* stimulation with PMA and ionomycin.
Results: Six days after αGalCer injection, about 10-18% of splenic *i*NKT cells were CD185+ and Bcl6+ and defined as NKTfh cells. When the cells were stimulated *in vitro* with PMA and ionomycin, both CD185 and Bcl-6 were downregulated and could not be used to identify NKTfh cells any longer. However, we were able to detect IL-21 production by intracellular cytokine staining in 18-20% of splenic *i*NKT cells. The majority of IL-21+ *i*NKT cells co-expressed IFNγ (25-40%) and IL-4 (12-24%) but did not express IL-10. Furthermore, the tested *i*NKT cell antigens differed in their ability to induce NKTfh cells, with a decreasing efficiency of OCH > DB06-1 > αGalCer > C-glycoside. The preparation of NKTfh and control *i*NKT cells for an RNAseq analysis is ongoing.
Conclusion: We provide novel data on the cytokine production of NKTfh cells and their antigenic requirement for *in vivo* induction, which may pave the way to utilize NKTfh cells for vaccine development.
